Création de règles AWS Config gérées à l'aide AWS CloudFormation de modèles

> **Important**
>
> Vous devez d'abord créer et démarrer l'enregistreur de AWS Config configuration afin de créer des règles AWS Config gérées avec AWS CloudFormation. Pour de plus amples informations, veuillez consulter Gestion de l'enregistreur de configuration.

Pour les règles AWS Config gérées prises en charge, vous pouvez utiliser les CloudFormation modèles pour créer la règle de votre compte ou mettre à jour une CloudFormation pile existante. Une pile est un ensemble de ressources associées que vous mettez en service et à jour en tant qu'unité unique. Lorsque vous lancez une pile avec un modèle, la règle gérée AWS Config est créée pour vous. Les modèles créent uniquement la règle et ne créent pas de AWS ressources supplémentaires.

> **Note**
>
> Lorsque les règles AWS Config gérées sont mises à jour, les modèles sont mis à jour pour tenir compte des dernières modifications. Pour enregistrer une version spécifique d'un modèle pour une règle, téléchargez le modèle et chargez-le dans votre compartiment S3.

Pour plus d'informations sur l'utilisation des AWS CloudFormation modèles, voir Getting Started with AWS CloudFormation dans le guide de AWS CloudFormation l'utilisateur.

Pour lancer une CloudFormation pile pour une règle AWS Config gérée

1. Accédez à la CloudFormationconsole et créez une nouvelle pile.
2. Pour Spécifier un modèle :
   - Si vous avez téléchargé le modèle, choisissez Charger un fichier de modèle, puis choisissez Choisir un fichier pour charger le modèle.

- Vous pouvez également sélectionner URL Amazon S3 et entrez l'URL du modèle `http://s3.amazonaws.com/aws-configservice-us-east-1/cloudformation-templates-for-managed-rules/THE_RULE_IDENTIFIER.template`.

> **Note**
>
> L'identificateur de la règle doit être écrit dans ALL_CAPS_WITH_UNDERSCORES. Par exemple, CLOUDWATCH_LOG_GROUP_ENCRYPTED au lieu de. cloudwatch-log-group-encrypted
>
> Pour certaines règles, l'identificateur de la règle est différent du nom de la règle. Veillez à utiliser l'identificateur de la règle. Par exemple, l'identificateur de la règle pour restricted-ssh est INCOMING_SSH_DISABLED.

3. Choisissez Suivant.
4. Pour Spécifier les détails de la pile, tapez le nom de la pile et entrez les valeurs des paramètres de la AWS Config règle. Par exemple, si vous utilisez le modèle de règle gérée `DESIRED_INSTANCE_TYPE`, vous pouvez spécifier le type d'instance comme « m4.large ».
5. Choisissez Next (Suivant).
6. Pour Options, vous pouvez créer des balises ou configurer d'autres options avancées. Celles-ci ne sont pas obligatoires.
7. Choisissez Suivant.
8. Pour Vérifier, vérifiez que le modèle, les paramètres et les autres options sont corrects.
9. Sélectionnez Créer. La pile est créée en quelques minutes. Vous pouvez afficher la règle créée dans la console AWS Config.

Vous pouvez utiliser les modèles pour créer une pile unique pour les règles AWS Config gérées ou pour mettre à jour une pile existante dans votre compte. Si vous supprimez une pile, les règles gérées créées à partir de cette pile sont également supprimées. Pour plus d'informations, veuillez consulter la rubrique Utilisation des piles dans le AWS CloudFormation Guide de l'utilisateur.

AWS Config Règles personnalisées

AWS Config Les règles personnalisées sont des règles que vous créez de toutes pièces. Il existe deux manières de créer des règles AWS Config personnalisées : avec les fonctions Lambda (Guide du AWS Lambda développeur) et avec Guard (Guard GitHub Repository), un policy-as-code langage.

AWS Config les règles personnalisées créées avec Lambda sont appelées règles AWS Config Lambda AWS Config personnalisées et les règles personnalisées créées avec Guard sont appelées AWS Config règles de politique personnalisées.

Avant d'utiliser des règles personnalisées, consultezConsidérations.

AWS Config Règles de politique personnalisées

Les règles écrites à l'aide de Guard peuvent être créées à partir de la AWS Config console ou à l'aide de la AWS Config règle APIs. AWS Config Les règles de politique personnalisées vous permettent de créer des règles AWS Config personnalisées sans avoir à utiliser Java ou Python pour développer des fonctions Lambda afin de gérer vos règles personnalisées. AWS Config Les règles de politique personnalisées sont initiées par des modifications de configuration. Pour plus d'informations sur Guard, consultez le GitHubréférentiel Guard.

AWS Config Règles Lambda personnalisées

Les règles Lambda personnalisées vous permettent d'utiliser Java ou Python pour créer une fonction Lambda pour une règle personnalisée. AWS Config Une fonction Lambda est un code personnalisé que vous téléchargez et qui est invoqué par des événements qui y sont publiés par une source d'événements. AWS Lambda Si la fonction Lambda est associée à une AWS Config règle, elle l' AWS Config invoque lorsque la règle est initiée. La fonction Lambda évalue ensuite les informations de configuration envoyées par et renvoie AWS Config les résultats de l'évaluation. Pour plus d'informations sur les fonctions Lambda, consultez Fonction et sources d'événements dans le Guide du développeur AWS Lambda .

Différences de format pour les règles AWS Config personnalisées

Le tableau suivant présente les différences de format entre les champs pour le type de ConfigurationItemdonnées et pour les règles AWS Config personnalisées.

ConfigurationItem	AWS Config Règle personnalisée
`version`	`configurationItemVersion`
`accountId`	`awsAccountId`
`arn`	`ARN`

ConfigurationItem	AWS Config Règle personnalisée
`configurationItemMD5Hash`	`configurationStateMd5Hash`

Rubriques

- Création de règles de politique AWS Config personnalisées
- Création de AWS Config règles Lambda personnalisées
- Gestion des ressources supprimées pour les règles Lambda AWS Config personnalisées

Création de règles de politique AWS Config personnalisées

Vous pouvez créer des règles de politique AWS Config personnalisées à partir de l' AWS Config API AWS Management Console AWS CLI, ou.

Ajouter AWS Config des règles de politique personnalisées

Using the console

1. Connectez-vous à la AWS Config console AWS Management Console et ouvrez-la à la https://console.aws.amazon.com/config/maison.
2. Dans le AWS Management Console menu, vérifiez que le sélecteur de région est défini sur une AWS région qui prend en charge les AWS Config règles. Pour obtenir la liste des régions prises en charge, consultez Régions et points de terminaison AWS Config dans le Référence générale d'Amazon Web Services.
3. Dans le volet de navigation de gauche, choisissez Règles.
4. Sur la page Règles, choisissez Ajouter une règle.
5. Sur la page Spécifier le type de règle, choisissez Créer une règle personnalisée à l'aide de Guard.
6. Sur la page Configurer une règle, créez la règle en réalisant les étapes suivantes :
   a. Saisissez un nom unique dans le champ Nom de la règle.
   b. Saisissez une description de la règle dans le champ Description.
   c. Pour la version d'exécution de Guard, choisissez le système d'exécution pour votre règle de politique AWS Config personnalisée.

d. Vous pouvez renseigner le Contenu de la règle avec la politique Guard personnalisée correspondant à votre règle.

e. Pour le mode d'évaluation, choisissez à quel moment du processus de création et de gestion des ressources vous AWS Config souhaitez évaluer vos ressources. Selon la règle, AWS Config vous pouvez évaluer vos configurations de ressources avant qu'une ressource ne soit provisionnée, après qu'une ressource ait été provisionnée, ou les deux.

   i. Choisissez Activer l'évaluation proactive pour évaluer les paramètres de configuration de vos ressources avant leur déploiement.

      Après avoir activé l'évaluation proactive, vous pouvez utiliser l'StartResourceEvaluationAPI et l'GetResourceEvaluationSummaryAPI pour vérifier si les ressources que vous spécifiez dans ces commandes seront signalées comme NON CONFORMES par les règles proactives de votre compte dans votre région.

      Pour plus d'informations sur l'utilisation de ces commandes, consultez la section Évaluation de vos ressources à l'aide de AWS Config règles. Pour obtenir la liste des règles gérées qui prennent en charge l'évaluation proactive, consultez la section Liste des règles AWS Config gérées par mode d'évaluation.

   ii. Choisissez Activer l'évaluation détective pour évaluer les paramètres de configuration de vos ressources existantes.

      À des fins d'évaluation préventive, les règles de politique AWS Config personnalisée sont initiées par les modifications de configuration. Cette option sera présélectionnée.

      - Ressources : lorsqu'une ressource qui correspond au type de ressource spécifié, ou au type plus à l'identifiant, est créée, modifiée ou supprimée.
      - Balises : lorsqu'une ressource portant la balise spécifiée est créée, modifiée ou supprimée.
      - Toutes les modifications : lorsqu'une ressource enregistrée par AWS Config est créée, modifiée ou supprimée.

      AWS Config exécute l'évaluation lorsqu'il détecte une modification apportée à une ressource correspondant au champ d'application de la règle. Vous pouvez utiliser la portée afin de limiter les ressources qui déclenchent des évaluations. Dans le cas

contraire, les évaluations sont lancées en cas de modification d'une ressource post-provisionnée.

f. Vous pouvez personnaliser les valeurs des clés fournies dans le champ Paramètres, si votre règle comprend des paramètres. Un paramètre est un attribut que vos ressources doivent respecter pour pouvoir être considérées conformes à la règle.

7. Sur la page Réviser et créer, passez en revue toutes vos sélections avant d'ajouter la règle à votre Compte AWS.
8. Lorsque vous avez vérifié vos règles, choisissez Ajouter une règle.

Using the AWS CLI

Utilisez la commande `put-config-rule`.

Le champ `Owner` doit présenter la valeur `CUSTOM_POLICY`. Les champs supplémentaires suivants sont obligatoires pour les règles de politique AWS Config personnalisée :

- `Runtime`: le système d'exécution de vos règles de politique AWS Config personnalisée.
- `PolicyText` : la définition de la politique contenant la logique de vos règles de politiques AWS Config personnalisées.
- `EnableDebugLogDelivery`: expression booléenne permettant d'activer la journalisation du débogage pour votre règle de politique AWS Config personnalisée. La valeur par défaut est `false`.

Using the API Reference

Utilisez l'action PutConfigRule.

Le champ `Owner` doit présenter la valeur `CUSTOM_POLICY`. Les champs supplémentaires suivants sont obligatoires pour les règles de politique AWS Config personnalisée :

- `Runtime`: le système d'exécution de vos règles de politique AWS Config personnalisée.
- `PolicyText` : la définition de la politique contenant la logique de vos règles de politiques AWS Config personnalisées.
- `EnableDebugLogDelivery`: expression booléenne permettant d'activer la journalisation du débogage pour votre règle de politique AWS Config personnalisée. La valeur par défaut est `false`.

Rédaction du contenu des règles pour les règles de politique AWS Config personnalisées

Avec les règles de politique AWS Config personnalisées, vous pouvez utiliser le langage spécifique au domaine (DSL) de AWS CloudFormation Guard pour évaluer les configurations des ressources. Cette rubrique fournit des modèles et des bonnes pratiques pour la rédaction de règles de politique personnalisées.

Pour plus d'informations sur la façon d'écrire des règles avec Guard, consultez la section Writing Guard dans le AWS CloudFormation guide de l'utilisateur de AWS CloudFormation Guard et les modes de fonctionnement de Guard 2.0 dans le GitHub référentiel Guard.

Structure des règles de base

Utilisez le format de base suivant pour créer des règles :

```
# Basic rule format
rule <rule_name> when
    resourceType == "<AWS::Service::Resource>" {
    # Evaluation clauses
}

# Example with filtering
let resources_of_type = Resources.*[ Type == 'AWS::Service::Resource' ]
rule check_resources when %resources_of_type !empty {
    %resources_of_type.configuration.property == expected_value
}
```

Composants clés

configuration

Contient le contenu de la configuration des ressources.

supplementaryConfiguration

Contient du contenu supplémentaire pour la configuration des ressources. AWS Config renvoie ce champ pour certains types de ressources afin de compléter les informations renvoyées pour le champ de configuration.

resourceType

AWS type de ressource en cours d'évaluation.

resourceId

L'ID de la ressource (par exemple,`sg-xxxxxx`).

accountId

L' Compte AWS identifiant à 12 chiffres associé à la ressource.

Schémas courants

Status checks

```
let allowed_status = ['ACTIVE', 'RUNNING']
rule check_resource_status when
    resourceType == "AWS::Service::Resource" {
    configuration.status IN %allowed_status
}
```

Required properties

```
rule check_required_properties when
    resourceType == "AWS::Service::Resource" {
    configuration.propertyName exists
    configuration.propertyName is_string  # or is_list, is_struct
}
```

Query blocks

```
configuration.Properties {
    property1 exists
    property2 is_string
    property3 IN [allowed_value1, allowed_value2]
}
```

Conditional evaluation

```
when configuration.feature_enabled == true {
    configuration.feature_settings exists
    configuration.feature_settings is_struct
```

```
}
```

Custom messages

```
rule check_compliance when
    resourceType == "AWS::Service::Resource" {
    configuration.property == expected_value <<Custom error message explaining the
 requirement>>
}}
```

Fonctionnalités avancées

Range checks

```
rule check_numeric_limits {
    # Inclusive range (lower_limit <= value <= upper_limit)
    configuration.value IN r[minimum_value, maximum_value]

    # Exclusive range (lower_limit < value < upper_limit)
    configuration.value IN r(exclusive_min, exclusive_max)

    # Left inclusive, right exclusive (lower_limit <= value < upper_limit)
    configuration.value IN r[minimum_value, exclusive_max)

    # Left exclusive, right inclusive (lower_limit < value <= upper_limit)
    configuration.value IN r(exclusive_min, maximum_value]
}
```

Combining conditions

```
# AND conditions (implicit through new lines)
condition_1
condition_2

# OR conditions (explicit)
condition_3 OR
condition_4
```

Chaining rules

```
rule check_prerequisites {
```

```
    configuration.required_setting exists
}

rule check_details when check_prerequisites {
    configuration.required_setting == expected_value
}
```

Bonnes pratiques

- Utilisez des variables avec des `let` instructions pour une meilleure lisibilité.
- Regroupez les vérifications associées à l'aide de blocs de règles nommés.
- Incluez des commentaires descriptifs.
- Utilisez les opérateurs appropriés (`exists`,`is_string`,`is_list`).
- Utilisez des modèles regex avec une correspondance insensible aux majuscules et minuscules.

Exemple : dynamodb-pitr-enabled

L'exemple suivant montre la définition de politique pour une version de règle de politique AWS Config personnalisée de la règle AWS Config gérée[dynamodb-pitr-enabled](). Cette règle vérifie si la restauration est activée pour les tables Point-in-Time DynamoDB.

```
# Check if DynamoDB tables have Point-in-Time Recovery enabled
let status = ['ACTIVE']

rule tableisactive when
    resourceType == "AWS::DynamoDB::Table" {
    configuration.tableStatus == %status
}

rule checkcompliance when
    resourceType == "AWS::DynamoDB::Table"
    tableisactive {
    let pitr =
 supplementaryConfiguration.ContinuousBackupsDescription.pointInTimeRecoveryDescription.pointIn
    %pitr == "ENABLED" <<DynamoDB tables must have Point-in-Time Recovery enabled>>
}
```

Création de AWS Config règles Lambda personnalisées

Vous pouvez développer des règles personnalisées et les ajouter à l' AWS Config aide de AWS Lambda fonctions.

Vous associez chaque règle personnalisée à une fonction Lambda, qui contient la logique qui évalue si vos AWS ressources sont conformes à la règle. Vous associez cette fonction à votre règle qui invoque la fonction soit en réponse aux changements de configuration, soit de façon périodique. La fonction évalue ensuite si vos ressources sont conformes à votre règle et envoie les résultats de son évaluation à AWS Config.

AWS Kit de développement de règles (RDK)

Le kit de développement de AWS règles (RDK) est conçu pour prendre en charge un flux de travail de « conformité en tant que code » intuitif et productif. Il élimine une grande partie de la charge de travail indifférenciée associée au déploiement de AWS Config règles soutenues par des fonctions Lambda personnalisées et fournit un processus itératif rationalisé. develop-deploy-monitor

Pour obtenir des step-by-step instructions, consultez la documentation du kit de développement de AWS règles (RDK).

Exemples de AWS Lambda fonctions pour AWS Config les règles (Node.js)

AWS Lambda exécute des fonctions en réponse à des événements publiés par les AWS services. La fonction d'une règle Lambda AWS Config personnalisée reçoit un événement publié par AWS Config, puis utilise les données qu'elle reçoit de l'événement et qu'elle extrait de l' AWS Config API pour évaluer la conformité de la règle. Les opérations dans une fonction pour une règle de configuration varient selon qu'il s'agisse d'une évaluation déclenchée par des changements de configuration ou de façon périodique.

Pour plus d'informations sur les modèles courants au sein des AWS Lambda fonctions, voir Modèle de programmation dans le Guide du AWS Lambda développeur.

Example Function for Evaluations Triggered by Configuration Changes

AWS Config invoquera une fonction comme dans l'exemple suivant lorsqu'elle détecte un changement de configuration pour une ressource comprise dans le champ d'application d'une règle personnalisée.

Si vous utilisez la AWS Config console pour créer une règle associée à une fonction comme dans cet exemple, choisissez Configuration changes comme type de

déclencheur. Si vous utilisez l' AWS Config API ou AWS CLI pour créer la règle, définissez l'`MessageType`attribut sur `ConfigurationItemChangeNotification` et`OversizedConfigurationItemChangeNotification`. Ces paramètres permettent à votre règle d'être déclenchée chaque fois qu'un élément de configuration ou un élément de configuration surdimensionné est AWS Config généré à la suite d'un changement de ressource.

Cet exemple évalue vos ressources et vérifie si les instances correspondent au type de ressource, `AWS::EC2::Instance`. La règle est déclenchée quand AWS Config génère un élément de configuration ou une notification d'élément de configuration surdimensionné.

```
'use strict';

import { ConfigServiceClient, GetResourceConfigHistoryCommand,
 PutEvaluationsCommand } from "@aws-sdk/client-config-service";

const configClient = new ConfigServiceClient({});

// Helper function used to validate input
function checkDefined(reference, referenceName) {
    if (!reference) {
        throw new Error(`Error: ${referenceName} is not defined`);
    }
    return reference;
}

// Check whether the message type is OversizedConfigurationItemChangeNotification,
function isOverSizedChangeNotification(messageType) {
    checkDefined(messageType, 'messageType');
    return messageType === 'OversizedConfigurationItemChangeNotification';
}

// Get the configurationItem for the resource using the getResourceConfigHistory
 API.
async function getConfiguration(resourceType, resourceId, configurationCaptureTime,

    const command = new GetResourceConfigHistoryCommand(input);
    await configClient.send(command).then(
        (data) => {
            callback(null, data.configurationItems[0]);
        },

        // Sends the evaluation results to AWS Config.
        await configClient.send(new PutEvaluationsCommand(putEvaluationsRequest));
    });

```

Opérations de la fonction

La fonction effectue les opérations suivantes lors de l'exécution :

1. La fonction s'exécute lorsque AWS Lambda l'`event`objet est transmis à la `handler` fonction. Dans cet exemple, la fonction accepte le `callback` paramètre facultatif, qu'elle utilise pour renvoyer des informations à l'appelant. AWS Lambda transmet également un `context` objet contenant des informations et des méthodes que la fonction peut utiliser pendant son exécution. Sachez que le contexte n'est plus utilisé dans les nouvelles versions de Lambda.
2. La fonction vérifie si le `messageType` pour l'événement est un élément de configuration ou un élément de configuration surdimensionné, puis renvoie l'élément de configuration.
3. Le gestionnaire appelle la fonction `isApplicable` afin de déterminer si la ressource a été supprimée.

   > **Note**
   >
   > Les règles signalant les ressources supprimées doivent renvoyer le résultat de l'évaluation `NOT_APPLICABLE` afin d'éviter des évaluations de règles inutiles.

4. Le gestionnaire appelle la `evaluateChangeNotificationCompliance` fonction et transmet les `ruleParameters` objets `configurationItem` et AWS Config publiés lors de l'événement.

   La fonction commence par évaluer si la ressource est une instance EC2. Si la ressource n'est pas une instance EC2, la fonction renvoie la valeur de conformité `NOT_APPLICABLE`.

   La fonction évalue ensuite si l'attribut `instanceType` de l'élément de configuration est égal à la valeur du paramètre `desiredInstanceType`. Si les valeurs sont égales, la fonction renvoie `COMPLIANT`. Si les valeurs ne sont pas égales, la fonction renvoie `NON_COMPLIANT`.
5. Le gestionnaire se prépare à envoyer les résultats de l'évaluation à AWS Config en initialisant l'`putEvaluationsRequest`objet. Cet objet comprend le paramètre `Evaluations` qui identifie le résultat de la conformité, le type et l'ID de la ressource qui a été évaluée. L'`putEvaluationsRequest`objet inclut également le jeton de résultat de l'événement, qui identifie la règle et l'événement pour AWS Config.
6. Le gestionnaire envoie les résultats de l'évaluation à AWS Config en transmettant l'objet à la `putEvaluations` méthode du `config` client.

Example Function for Periodic Evaluations

AWS Config invoquera une fonction comme dans l'exemple suivant pour les évaluations périodiques. Des évaluations périodiques se produisent à la fréquence que vous spécifiez lorsque vous définissez la règle dans AWS Config.

Si vous utilisez la AWS Config console pour créer une règle associée à une fonction comme dans cet exemple, choisissez Périodique comme type de déclencheur. Si vous utilisez l' AWS Config API ou AWS CLI pour créer la règle, définissez l'`MessageType`attribut sur`ScheduledNotification`.

Cet exemple vérifie si le nombre total d'une ressource donnée dépasse le maximum spécifié.

```
'use strict';
import { ConfigServiceClient, ListDiscoveredResourcesCommand,
 PutEvaluationsCommand } from "@aws-sdk/client-config-service";

const configClient = new ConfigServiceClient({});

// Receives the event and context from AWS Lambda.
export const handler = async (event, context, callback) => {
    // Parses the invokingEvent and ruleParameters values, which contain JSON
 objects passed as strings.
    var invokingEvent = JSON.parse(event.invokingEvent),
        ruleParameters = JSON.parse(event.ruleParameters),
        numberOfResources = 0;

    if (isScheduledNotification(invokingEvent) &&
 hasValidRuleParameters(ruleParameters, callback)) {
        await countResourceTypes(ruleParameters.applicableResourceType, "",
 numberOfResources, async function (err, count) {
            if (err === null) {
                var putEvaluationsRequest;
                const compliance = evaluateCompliance(ruleParameters.maxCount,
 count);
                var annotation = '';
                if (compliance === "NON_COMPLIANT") {
                    annotation = "Description of why the resource is not
 compliant.";
                }
                // Initializes the request that contains the evaluation results.
                if (annotation) {
                    putEvaluationsRequest = {
```

```
                        Evaluations: [{
                            // Applies the evaluation result to the AWS account

```

Opérations de la fonction

La fonction effectue les opérations suivantes lors de l'exécution :

1. La fonction s'exécute lorsque AWS Lambda l'`event`objet est transmis à la `handler` fonction. Dans cet exemple, la fonction accepte le `callback` paramètre facultatif, qu'elle utilise pour renvoyer des informations à l'appelant. AWS Lambda transmet également un `context` objet contenant des informations et des méthodes que la fonction peut utiliser pendant son exécution. Sachez que le contexte n'est plus utilisé dans les nouvelles versions de Lambda.
2. Pour compter les ressources du type spécifié, le gestionnaire appelle la fonction `countResourceTypes` et il transmet le paramètre `applicableResourceType` qu'il a reçu de l'événement. La fonction `countResourceTypes` appelle la méthode `listDiscoveredResources` du client `config`, qui retourne une liste d'identificateurs pour les ressources applicables. La fonction utilise la longueur de cette liste pour déterminer le nombre de ressources applicables, et elle retourne ce nombre au gestionnaire.
3. Le gestionnaire se prépare à envoyer les résultats de l'évaluation à AWS Config en initialisant l'`putEvaluationsRequest`objet. Cet objet inclut le `Evaluations` paramètre, qui identifie le résultat de conformité et celui Compte AWS qui a été publié lors de l'événement. Vous pouvez utiliser le paramètre `Evaluations` pour appliquer le résultat à n'importe quel type de ressource pris en charge par AWS Config. L'`putEvaluationsRequest`objet inclut également le jeton de résultat de l'événement, qui identifie la règle et l'événement pour AWS Config.
4. Au sein de l'objet `putEvaluationsRequest`, le gestionnaire appelle la fonction `evaluateCompliance`. Cette fonction teste si le nombre de ressources applicables dépasse le maximum attribué au paramètre `maxCount` fourni par l'événement. Si le nombre maximum de ressources est dépassé, la fonction renvoie `NON_COMPLIANT`. Si le nombre maximum de ressources n'est pas dépassé, la fonction renvoie `COMPLIANT`.
5. Le gestionnaire envoie les résultats de l'évaluation à AWS Config en transmettant l'objet à la `putEvaluations` méthode du `config` client.

Exemples de AWS Lambda fonctions pour AWS Config les règles (Python)

AWS Lambda exécute des fonctions en réponse à des événements publiés par les AWS services. La fonction d'une règle Lambda AWS Config personnalisée reçoit un événement publié par AWS Config, puis utilise les données qu'elle reçoit de l'événement et qu'elle extrait de l' AWS Config API pour évaluer la conformité de la règle. Les opérations dans une fonction pour une règle de configuration varient selon qu'il s'agisse d'une évaluation déclenchée par des changements de configuration ou de façon périodique.

Pour plus d'informations sur les modèles courants au sein des AWS Lambda fonctions, voir Modèle de programmation dans le Guide du AWS Lambda développeur.

Example Function for Evaluations Triggered by Configuration Changes

AWS Config invoquera une fonction comme dans l'exemple suivant lorsqu'elle détecte un changement de configuration pour une ressource comprise dans le champ d'application d'une règle personnalisée.

Si vous utilisez la AWS Config console pour créer une règle associée à une fonction comme dans cet exemple, choisissez Configuration changes comme type de déclencheur. Si vous utilisez l' AWS Config API ou AWS CLI pour créer la règle, définissez l'`MessageType`attribut sur `ConfigurationItemChangeNotification` et`OversizedConfigurationItemChangeNotification`. Ces paramètres permettent à votre règle d'être déclenchée chaque fois qu'un élément de configuration ou un élément de configuration surdimensionné est AWS Config généré à la suite d'un changement de ressource.

Opérations de la fonction

La fonction effectue les opérations suivantes lors de l'exécution :

1. La fonction s'exécute lorsque AWS Lambda l'`event`objet est transmis à la `handler` fonction. Dans cet exemple, la fonction accepte le `callback` paramètre facultatif, qu'elle utilise pour renvoyer des informations à l'appelant. AWS Lambda transmet également un `context` objet contenant des informations et des méthodes que la fonction peut utiliser pendant son exécution. Sachez que le contexte n'est plus utilisé dans les nouvelles versions de Lambda.
2. La fonction vérifie si le `messageType` pour l'événement est un élément de configuration ou un élément de configuration surdimensionné, puis renvoie l'élément de configuration.
3. Le gestionnaire appelle la fonction `isApplicable` afin de déterminer si la ressource a été supprimée.

   > **Note**
   >
   > Les règles signalant les ressources supprimées doivent renvoyer le résultat de l'évaluation `NOT_APPLICABLE` afin d'éviter des évaluations de règles inutiles.

4. Le gestionnaire appelle la `evaluateChangeNotificationCompliance` fonction et transmet les `ruleParameters` objets `configurationItem` et AWS Config publiés lors de l'événement.

   La fonction commence par évaluer si la ressource est une instance EC2. Si la ressource n'est pas une instance EC2, la fonction renvoie la valeur de conformité `NOT_APPLICABLE`.

La fonction évalue ensuite si l'attribut `instanceType` de l'élément de configuration est égal à la valeur du paramètre `desiredInstanceType`. Si les valeurs sont égales, la fonction renvoie `COMPLIANT`. Si les valeurs ne sont pas égales, la fonction renvoie `NON_COMPLIANT`.

5. Le gestionnaire se prépare à envoyer les résultats de l'évaluation à AWS Config en initialisant l'`putEvaluationsRequest`objet. Cet objet comprend le paramètre `Evaluations` qui identifie le résultat de la conformité, le type et l'ID de la ressource qui a été évaluée. L'`putEvaluationsRequest`objet inclut également le jeton de résultat de l'événement, qui identifie la règle et l'événement pour AWS Config.
6. Le gestionnaire envoie les résultats de l'évaluation à AWS Config en transmettant l'objet à la `putEvaluations` méthode du `config` client.

Opérations de la fonction

1. La fonction s'exécute lorsque AWS Lambda l'`event`objet est transmis à la `handler` fonction. Dans cet exemple, la fonction accepte le `callback` paramètre facultatif, qu'elle utilise pour renvoyer des informations à l'appelant. AWS Lambda transmet également un `context` objet contenant des informations et des méthodes que la fonction peut utiliser pendant son exécution. Sachez que le contexte n'est plus utilisé dans les nouvelles versions de Lambda.
2. Pour compter les ressources du type spécifié, le gestionnaire appelle la fonction `countResourceTypes` et il transmet le paramètre `applicableResourceType` qu'il a reçu de l'événement. La fonction `countResourceTypes` appelle la méthode `listDiscoveredResources` du client `config`, qui retourne une liste d'identificateurs pour les ressources applicables. La fonction utilise la longueur de cette liste pour déterminer le nombre de ressources applicables, et elle retourne ce nombre au gestionnaire.
3. Le gestionnaire se prépare à envoyer les résultats de l'évaluation à AWS Config en initialisant l'`putEvaluationsRequest`objet. Cet objet inclut le `Evaluations` paramètre, qui identifie le résultat de conformité et celui Compte AWS qui a été publié lors de l'événement. Vous pouvez utiliser le paramètre `Evaluations` pour appliquer le résultat à n'importe quel type de ressource pris en charge par AWS Config. L'`putEvaluationsRequest`objet inclut également le jeton de résultat de l'événement, qui identifie la règle et l'événement pour AWS Config.

4. Au sein de l'objet `putEvaluationsRequest`, le gestionnaire appelle la fonction `evaluateCompliance`. Cette fonction teste si le nombre de ressources applicables dépasse le maximum attribué au paramètre `maxCount` fourni par l'événement. Si le nombre maximum de ressources est dépassé, la fonction renvoie `NON_COMPLIANT`. Si le nombre maximum de ressources n'est pas dépassé, la fonction renvoie `COMPLIANT`.
5. Le gestionnaire envoie les résultats de l'évaluation à AWS Config en transmettant l'objet à la `putEvaluations` méthode du `config` client.

Exemples d'événements pour les AWS Config règles

Lorsque le déclencheur d'une règle se produit, AWS Config invoque la AWS Lambda fonction de la règle en publiant un événement. AWS Lambda Exécute ensuite la fonction en transmettant l'événement au gestionnaire de la fonction.

Example Event for Evaluations Triggered by Configuration Changes

AWS Config publie un événement lorsqu'il détecte un changement de configuration pour une ressource comprise dans le champ d'application d'une règle. L'exemple d'événement suivant montre que la règle a été déclenchée par une modification de la configuration d'une instance EC2.

```
{

Attributs d'événement

L'objet JSON d'un AWS Config événement contient les attributs suivants :

`invokingEvent`

L'événement qui déclenche l'évaluation d'une règle. Si l'événement est publié en réponse à un changement de configuration de ressource, la valeur de cet attribut est une chaîne qui contient un élément de configuration JSON `configurationItem` ou un `configurationItemSummary` (pour les éléments de configuration surdimensionnés). L'élément de configuration représente l'état de la ressource au moment où le changement a AWS Config été détecté. Pour un exemple d'élément de configuration, consultez le résultat produit par la `get-resource-config-history` AWS CLI commande dansAffichage de l'historique de configuration.

Si l'événement est publié pour une évaluation périodique, la valeur est une chaîne qui contient un objet JSON. L'objet comporte des informations sur l'évaluation qui a été déclenchée.

Pour chaque type d'événement, une fonction doit analyser la chaîne avec un analyseur JSON afin d'être en mesure d'évaluer son contenu, comme illustré dans l'exemple suivant de Node.js :

```
var invokingEvent = JSON.parse(event.invokingEvent);
```

`ruleParameters`

Paires clé/valeur que la fonction traite dans le cadre de sa logique d'évaluation. Vous définissez des paramètres lorsque vous utilisez la AWS Config console pour créer une règle Lambda personnalisée. Vous pouvez également définir des paramètres avec l'`InputParameters`attribut dans la demande `PutConfigRule` AWS Config d'API ou dans la `put-config-rule` AWS CLI commande.

Le code JSON pour les paramètres est contenu dans une chaîne, donc une fonction doit analyser la chaîne avec un analyseur JSON afin d'être en mesure d'évaluer son contenu, comme illustré dans l'exemple suivant de Node.js :

```
var ruleParameters = JSON.parse(event.ruleParameters);
```

`resultToken`

Un jeton auquel la fonction doit être transmise AWS Config lors de l'`PutEvaluations`appel.

`eventLeftScope`

Valeur booléenne qui indique si la AWS ressource à évaluer a été supprimée du champ d'application de la règle. Si la valeur est `true`, la fonction indique que l'évaluation peut être ignorée en transmettant `NOT_APPLICABLE` en tant que valeur pour l'attribut `ComplianceType` dans l'appel de `PutEvaluations`.

`executionRoleArn`

L'ARN du rôle IAM attribué à AWS Config.

`configRuleArn`

L'ARN AWS Config attribué à la règle.

`configRuleName`

Le nom que vous avez attribué à la règle qui a entraîné la publication AWS Config de l'événement et l'appel de la fonction.

`configRuleId`

L'ID AWS Config attribué à la règle.

`accountId`

L'ID du propriétaire Compte AWS de la règle.

`version`

Numéro de version attribué par AWS. La version augmentera si des attributs sont AWS ajoutés aux AWS Config événements. Si une fonction requiert un attribut qui figure uniquement dans des événements qui correspondent à ou dépassent une version spécifique, cette fonction peut vérifier la valeur de cet attribut.

La version actuelle pour les AWS Config événements est 1.0.

Gestion des ressources supprimées pour les règles Lambda AWS Config personnalisées

Les règles signalant les ressources supprimées doivent renvoyer le résultat de l'évaluation `NOT_APPLICABLE` afin d'éviter des évaluations de règles inutiles.

Lorsque vous supprimez une ressource, AWS Config crée un `configurationItem` avec `ResourceDeleted` pour`configurationItemStatus`. Vous pouvez utiliser ces métadonnées pour vérifier si une règle signale une ressource supprimée. Pour plus d'informations sur les éléments de configuration, consultez Concepts | Éléments de configuration.

Incluez les extraits de code suivants pour vérifier les ressources supprimées et définissez le résultat de l'évaluation d'une règle Lambda AWS Config personnalisée sur le fait qu'elle indique une ressource supprimée : `NOT_APPLICABLE`

Custom Lambda Rules (Node.js)

```
// Check whether the resource has been deleted. If the resource was deleted, then
 the evaluation returns not applicable.
function isApplicable(configurationItem, event) {
    checkDefined(configurationItem, 'configurationItem');
    checkDefined(event, 'event');
    const status = configurationItem.configurationItemStatus;
    const eventLeftScope = event.eventLeftScope;
    return (status === 'OK' || status === 'ResourceDiscovered') && eventLeftScope
 === false;
}
```

Custom Lambda Rules (Python)

```
# Check whether the resource has been deleted. If the resource was deleted, then the
 evaluation returns not applicable.
def is_applicable(configurationItem, event):
    try:
        check_defined(configurationItem, 'configurationItem')
        check_defined(event, 'event')
    except:

```

```
    status = configurationItem['configurationItemStatus']

Règles liées aux services AWS Config

Une AWS Config règle liée à un service est un type unique de règles AWS Config gérées qui permet à d'autres AWS services de créer des AWS Config règles dans votre compte. Les règles liées aux services sont prédéfinies pour inclure toutes les autorisations requises pour appeler d'autres AWS services en votre nom. Ces règles sont similaires aux normes qu'un AWS service vous recommande Compte AWS pour la vérification de conformité.

Ces AWS Config règles liées aux services sont détenues par les équipes de AWS service. L'équipe AWS de service crée ces règles dans votre Compte AWS. Vous disposez d'un accès en lecture seule à ces règles. Vous ne pouvez pas modifier ou supprimer ces règles si vous êtes abonné à AWS un service auquel ces règles sont liées.

Les règles liées aux services et le AWS Command Line Interface

L'accès AWS CLI, le PutConfigRuleDeleteConfigRule, et le DeleteEvaluationResults APIs retour étant refusé avec le message d'erreur suivant :

```
INSUFFICIENT_SLCR_PERMISSIONS = "An AWS service owns
ServiceLinkedConfigRule. You do not have permissions to take action on this
rule."
```

Les règles liées aux services et la console AWS Config

Dans la AWS Config console, les AWS Config règles liées au service sont visibles sur la page Règles. Les boutons Modifier et Supprimer les résultats sont grisés dans la console pour vous empêcher de modifier la règle. Vous pouvez consulter les détails de la règle en choisissant celle-ci.

Règles liées aux services, actions correctives et packs de conformité

Pour ajouter des actions de correction à des règles liées à un service dans un pack de conformité, vous devez ajouter l'action de correction au modèle de pack de conformité lui-même, puis mettre à jour le pack de conformité avec votre modèle mis à jour. Pour plus d'informations sur la mise à jour des packs de conformité, consultez les sections Déploiement d'un pack de conformité (console), Déploiement d'un pack de conformité (AWS CLI) et Gestion des packs de conformité organisationnels.

Modification et suppression de règles liées à un service

Pour modifier ou supprimer une règle liée à un service, contactez le AWS service qui a créé la règle. Par exemple, pour les règles liées à un service créées par AWS Security Hub CSPM, vous pouvez supprimer une règle liée à un service en suivant les étapes décrites dans le Guide de l'AWS Security Hub CSPM utilisateur : Désactivation d'une norme de sécurité.

Gestion des AWS Config règles pour tous les comptes de votre organisation

> **Important**
>
> Les règles organisationnelles ne peuvent être créées qu'à l'aide de l'API ou de la CLI. Cette opération n'est pas prise en charge dans la AWS Config console.

AWS Config vous permet de gérer les AWS Config règles dans l'ensemble Comptes AWS d'une organisation. Vous pouvez effectuer les actions suivantes :

- Créez, mettez à jour et supprimez des AWS Config règles centralisées pour tous les comptes de votre organisation.
- Déployez un ensemble de AWS Config règles communes à tous les comptes et spécifiez les comptes pour lesquels AWS Config les règles ne doivent pas être créées.

- Utilisez le compte APIs de gestion AWS Organizations pour renforcer la gouvernance en vous assurant que les AWS Config règles sous-jacentes ne sont pas modifiables par les comptes membres de votre organisation.

Considérations

Pour les déploiements dans différentes régions

L'appel d'API pour déployer des règles et des packs de conformité entre les comptes est spécifique à AWS la région. Au niveau de l'organisation, vous devez modifier le contexte de votre appel d'API vers une autre région si vous souhaitez déployer des règles dans d'autres régions. Par exemple, pour déployer une règle dans la région USA Est (Virginie du Nord), remplacez la région par USA Est (Virginie du Nord), puis appelez `PutOrganizationConfigRule`.

Pour les comptes au sein d'une organisation

Si un nouveau compte rejoint une organisation, la règle ou le pack de conformité est déployé(e) sur ce compte. Lorsqu'un compte quitte une organisation, la règle ou le pack de conformité est supprimé(e).

Si vous déployez une règle organisationnelle ou un pack de conformité dans un compte administrateur d'organisation avant d'établir un administrateur délégué et de déployer une règle organisationnelle ou un pack de conformité dans le compte administrateur délégué, vous ne pourrez pas voir la règle organisationnelle ou le pack de conformité dans le compte administrateur de l'organisation depuis le compte administrateur délégué, ni voir la règle organisationnelle ou le pack de conformité dans le compte administrateur délégué depuis le compte administrateur de l'organisation. Le DescribeOrganizationConfigRuleset DescribeOrganizationConformancePacks APIs peut uniquement voir et interagir avec les ressources liées à l'organisation qui ont été déployées depuis le compte qui les appelle. APIs

Mécanisme de nouvelle tentative pour les nouveaux comptes ajoutés à une organisation

Le déploiement des règles organisationnelles et des packs de conformité existants fera l'objet d'une nouvelle tentative uniquement dans les 7 heures suivant l'ajout d'un compte à votre organisation si aucun enregistreur n'est disponible. Vous devez créer un enregistreur s'il n'en existe pas dans les 7 heures qui suivent l'ajout d'un compte à votre organisation.

Comptes de gestion de l'organisation, administrateurs délégués et rôles liés aux services

Si vous utilisez un compte de gestion d'organisation et que vous avez l'intention de faire appel à un administrateur délégué pour le déploiement organisationnel, sachez que cela AWS Config ne créera pas automatiquement le rôle lié au service (SLR). Vous devez créer manuellement le rôle lié au service (SLR) séparément à l'aide d'IAM.

Si vous ne possédez pas de reflex pour votre compte de gestion, vous ne pourrez pas déployer de ressources vers ce compte à partir d'un compte d'administrateur délégué. Vous pourrez toujours déployer des AWS Config règles sur les comptes membres depuis les comptes de gestion et les comptes d'administrateur délégué. Pour plus d'informations, consultez la section Utilisation des rôles liés à un service dans le Guide de l'Gestion des identités et des accès AWS utilisateur (IAM).

Déploiement

Pour plus d'informations sur la manière AWS Config d'intégrer AWS Organizations, consultez AWS Config et AWS Organizations dans le Guide de AWS Organizations l'utilisateur. Assurez-vous que AWS Config l'enregistrement est activé avant d'utiliser les méthodes suivantes APIs pour gérer les AWS Config règles Comptes AWS dans l'ensemble d'une organisation :

- PutOrganizationConfigRule, ajoute ou met à jour une règle de configuration d'organisation pour l'ensemble de votre organisation en évaluant si vos AWS ressources sont conformes aux configurations souhaitées.
- DescribeOrganizationConfigRules, renvoie une liste des règles de configuration de l'organisation.
- GetOrganizationConfigRuleDetailedStatus, renvoie le statut détaillé de chaque compte membre au sein d'une organisation pour une règle de configuration d'organisation donnée.
- GetOrganizationCustomRulePolicy, renvoie la définition de politique contenant la logique de la règle de politique personnalisée de configuration de votre organisation.
- DescribeOrganizationConfigRuleStatuses, fournit l'état de déploiement des règles de configuration d'une organisation.
- DeleteOrganizationConfigRule, supprime la règle de configuration d'organisation spécifiée et tous ses résultats d'évaluation de tous les comptes membres de cette organisation.

> Lorsque vous ajoutez une nouvelle règle, AWS Config elle évalue les ressources applicables dans votre inventaire de ressources, y compris les ressources précédemment enregistrées. Par exemple, si vous avez enregistré `AWS::IoT::Policy` des ressources mais que vous les avez ultérieurement exclues de l'enregistrement AWS Config , les éléments de configuration initiaux (CIs) sont conservés dans votre inventaire. Bien qu'il AWS Config ne les mette plus à jour CIs lorsque les types de ressources associés sont exclus de l'enregistrement, il conserve leur dernier état enregistré et les évalue lorsque vous ajoutez des règles applicables.

Ajout de règles

Pour ajouter une règle

1. Connectez-vous à la AWS Config console AWS Management Console et ouvrez-la à la https://console.aws.amazon.com/config/maison.
2. Dans le AWS Management Console menu, vérifiez que le sélecteur de région est défini sur une région qui prend en charge les AWS Config règles. Pour obtenir la liste des régions prises en charge, consultez la section Régions et points de terminaison AWS Config dans le Référence générale d'Amazon Web Services.
3. Dans le volet de navigation de gauche, choisissez Règles.
4. Sur la page Règles, choisissez Ajouter une règle.
5. Sur la page Spécifier le type de règle, indiquez le type de règle en effectuant les étapes suivantes :

   a. Commencez une saisie dans le champ de recherche pour filtrer la liste des règles gérées par nom de règle, description et étiquette. Par exemple, tapez EC2 pour renvoyer des règles permettant d'évaluer des types de ressources EC2 ou tapez périodique pour renvoyer des règles déclenchées de façon périodique.

   b. Vous pouvez également créer votre propre règles personnalisée. Choisissez Créer une règle personnalisée à l'aide de Lambda ou Créer une règle personnalisée à l'aide de Guard, puis suivez la procédure décrite dans Création de règles AWS Config Lambda personnalisées ou Création AWS Config de règles de politique personnalisées.
6. Sur la page Configurer une règle, configurez la règle en réalisant les étapes suivantes :

   a. Dans Nom, tapez un nom unique pour la règle.

   b. Saisissez une description de la règle dans le champ Description.

   c. Pour le mode d'évaluation, choisissez à quel moment du processus de création et de gestion des ressources vous AWS Config souhaitez évaluer vos ressources. Selon la règle, AWS Config vous pouvez évaluer vos configurations de ressources avant le déploiement d'une ressource, après le déploiement d'une ressource, ou les deux.

      i. Choisissez Activer l'évaluation proactive pour évaluer les paramètres de configuration de vos ressources avant leur déploiement.

         Après avoir activé l'évaluation proactive, vous pouvez utiliser l'StartResourceEvaluationAPI et l'GetResourceEvaluationSummaryAPI pour vérifier si

les ressources que vous spécifiez dans ces commandes seront signalées comme NON CONFORMES par les règles proactives de votre compte dans votre région.

Pour plus d'informations sur l'utilisation de ces commandes, consultez la section Évaluation de vos ressources à l'aide de AWS Config règles. Pour obtenir la liste des règles gérées qui prennent en charge l'évaluation proactive, consultez la section Liste des règles AWS Config gérées par mode d'évaluation.

ii. Choisissez Activer l'évaluation détective pour évaluer les paramètres de configuration de vos ressources existantes.

Deux types de déclencheurs sont disponibles pour l'évaluation détective : Lors de changements de configuration et Périodique.

A. Si les types de déclencheurs de votre règle incluent des modifications de configuration, spécifiez l'une des options suivantes pour Étendue des modifications avec laquelle AWS Config votre fonction Lambda est appelée :

- Ressources : lorsqu'une ressource qui correspond au type de ressource spécifié, ou au type plus à l'identifiant, est créée, modifiée ou supprimée.
- Balises : lorsqu'une ressource portant la balise spécifiée est créée, modifiée ou supprimée.
- Toutes les modifications : lorsqu'une ressource enregistrée par AWS Config est créée, modifiée ou supprimée.

AWS Config exécute l'évaluation lorsqu'il détecte une modification apportée à une ressource correspondant au champ d'application de la règle. Vous pouvez utiliser la portée afin de définir les ressources qui déclenchent des évaluations.

B. Si les types de déclencheurs de votre règle incluent Periodic, spécifiez la fréquence à laquelle votre fonction Lambda est AWS Config invoquée.

d. Vous pouvez personnaliser les valeurs des clés fournies dans le champ Paramètres, si votre règle comprend des paramètres. Un paramètre est un attribut que vos ressources doivent respecter pour pouvoir être considérées conformes à la règle.

7. Sur la page Réviser et créer, passez en revue toutes vos sélections avant d'ajouter la règle à votre Compte AWS. Si la règle ne fonctionne pas comme prévu, l'un des messages suivants relatifs à la Conformité s'affiche :

- Aucun résultat n'a été signalé. Vos ressources ont AWS Config été évaluées par rapport à la règle. La règle ne s'appliquait pas aux AWS ressources incluses dans son champ d'application, les ressources spécifiées ont été supprimées ou les résultats de l'évaluation ont été supprimés. Pour obtenir les résultats de l'évaluation, mettez à jour la règle, modifiez sa portée ou choisissez Re-evaluate (Réévaluer).

  Ce message peut également apparaître si la règle n'a pas renvoyé de résultats d'évaluation.
- Aucune ressource dans le champ d'application : AWS Config impossible d'évaluer vos AWS ressources enregistrées par rapport à cette règle car aucune de vos ressources n'entre dans le champ d'application de la règle. Pour obtenir les résultats de l'évaluation, modifiez la règle et sa portée, ou ajoutez des ressources AWS Config à enregistrer à l'aide de la page Paramètres.
- Evaluations failed (Échec des évaluations) - pour obtenir des informations susceptibles de vous aider à déterminer le problème, choisissez le nom de la règle pour ouvrir sa page de détails et voir le message d'erreur.

Ajouter des règles (AWS SDKs)

Ajout de règles

Les exemples de code suivants illustrent comment utiliser `PutConfigRule`.

CLI

AWS CLI

Pour ajouter une règle Config AWS gérée

La commande suivante fournit du code JSON pour ajouter une règle de configuration AWS gérée :

```
aws configservice put-config-rule --config-rule file://
RequiredTagsForEC2Instances.json
```

`RequiredTagsForEC2Instances.json` est un fichier JSON qui contient la configuration de la règle :

```
{
```

```
  "ConfigRuleName": "RequiredTagsForEC2Instances",
  "Description": "Checks whether the CostCenter and Owner tags are applied to EC2
 instances.",
  "Scope": {
    "ComplianceResourceTypes": [
      "AWS::EC2::Instance"
    ]
  },
  "Source": {
    "Owner": "AWS",
    "SourceIdentifier": "REQUIRED_TAGS"
  },
  "InputParameters": "{\"tag1Key\":\"CostCenter\",\"tag2Key\":\"Owner\"}"
}
```

Pour l'`ComplianceResourceTypes`attribut, ce code JSON limite la portée aux ressources de ce `AWS::EC2::Instance` type, de sorte que AWS Config évaluera uniquement les instances EC2 par rapport à la règle. Puisque la règle est une règle gérée, l'attribut `Owner` est défini sur `AWS` et l'attribut `SourceIdentifier` est défini sur l'identifiant de règle, `REQUIRED_TAGS`. Pour l'attribut `InputParameters`, les clés de balise requises par la règle, `CostCenter` et `Owner`, sont spécifiées.

Si la commande aboutit, AWS Config ne renvoie aucune sortie. Pour vérifier la configuration de la règle, exécutez la describe-config-rules commande et spécifiez le nom de la règle.

Pour ajouter une règle Config gérée par le client

La commande suivante fournit du code JSON pour ajouter une règle Config gérée par le client :

```
aws configservice put-config-rule --config-rule file://
InstanceTypesAreT2micro.json
```

`InstanceTypesAreT2micro.json` est un fichier JSON qui contient la configuration de la règle :

```
{
  "ConfigRuleName": "InstanceTypesAreT2micro",
  "Description": "Evaluates whether EC2 instances are the t2.micro type.",
  "Scope": {
    "ComplianceResourceTypes": [
      "AWS::EC2::Instance"
```

```
    ]
  },
  "Source": {
    "Owner": "CUSTOM_LAMBDA",
    "SourceIdentifier": "arn:aws:lambda:us-
east-1:123456789012:function:InstanceTypeCheck",
    "SourceDetails": [
      {
        "EventSource": "aws.config",
        "MessageType": "ConfigurationItemChangeNotification"
      }
    ]
  },
  "InputParameters": "{\"desiredInstanceType\":\"t2.micro\"}"
}
```

Pour l'`ComplianceResourceTypes`attribut, ce code JSON limite la portée aux ressources de ce `AWS::EC2::Instance` type, de sorte que AWS Config évaluera uniquement les instances EC2 par rapport à la règle. Comme cette règle est une règle gérée par le client, l'`Owner`attribut est défini sur`CUSTOM_LAMBDA`, et l'`SourceIdentifier`attribut est défini sur l'ARN de la fonction AWS Lambda. L'objet `SourceDetails` est obligatoire. Les paramètres spécifiés pour l'`InputParameters`attribut sont transmis à la fonction AWS Lambda lorsque AWS Config l'invoque pour évaluer les ressources par rapport à la règle.

Si la commande aboutit, AWS Config ne renvoie aucune sortie. Pour vérifier la configuration de la règle, exécutez la describe-config-rules commande et spécifiez le nom de la règle.

Pour l'`ComplianceResourceTypes`attribut, ce code JSON limite la portée aux ressources de ce `AWS::EC2::Instance` type. AWS Config évaluera donc uniquement les instances EC2 par rapport à la règle. Cette règle étant une règle gérée par le client, l'`Owner`attribut est défini sur`CUSTOM_LAMBDA`, et l'`SourceIdentifier`attribut est défini sur l'ARN de la fonction AWS Lambda. L'objet `SourceDetails` est obligatoire. Les paramètres spécifiés pour l'`InputParameters`attribut sont transmis à la fonction AWS Lambda lorsque AWS Config l'invoque pour évaluer les ressources par rapport à la règle.

Si la commande aboutit, AWS Config ne renvoie aucune sortie. Pour vérifier la configuration des règles, exécutez la describe-config-rules commande et spécifiez le nom de la règle.

Supprimer des AWS Config règles

Vous pouvez utiliser la AWS Config console ou le AWS SDKs pour supprimer vos règles.

Considérations

Recommandation : envisagez d'exclure le type de **`AWS::Config::ResourceCompliance`** ressource de l'enregistrement avant de supprimer les règles

La suppression de règles crée des éléments de configuration (CIs) `AWS::Config::ResourceCompliance` qui peuvent avoir une incidence sur le coût de l'enregistreur de configuration. Si vous supprimez des règles qui évaluent un grand nombre de types de ressources, cela peut entraîner une augmentation du nombre de ressources CIs enregistrées.

Pour éviter les coûts associés, vous pouvez choisir de désactiver l'enregistrement pour le type de `AWS::Config::ResourceCompliance` ressource avant de supprimer les règles, et de réactiver l'enregistrement une fois les règles supprimées.

Toutefois, étant donné que la suppression de règles est un processus asynchrone, cela peut prendre une heure ou plus. Pendant la période pendant laquelle l'enregistrement est désactivé`AWS::Config::ResourceCompliance`, les évaluations des règles ne seront pas enregistrées dans l'historique de la ressource associée.

Supprimer des règles (console)

La page Règles affiche vos règles et leurs résultats de conformité actuels sous forme de tableau. Le résultat pour chaque règle est Evaluer... jusqu'à la AWS Config fin de l'évaluation de vos ressources par rapport à la règle. Vous pouvez mettre à jour les résultats avec le bouton Refresh. Lorsque AWS Config les évaluations sont terminées, vous pouvez voir les règles et les types de ressources conformes ou non conformes. Pour de plus amples informations, veuillez consulter Afficher les informations de conformité et les résultats d'évaluation de vos AWS ressources avec AWS Config.

> **Note**
>
> AWS Config évalue uniquement les types de ressources qu'il enregistre. Par exemple, si vous ajoutez la règle compatible avec Cloudtrail mais que vous n'enregistrez pas le type de ressource de CloudTrail suivi, vous ne AWS Config pouvez pas évaluer si les sentiers de

votre compte sont conformes ou non conformes. Pour de plus amples informations, veuillez consulter AWS Ressources d'enregistrement avec AWS Config.

Suppression de règles

Pour supprimer une règle

1. Connectez-vous à la AWS Config console AWS Management Console et ouvrez-la à la https://console.aws.amazon.com/config/maison.
2. Dans le AWS Management Console menu, vérifiez que le sélecteur de région est défini sur une région qui prend en charge les AWS Config règles. Pour obtenir la liste des régions prises en charge, consultez la section Régions et points de terminaison AWS Config dans le Référence générale d'Amazon Web Services.
3. Dans le volet de navigation de gauche, choisissez Règles.
4. Choisissez la règle que vous souhaitez supprimer dans le tableau.
5. Dans la liste déroulante Actions, choisissez Supprimer une règle.
6. Lorsque vous y êtes invité, tapez « Supprimer » (cette entrée est sensible à la casse), puis choisissez Supprimer.

Activer l'évaluation proactive des AWS Config règles

Vous pouvez utiliser la AWS Config console ou le AWS SDKs pour activer les règles d'évaluation proactives. Pour obtenir la liste des types de ressources et des règles gérées qui prennent en charge l'évaluation proactive, voir Composants d'une règle | Modes d'évaluation.

Rubriques

- Activer l'évaluation proactive (console)
- Activer l'évaluation proactive (AWS SDKs)

Activer l'évaluation proactive (console)

La page Règles affiche vos règles et leurs résultats de conformité actuels sous forme de tableau. Le résultat pour chaque règle est Evaluer... jusqu'à la AWS Config fin de l'évaluation de vos ressources par rapport à la règle. Vous pouvez mettre à jour les résultats avec le bouton Refresh.

Lorsque AWS Config les évaluations sont terminées, vous pouvez voir les règles et les types de ressources conformes ou non conformes. Pour de plus amples informations, veuillez consulter Afficher les informations de conformité et les résultats d'évaluation de vos AWS ressources avec AWS Config.

> **Note**
>
> AWS Config évalue uniquement les types de ressources qu'il enregistre. Par exemple, si vous ajoutez la règle compatible avec Cloudtrail mais que vous n'enregistrez pas le type de ressource de CloudTrail suivi, vous ne AWS Config pouvez pas évaluer si les sentiers de votre compte sont conformes ou non conformes. Pour de plus amples informations, veuillez consulter AWS Ressources d'enregistrement avec AWS Config.

Activation de l'évaluation proactive

Vous pouvez utiliser l'évaluation proactive pour évaluer les ressources avant leur déploiement. Cela vous permet d'évaluer si un ensemble de propriétés de ressources, s'il est utilisé pour définir une AWS ressource, serait CONFORME ou NON_COMPLIANT compte tenu de l'ensemble de règles proactives que vous avez dans votre compte dans votre région.

Le schéma du type de ressource indique les propriétés d'une ressource. Vous pouvez trouver le schéma du type de ressource dans « extensions AWS publiques » du AWS CloudFormation registre ou à l'aide de la commande CLI suivante :

```
aws cloudformation describe-type --type-name "AWS::S3::Bucket" --type RESOURCE
```

Pour plus d'informations, consultez la section Gestion des extensions via le CloudFormation registre et la référence aux types de AWS ressources et de propriétés dans le guide de AWS CloudFormation l'utilisateur.

> **Note**
>
> Les règles proactives ne corrigent pas les ressources marquées comme NON_COMPLIANT et n'empêchent pas leur déploiement.

Pour activer l'évaluation proactive

1. Connectez-vous à la AWS Config console AWS Management Console et ouvrez-la à la https://console.aws.amazon.com/config/maison.
2. Dans le AWS Management Console menu, vérifiez que le sélecteur de région est défini sur une région qui prend en charge les AWS Config règles. Pour obtenir la liste des régions AWS prises

en charge, consultez Régions et points de terminaison AWS Config dans le Référence générale d'Amazon Web Services.

3. Dans le volet de navigation de gauche, choisissez Règles. Pour obtenir la liste des règles gérées qui prennent en charge l'évaluation proactive, consultez la section Liste des règles AWS Config gérées par mode d'évaluation.
4. Choisissez une règle et l'option Modifier la règle correspondant à la règle que vous souhaitez mettre à jour.
5. Choisissez Activer l'évaluation proactive pour le Mode d'évaluation afin de pouvoir évaluer les paramètres de configuration de vos ressources avant leur déploiement.
6. Choisissez Enregistrer.

Après avoir activé l'évaluation proactive, vous pouvez utiliser l'StartResourceEvaluationAPI et l'GetResourceEvaluationSummaryAPI pour vérifier si les ressources que vous spécifiez dans ces commandes seront signalées comme NON CONFORMES par les règles proactives de votre compte dans votre région.

Par exemple, commencez par l' StartResourceEvaluation API :

```
aws configservice start-resource-evaluation --evaluation-mode PROACTIVE
                --resource-details '{"ResourceId":"MY_RESOURCE_ID",
                                     "ResourceType":"AWS::RESOURCE::TYPE",

 "ResourceConfiguration":"RESOURCE_DEFINITION_AS_PER_THE_RESOURCE_CONFIGURATION_SCHEMA",

 "ResourceConfigurationSchemaType":"CFN_RESOURCE_SCHEMA"}'
```

Vous devriez recevoir le `ResourceEvaluationId` dans la sortie :

```
{
    "ResourceEvaluationId": "MY_RESOURCE_EVALUATION_ID"
}
```

Ensuite, utilisez l'API `ResourceEvaluationId` avec l' GetResourceEvaluationSummary API pour vérifier le résultat de l'évaluation :

```
aws configservice get-resource-evaluation-summary
```

```
    --resource-evaluation-id MY_RESOURCE_EVALUATION_ID
```

Votre résultat doit être similaire à ce qui suit :

```
{
    "ResourceEvaluationId": "MY_RESOURCE_EVALUATION_ID",
    "EvaluationMode": "PROACTIVE",
    "EvaluationStatus": {
        "Status": "SUCCEEDED"
    },
    "EvaluationStartTimestamp": "2022-11-15T19:13:46.029000+00:00",
    "Compliance": "COMPLIANT",
    "ResourceDetails": {
        "ResourceId": "MY_RESOURCE_ID",
        "ResourceType": "AWS::RESOURCE::TYPE",
        "ResourceConfiguration":
 "RESOURCE_DEFINITION_AS_PER_THE_RESOURCE_CONFIGURATION_SCHEMA"
    }
}
```

Pour obtenir des informations supplémentaires sur le résultat de l'évaluation, telles que la règle qui a marqué une ressource comme NON_COMPLIANT, utilisez l'API. GetComplianceDetailsByResource

Activer l'évaluation proactive (AWS SDKs)

Activer l'évaluation proactive (AWS CLI)

Vous pouvez utiliser l'évaluation proactive pour évaluer les ressources avant leur déploiement. Cela vous permet d'évaluer si un ensemble de propriétés de ressources, s'il est utilisé pour définir une AWS ressource, serait CONFORME ou NON_COMPLIANT compte tenu de l'ensemble de règles proactives que vous avez dans votre compte dans votre région.

Le schéma du type de ressource indique les propriétés d'une ressource. Vous pouvez trouver le schéma du type de ressource dans « extensions AWS publiques » du AWS CloudFormation registre ou à l'aide de la commande CLI suivante :

```
aws cloudformation describe-type --type-name "AWS::S3::Bucket" --type RESOURCE
```

Pour plus d'informations, consultez la section Gestion des extensions via le CloudFormation registre et la référence aux types de AWS ressources et de propriétés dans le guide de AWS CloudFormation l'utilisateur.

> **Note**
>
> Les règles proactives ne corrigent pas les ressources marquées comme NON_COMPLIANT et n'empêchent pas leur déploiement.

Pour activer l'évaluation proactive

Utilisez la commande `put-config-rule` et activez `PROACTIVE` pour `EvaluationModes`.

Après avoir activé l'évaluation proactive, vous pouvez utiliser les commandes CLI et start-resource-evaluationget-resource-evaluation-summaryCLI pour vérifier si les ressources que vous spécifiez dans ces commandes seront signalées comme NON_COMPLIANT par les règles proactives de votre compte dans votre région.

Commencez par exemple avec la commande start-resource-evaluation :

```
aws configservice start-resource-evaluation --evaluation-mode PROACTIVE
                --resource-details '{"ResourceId":"MY_RESOURCE_ID",
                                     "ResourceType":"AWS::RESOURCE::TYPE",

 "ResourceConfiguration":"RESOURCE_DEFINITION_AS_PER_THE_RESOURCE_CONFIGURATION_SCHEMA",

 "ResourceConfigurationSchemaType":"CFN_RESOURCE_SCHEMA"}'
```

Vous devriez recevoir le `ResourceEvaluationId` dans la sortie :

```
{
    "ResourceEvaluationId": "MY_RESOURCE_EVALUATION_ID"
}
```

Utilisez ensuite l'`ResourceEvaluationId` avec get-resource-evaluation-summary pour vérifier le résultat de l'évaluation :

```
aws configservice get-resource-evaluation-summary
    --resource-evaluation-id MY_RESOURCE_EVALUATION_ID
```

Votre résultat doit être similaire à ce qui suit :

```
{
```

```
    "ResourceEvaluationId": "MY_RESOURCE_EVALUATION_ID",
    "EvaluationMode": "PROACTIVE",
    "EvaluationStatus": {
        "Status": "SUCCEEDED"
    },
    "EvaluationStartTimestamp": "2022-11-15T19:13:46.029000+00:00",
    "Compliance": "COMPLIANT",
    "ResourceDetails": {
        "ResourceId": "MY_RESOURCE_ID",
        "ResourceType": "AWS::RESOURCE::TYPE",
        "ResourceConfiguration":
 "RESOURCE_DEFINITION_AS_PER_THE_RESOURCE_CONFIGURATION_SCHEMA"
    }
}
```

Pour obtenir des informations supplémentaires sur le résultat de l'évaluation, telles que la règle qui a marqué une ressource comme NON_COMPLIANT, utilisez la commande CLI -resourceget-compliance-details-by.

> **Note**
>
> Pour obtenir la liste des règles gérées qui prennent en charge l'évaluation proactive, consultez la section Liste des règles AWS Config gérées par mode d'évaluation.

Envoi d'évaluations de règles à Security Hub CSPM

Après avoir ajouté une AWS Config règle, vous pouvez également envoyer des évaluations de règles à AWS Security Hub CSPM. L'intégration entre Security Hub CSPM AWS Config et Security Hub vous permet de trier et de corriger les évaluations des règles ainsi que d'autres erreurs de configuration et problèmes de sécurité.

Envoyer des évaluations de règles à Security Hub CSPM

Pour envoyer des évaluations de règles à Security Hub CSPM, vous devez d'abord configurer AWS Security Hub CSPM puis AWS Config ajouter au moins une règle AWS Config gérée ou personnalisée. Ensuite, commence AWS Config immédiatement à envoyer les évaluations des règles à Security Hub CSPM. Security Hub CSPM enrichit les évaluations des règles et les transforme en conclusions du Security Hub CSPM.

Pour plus d'informations sur cette intégration, consultez la section Intégrations AWS de services disponibles dans le guide de l' AWS Security Hub CSPM utilisateur.

Évaluer vos ressources à l'aide de AWS Config règles

Lorsque vous créez des règles personnalisées ou que vous utilisez des règles gérées, vos ressources AWS Config sont évaluées par rapport à ces règles. Vous pouvez exécuter des évaluations à la demande pour les ressources par rapport à vos règles. Par exemple, cela est utile lorsque vous créez une règle personnalisée et que vous souhaitez vérifier AWS Config qu'elle évalue correctement vos ressources ou pour identifier s'il existe un problème avec la logique d'évaluation de votre AWS Lambda fonction.

Exemple

1. Vous créez une règle personnalisée qui évalue si vos utilisateurs IAM disposent de clés d'accès actives.
2. AWS Config évalue vos ressources par rapport à votre règle personnalisée.
3. Votre compte comporte un utilisateur IAM sans clé d'accès active. Votre règle ne signale pas correctement cette ressource comme NON_COMPLIANT.
4. Vous corrigez la règle et recommencez l'évaluation.
5. Étant donné que vous avez corrigé votre règle, celle-ci évalue correctement vos ressources et indique que la ressource d'utilisateur IAM est NON_COMPLIANT.

Lorsque vous ajoutez une règle à votre compte, vous pouvez indiquer à quel moment du processus de création et de gestion des ressources vous AWS Config souhaitez évaluer vos ressources. Le processus de création et de gestion des ressources est connu sous le nom de mise en service des ressources. Vous choisissez le mode d'évaluation pour spécifier à quel moment vous souhaitez évaluer vos ressources AWS Config au cours de ce processus.

Selon la règle, AWS Config vous pouvez évaluer vos configurations de ressources avant le déploiement d'une ressource, après le déploiement d'une ressource, ou les deux. L'évaluation d'une ressource avant son déploiement est une évaluation proactive. L'évaluation d'une ressource après son déploiement est une évaluation détective.

Mode proactif

Utilisez l'évaluation proactive pour évaluer les ressources avant leur déploiement. Cela vous permet d'évaluer si un ensemble de propriétés de ressources, s'il est utilisé pour définir une AWS ressource, serait CONFORME ou NON_COMPLIANT compte tenu de l'ensemble de règles proactives que vous avez dans votre compte dans votre région.

Le schéma du type de ressource indique les propriétés d'une ressource. Vous pouvez trouver le schéma du type de ressource dans « extensions AWS publiques » du AWS CloudFormation registre ou à l'aide de la commande CLI suivante :

```
aws cloudformation describe-type --type-name "AWS::S3::Bucket" --type RESOURCE
```

Pour plus d'informations, consultez la section Gestion des extensions via le CloudFormation registre et la référence aux types de AWS ressources et de propriétés dans le guide de AWS CloudFormation l'utilisateur.

> **Note**
>
> Les règles proactives ne corrigent pas les ressources marquées comme NON_COMPLIANT et n'empêchent pas leur déploiement.

Évaluation de vos ressources

Pour activer l'évaluation proactive

1. Connectez-vous à la AWS Config console AWS Management Console et ouvrez-la à la https://console.aws.amazon.com/config/maison.
2. Dans le AWS Management Console menu, vérifiez que le sélecteur de région est défini sur une région qui prend en charge les AWS Config règles. 5. Choisissez Activer l'évaluation proactive pour le Mode d'évaluation afin de pouvoir évaluer les paramètres de configuration de vos ressources avant leur déploiement.
6. Choisissez Enregistrer.

> **Note**
>
> Vous pouvez également activer l'évaluation proactive à l'aide de la `put-config-rule`commande et en activant `PROACTIVE` `EvaluationModes` ou en utilisant l'PutConfigRuleaction et en activant `PROACTIVE` pour`EvaluationModes`.

Après avoir activé l'évaluation proactive, vous pouvez utiliser l'StartResourceEvaluationAPI et l'GetResourceEvaluationSummaryAPI pour vérifier si les ressources que vous spécifiez dans ces commandes seront signalées comme NON CONFORMES par les règles proactives de votre compte dans votre région.

Par exemple, commencez par l' StartResourceEvaluation API :

```
aws configservice start-resource-evaluation --evaluation-mode PROACTIVE
                --resource-details '{"ResourceId":"MY_RESOURCE_ID",

 "ResourceConfiguration":"RESOURCE_DEFINITION_AS_PER_THE_RESOURCE_CONFIGURATION_SCHEMA",

 "ResourceConfigurationSchemaType":"CFN_RESOURCE_SCHEMA"}'
```

Vous devriez recevoir le `ResourceEvaluationId` dans la sortie :

```
{
    "ResourceEvaluationId": "MY_RESOURCE_EVALUATION_ID"
}
```

Ensuite, utilisez l'API `ResourceEvaluationId` avec l' GetResourceEvaluationSummary API pour vérifier le résultat de l'évaluation :

```
aws configservice get-resource-evaluation-summary
    --resource-evaluation-id MY_RESOURCE_EVALUATION_ID
```

Votre résultat doit être similaire à ce qui suit :

```
{
    "ResourceEvaluationId": "MY_RESOURCE_EVALUATION_ID",
    "EvaluationMode": "PROACTIVE",
```

```
    "EvaluationStatus": {
        "Status": "SUCCEEDED"

        "ResourceType": "AWS::RESOURCE::TYPE",
        "ResourceConfiguration":
 "RESOURCE_DEFINITION_AS_PER_THE_RESOURCE_CONFIGURATION_SCHEMA"
    }
}
```

Pour obtenir des informations supplémentaires sur le résultat de l'évaluation, telles que la règle qui a marqué une ressource comme NON_COMPLIANT, utilisez l'API. GetComplianceDetailsByResource

Mode détectif

Utilisez l'évaluation détective pour évaluer les ressources déjà déployées. Ce type d'évaluation vous permet d'évaluer les paramètres de configuration de vos ressources existantes.

Évaluation de vos ressources (console)

1. Connectez-vous à la AWS Config console AWS Management Console et ouvrez-la à la https://console.aws.amazon.com/config/maison.
2. Dans le AWS Management Console menu, vérifiez que le sélecteur de région est défini sur une région compatible avec les AWS Config règles. Pour obtenir la liste des régions prises en charge, consultez la section Régions et points de terminaison AWS Config dans le Référence générale d'Amazon Web Services.
3. Dans le panneau de navigation, choisissez Rules. La page Règles indique le nom, les mesures correctives associées et l'état de conformité de chaque règle.
4. Choisissez une règle dans le tableau.
5. Dans la liste déroulante Actions, choisissez Réévaluer.
6. AWS Config commence à évaluer les ressources par rapport à votre règle.

> **Note**
>
> Vous pouvez réévaluer une règle une fois par minute. Vous devez attendre AWS Config que l'évaluation de votre règle soit terminée avant de commencer une autre évaluation. Vous ne

pouvez pas exécuter une évaluation si une mise à jour ou une suppression de règle sont en cours en même temps.

Évaluation de vos ressources (CLI)

- Utilisez la commande start-config-rules-evaluation :

```
$ aws configservice start-config-rules-evaluation --config-rule-
names ConfigRuleName
```

AWS Config commence à évaluer les configurations de ressources enregistrées par rapport à votre règle. Vous pouvez également spécifier plusieurs règles dans votre demande :

```
$ aws configservice start-config-rules-evaluation --config-rule-
names ConfigRuleName1 ConfigRuleName2 ConfigRuleName3
```

Évaluation de vos ressources (API)

Utilisez l'action StartConfigRulesEvaluation.

Supprimer les résultats d'évaluation des AWS Config règles

Après avoir AWS Config évalué votre règle, vous pouvez voir les résultats de l'évaluation sur la page Règles ou sur la page des détails des règles de la règle. Si les résultats de l'évaluation sont incorrects ou si vous souhaitez effectuer à nouveau l'évaluation, vous pouvez supprimer les résultats de l'évaluation actuelle pour la règle. Par exemple, si votre règle a évalué incorrectement vos ressources ou si vous avez supprimé récemment des ressources de votre compte, vous pouvez supprimer les résultats de l'évaluation, puis en exécuter une nouvelle.

Deleting Evaluation Results (Console)

1. Connectez-vous à la AWS Config console AWS Management Console et ouvrez-la à la https://console.aws.amazon.com/config/maison.
2. Dans le AWS Management Console menu, vérifiez que le sélecteur de région est défini sur une AWS région qui prend en charge les AWS Config règles. Pour obtenir la liste des régions prises en charge, consultez Régions et points de terminaison AWS Config dans le Référence générale d'Amazon Web Services.

3. Dans le panneau de navigation, choisissez Rules. La page Règles indique le nom, les mesures correctives associées et l'état de conformité de chaque règle.
4. Choisissez une règle dans le tableau.
5. Dans la liste déroulante Actions, choisissez Supprimer les résultats.
6. Lorsque vous y êtes invité, tapez Supprimer (cette entrée est sensible à la casse), puis choisissez Supprimer. Une évaluation supprimée ne peut pas être récupérée.
7. Une fois que les résultats de l'évaluation ont été supprimés, vous pouvez démarrer manuellement une nouvelle évaluation.

Deleting Evaluation Results (CLI)

- Utilisez la commande delete-evaluation-results.

```
$ aws configservice delete-evaluation-results --config-rule-name ConfigRuleName
```

  AWS Config supprime les résultats de l'évaluation de la règle.

Deleting Evaluation Results (API)

Utilisez l'action DeleteEvaluationResults.

Résolution des problèmes liés aux AWS Config règles

Vérifiez les problèmes suivants pour les résoudre si vous ne parvenez pas à supprimer une AWS Config règle ou si vous recevez un message d'erreur similaire à ce qui suit : « Une erreur s'est produite avec AWS Config ».

L'entité Gestion des identités et des accès AWS (IAM) dispose d'autorisations pour l'API DeleteConfigRule

1. Ouvrez la console IAM à l’adresse https://console.aws.amazon.com/iam/.
2. Dans le volet de navigation, sélectionnez Utilisateurs ou Rôles.
3. Choisissez l'utilisateur ou le rôle que vous avez utilisé pour supprimer la AWS Config règle, puis développez les politiques d'autorisations.
4. Dans l'onglet Autorisations, choisissez JSON.

5. Dans le volet d'aperçu JSON, vérifiez que la politique IAM autorise les autorisations pour l'DeleteConfigRuleAPI.

La limite d'autorisation de l'entité IAM autorise l'API DeleteConfigRule

Si l'entité IAM possède une limite d'autorisations, assurez-vous qu'elle autorise les autorisations pour l' DeleteConfigRule API.

1. Ouvrez la console IAM à l'adresse https://console.aws.amazon.com/iam/.
2. Dans le volet de navigation, sélectionnez Utilisateurs ou Rôles.
3. Choisissez l'utilisateur ou le rôle que vous avez utilisé pour supprimer la AWS Config règle, étendez la limite des autorisations, puis choisissez JSON.
4. Dans le volet d'aperçu JSON, vérifiez que la politique IAM autorise les autorisations pour l'DeleteConfigRuleAPI.

> **Warning**
>
> Les utilisateurs IAM disposent d'informations d'identification à long terme, ce qui présente un risque de sécurité. Pour atténuer ce risque, nous vous recommandons de ne fournir à ces utilisateurs que les autorisations dont ils ont besoin pour effectuer la tâche et de supprimer ces autorisations lorsqu'elles ne sont plus nécessaires.

La politique de contrôle des services (SCP) autorise l'API DeleteConfigRule

1. Ouvrez la AWS Organizations console à https://console.aws.amazon.com/organizations/ l'adresse « Utiliser le compte de gestion de l'organisation ».
2. Dans Nom du compte, choisissez le Compte AWS.
3. Dans Politiques, développez les politiques de contrôle des services et notez les politiques SCP associées.
4. En haut de la page, sélectionnez Politiques.
5. Sélectionnez la politique, puis choisissez Afficher les détails.
6. Dans le volet d'aperçu JSON, vérifiez que la politique autorise l'DeleteConfigRuleAPI.

La règle n'est pas une règle liée à un service

Lorsque vous activez une norme de sécurité, elle AWS Security Hub CSPM crée des règles liées au service pour vous. Vous ne pouvez pas supprimer ces règles liées aux services à l'aide de AWS Config, et le bouton de suppression est grisé. Pour supprimer une règle liée à un service, consultez la section Désactivation d'une norme de sécurité dans le Guide de l'utilisateur du Security Hub CSPM.

Aucune action corrective n'est en cours

Vous ne pouvez pas supprimer AWS Config les règles qui comportent des actions de correction en cours. Suivez les étapes pour supprimer l'action de correction associée à cette règle. Réessayez ensuite de supprimer la règle.

> **Important**
>
> Supprimez uniquement les actions de correction dont l'état a échoué ou réussi.

Packs de conformité pour AWS Config

Un pack de conformité est un ensemble de AWS Config règles et d'actions correctives qui peuvent être facilement déployées en tant qu'entité unique dans un compte et une région ou au sein d'une organisation dans. AWS Organizations

Les packs de conformité sont créés au moyen d'un modèle YAML qui contient la liste des règles gérées ou personnalisées et des actions de correction AWS Config . Vous pouvez également utiliser AWS Systems Manager des documents (documents SSM) pour stocker vos modèles de packs de conformité AWS et les déployer directement à l'aide des noms de documents SSM. Vous pouvez déployer le modèle à l'aide de la console AWS Config ou de la AWS CLI.

Pour démarrer rapidement et évaluer votre AWS environnement, utilisez l'un des exemples de modèles de pack de conformité. Vous pouvez également créer un fichier YAML de pack de conformité à partir de zéro sur la base du pack de conformité personnalisé.

Affichage des données de conformité dans le tableau de bord des packs de conformité pour AWS Config

La page principale Packs de conformité affiche tous les packs de conformité actuellement disponibles dans votre Compte AWS. La page contient également le nom, l'état de déploiement et le score de conformité de chaque pack de conformité. Le score de conformité est le pourcentage du nombre de combinaisons règle-ressource conformes dans un pack de conformité par rapport au nombre total de combinaisons règles-ressources possibles dans le pack de conformité.

Vous pouvez utiliser ce tableau de bord pour déterminer le niveau de conformité de vos packs de conformité et utiliser le score de conformité pour suivre la progression des mesures correctives, effectuer des comparaisons entre différents ensembles d'exigences et évaluer l'impact d'un changement ou d'un déploiement spécifique sur un pack de conformité.

Navigation sur la page principale des packs de conformité

1. Connectez-vous à la AWS Config console AWS Management Console et ouvrez-la à la https://console.aws.amazon.com/config/maison.
2. Accédez à la page Pack de conformité. Examinez vos packs de conformité et leurs scores de conformité. Vous pouvez également effectuer les opérations suivantes :
   - Pour ajouter et configurer un nouveau pack de conformité, choisissez Déployer le pack de conformité.
   - Pour supprimer un pack de conformité et ses données, modifier les paramètres de configuration ou consulter des détails supplémentaires, tels que l'emplacement ou les paramètres de diffusion, choisissez un pack de conformité, puis Actions.

     > **Note**
     >
     > Un pack de conformité déployé ne peut pas être modifié. Vous pouvez modifier les autres sélections à tout moment en choisissant le nom du pack de conformité et en sélectionnant Modifier dans le menu déroulant Actions.

   - Pour consulter l'historique des changements d'état de conformité, choisissez un pack de conformité, puis Chronologie du pack de conformité. Pour plus d'informations, consultez Affichage de la chronologie de l'historique de conformité des packs de conformité.

- Pour afficher l'état du déploiement, le score de conformité, la chronologie des scores de conformité et les règles d'un pack de conformité dans une vue détaillée, choisissez un pack de conformité, puis Afficher.

Prérequis pour les packs de conformité pour AWS Config

Avant de déployer votre pack de conformité, activez l' AWS Config enregistrement.

Rubriques

- Étape 1 : Lancer AWS Config l'enregistrement (obligatoire pour tous les packs de conformité)
- Étape 2 : Conditions préalables supplémentaires par type de pack de conformité

Étape 1 : Lancer AWS Config l'enregistrement (obligatoire pour tous les packs de conformité)

1. Connectez-vous à la AWS Config console AWS Management Console et ouvrez-la à la https://console.aws.amazon.com/config/maison.
2. Choisissez Settings (Paramètres) dans le volet de navigation.
3. Pour démarrer l'enregistrement, sous Recording is off (L'enregistrement est désactivé), choisissez Turn on (Activer). À l'invite, choisissez Continuer.

Étape 2 : Conditions préalables supplémentaires par type de pack de conformité

A. Conditions préalables à l'utilisation d'un pack de conformité avec correction

Avant de déployer des packs de conformité à l'aide d'exemples de modèles avec correction, vous devez créer des ressources appropriées telles que l'automatisation assume le rôle et d'autres AWS ressources en fonction de votre objectif de correction.

Si vous disposez d'un rôle d'automatisation existant que vous utilisez pour la correction à l'aide de documents SSM, vous pouvez directement fournir l'ARN de ce rôle. Si vous disposez de ressources, vous pouvez les fournir dans le modèle.

> **Note**
>
> Lors du déploiement d'un pack de conformité avec la correction dans une organisation, l'ID du compte de gestion de l'organisation doit être spécifié. Dans le cas contraire, lors du déploiement du pack de conformité de l'organisation, AWS Config remplace automatiquement l'ID du compte de gestion par l'ID du compte membre.

AWS Config ne prend pas en charge les fonctions CloudFormation intrinsèques du rôle d'exécution de l'automatisation ou du`ConfigRuleName`. Vous devez fournir l'ARN exact du rôle sous forme de chaîne, et vous devez utiliser le nom complet de la règle sans fonctions intrinsèques.

Pour de plus amples informations sur la façon de transmettre l'ARN exact, veuillez consulter Exemples de modèles de packs de conformité pour AWS Config. Lors de l'utilisation d'exemples de modèles, mettez à jour votre ID de compte et votre ID de compte de gestion pour l'organisation.

B. Conditions préalables à l'utilisation d'un pack de conformité avec une ou plusieurs règles personnalisées AWS Config

Avant de déployer un pack de conformité avec une ou plusieurs AWS Config règles personnalisées, créez les ressources appropriées telles que la AWS Lambda fonction et le rôle d'exécution correspondant.

Si vous avez une AWS Config règle personnalisée existante, vous pouvez directement fournir la AWS Lambda fonction `ARN` of pour créer une autre instance de cette règle personnalisée dans le cadre du pack.

Si aucune AWS Config règle personnalisée n'existe, vous pouvez créer une AWS Lambda fonction et utiliser l'ARN de la fonction Lambda. Pour de plus amples informations, veuillez consulter AWS Config Règles personnalisées.

Si votre AWS Lambda fonction est présente dans un autre Compte AWS, vous pouvez créer des AWS Config règles avec l'autorisation appropriée pour les AWS Lambda fonctions inter-comptes. Pour plus d'informations, consultez Comment gérer de manière centralisée les AWS Config règles sur plusieurs Comptes AWS articles de blog.

C. Conditions préalables pour les packs de conformité organisationnels

Spécifiez un ARN de rôle d'exécution d'automatisation pour cette correction dans le modèle, si le modèle d'entrée possède une configuration de correction automatique. Vérifiez qu'un rôle portant le nom spécifié existe dans tous les comptes (gestion et membres) d'une organisation. Vous devez créer ce rôle dans tous les comptes avant d'appeler `PutOrganizationConformancePack`. Vous pouvez créer ce rôle manuellement ou utiliser les AWS CloudFormation stack-sets pour créer ce rôle dans chaque compte.

Si votre modèle utilise une fonction AWS CloudFormation intrinsèque `Fn::ImportValue` pour importer une variable particulière, cette variable doit être définie comme un `Export Value` dans tous les comptes membres de cette organisation.

Pour les AWS Config règles personnalisées, consultez Comment gérer de manière centralisée AWS Config les règles sur plusieurs Comptes AWS blogs pour configurer les autorisations appropriées.

AWS Config Contrôles de processus dans le cadre d'un pack de conformité pour AWS Config

Les contrôles de processus sont un type de AWS Config règle qui vous permet de suivre vos tâches externes et internes qui nécessitent une vérification dans le cadre des packs de conformité. Ces vérifications peuvent être ajoutées à un pack de conformité existant ou à un nouveau pack de conformité. Vous pouvez suivre l'ensemble de la conformité, y compris AWS Config les durées et les contrôles manuels, en un seul endroit.

Les vérifications des processus vous permettent de répertorier la conformité des exigences et des actions en un seul endroit. Ces vérifications des processus permettent d'augmenter la couverture des packs de conformité basés sur des régimes de conformité. Vous pouvez étendre le pack de conformité en ajoutant de nouvelles vérifications de processus qui suivent les processus et les actions nécessitant une vérification et un suivi manuels. Cela permet au pack de conformité de devenir le modèle fournissant des détails sur les AWS Config durées et les processus manuels d'un régime de conformité.

Vous pouvez suivre et gérer la conformité des processus qui ne sont pas associés à des modifications de configuration des ressources au sein d'un pack de conformité sous forme de vérifications des processus. Par exemple, vous pouvez ajouter une vérification de processus pour suivre l'exigence de conformité à la norme PCI-DSS, qui consiste à stocker la sauvegarde multimédia dans un emplacement hors site. Vous évaluerez manuellement la conformité de ce processus selon les directives PCI-DSS ou selon les directives de votre organisation.

Disponibilité régionale : les contrôles de processus avec les packs de conformité sont disponibles dans tous les pays Régions AWS où des packs de AWS Config conformité sont disponibles. Pour de plus amples informations, veuillez consulter Prise en charge de la région.

Comprend Process Checks Within a Conformance Pack

1. Ajoutez une vérification de processus dans le modèle de pack de conformité. Reportez-vous à Exemple de modèle de pack de conformité pour créer des vérifications de processus.

   ```
   Resources:
     ConfigEnabledAllRegions:
       Properties:
         ConfigRuleName: Config-Enabled-All-Regions
         Description: Ensure AWS Config is enabled in all Regions.
         Source:
           Owner: AWS
           SourceIdentifier: AWS_CONFIG_PROCESS_CHECK
       Type: AWS::Config::ConfigRule
   ```

2. Saisissez le nom de la vérification de processus.
3. Saisissez la description de la vérification de processus.
4. Déployez le pack de conformité. Pour de plus amples informations, veuillez consulter Déploiement de packs de conformité pour AWS Config.

Modifier le statut de conformité d'une vérification de processus

Vous pouvez modifier l'état de conformité d'un contrôle de processus à l'aide de la AWS Config console AWS CLI, du et APIs.

Change Compliance Status for Process Checks (Console)

1. Connectez-vous à la AWS Config console AWS Management Console et ouvrez-la à la https://console.aws.amazon.com/config/maison.
2. Accédez à la page AWS Config Règles.

3. Choisissez le nom de la vérification de processus que vous avez spécifié dans le modèle, ainsi que l'identifiant, dans le pack de conformité.

> **Note**
>
> Toutes les vérifications de processus du même pack de conformité ont le même suffixe.

4. Sur la page Détails de la règle, vous ne pouvez pas modifier la règle, mais vous pouvez modifier sa conformité. Dans la section Conformité manuelle, choisissez Modifier la conformité.
5. Choisissez la conformité appropriée dans la liste déroulante.
6. (Facultatif) Saisissez une description pour le statut de conformité.
7. Choisissez Enregistrer.

Change the Compliance Status for Process Checks (AWS CLI)

Vous pouvez mettre à jour la conformité des contrôles de processus dans un pack de conformité à l'aide du AWS Command Line Interface (AWS CLI).

Pour l'installer AWS CLI sur votre ordinateur local, consultez la section Installation du AWS CLI dans le guide de AWS CLI l'utilisateur.

Si nécessaire, saisissez `AWS Config ure` pour configurer le AWS CLI afin d'utiliser une AWS région dans laquelle des packs de AWS Config conformité sont disponibles.

1. Ouvrez une invite de commande ou une fenêtre de terminal.
2. Entrez la commande suivante pour mettre à jour la conformité d'un processus, vérifiez où se `ComplianceResourceId` trouve votre`Account ID`, et incluez le nom de votre règle.

```
aws configservice put-external-evaluation --config-rule-
name process-check-rule-name  --external-evaluation
 ComplianceResourceType=AWS::::Account,ComplianceResourceId=Account
 ID,ComplianceType=NON_COMPLIANT,OrderingTimestamp=2020-12-17T00:10:00.000Z
```

3. Appuyez sur Entrée pour exécuter la commande.

Change the Compliance Status for Process Checks (API)

Une fois le déploiement terminé, pour mettre à jour les évaluations et la conformité des vérifications de processus, utilisez l'API `PutExternalEvaluation`. Pour de plus amples informations, veuillez consulter PutExternalEvaluation.

Afficher et modifier la vérification du processus (Console)

Vous ne pouvez afficher les vérifications de processus que lorsqu'un état de conformité a été ajouté aux vérifications de processus. Sélectionnez le pack de conformité spécifique pour afficher toutes les vérifications de processus dans ce pack de conformité. Vous pouvez voir ici une liste des contrôles de processus conformes et non conformes.

Comme il s'agit d'une règle liée à un service, vous ne pouvez pas modifier la vérification du processus à partir de la page Détails de la règle.

> **Note**
>
> Toutefois, vous pouvez mettre à jour la conformité du contrôle de processus en choisissant Modifier la conformité et en sélectionnant la valeur appropriée parmi Conforme, Non conforme ou Non applicable.

Vous pouvez modifier ou supprimer une vérification de processus depuis le pack de conformité dans lequel vous avez ajouté les vérifications de processus.

Exemples de modèles de packs de conformité pour AWS Config

Voici les modèles YAML du pack de conformité que vous pouvez voir dans AWS Config la console. Dans chaque modèle de pack de conformité, vous pouvez utiliser une ou plusieurs AWS Config règles et actions correctives. Les AWS Config règles répertoriées dans le pack de conformité peuvent être des règles AWS Config gérées et/ou des règles AWS Config personnalisées. Vous pouvez télécharger tous les modèles de packs de conformité depuis GitHub.

des coûts à l'aide de AWS Config règles gérées ou personnalisées et d'actions correctives. AWS Config AWS Les modèles d'exemples de packs de conformité visent à vous aider à créer vos propres packs de conformité avec des règles, des paramètres d'entrée et des actions correctives différents ou supplémentaires adaptés à votre environnement. Les exemples de modèle, y compris ceux liés aux normes de conformité et aux référence du secteur, ne sont pas conçus pour assurer votre conformité à une norme de gouvernance spécifique. Ils ne peuvent ni remplacer vos efforts internes ni garantir que vous réussirez une évaluation de conformité.

Note

Il est recommandé de consulter les règles disponibles dans la région où vous déployez un pack de conformité (liste des règles AWS Config gérées par disponibilité régionale) et de modifier le modèle pour les règles qui ne sont pas encore disponibles dans cette région avant le déploiement.

Bonnes pratiques de fonctionnement pour les charges de travail ABS CCIG 2.0 Material

Les packs de conformité fournissent un cadre de conformité à usage général conçu pour vous permettre de créer des contrôles de gouvernance en matière de sécurité, d'exploitation ou d'optimisation des coûts à l'aide de AWS Config règles gérées ou personnalisées et d'actions correctives. AWS Config Les packs de conformité, en tant qu'exemples de modèle, ne sont pas conçus pour garantir pleinement la conformité à une norme de gouvernance ou de conformité spécifique. Il vous incombe de déterminer vous-même si votre utilisation des services est conforme aux exigences légales et réglementaires applicables.

Vous trouverez ci-dessous un exemple de mappage entre le Guide de mise en œuvre du cloud computing ABS 2.0 - Material Workloads et les règles de configuration AWS gérées. Chaque règle de

configuration s'applique à une AWS ressource spécifique et concerne un ou plusieurs contrôles du guide d'implémentation de l'ABS Cloud Computing. Un contrôle du guide d'implémentation du cloud computing ABS peut être lié à plusieurs règles de configuration. Reportez-vous au tableau ci-dessous pour obtenir plus de détails et des conseils relatifs à ces mappages.

section 4 -2 charges de travail standard a-govern-the-cloud	account-part-of-organizations	La gestion centralisée Comptes AWS au sein des AWS Organisations permet de garantir la conformité des comptes. L'absence de gouvernance centralisée des comptes peut entraîner des configurations de comptes incohérentes, ce qui peut exposer des ressources et des données sensibles.
section 4 -2 charges de travail standard a-govern-the-cloud	cloudtrail-s3-dataevents-enabled	La collecte d'événements de données Simple Storage Service (Amazon S3) aide à détecter toute activité anormale. Les détails incluent les informations du compte AWS qui a accédé à un compartiment Amazon S3, l'adresse IP et l'heure de l'événement.

section 4 -2 charges de travail standard a-govern-the-cloud	cloudtrail-security-trail-enabled	Cette règle permet de garantir l'utilisation des meilleures pratiques de sécurité AWS recommandées pour AWS CloudTrail, en vérifiant l'activat ion de plusieurs paramètre s. Il s'agit notamment de l'utilisation du chiffrement des journaux, de la validation des journaux et de AWS CloudTrai l l'activation dans plusieurs régions.
section 4 -2 charges de travail standard a-govern-the-cloud	cloudwatch-alarm-action-che ck	Amazon CloudWatch émet une alerte lorsqu'un indicateu r dépasse le seuil pour un certain nombre de périodes d'évaluation. L'alarme réalise une ou plusieurs actions en fonction de la valeur de la métrique ou de l'express ion par rapport à un seuil sur un certain nombre de périodes. Cette règle nécessite une valeur pour alarmActionRequired (Config Default : True), insuffici entDataAction Required (Config Default : True), okActionRequired (Config Default : False). La valeur réelle doit refléter les actions d'alarme de votre environne ment.

section 4 -3 - charges de travail matérielles a-govern-the-cloud	dynamodb-throughput-limit-check	Activez cette règle pour vous assurer que la capacité de débit allouée est vérifiée sur vos tables Amazon DynamoDB. Il s'agit de la quantité d' read/write activité que chaque table peut supporter. DynamoDB utilise ces informations pour réserver des ressources système suffisantes pour répondre à vos exigences de débit. Cette règle génère une alerte lorsque le débit approche de la limite maximale pour le compte d'un client. Cette règle vous permet de définir éventuellement les paramètres du RCUThreshold pourcentage du compte (par défaut de configuration : 80) et du WCUThreshold pourcentage du compte (par défaut de configuration : 80). Cette règle permet de surveille r les utilisations non utilisées EIPs dans votre environne ment.
section 4 -3 - charges de travail standard a-govern-the-cloud	vpc-network-acl-unused-véri fier	Cette règle garantit que les listes de contrôle d'accès au réseau Amazon Virtual Private Cloud (VPC) sont utilisées. section 4 - les charges de travail standard du cloud 1 b-design-and-secure	ec2- instance-profile-attached	Les profils d'instance EC2 transmettent un rôle IAM à une instance EC2. L'associa tion d'un profil d'instance à vos instances peut faciliter la gestion du moindre privilège et des autorisations.
section 4 - les charges de travail standard du cloud 1 b-design-and-secure	ecs-task-definition-user-for-host-mode-check	Si une définition de tâche dispose de privilèges élevés, c'est parce que le client a spécifiquement opté pour ces configurations. Ce contrôle vérifie qu'il n'y a pas d'élévati on des privilèges inattendue lorsqu'une définition de tâche a activé la mise en réseau de l'hôte, mais que le client n'a pas opté pour l'élévation des privilèges.

section 4 - les charges de travail standard du cloud 1 b-design-and-secure	emr-kerberos-enabled	Les autorisations d'accès peuvent être gérées et intégrées selon les principes du moindre privilège et de la séparation des tâches, en activant Kerberos pour les clusters Amazon EMR. Dans Kerberos, les services et utilisateurs qui ont besoin de s'authentifier sont appelés principaux. Les principaux existent au sein d'un domaine Kerberos. Dans le domaine, un serveur Kerberos est connu sous le nom de centre de diffusion des clés (KDC). Il fournit aux principaux un moyen de s'authentifier. Le KDC s'authentifie en émettant des tickets d'authentification. Il gère une base de données des principaux au sein de son domaine, leurs mots de passe, ainsi que d'autres informations administratives sur chaque principal.

section 4 - les charges de travail standard du cloud 1 b-design-and-secure	iam-inline-policy-blocked-kms-actions	Assurez-vous qu'un utilisateur, un rôle IAM ou un groupe IAM (AWS Identity and Access Management) ne dispose pas d'une politique intégrée autorisant le blocage d'actions sur toutes les clés du service de gestion des clés. AWS AWS recommande d'utiliser des politiques gérées plutôt que des politiques intégrées. Les politiques gérées permettent la réutilisation, la gestion des versions, la restauration, ainsi que la délégation de la gestion des autorisations. Cette règle vous permet de définir le blockedActionsPatterns paramètre. (Valeur des meilleures pratiques de sécuritéAWS fondamentales : kms: Déchiffrer, kms:ReEncryptFrom). Accorder aux utilisateurs plus de privilèges que nécessaire pour effectuer une tâche peut enfreindre le principe du moindre privilège et de la séparation des tâches.
section 4 - les charges de travail standard du cloud 1 b-design-and-secure	iam-user-mfa-enabled	Activez cette règle pour limiter l'accès aux ressources dans le Cloud AWS . Cette règle garantit que l'authentification multifactorielle (MFA) est activée pour tous les utilisateurs. L'authentification MFA ajoute une couche de sécurité supplémentaire, en plus d'un nom d'utilisateur et d'un mot de passe. Réduisez les incidents de comptes compromis en imposant la MFA aux utilisateurs.

CloudTrail fournira les fichiers journaux de toutes les AWS régions à votre compartiment S3 si MULTI_REGION_CLOUD _TRAIL_ENABLED est activé. De plus, lors du AWS lancement d'une nouvelle région, le même parcours CloudTrail sera créé dans la nouvelle région. Par conséquent, vous recevrez des fichiers journaux contenant l'activité de l'API pour la nouvelle région sans avoir à faire quoi que ce soit.

section 4 - 5 charges de travail standard c-run-the-cloud	dynamodb-autoscaling-enabled	Amazon DynamoDB Auto Scaling AWS utilise le service Application Auto Scaling pour ajuster la capacité de débit allouée afin de répondre automatiquement aux modèles de trafic réels. Cela permet à une table ou à un index secondaire global d'augmenter sa read/write capacité provisionnée afin de gérer les augmentations soudaines du trafic, sans limitation.

AWS Config Les packs de conformité, en tant qu'exemples de modèle, ne sont pas conçus pour garantir pleinement la conformité à une norme de gouvernance ou de conformité spécifique. Il vous incombe de déterminer vous-même si votre utilisation des services est conforme aux exigences légales et réglementaires applicables.

Vous trouverez ci-dessous un exemple de mappage entre le Guide de mise en œuvre du cloud computing ABS 2.0 - Standard Workloads et les règles de configuration AWS gérées. section 4 -3 - charges de travail standard c-run-the-cloud	cloud-trail-log-file-activé pour la validation	Utilisez la validation des fichiers AWS CloudTrail journaux pour vérifier l'intégri té des CloudTrail journaux. La validation du fichier journal permet de détermine r si un fichier journal a été modifié, supprimé ou inchangé après CloudTrail sa livraison . Cette fonctionnalité est créée grâce à des algorithm es standard du secteur : SHA-256 pour le hachage et SHA-256 avec RSA pour la signature numérique. Il est donc impossible, sur le plan informatique, de modifier, de supprimer ou de falsifier des fichiers CloudTrail journaux sans détection.
section 4 -3 - charges de travail standard c-run-the-cloud	elasticsearch-logs-to-cloud watch	Assurez-vous que les journaux d'erreurs sont activés sur les domaines Amazon OpenSearch Service et qu'ils sont transmis à Amazon CloudWatch Logs à des fins de conservation et de réponse. Les journaux d'erreurs de domaine peuvent faciliter les audits de sécurité et d'accès, ainsi que le diagnostic des problèmes de disponibilité.

section 4 -3 - charges de travail standard c-run-the-cloud	elb-logging-enabled	L'activité Elastic Load Balancing est un point de communication central au sein d'un environnement. Assurez-vous que la journalisation ELB est activée. Les données collectées fournissent des informations détaillées sur les demandes envoyées à l'ELB. Chaque journal contient des informations comme l'heure à laquelle la demande a été reçue, l'adresse IP du client, les latences, les chemins de demande et les réponses du serveur.
section 4 -3 - charges de travail standard c-run-the-cloud	guardduty-enabled-centralized	Amazon GuardDuty peut vous aider à surveiller et à détecter les événements potentiel s liés à la cybersécurité en utilisant des flux de renseigne ments sur les menaces. Il s'agit notamment de listes de programmes malveillants IPs et d'apprentissage automatiq ue pour identifier les activités inattendues, non autorisées et malveillantes au sein de votre environnement AWS cloud.

section 4 -3 - charges de travail standard c-run-the-cloud	multi-region-cloudtrail-enabled	AWS CloudTrail enregistre les actions AWS de la console de gestion et les appels d'API. Vous pouvez identifier les utilisateurs et les comptes appelés AWS, l'adresse IP source à partir de laquelle les appels ont été effectués et la date des appels. CloudTrail fournira les fichiers journaux de toutes les AWS régions à votre compartiment S3 si MULTI_REGION_CLOUD _TRAIL_ENABLED est activé. De plus, lors du AWS lancement d'une nouvelle région, le même parcours CloudTrail sera créé dans la nouvelle région. Par conséquent, vous recevrez des fichiers journaux contenant l'activité de l'API pour la nouvelle région sans avoir à faire quoi que ce soit.

Vous devez également vous assurer que les configura tions requises sont déployées sur les clusters Amazon Redshift. La journalisation des audits doit être activée pour fournir des informati ons sur les connexions et les activités de l'utilisateur dans la base de données. Cette règle nécessite qu'une valeur soit définie pour clusterDb Encrypted (Config Default : TRUE) et LoggingEnabled (Config Default : TRUE). section 4 -3 - charges de travail standard c-run-the-cloud	s3- bucket-logging-enabled	La journalisation des accès au serveur Amazon Simple Storage Service (Amazon S3) permet de surveiller le réseau pour détecter d'éventuels événements de cybersécu rité. Les événements sont surveillés en capturant des enregistrements détaillés pour les demandes envoyées à un compartiment Amazon S3. Chaque enregistrement du journal des accès fournit des détails sur une unique demande d'accès. Les détails incluent le demandeur, le nom du compartiment, l'heure de la demande, l'action de la demande, l'état de la réponse et un code d'erreur, le cas échéant.

AWS La journalisation WAF fournit des informations détaillées sur le trafic analysé par votre ACL Web. Les journaux enregistr ent l'heure à laquelle AWS WAF a reçu la demande de votre AWS ressource, des informations sur la demande et une action pour la règle à laquelle chaque demande correspondait.
section 4 -3 - charges de travail standard c-run-the-cloud	opensearch-audit-logging-en abled	Assurez-vous que la journalis ation des audits est activée sur vos domaines Amazon OpenSearch Service. Bonnes pratiques de fonctionnement pour ACSC Essentials 8

Les packs de conformité fournissent un cadre de conformité à usage général conçu pour vous permettre de créer des contrôles de gouvernance en matière de sécurité, d'exploitation ou d'optimisation des coûts à l'aide de AWS Config règles gérées ou personnalisées et d'actions correctives. AWS Config Les packs de conformité, en tant qu'exemples de modèle, ne sont pas conçus pour garantir pleinement la conformité à une norme de gouvernance ou de conformité spécifique. Il vous incombe de déterminer vous-même si votre utilisation des services est conforme aux exigences légales et réglementaires applicables.

Vous trouverez ci-dessous un exemple de mappage entre le modèle de maturité Essential Eight du Centre australien de cybersécurité (ACSC) et les règles de configuration AWS gérées. Chaque règle de configuration s'applique à une AWS ressource spécifique et concerne un ou plusieurs contrôles ACSC Essential Eight. Un contrôle ACSC Essential Eight peut être associé à plusieurs règles de configuration. Reportez-vous au tableau ci-dessous pour obtenir plus de détails et des conseils relatifs à ces mappages. Certains des mappages vers les règles de configuration concernent la

Les packs de conformité fournissent un cadre de conformité à usage général conçu pour vous permettre de créer des contrôles de gouvernance en matière de sécurité, d'exploitation ou d'optimisation des coûts à l'aide de AWS Config règles gérées ou personnalisées et d'actions correctives. AWS Config Les packs de conformité, en tant qu'exemples de modèle, ne sont pas conçus pour garantir pleinement la conformité à une norme de gouvernance ou de conformité spécifique. Il vous incombe de déterminer vous-même si votre utilisation des services est conforme aux exigences légales et réglementaires applicables.

Vous trouverez ci-dessous un exemple de mappage entre le manuel de sécurité de l'information (ISM) 2020-06 du Centre australien de cybersécurité (ACSC) et les règles de AWS configuration gérées. Chaque règle Config s'applique à une AWS ressource spécifique et concerne un ou plusieurs

Meilleures pratiques opérationnelles pour ACSC ISM - Partie 2

Les packs de conformité fournissent un cadre de conformité à usage général conçu pour vous permettre de créer des contrôles de gouvernance en matière de sécurité, d'exploitation ou d'optimisation des coûts à l'aide de AWS Config règles gérées ou personnalisées et d'actions correctives. AWS Config Les packs de conformité, en tant qu'exemples de modèle, ne sont pas conçus pour garantir pleinement la conformité à une norme de gouvernance ou de conformité spécifique. Il vous incombe de déterminer vous-même si votre utilisation des services est conforme aux exigences légales et réglementaires applicables.

Vous trouverez ci-dessous un exemple de mappage supplémentaire entre le manuel de sécurité de l'information (ISM) 2020-06 du Centre australien de cybersécurité (ACSC) et les règles de AWS configuration gérées. Chaque règle Config s'applique à une AWS ressource spécifique et concerne un ou plusieurs contrôles ISM. Un contrôle ISM peut être associé à plusieurs règles de configuration. Reportez-vous au tableau ci-dessous pour obtenir plus de détails et des conseils relatifs à ces mappages.

Cet exemple de modèle de pack de conformité contient des mappages vers les contrôles du cadre ISM, qui a été créé par le Commonwealth d'Australie et peut être consulté dans le Manuel de sécurité des informations du gouvernement australien. 1 984	appmesh-virtual-gateway-backend-defaults-tls	Vérifie si les paramètres par défaut du backend pour les passerelles AWS App Mesh virtuelles nécessitent que les passerelles virtuelles communiquent avec tous les ports à l'aide du protocole TLS. La règle est NON_COMPLIANT si Configuration.spec. BackendDefaults. ClientPolicy.Tls.Enforce est faux.

1 984	appmesh-virtual-node-backend-defaults-tls-on	Vérifie si les paramètres par défaut du backend pour les nœuds AWS App Mesh virtuels nécessitent que les nœuds virtuels communiquent avec tous les ports à l'aide du protocole TLS. La règle est NON_COMPLIANT si Configuration.spec.BackendDefaults. ClientPolicy.Tls.Enforce est faux.
1 984	msk-in-cluster-node-require-tls	Vérifie si un cluster Amazon MSK applique le chiffrement en transit à l'aide du protocole HTTPS (TLS) avec les nœuds d'agent du cluster. La règle est NON_COMPLIANT si la communication en texte brut est activée pour les connexions de nœuds d'agent au sein du cluster.
1 984	rds-mysql-instance-encrypted-en transit	Vérifie si les connexions aux instances de base de données Amazon RDS for MySQL sont configurées pour utiliser le chiffrement en transit. La règle est NON_COMPLIANT si le groupe de paramètres de base de données associé n'est pas synchronisé ou si le paramètre require_secure_transport n'est pas défini sur 1.

1 984	rds-postgres-instance-encrypted-en transit	Vérifie si les connexions aux instances de base de données Amazon RDS for PostgreSQL sont configurées pour utiliser le chiffrement en transit. La règle est NON_COMPLIANT si le groupe de paramètres de base de données associé n'est pas synchronisé ou si le paramètre rds.force_ssl n'est pas défini sur 1.
1985	ebs-snapshot-public-restorable-vérifier	Vérifie si les instantanés Amazon Elastic Block Store (Amazon EBS) ne sont pas publiquement restaurables. La règle est NON_COMPLIANT si un ou plusieurs instantanés avec RestorableByUserIds champ sont définis sur tous, c'est-à-dire que les instantanés Amazon EBS sont publics.
1985	s3- bucket-mfa-delete-enabled	Vérifie si les instantanés Amazon Elastic Block Store (Amazon EBS) ne sont pas publiquement restaurables. La règle est NON_COMPLIANT si un ou plusieurs instantanés avec RestorableByUserIds champ sont définis sur tous, c'est-à-dire que les instantanés Amazon EBS sont publics.

1985	s3- bucket-public-read-prohibited	Vérifie que vos compartiments Amazon S3 n'autorisent pas un accès public en lecture. La règle vérifie les paramètres de blocage d'accès public , la stratégie de compartiment et la liste de contrôle d'accès (ACL) du compartiment. La règle est conforme lorsque les deux conditions suivantes sont réunies : • Le paramètre de blocage d'accès public limite les politiques publiques ou la politique de compartiment n'autorise pas l'accès public en lecture. • Le paramètre Bloquer l'accès public restreint le public ACLs ou l'ACL du bucket n'autorise pas l'accès public en lecture. La règle n'est pas conforme lorsque : • Si le paramètre Bloquer l'accès public ne restreint pas les politiques publiques , AWS Config évalue si la politique autorise l'accès public en lecture. Si la politique autorise l'accès

1985	aurora-resources-in-logically-air-gapped-vault	Vérifie si les clusters de base de données Amazon Aurora se trouvent dans un coffre-fort isolé de manière logique. La règle est NON_COMPLIANT si un cluster de base de données Amazon Aurora ne se trouve pas dans un coffre-fort logiquement isolé pendant la période spécifiée.
1985	ebs-resources-in-logically-air-gapped-vault	Vérifie si les volumes Amazon Elastic Block Store (Amazon EBS) se trouvent dans un coffre-fort ventilé de manière logique. La règle est NON_COMPLIANT si un volume Amazon EBS ne se trouve pas dans un coffre-fort logiquement espacé pendant la période spécifiée.

La règle est NON_COMPLIANT si une instance Amazon EBS ne se trouve pas dans un coffre-fort logiquement espacé pendant la période spécifiée.
1985	efs-resources-in-logically-air-gapped-vault	Vérifie si les systèmes de fichiers Amazon Elastic File System (Amazon EFS) se trouvent dans un coffre-fo rt isolé de manière logique. La règle est NON_COMPL IANT si un système de fichiers Amazon EFS ne se trouve pas dans un coffre-fort logiqueme nt espacé pendant la période spécifiée.
1985	s3- resources-in-logically-air -gapped-vault	Vérifie si les compartiments Amazon Simple Storage Service (Amazon S3) se trouvent dans un coffre-fort à espacement logique. La règle est NON_COMPLIANT si un compartiment Amazon S3 ne se trouve pas dans un coffre-fort logiquement isolé pendant la période spécifiée.

36b	cloudtrail-security-trail-enabled	Cette règle permet de garantir l'utilisation des meilleures pratiques de sécurité AWS recommandées pour AWS CloudTrail, en vérifiant l'activat ion de plusieurs paramètre s. Il s'agit notamment de l'utilisation du chiffrement des journaux, de la validation des journaux et de AWS CloudTrai l l'activation dans plusieurs régions.

36b	redshift-cluster-maintenancesettings-check	Cette règle garantit que les clusters Amazon Redshift disposent des paramètres préférés de votre organisation. Plus précisément, qu'ils disposent de fenêtres de maintenance préférées et de périodes de conservation des instantanées automatisées pour la base de données. Cette règle vous oblige à définir le allowVersionUpgrade. Par défaut, la valeur est true. Il vous permet également de définir éventuellement le preferredMaintenanceWindow (la valeur par défaut est samedi : 16h00 - samedi : 16h30) et la automated SnapshotRetention période (la valeur par défaut est 1). Les valeurs réelles doivent refléter les politiques de votre organisation.

36b	elastic-beanstalk-managed-updates-activé	L'activation des mises à jour de plateforme gérées pour un environnement Amazon Elastic Beanstalk garantit l'installation des derniers correctifs, mises à jour et fonctionnalités de la plateform e disponibles pour l'environ nement. La sécurisation des systèmes passe par la mise à jour de l'installation des correctifs.
36b	rds-automatic-minor-version-activé pour la mise à niveau	Activez les mises à niveau automatiques des versions mineures sur vos instances Amazon Relational Database Service (RDS) pour vous assurer que les dernières mises à jour mineures du système de gestion de base de données relationnelle (RDBMS) sont installées, lesquelles peuvent inclure des correctifs de sécurité et des correctifs de bogues.

ID du contrôle	AWS Règle de configuration	Conseils
36c	iam-policy-no-statements-with-admin-access	AWS Identity and Access Management (IAM) peut vous aider à intégrer les principes du moindre privilège et de la séparation des tâches dans les autorisations et autorisat ions d'accès, en empêchant les politiques de contenir « Effect » : « Autoriser » avec « Action » : « * » plutôt que « Ressource » : « * ». Permettre aux utilisateurs d'avoir plus de privilèges que nécessaire pour effectuer une tâche peut enfreindre le principe du moindre privilège et de la séparation des tâches.
36c	iam-user-group-membership-vérifier	AWS Identity and Access Management (IAM) peut vous aider à restreindre les autorisations et autorisations d'accès en vous assurant que les utilisateurs sont membres d'au moins un groupe. Accorder aux utilisate urs plus de privilèges que nécessaire pour effectuer une tâche peut enfreindre le principe du moindre privilège et de la séparation des tâches.

ID du contrôle	AWS Règle de configuration	Conseils
36c	iam-no-inline-policy-vérifier	Assurez-vous qu'un utilisateur, un rôle IAM ou un groupe IAM (AWS Identity and Access Management) ne dispose pas d'une politique intégrée pour contrôler l'accès aux systèmes et aux actifs. AWS recommande d'utiliser des politiques gérées plutôt que des politiques intégrées. Les politiques gérées permettent la réutilisation, la gestion des versions et la restauration, ainsi que la délégation de la gestion des autorisations.

ID du contrôle	AWS Règle de configuration	Conseils
36c	restricted-common-ports	Gérez l'accès aux ressources dans le AWS cloud en vous assurant que les ports courants sont restreints sur les groupes de sécurité Amazon Elastic Compute Cloud (Amazon EC2). Le fait de ne pas limiter l'accès aux ports à des sources fiables peut entraîner des attaques mettant en péril la disponibilité, l'intégrité et la confidentialité des systèmes. Cette règle vous permet éventuellement de définir les paramètres blockedPort1 à blockedPort5 (configuration par défaut : 20,21,3389,3306,4333). Les valeurs réelles doivent refléter les politiques de votre organisation.

ID du contrôle	AWS Règle de configuration	Conseils
36c	vpc-sg-open-only-to-authorized-ports	Gérez l'accès aux ressources dans le AWS cloud en vous assurant que les ports courants sont restreints sur les groupes de sécurité Amazon Elastic Compute Cloud (Amazon EC2). Le fait de ne pas limiter l'accès aux ports à des sources fiables peut entraîner des attaques mettant en péril la disponibilité, l'intégrité et la confidentialité des systèmes. En limitant l'accès aux ressources d'un groupe de sécurité depuis Internet (0.0.0.0/0), il est possible de contrôler l'accès à distance aux systèmes internes.
36c	restricted-ssh	Les groupes de sécurité Amazon Elastic Compute Cloud (Amazon EC2) peuvent aider à gérer l'accès au réseau en fournissant un filtrage dynamique du trafic réseau entrant et sortant vers les ressources. AWS Ne pas autoriser le trafic entrant (ou distant) de 0.0.0.0/0 vers le port 22 sur vos ressources vous aide à restreindre l'accès à distance.

ID du contrôle	AWS Règle de configuration	Conseils
36c	ec2- instance-profile-attached	Les profils d'instance EC2 transmettent un rôle IAM à une instance EC2. L'association d'un profil d'instance à vos instances peut faciliter la gestion du moindre privilège et des autorisations.
36c	iam-policy-no-statements-with-full-access	Assurez-vous que les actions IAM sont limitées aux seules actions nécessaires. Permettre aux utilisateurs d'avoir plus de privilèges que nécessaire pour effectuer une tâche peut enfreindre le principe du moindre privilège et de la séparation des tâches.
36c	ecs-task-definition-user-for-host-mode-check	Si une définition de tâche dispose de privilèges élevés, c'est parce que le client a spécifiquement opté pour ces configurations. Ce contrôle vérifie qu'il n'y a pas d'élévation des privilèges inattendue lorsqu'une définition de tâche a activé la mise en réseau de l'hôte, mais que le client n'a pas opté pour l'élévation des privilèges.

ID du contrôle	AWS Règle de configuration	Conseils
36d	dms-replication-not-public	Gérez l'accès au AWS cloud en vous assurant que les instances de réplication DMS ne sont pas accessibl es au public. Les instances de réplication DMS peuvent contenir des informations sensibles, c'est pourquoi un contrôle des accès est requis pour ces comptes.
36d	ebs-snapshot-public-restora ble-vérifier	Gérez l'accès au AWS cloud en vous assurant que les instantanés EBS ne sont pas restaurables publiquement. Les instantanés des volumes EBS peuvent contenir des informations sensibles, c'est pourquoi un contrôle des accès est requis pour ces comptes.
36d	ec2- instance-no-public-ip	Gérez l'accès au AWS cloud en vous assurant que les instances Amazon Elastic Compute Cloud (Amazon EC2) ne sont pas accessibl es au public. Les instances Amazon EC2 peuvent contenir des informations sensibles , c'est pourquoi un contrôle des accès est requis pour ces comptes.

ID du contrôle	AWS Règle de configuration	Conseils
36d	elasticsearch-in-vpc-only	Gérez l'accès au AWS cloud en vous assurant que les domaines Amazon OpenSearch OpenSearch Service (Service) se trouvent dans un Amazon Virtual Private Cloud (Amazon VPC). Un domaine de OpenSearch service au sein d'un Amazon VPC permet une communication sécurisée entre le OpenSearch service et les autres services au sein d'Amazon VPC sans avoir besoin d'une passerelle Internet, d'un appareil NAT ou d'une connexion VPN.
36d	emr-master-no-public-IP	Gérez l'accès au AWS cloud en vous assurant que les nœuds maîtres du cluster Amazon EMR ne sont pas accessibles au public. Les nœuds principaux du cluster Amazon EMR peuvent contenir des informations sensibles, c'est pourquoi un contrôle des accès est requis pour ces comptes.

ID du contrôle	AWS Règle de configuration	Conseils
36d	ec2- instances-in-vpc	Déployez des instances Amazon Elastic Compute Cloud (Amazon EC2) au sein d'un réseau Amazon Virtual Private Cloud (Amazon VPC) pour permettre une communication sécurisée entre une instance et les autres services au sein du réseau Amazon VPC, sans nécessiter de passerelle Internet, de périphérique NAT ou de connexion VPN. Tout le trafic reste sécurisé dans le AWS cloud. En raison de leur isolement logique, les domaines résidant au sein d'un réseau Amazon VPC possèdent une couche de sécurité supplémentaire par rapport aux domaines qui utilisent des points de terminaison publics. Attribuez des instances Amazon EC2 à un réseau Amazon VPC pour une gestion correcte des accès.

ID du contrôle	AWS Règle de configuration	Conseils
36d	internet-gateway-authorized-vpc-uniquement	Gérez l'accès aux ressources dans le AWS cloud en vous assurant que les passerelles Internet ne sont connectées qu'à Amazon Virtual Private Cloud (Amazon VPC) autorisé. Les passerelles Internet permettent un accès bidirectionnel à Internet depuis et vers le réseau Amazon VPC, ce qui peut potentiellement entraîner un accès non autorisé aux ressources Amazon VPC.
36d	lambda-function-public-access-interdit	Gérez l'accès aux ressources dans le AWS cloud en vous assurant que les fonctions AWS Lambda ne sont pas accessibles au public. Un accès public peut potentiellement entraîner une dégradation de la disponibilité des ressources.

ID du contrôle	AWS Règle de configuration	Conseils
36d	lambda-inside-vpc	Déployez les fonctions AWS Lambda au sein d'un Amazon Virtual Private Cloud (Amazon VPC) pour une communication sécurisée entre une fonction et les autres services au sein d'Amazon VPC. Avec cette configuration, il n'est pas nécessaire d'avoir une passerelle Internet, un périphérique NAT ou une connexion VPN. Tout le trafic reste sécurisé dans le AWS cloud. En raison de leur isolement logique, les domaines résidant au sein d'un réseau Amazon VPC possèdent une couche de sécurité supplémentaire par rapport aux domaines qui utilisent des points de terminaison publics. Pour gérer correctement l'accès, les fonctions AWS Lambda doivent être attribuées à un VPC.

ID du contrôle	AWS Règle de configuration	Conseils
36d	rds-instance-public-access-vérifier	Gérez l'accès aux ressources dans le AWS cloud en vous assurant que les instances Amazon Relational Database Service (Amazon RDS) ne sont pas publiques. Les instances de base de données Amazon RDS peuvent contenir des informations sensibles, c'est pourquoi des principes et un contrôle des accès sont requis pour ces comptes.
36d	rds-snapshots-public-prohibited	Gérez l'accès aux ressources dans le AWS cloud en vous assurant que les instances Amazon Relational Database Service (Amazon RDS) ne sont pas publiques. Les instances de base de données Amazon RDS peuvent contenir des informations sensibles, c'est pourquoi des principes et un contrôle des accès sont requis pour ces comptes.

36d	redshift-cluster-public-access-vérifier	Gérez l'accès aux ressources dans le AWS cloud en vous assurant que les clusters Amazon Redshift ne sont pas publics. Les clusters Amazon Redshift peuvent contenir des informations sensibles, c'est pourquoi des principes et un contrôle des accès sont requis pour ces comptes.
36d	s3- bucket-public-read-prohibited	Gérez l'accès aux ressources dans le AWS cloud en autorisant uniquement les utilisateurs, les processus et les appareils autorisés à accéder aux compartiments Amazon Simple Storage Service (Amazon S3). La gestion des accès doit être cohérente avec la classification des données.
36d	s3- bucket-public-write-prohibited	Gérez l'accès aux ressources dans le AWS cloud en autorisant uniquement les utilisateurs, les processus et les appareils autorisés à accéder aux compartiments Amazon Simple Storage Service (Amazon S3). La gestion des accès doit être cohérente avec la classification des données.

ID du contrôle	AWS Règle de configuration	Conseils
36d	sagemaker-notebook-no-direct-accès à Internet	Gérez l'accès aux ressources dans le AWS cloud en vous assurant que les SageMaker blocs-notes Amazon ne permettent pas un accès direct à Internet. En empêchant l'accès direct à Internet, vous pouvez empêcher les utilisateurs non autorisés d'accéder à des données sensibles.
36d	access-keys-rotated	Les informations d'identification sont auditées pour les appareils, les utilisateurs et les processus autorisés en veillant à ce que les clés d'accès IAM soient alternées conformément à la politique de l'organisation. La modification régulière des clés d'accès est une bonne pratique de sécurité. Cela permet de raccourcir la période pendant laquelle une clé d'accès est active et de réduire l'impact commercial en cas de compromission des clés. Cette règle nécessite une valeur de rotation des clés d'accès (configuration par défaut : 90). La valeur réelle doit refléter les politiques de votre organisation.

ID du contrôle	AWS Règle de configuration	Conseils
36d	emr-kerberos-enabled	Les autorisations d'accès peuvent être gérées et intégrées selon les principes du moindre privilège et de la séparation des tâches, en activant Kerberos pour les clusters Amazon EMR. Dans Kerberos, les services et utilisateurs qui ont besoin de s'authentifier sont appelés principaux. Les principaux existent au sein d'un domaine Kerberos. Dans le domaine, un serveur Kerberos est connu sous le nom de centre de diffusion des clés (KDC). Il fournit aux principaux un moyen de s'authentifier. Le KDC s'authentifie en émettant des tickets d'authentification. Il gère une base de données des principaux au sein de son domaine, leurs mots de passe, ainsi que d'autres informations administratives sur chaque principal.

36d	iam-password-policy	Les identités et les informations d'identification sont émises, gérées et vérifiées conformément à une politique de mot de passe IAM organisationnelle. Ils respectent ou dépassent les exigences énoncées par le NIST SP 800-63 et par la norme AWS Foundational Security Best Practices en matière de robustesse des mots de passe. Cette règle vous permet de définir éventuellement RequireUppercaseCharacters (valeur des meilleures pratiques de sécurité de AWS base : vrai), RequireLowercaseCharacters (valeur des meilleures pratiques de sécurité de AWS base : vrai), RequireSymbols (valeur des meilleures pratiques de sécurité de AWS base : vrai), RequireNumbers (valeur des meilleures pratiques de sécurité de AWS base : vrai), MinimumPasswordLength (valeur des meilleures pratiques de sécurité de AWS base : 14), PasswordReusePrevention (valeur des meilleures pratiques de sécurité de AWS

Permettre aux utilisateurs d'avoir plus de privilèges que nécessaire pour effectuer une tâche peut enfreindre le principe du moindre privilège et de la séparation des tâches.

ID du contrôle	AWS Règle de configuration	Conseils
36d	iam-root-access-key-vérifier	L'accès aux systèmes et aux actifs peut être contrôlé en vérifiant que l'utilisateur root ne dispose pas de clés d'accès associées à son AWS rôle Identity and Access Management (IAM). Assurez-vous que les clés d'accès root ont été supprimées. Créez et utilisez plutôt la fonction basée sur Comptes AWS les rôles pour intégrer le principe de moindre fonctionnalité.
36d	iam-user-group-membership-vérifier	AWS Identity and Access Management (IAM) peut vous aider à restreindre les autorisations et autorisations d'accès en vous assurant que les utilisateurs sont membres d'au moins un groupe. Accorder aux utilisateurs plus de privilèges que nécessaire pour effectuer une tâche peut enfreindre le principe du moindre privilège et de la séparation des tâches.

36d	iam-user-mfa-enabled	Activez cette règle pour limiter l'accès aux ressources dans le Cloud AWS . Cette règle garantit que l'authentification multifactorielle (MFA) est activée pour tous les utilisate urs. L'authentification MFA ajoute une couche de sécurité supplémentaire, en plus d'un nom d'utilisateur et d'un mot de passe. Réduisez les incidents de comptes compromis en imposant la MFA aux utilisateurs.
36d	iam-user-no-policies-vérifier	Cette règle garantit que les politiques AWS Identity and Access Management (IAM) ne sont associées qu'à des groupes ou à des rôles afin de contrôler l'accès aux systèmes et aux actifs. L'attribution de privilèges au niveau du groupe ou du rôle permet de réduire les risques qu'une identité reçoive ou conserve des privilèges excessifs.

36d	iam-user-unused-credentials-vérifier	AWS Identity and Access Management (IAM) peut vous aider à obtenir des autorisations et des autorisat ions d'accès en vérifiant les mots de passe et les clés d'accès IAM qui ne sont pas utilisés pendant une période donnée. Si ces informations d'identification non utilisées sont identifiées, vous devez désactiver la and/or suppressi on des informations d'identif ication, car cela pourrait violer le principe du moindre privilège. Cette règle vous oblige à définir une valeur sur maxCredentialUsage Age (Config Default : 90). La valeur réelle doit refléter les politique s de votre organisation.

36d	mfa-enabled-for-iam-accès à la console	Gérez l'accès aux ressources dans le AWS cloud en vous assurant que le MFA est activé pour tous les utilisateurs AWS d'Identity and Access Management (IAM) dotés d'un mot de passe de console. La MFA ajoute une couche supplémentaire de protection, en plus des informations d'identification de connexion. En exigeant la MFA pour les utilisateurs, vous pouvez réduire les incidents liés à des comptes compromis et empêcher les utilisateurs non autorisés d'accéder aux données sensibles.

Meilleures pratiques opérationnelles pour le pilier de fiabilité du AWS framework Well-Architected

Les packs de conformité fournissent un cadre de conformité à usage général conçu pour vous permettre de créer des contrôles de gouvernance en matière de sécurité, d'exploitation ou d'optimisation des coûts à l'aide de AWS Config règles gérées ou personnalisées et d'actions correctives. AWS Config Les packs de conformité, en tant qu'exemples de modèle, ne sont pas conçus pour garantir pleinement la conformité à une norme de gouvernance ou de conformité spécifique. Il vous incombe de déterminer vous-même si votre utilisation des services est conforme aux exigences légales et réglementaires applicables.

Vous trouverez ci-dessous un exemple de mappage entre le pilier de fiabilité Well-Architected Framework d'Amazon Web Services et AWS les règles de configuration gérées. Chaque règle de Config s'applique à une AWS ressource spécifique et concerne un ou plusieurs principes de conception du pilier. Une catégorie de cadre Well-Architected peut être associée à plusieurs règles de configuration. REL-6	Comment surveiller les ressources de charge de travail ? Les journaux et les métriques sont des outils puissants qui permettent de mieux comprendre l'état de santé de votre charge de travail. Vous pouvez configurer votre charge de travail pour qu'elle surveille les journaux et les métriques et envoie des notifications lorsque des seuils sont franchis ou que des événements importants se produisent. La surveillance permet à votre charge de travail de reconnaître le franchissement de seuils de faible performance ou l'apparition de défaillances, afin qu'elle puisse se rétablir automatiquement en réponse.	cloudwatch-alarm-action-check	Amazon CloudWatch émet une alerte lorsqu'un indicateur dépasse le seuil pour un certain nombre de périodes d'évaluation. L'alarme réalise une ou plusieurs actions en fonction de la valeur de la métrique ou de l'expression par rapport à un seuil sur un certain nombre de périodes. Cette règle nécessite une valeur pour alarmActionRequired (Config Default : True), insufficientDataAction Required (Config Default : True), okActionRequired (Config Default : False). La valeur réelle doit refléter les actions d'alarme de votre environnement.

Meilleures pratiques opérationnelles pour le pilier de sécurité du AWS framework Well-Architected

Les packs de conformité fournissent un cadre de conformité à usage général conçu pour vous permettre de créer des contrôles de gouvernance en matière de sécurité, d'exploitation ou d'optimisation des coûts à l'aide de AWS Config règles gérées ou personnalisées et d'actions correctives. AWS Config Les packs de conformité, en tant qu'exemples de modèle, ne sont pas conçus pour garantir pleinement la conformité à une norme de gouvernance ou de conformité spécifique. Il vous incombe de déterminer vous-même si votre utilisation des services est conforme aux exigences légales et réglementaires applicables.

Vous trouverez ci-dessous un exemple de mappage entre le pilier de sécurité Well-Architected Framework d'Amazon Web Services et AWS les règles de configuration gérées. Chaque règle de Config s'applique à une AWS ressource spécifique et concerne un ou plusieurs principes de conception du pilier. Une catégorie de cadre Well-Architected peut être associée à plusieurs règles de configuration. Reportez-vous au tableau ci-dessous pour obtenir plus de détails et des conseils relatifs à ces mappages.

Les ressources de calcul incluent les instances EC2, les conteneurs, les fonctions AWS Lambda, les services de base de données, les appareils IoT, etc.	cloud-trail-log-file-activé pour la validation	Utilisez la validation des fichiers AWS CloudTrail journaux pour vérifier l'intégrité des CloudTrail journaux. La validation du fichier journal permet de déterminer si un fichier journal a été modifié, supprimé ou inchangé après CloudTrail sa livraison. Cette fonctionnalité est créée grâce à des algorithmes standard du secteur : SHA-256 pour le hachage et SHA-256 avec RSA pour la signature numérique. Il est donc impossible, sur le plan informatique, de modifier, de supprimer ou de falsifier des fichiers CloudTrail journaux sans détection.

Bonnes pratiques de fonctionnement pour le BCP et la DR

Ce pack de conformité contient des AWS Config règles basées sur le BCP et le DR. AWS Pour obtenir la liste de toutes les règles gérées prises en charge par AWS Config, consultez la section Liste des règles AWS Config gérées.

Consultez la `Parameters` section du modèle suivant pour connaître les noms et les descriptions des paramètres requis.

Le modèle est disponible sur GitHub : Operational Best Practices for BCP and DR.

Bonnes pratiques opérationnelles pour BNM T RMi

Les packs de conformité fournissent un cadre de conformité à usage général conçu pour vous permettre de créer des contrôles de gouvernance en matière de sécurité, d'exploitation ou d'optimisation des coûts à l'aide de AWS Config règles gérées ou personnalisées et d'actions correctives. AWS Config Les packs de conformité, en tant qu'exemples de modèle, ne sont pas conçus pour garantir pleinement la conformité à une norme de gouvernance ou de conformité spécifique. Il vous incombe de déterminer vous-même si votre utilisation des services est conforme aux exigences légales et réglementaires applicables.

Vous trouverez ci-dessous un exemple de mappage entre les règles de gestion des risques technologiques (RMiT) de Bank Negara Malaysia (BNM) et les règles de configuration gérées AWS . Chaque règle de configuration s'applique à une AWS ressource spécifique et concerne un ou plusieurs contrôles BNM RMi T. Un contrôle BNM RMi T peut être associé à plusieurs règles de Config. Reportez-vous au tableau ci-dessous pour obtenir plus de détails et des conseils relatifs à ces mappages.

Bonnes pratiques de fonctionnement pour le profil moyen de contrôle du cloud du Canadian Centre for Cyber Security (CCCS)

Les packs de conformité fournissent un cadre de conformité à usage général conçu pour vous permettre de créer des contrôles de gouvernance en matière de sécurité, d'exploitation ou d'optimisation des coûts à l'aide de AWS Config règles gérées ou personnalisées et d'actions correctives. AWS Config Les packs de conformité, en tant qu'exemples de modèle, ne sont pas conçus pour garantir pleinement la conformité à une norme de gouvernance ou de conformité spécifique. Il vous incombe de déterminer vous-même si votre utilisation des services est conforme aux exigences légales et réglementaires applicables.

Voici un exemple de mappage entre le profil de contrôle du cloud moyen du Centre canadien pour la cybersécurité (CCCS) et les règles de configuration AWS gérées. Chaque règle de configuration s'applique à une AWS ressource spécifique et concerne un ou plusieurs contrôles CCCS Medium Cloud Control Profile. Un contrôle de profil moyen de contrôle du cloud CCCS peut être associé à plusieurs règles de configuration. Reportez-vous au tableau ci-dessous pour obtenir plus de détails et des conseils relatifs à ces mappages.

CCCS-fPBMM-AC-6(9)	Moindre privilège AC-6 (9) | Audit de l'utilisation des fonctions privilégiées	cloudtrail-s3-data events-enabled	La collecte d'événements de données Simple Storage Service (Amazon S3) aide à détecter toute activité anormale. Les détails incluent les informations du compte AWS qui a accédé à un compartiment Amazon S3, l'adresse IP et l'heure de l'événement.
CCCS-fPBMM-AC-6(9)	Moindre privilège AC-6 (9) | Audit de l'utilisation des fonctions privilégiées	cloud-trail-cloud-watch-activé pour les journaux	Utilisez Amazon CloudWatch pour collecter et gérer de manière centralisée l'activité des événements du journal. L'inclusion de AWS CloudTrail données fournit des détails sur l'activité des appels d'API au sein de votre Compte AWS.

CCCS-fPBMM-AC-6(9)	Moindre privilège AC-6 (9) | Audit de l'utilisation des fonctions privilégiées	cloudtrail-enabled	AWS CloudTrail peut contribuer à la non-répudiation en enregistrant les actions de la console AWS de gestion et les appels d'API. Vous pouvez identifie r les utilisateurs et la Comptes AWS personne qui a appelé un AWS service, l'adresse IP source à laquelle les appels ont été générés et les horaires des appels. Les détails des données capturées sont affichés dans le contenu de l' AWS CloudTrail enregistr ement.

CCCS-fPBMM-AC-6(9)	Moindre privilège AC-6 (9) | Audit de l'utilisation des fonctions privilégiées	multi-region-cloudtrail-enabled	AWS CloudTrail enregistre les actions AWS de la console de gestion et les appels d'API. Vous pouvez identifier les utilisateurs et les comptes appelés AWS, l'adresse IP source à partir de laquelle les appels ont été effectués et la date des appels. CloudTrail fournira les fichiers journaux de toutes les AWS régions à votre compartiment S3 si MULTI_REGION_CLOUD_TRAIL_ENABLED est activé. De plus, lors du AWS lancement d'une nouvelle région, le même parcours CloudTrail sera créé dans la nouvelle région. Par conséquent, vous recevrez des fichiers journaux contenant l'activité de l'API pour la nouvelle région

CCCS-fPBMM-AC-6(9)	Moindre privilège AC-6 (9) | Audit de l'utilisation des fonctions privilégiées	redshift-cluster-configuration-check	Pour protéger les données au repos, assurez-vous que le chiffrement est activé pour vos clusters Amazon Redshift. Vous devez également vous assurer que les configurations requises sont déployées sur les clusters Amazon Redshift. La journalisation des audits doit être activée pour fournir des informations sur les connexions et les activités de l'utilisateur dans la base de données. Cette règle nécessite qu'une valeur soit définie pour clusterDbEncrypted (Config Default : TRUE) et LoggingEnabled (Config Default : TRUE). Les valeurs réelles doivent refléter les politiques de votre organisation.

CCCS-fPBMM-AC-6(9)	Moindre privilège AC-6 (9) | Audit de l'utilisation des fonctions privilégiées	s3- bucket-logging-enabled	La journalisation des accès au serveur Amazon Simple Storage Service (Amazon S3) permet de surveille r le réseau pour détecter d'éventue ls événements de cybersécurité. Les événement s sont surveillés en capturant des enregistrements détaillés pour les demandes envoyées à un compartiment Amazon S3. Chaque enregistrement du journal des accès fournit des détails sur une unique demande d'accès. Les détails incluent le demandeur , le nom du compartim ent, l'heure de la demande, l'action de la demande, l'état de la réponse et un code d'erreur, le cas échéant.
