AWS Glue 5.0	• Spark 3.5.4 • Python 3.11 • Scala 2.12.18	Java 17	In addition to the framework updates, there are optimizations and upgrades built into this AWS Glue release, such as: • Amazon SageMaker Unified Studio support • Amazon SageMaker Lakehouse support • Open Table Formats (OTF) updated to Hudi 0.15.0, Iceberg 1.7.1, and Delta Lake 3.3.0 • Spark-native fine-grained access control using Lake Formation. • Amazon S3 Access Grants support • `requirements.txt` support to install additional Python libraries • Data lineage support in Amazon DataZone

AWS Glue version	Supported runtime environment versions	Supported Java version	Changes in functionality
			• Amazon S3 Table Bucket support • AWS Glue Data Catalog multi-dialect view support **Limitations** The following are limitations with AWS Glue 5.0: • Glue Dynamic Frame / `GlueContext` - based table-level access control with AWS Lake Formation permissions supported in Glue 4.0 or before is not supported in Glue 5.0. Use the new Spark native fine-grained access control (FGAC) in Glue 5.0. For more information about migrating to AWS Glue version 5.0, see Migrating AWS

AWS Glue version	Supported runtime environment versions	Supported Java version	Changes in functionality
			Glue for Spark jobs to AWS Glue version 5.0.

AWS Glue version	Supported runtime environment versions	Supported Java version	Changes in functionality

AWS Glue 4.0	**Spark environment versions**
	• Spark 3.3.0
	• Python 3.10
		Java 8	AWS Glue 4.0 has a number of optimizations and upgrades built into this AWS Glue release, such as:
			• Many Spark functionality upgrades from Spark 3.1 to Spark 3.3:
			  • Several functionality improvements when paired with Pandas. For more information, see What's New in Spark 3.3.
			  • Additional optimizations developed on Amazon EMR.
			  • Upgrade to EMR File System (EMRFS) 2.53.
			• Log4j 2 migration from Log4j 1.x
			• Several Python module updates from AWS Glue 3.0, such as an

AWS Glue version	Supported runtime environment versions	Supported Java version	Changes in functionality
			upgraded version of Boto. • Upgrade of several connectors, including the default Amazon Redshift connector. See Appendix C: Connector upgrades. • Upgrade of several JDBC drivers. See Appendix B: JDBC driver upgrades. • Updated with a new Amazon Redshift connector and JDBC driver. • Native support for open-data lake frameworks with Apache Hudi, Delta Lake, and Apache Iceberg. • Native support for the Amazon S3-based Cloud Shuffle Storage Plugin (an Apache Spark plugin) to use Amazon S3 for shuffling and

AWS Glue version	Supported runtime environment versions	Supported Java version	Changes in functionality
			elastic storage capacity. **Limitations** The following are limitations with AWS Glue 4.0: • AWS Glue machine learning and personally identifiable information (PII) transforms are not yet available in AWS Glue 4.0. For more information about migrating to AWS Glue version 4.0, see Migrating AWS Glue for Spark jobs to AWS Glue version 4.0.

AWS Glue version	Supported runtime environment versions	Supported Java version	Changes in functionality
	Ray environment versions • Ray 2.4.0 Python 3.9	N/A	Build and run distributed Python applications with AWS Glue for Ray. • Supports Ray-2.4.0 data distribution (`ray[data]`) with Python 3.9. For more information on this Ray release, see Ray-2.4.0 in the Ray GitHub repository. • Supports installing additional Python libraries into the `Ray2.4` runtime environment. For more information, see the section called "Additional Python modules for Ray jobs". • Integrates logs and metrics from Ray jobs with Amazon CloudWatch. For more information, see the section called "Troubleshooting Ray errors"

AWS Glue version	Supported runtime environment versions	Supported Java version	Changes in functionality
			and the section called “Ray job metrics”. • Aggregates and visualizes metrics for Ray jobs in AWS Glue Studio, on each job run page. • Supports distributing files to each working directory across your cluster, spilling objects from the Ray object store to Amazon S3, and controlling the minimum number of worker nodes allocated to your Ray job. For more information, see the section called “Ray job parameters”. **Limitations on Ray jobs in AWS Glue 4.0** • AWS Glue interactive sessions for Ray remain in preview for this release.

AWS Glue version	Supported runtime environment versions	Supported Java version	Changes in functionality
			• AWS Glue for Ray integration with Amazon VPC is not currently available . Resources in a VPC in AWS will not be accessible without a public route. For more information about using AWS Glue with Amazon VPC, see the section called “Configuring interface VPC endpoints (AWS PrivateLink) for AWS Glue ”. • AWS Glue for Ray is available in US East (N. Virginia), US East (Ohio), US West (Oregon), Asia Pacific (Tokyo), and Europe (Ireland).

AWS Glue version	Supported runtime environment versions	Supported Java version	Changes in functionality

AWS Glue 3.0	• Spark 3.1.1
	• Python 3.7
		Java 8	In addition to the Spark engine upgrade to 3.0, there are optimizations and upgrades built into this AWS Glue release, such as:
			• Builds the AWS Glue ETL Library against Spark 3.0, which is a major release for Spark.
			• Streaming jobs are supported on AWS Glue 3.0.
			• Includes new AWS Glue Spark runtime optimizations for performance and reliability:
			  • Faster in-memory columnar processing based on Apache Arrow for reading CSV data.
			  • SIMD-based execution for vectorized reads with CSV data.

AWS Glue version	Supported runtime environment versions	Supported Java version	Changes in functionality
			• Spark upgrade also includes additional optimizations developed on Amazon EMR. • Upgraded EMRFS from 2.38 to 2.46 enabling new features and bug fixes for Amazon S3 access. • Upgraded several dependencies that were required for the new Spark version. • Upgraded JDBC drivers for our natively supported data sources. **Limitations** The following are limitations with AWS Glue 3.0: • AWS Glue machine learning transforms are not yet

AWS Glue version	Supported runtime environment versions	Supported Java version	Changes in functionality
			available in AWS Glue 3.0. • Some custom Spark connectors do not work with AWS Glue 3.0 if they depend on Spark 2.4 and do not have compatibility with Spark 3.1.

AWS Glue version	Supported runtime environment versions	Supported Java version	Changes in functionality
AWS Glue 2.0 (end of life on April 1, 2026)	• Spark 2.4.3 • Python 3.7	N/A	In addition to the features provided in AWS Glue version 1.0, AWS Glue version 2.0 also provides: • An upgraded infrastructure for running Apache Spark ETL jobs in AWS Glue with reduced startup times. • Default logging is now real time, with separate streams for drivers and executors, and outputs and errors. • Support for specifying additional Python modules or different versions at the job level. **Note** AWS Glue version 2.0 differs from AWS Glue

AWS Glue version	Supported runtime environment versions	Supported Java version	Changes in functionality
			version 1.0 for some dependencies and versions due to underlying architectural changes. Validate your AWS Glue jobs before migrating across major AWS Glue version releases.

AWS Glue version	Supported runtime environment versions	Supported Java version	Changes in functionality
AWS Glue 1.0 (end of life on April 1, 2026)	• Spark 2.4.3 • Python 2.7 • Python 3.6	N/A	You can maintain job bookmarks for Parquet and ORC formats in AWS Glue ETL jobs (using AWS Glue version 1.0). Previously, you were only able to bookmark common Amazon S3 source formats such as JSON, CSV, Apache Avro, and XML in AWS Glue ETL jobs. When setting format options for ETL inputs and outputs, you can specify to use Apache Avro reader/writer format 1.8 to support Avro logical type reading and writing (using AWS Glue version 1.0). Previously, only the version 1.7 Avro reader/writer format was supported. The DynamoDB connection type supports a writer

AWS Glue version	Supported runtime environment versions	Supported Java version	Changes in functionality
			option (using AWS Glue version 1.0). **Limitations** The following are limitations with AWS Glue 1.0: • AWS Glue versions 0.9 and 1.0 are not available in the Asia Pacific (Jakarta) (`ap-southeast-3`), Middle East (UAE) (`me-central-1`), or other new Regions going forward.

AWS Glue version	Supported runtime environment versions	Supported Java version	Changes in functionality
AWS Glue 0.9 (end of life on April 1, 2026)	• Spark 2.2.1 • Python 2.7	N/A	**Limitations** The following are limitations with AWS Glue 0.9: • AWS Glue versions 0.9 and 1.0 are not available in the Asia Pacific (Jakarta) (`ap-southeast-3`), Middle East (UAE) (`me-central-1`), or other new Regions going forward.

Note

The following Glue versions support these versions of PythonShell:

- PythonShell v3.6 is supported in Glue version 1.0.
- PythonShell v3.9 is supported in Glue version 3.0.

Additionally, dev endpoints are supported only in Glue version 1.0, and 0.9.

AWS Glue version support policy

AWS Glue is a serverless data integration service that makes it easy to discover, prepare, and combine data for analytics, machine learning, and application development. An *AWS Glue job*

contains the business logic that performs the data integration work in AWS Glue. There are three types of jobs in AWS Glue: *Spark (batch and streaming)*, *Ray* and *Python shell*. When you define your job, you specify the AWS Glue version, which configures versions in the underlying Spark, Ray or Python runtime environment. For example: an AWS Glue version 5.0 Spark job supports Spark 3.5.4 and Python 3.11.

Support policy

AWS Glue versions are built around a combination of operating system, programming language, and software libraries that are subject to maintenance and security updates. AWS Glue's version support policy is to end support for a version when any major component of the version reaches the end of community long-term support (LTS) and security updates are no longer available. AWS Glue's version support policy includes the following statuses:

End of Support (EOS) - When an AWS Glue version reaches EOS:

- AWS Glue will no longer apply security patches or other updates to EOS versions.
- AWS Glue jobs on EOS versions are not eligible for technical support.
- AWS Glue may not honor SLAs when jobs are run on EOS versions.

End of Life (EOL) - When an AWS Glue version reaches EOL:

- You can no longer create new AWS Glue jobs or interactive sessions on EOL versions.
- You can no longer start job runs on these AWS Glue versions.
- AWS Glue will stop existing job runs and interactive sessions on EOL versions.
- EOL versions will be removed from AWS Glue SDKs and APIs.

The following AWS Glue versions have reached end of support and will no longer be available after the end of life date. Changes to a version’s support status start at midnight (Pacific time zone) on the specified date.

Type	Glue version	End of support	End of life
Spark	Glue version 0.9 (Spark 2.2, Scala 2, Python 2)	6/1/2022	4/1/2026

Type	Glue version	End of support	End of life
Spark	Glue version 1.0 (Spark 2.4, Python 2)	6/1/2022	4/1/2026
Spark	Glue version 1.0 (Spark 2.4, Scala 2, Python 3)	9/30/2022	4/1/2026
Spark	Glue version 2.0 (Spark 2.4, Python 3)	1/31/2024	4/1/2026
Type	**Python version**	**End of support**	**End of life**
Python shell	Python 2 (AWS Glue Version 1.0)	6/1/2022	4/1/2026
Python shell	PythonShell 3.6 (Glue version 1.0)	3/31/2026	NA
Type	**Notebook version**	**End of support**	**End of life**
Development endpoint	Zeppelin notebook	9/30/2022	NA

Note

Creating new AWS Glue Python Shell 3.6 jobs will not be allowed once end of support is reached on March 31, 2026, but you can continue to update and run existing jobs. However, jobs running on discontinued versions are not eligible for technical support. AWS Glue will not apply security patches or other updates to discontinued versions. AWS Glue will also not honor SLAs when jobs are run on discontinued versions.

AWS strongly recommends that you migrate your jobs to supported versions.

For information on migrating your Spark jobs to the latest AWS Glue version, see Migrating AWS Glue jobs to AWS Glue version 5.1.

For migrating your Python shell jobs to the latest AWS Glue version:

- In the console, choose `Python 3 (Glue Version 5.1)`.
- In the CreateJob/UpdateJob API, set the `GlueVersion` parameter to `5.1`, and the `PythonVersion` to `3` under the `Command` parameter. The `GlueVersion` configuration does not affect the behavior of Python shell jobs, so there is no advantage to incrementing `GlueVersion`.
- You need to make your job script compatible with Python 3.

Migrating AWS Glue for Spark jobs to AWS Glue version 5.1

This topic describes the changes between AWS Glue versions 0.9, 1.0, 2.0, 3.0, 4.0 and 5.0 to allow you to migrate your Spark applications and ETL jobs to AWS Glue 5.1. It also describes the features in AWS Glue 5.1 and the advantages of using it.

To use this feature with your AWS Glue ETL jobs, choose **`5.1`** for the `Glue version` when creating your jobs.

Topics

- New features
- Actions to migrate to AWS Glue 5.1
- Migration checklist
- Migrating from AWS Glue 5.0 to AWS Glue 5.1
- Migrating from Older AWS Glue Versions to AWS Glue 5.1
- Connector and JDBC driver migration for AWS Glue 5.1

New features

This section describes new features and advantages of AWS Glue version 5.1.

- Apache Spark update from 3.5.4 in AWS Glue 5.0 to 3.5.6 in AWS Glue 5.1.
- Open Table Formats (OTF) updated to Hudi 1.0.2, Iceberg 1.10.0, and Delta Lake 3.3.2
- **Iceberg Materialized Views** - Create and manage Iceberg Materialized Views (MV). For more information, see blog post

- **Iceberg format version 3.0** - Extends data types and existing metadata structures to add new capabilities. For more information, see the Iceberg Table Spec.
- **Hudi Full Table Access** - Full Table Access (FTA) control for Apache Hudi in Apache Spark based on your policies defined in AWS Lake Formation. This feature enables read and write operations from your AWS Glue ETL jobs on AWS Lake Formation registered tables when the job role has full table access.
- **Spark native fine-grained access control (FGAC) support using AWS Lake Formation** - DDL/DML operations (like CREATE, ALTER, DELETE, DROP) with fine grained access control for Apache Hive, Apache Iceberg and Delta Lake tables registered in AWS Lake Formation.
- **Audit context for Spark jobs** - Audit context for AWS Glue ETL jobs will be available for AWS Glue and AWS Lake Formation API calls in the AWS CloudTrail logs.

Known Issues and Limitations

Note the following known issues and limitations:

- Limited support for view SQL clause for creation of materialized views, query rewrite and incremental refresh. More details can be found in the Iceberg Materialized Views feature documentation page
- **Hudi FTA writes** require using HoodieCredentialedHadoopStorage for credential vending during job execution. Set the following configuration when running Hudi jobs:

  ```
  hoodie.storage.class=org.apache.spark.sql.hudi.storage.HoodieCredentialedHadoop
  ```

- Hudi FTA write support works only with the default Hudi configurations. Custom or non-default Hudi settings may not be fully supported and could result in unexpected behavior. Clustering for Hudi Merge-On-Read (MOR) tables is also not supported under FTA write mode.

Breaking changes

Note the following breaking changes:

- S3A filesystem has replaced EMRFS as the default S3 connector. For information on how to migrate, see Migrating from AWS Glue 5.0 to AWS Glue 5.1.

Actions to migrate to AWS Glue 5.1

For existing jobs, change the `Glue version` from the previous version to `Glue 5.1` in the job configuration.

- In AWS Glue Studio, choose `Glue 5.1 - Supports Spark 3.5.6, Scala 2, Python 3` in `Glue version`.
- In the API, choose **`5.1`** in the `GlueVersion` parameter in the `UpdateJob` API operation.

For new jobs, choose `Glue 5.1` when you create a job.

- In the console, choose `Spark 3.5.6, Python 3 (Glue Version 5.1) or Spark 3.5.6, Scala 2 (Glue Version 5.1)` in `Glue version`.
- In AWS Glue Studio, choose `Glue 5.1 - Supports Spark 3.5.6, Scala 2, Python 3` in `Glue version`.
- In the API, choose **`5.1`** in the `GlueVersion` parameter in the `CreateJob` API operation.

To view Spark event logs of AWS Glue 5.1 coming from AWS Glue 2.0 or earlier, launch an upgraded Spark history server for AWS Glue 5.1 using CloudFormation or Docker.

Migration checklist

Review this checklist for migration:

- [Python] Update boto references from 1.34 to 1.40.

Migrating from AWS Glue 5.0 to AWS Glue 5.1

All existing job parameters and major features that exist in AWS Glue 5.0 will exist in AWS Glue 5.1. Note the following changes when migrating:

- In AWS Glue 5.1, S3A filesystem has replaced EMRFS as the default S3 connector. If both `spark.hadoop.fs.s3a.endpoint` and `spark.hadoop.fs.s3a.endpoint.region` are not set, the default region used by S3A is `us-east-2`. This can cause issues, such as S3 upload timeout errors, especially for VPC jobs. To mitigate the issues caused by this change, set the `spark.hadoop.fs.s3a.endpoint.region` Spark configuration when using the S3A file system in AWS Glue 5.1.

- To continue using EMRFS instead of S3A, set the following spark configurations:

```
   --conf spark.hadoop.fs.s3.impl=com.amazon.ws.emr.hadoop.fs.EmrFileSystem
   --conf spark.hadoop.fs.s3n.impl=com.amazon.ws.emr.hadoop.fs.EmrFileSystem
   --conf
spark.hadoop.fs.AbstractFileSystem.s3.impl=org.apache.hadoop.fs.s3.EMRFSDelegate
```

Refer to the Spark migration documentation:

- Migration Guide: Spark Core
- Migration Guide: SQL, Datasets and DataFrame
- Migration Guide: Structured Streaming
- Upgrading PySpark

Migrating from Older AWS Glue Versions to AWS Glue 5.1

- For migration steps related to AWS Glue 4.0 to AWS Glue 5.0, see Migrating from AWS Glue 4.0 to AWS Glue 5.0.
- For migration steps related to AWS Glue 3.0 to AWS Glue 5.0, see Migrating from AWS Glue 3.0 to AWS Glue 5.0.
- For migration steps related to AWS Glue 2.0 to AWS Glue 5.0 and a list of migration differences between AWS Glue version 2.0 and 4.0, see Migrating from AWS Glue 2.0 to AWS Glue 5.0.

Connector and JDBC driver migration for AWS Glue 5.1

For the versions of JDBC and data lake connectors that were upgraded, see:

- Appendix B: JDBC driver upgrades
- Appendix C: Connector upgrades
- Appendix D: Open table format upgrades

The following changes apply to the OTF version upgrades identified in Appendix D: Open table format upgrades for AWS Glue 5.1.

Apache Hudi

Note the following changes:

- Support FTA read and write access on Lake Formation registered tables.

Apache Iceberg

Note the following changes:

- Support Iceberg format version 3. The following features are supported:
  - Multi-argument transforms for partitioning and sorting.
  - Row Lineage tracking.
  - Deletion vectors. Learn more in blog post
  - Table encryption keys.
  - Default value support for columns.
- Support Spark-native FGAC writes on AWS Lake Formation registered tables.
- Athena SQL compatibility - Cannot read Iceberg V3 tables created by EMR Spark due to error: `GENERIC_INTERNAL_ERROR: Cannot read unsupported version 3`

Delta Lake

Note the following changes:

- Support FTA read and write access on Lake Formation registered tables.

Appendix A: Notable dependency upgrades

The following are dependency upgrades:

Dependency	Version in AWS Glue 5.1	Version in AWS Glue 5.0	Version in AWS Glue 4.0	Version in AWS Glue 3.0	Version in AWS Glue 2.0	Version in AWS Glue 1.0
Java	17	17	8	8	8	8
Spark	3.5.6	3.5.4	3.3.0-amzn-1	3.1.1-amzn-0	2.4.3	2.4.3

Dependency	Version in AWS Glue 5.1	Version in AWS Glue 5.0	Version in AWS Glue 4.0	Version in AWS Glue 3.0	Version in AWS Glue 2.0	Version in AWS Glue 1.0
Hadoop	3.4.1	3.4.1	3.3.3-amzn-0	3.2.1-amzn-3	2.8.5-amzn-5	2.8.5-amzn-1
Scala	2.12.18	2.12.18	2.12	2.12	2.11	2.11
Jackson	2.15.2	2.15.2	2.12	2.12	2.11	2.11
Hive	2.3.9-amzn-4	2.3.9-amzn-4	2.3.9-amzn-2	2.3.7-amzn-4	1.2	1.2
EMRFS	2.73.0	2.69.0	2.54.0	2.46.0	2.38.0	2.30.0
Json4s	3.7.0-M11	3.7.0-M11	3.7.0-M11	3.6.6	3.5.x	3.5.x
Arrow	12.0.1	12.0.1	7.0.0	2.0.0	0.10.0	0.10.0
AWS Glue Data Catalog client	4.9.0	4.5.0	3.7.0	3.0.0	1.10.0	N/A
AWS SDK for Java	2.35.5	2.29.52	1.12	1.12		
Python	3.11	3.11	3.10	3.7	2.7 & 3.6	2.7 & 3.6
Boto	1.40.61	1.34.131	1.26	1.18	1.12	N/A
EMR DynamoDB connector	5.7.0	5.6.0	4.16.0			

Appendix B: JDBC driver upgrades

The following are JDBC driver upgrades:

Driver	JDBC driver version in AWS Glue 5.1	JDBC driver version in AWS Glue 5.0	JDBC driver version in AWS Glue 4.0	JDBC driver version in AWS Glue 3.0	JDBC driver version in past AWS Glue versions
MySQL	8.0.33	8.0.33	8.0.23	8.0.23	5.1
Microsoft SQL Server	10.2.0	10.2.0	9.4.0	7.0.0	6.1.0
Oracle Databases	23.3.0.23.09	23.3.0.23.09	21.7	21.1	11.2
PostgreSQL	42.7.3	42.7.3	42.3.6	42.2.18	42.1.0
Amazon Redshift	redshift-jdbc42-2.1.0.29	redshift-jdbc42-2.1.0.29	redshift-jdbc42-2.1.0.16	redshift-jdbc41-1.2.12.1017	redshift-jdbc41-1.2.12.1017
SAP Hana	2.20.17	2.20.17	2.17.12		
Teradata	20.00.00.33	20.00.00.33	20.00.00.06		

Appendix C: Connector upgrades

The following are connector upgrades:

Driver	Connector version in AWS Glue 5.1	Connector version in AWS Glue 5.0	Connector version in AWS Glue 4.0	Connector version in AWS Glue 3.0
EMR DynamoDB connector	5.7.0	5.6.0	4.16.0	
Amazon Redshift	6.4.2	6.4.0	6.1.3	
OpenSearch	1.2.0	1.2.0	1.0.1	

Driver	Connector version in AWS Glue 5.1	Connector version in AWS Glue 5.0	Connector version in AWS Glue 4.0	Connector version in AWS Glue 3.0
MongoDB	10.3.0	10.3.0	10.0.4	3.0.0
Snowflake	3.1.1	3.0.0	2.12.0	
Google BigQuery	0.32.2	0.32.2	0.32.2	
AzureCosmos	4.33.0	4.33.0	4.22.0	
AzureSQL	1.3.0	1.3.0	1.3.0	
Vertica	3.3.5	3.3.5	3.3.5	

Appendix D: Open table format upgrades

The following are open table format upgrades:

OTF	Connector version in AWS Glue 5.1	Connector version in AWS Glue 5.0	Connector version in AWS Glue 4.0	Connector version in AWS Glue 3.0
Hudi	1.0.2	0.15.0	0.12.1	0.10.1
Delta Lake	3.3.2	3.3.0	2.1.0	1.0.0
Iceberg	1.10.0	1.7.1	1.0.0	0.13.1

Migrating AWS Glue for Spark jobs to AWS Glue version 5.0

This topic describes the changes between AWS Glue versions 0.9, 1.0, 2.0, 3.0, and 4.0 to allow you to migrate your Spark applications and ETL jobs to AWS Glue 5.0. It also describes the features in AWS Glue 5.0 and the advantages of using it.

To use this feature with your AWS Glue ETL jobs, choose **`5.0`** for the `Glue version` when creating your jobs.

Topics

- New features
- Actions to migrate to AWS Glue 5.0
- Migration checklist
- AWS Glue 5.0 features
- Migrating from AWS Glue 4.0 to AWS Glue 5.0
- Migrating from AWS Glue 3.0 to AWS Glue 5.0
- Migrating from AWS Glue 2.0 to AWS Glue 5.0
- Logging behavior changes in AWS Glue 5.0
- Connector and JDBC driver migration for AWS Glue 5.0

New features

This section describes new features and advantages of AWS Glue version 5.0.

- Apache Spark update from 3.3.0 in AWS Glue 4.0 to 3.5.4 in AWS Glue 5.0. See Major enhancements from Spark 3.3.0 to Spark 3.5.4.
- Spark-native fine-grained access control (FGAC) using Lake Formation. This includes FGAC for Iceberg, Delta and Hudi tables. For more information, see Using AWS Glue with AWS Lake Formation for fine-grained access control.

  Note the following considerations or limitations for Spark-native FGAC:

  - Currently data writes are not supported
  - Writing into Iceberg through `GlueContext` using Lake Formation requires use of IAM access control instead

  For a complete list of limitations and considerations when using Spark-native FGAC, see the section called “Considerations”.
- Support for Amazon S3 Access Grants as a scalable access control solution to your Amazon S3 data from AWS Glue. For more information, see Using Amazon S3 Access Grants with AWS Glue.
- Open Table Formats (OTF) updated to Hudi 0.15.0, Iceberg 1.7.1, and Delta Lake 3.3.0
- Amazon SageMaker Unified Studio support.

- Amazon SageMaker Lakehouse and data abstraction integration. For more information, see Querying metastore data catalogs from AWS Glue ETL.
- Support to install additional Python libraries using `requirements.txt`. For more information, see Installing additional Python libraries in AWS Glue 5.0 or above using requirements.txt.
- AWS Glue 5.0 supports data lineage in Amazon DataZone. You can configure AWS Glue to automatically collect lineage information during Spark job runs and send the lineage events to be visualized in Amazon DataZone. For more information, see Data lineage in Amazon DataZone.

  To configure this on the AWS Glue console, turn on **Generate lineage events**, and enter your Amazon DataZone domain ID on the **Job details** tab.

  Alternatively, you can provide the following job parameter (provide your DataZone domain ID):

  - Key: `--conf`
  - Value:

```
extraListeners=io.openlineage.spark.agent.OpenLineageSparkListener
—conf spark.openlineage.transport.type=amazon_datazone_api
-conf spark.openlineage.transport.domainId=<your-domain-ID>
```

- Connector and JDBC driver updates. For more information, see Appendix B: JDBC driver upgrades and Appendix C: Connector upgrades.
- Java update from 8 to 17.
- Increased storage for AWS Glue `G.1X` and `G.2X` workers with disk space increasing to 94GB and 138GB respectively. Additionally, new worker types `G.12X`, `G.16X`, and memory-optimized `R.1X`, `R.2X`, `R.4X`, `R.8X` are available in AWS Glue 4.0 and later versions. For more information, see Jobs
- **Support for AWS SDK for Java, version 2** - AWS Glue 5.0 jobs can use the for Java versions 1.12.569 or 2.28.8 if the job supports v2. The AWS SDK for Java 2.x is a major rewrite of the version 1.x code base. It's built on top of Java 8+ and adds several frequently requested features. These include support for non-blocking I/O, and the ability to plug in a different HTTP

implementation at runtime. For more information, including a Migration Guide from SDK for Java v1 to v2, see the AWS SDK for Java, version 2 guide.

Breaking changes

Note the following breaking changes:

- In AWS Glue 5.0, when using the S3A file system and if both `fs.s3a.endpoint` and `fs.s3a.endpoint.region` are not set, the default region used by S3A is `us-east-2`. This can cause issues, such as S3 upload timeout errors, especially for VPC jobs. To mitigate the issues caused by this change, set the `fs.s3a.endpoint.region` Spark configuration when using the S3A file system in AWS Glue 5.0.
- Lake Formation Fine-grained Access Control (FGAC)
  - AWS Glue 5.0 only supports the new Spark-native FGAC using Spark DataFrames. It does not support FGAC using AWS Glue DynamicFrames.
    - Use of FGAC in 5.0 requires migrating from AWS Glue DynamicFrames to Spark DataFrames
    - If you don't need FGAC, then it is not necessary to migrate to Spark DataFrame and GlueContext features, like job bookmarks and push down predicates, will continue to work.
  - Jobs with Spark-native FGAC require a minimum of 4 workers: one user driver, one system driver, one system executor, and one standby user executor.
  - For more information, see Using AWS Glue with AWS Lake Formation for fine-grained access control.
- Lake Formation Full Table Access (FTA)
  - AWS Glue 5.0 supports FTA with Spark-native DataFrames (new) and GlueContext DynamicFrames (legacy, with limitations)
  - Spark-native FTA
    - If 4.0 script uses GlueContext, migrate to using native spark.
    - This feature is limited to hive and iceberg tables
    - For more information on configuring a 5.0 job to use Spark native FTA, see Native Spark FTA in AWS Glue 5.0.
  - GlueContext DynamicFrame FTA
    - No code change necessary
    - This feature is limited to non-OTF tables - it will not work with Iceberg, Delta Lake, and Hudi.
- Vectorized SIMD CSV reader is not supported.

- Continuous logging to output log group is not supported. Use `error` log group instead.
- The AWS Glue job run insights `job-insights-rule-driver` has been deprecated. The `job-insights-rca-driver` log stream is now located in the error log group.
- Athena-based custom/marketplace connectors are not supported.
- Adobe Marketo Engage, Facebook Ads, Google Ads, Google Analytics 4, Google Sheets, Hubspot, Instagram Ads, Intercom, Jira Cloud, Oracle NetSuite, Salesforce, Salesforce Marketing Cloud, Salesforce Marketing Cloud Account Engagement, SAP OData, ServiceNow, Slack, Snapchat Ads, Stripe, Zendesk and Zoho CRM connectors are not supported.
- Custom log4j properties are not supported in AWS Glue 5.0.

Major enhancements from Spark 3.3.0 to Spark 3.5.4

Note the following enhancements:

- Python client for Spark Connect (SPARK-39375).
- Implement support for DEFAULT values for columns in tables (SPARK-38334).
- Support "Lateral Column Alias References" (SPARK-27561).
- Harden SQLSTATE usage for error classes (SPARK-41994).
- Enable Bloom filter Joins by default (SPARK-38841).
- Better Spark UI scalability and driver stability for large applications (SPARK-41053).
- Async Progress Tracking in Structured Streaming (SPARK-39591).
- Python arbitrary stateful processing in structured streaming (SPARK-40434).
- Pandas API coverage improvements (SPARK-42882) and NumPy input support in PySpark (SPARK-39405).
- Provide a memory profiler for PySpark user-defined functions (SPARK-40281).
- Implement PyTorch distributor (SPARK-41589).
- Publish SBOM artifacts (SPARK-41893).
- Support IPv6-only environment (SPARK-39457).
- Customized K8s scheduler (Apache YuniKorn and Volcano) GA (SPARK-42802).
- Scala and Go client support in Spark Connect (SPARK-42554) and (SPARK-43351).
- PyTorch-based distributed ML Support for Spark Connect (SPARK-42471).
- Structured streaming support for Spark Connect in Python and Scala (SPARK-42938).

- Pandas API support for the Python Spark Connect Client (SPARK-42497).
- Introduce Arrow Python UDFs (SPARK-40307).
- Support Python user-defined table functions (SPARK-43798).
- Migrate PySpark errors onto error classes (SPARK-42986).
- PySpark test framework (SPARK-44042).
- Add support for Datasketches HllSketch (SPARK-16484).
- Built-in SQL function improvement (SPARK-41231).
- IDENTIFIER clause (SPARK-43205).
- Add SQL functions into Scala, Python and R API (SPARK-43907).
- Add named argument support for SQL functions (SPARK-43922).
- Avoid unnecessary task rerun on decommissioned executor lost if shuffle data migrated (SPARK-41469).
- Distributed ML <> spark connect (SPARK-42471).
- DeepSpeed distributor (SPARK-44264).
- Implement changelog checkpointing for RocksDB state store (SPARK-43421).
- Introduce watermark propagation among operators (SPARK-42376).
- Introduce dropDuplicatesWithinWatermark (SPARK-42931).
- RocksDB state store provider memory management enhancements (SPARK-43311).

Actions to migrate to AWS Glue 5.0

For existing jobs, change the `Glue version` from the previous version to `Glue 5.0` in the job configuration.

- In AWS Glue Studio, choose `Glue 5.0 - Supports Spark 3.5.4, Scala 2, Python 3` in `Glue version`.
- In the API, choose **`5.0`** in the `GlueVersion` parameter in the `UpdateJob` API operation.

For new jobs, choose `Glue 5.0` when you create a job.

- In the console, choose `Spark 3.5.4, Python 3 (Glue Version 5.0) or Spark 3.5.4, Scala 2 (Glue Version 5.0)` in `Glue version`.

- In AWS Glue Studio, choose `Glue 5.0 - Supports Spark 3.5.4, Scala 2, Python 3` in `Glue version`.
- In the API, choose **`5.0`** in the `GlueVersion` parameter in the `CreateJob` API operation.

To view Spark event logs of AWS Glue 5.0 coming from AWS Glue 2.0 or earlier, launch an upgraded Spark history server for AWS Glue 5.0 using CloudFormation or Docker.

Migration checklist

Review this checklist for migration:

- Java 17 updates
- [Scala] Upgrade AWS SDK calls from v1 to v2
- Python 3.10 to 3.11 migration
- [Python] Update boto references from 1.26 to 1.34

AWS Glue 5.0 features

This section describes AWS Glue features in more detail.

Querying metastore data catalogs from AWS Glue ETL

You can register your AWS Glue job to access the AWS Glue Data Catalog, which makes tables and other metastore resources available to disparate consumers. The Data Catalog supports a multi-catalog hierarchy, which unifies all your data across Amazon S3 data lakes. It also provides both a Hive metastore API and an open-source Apache Iceberg API for accessing the data. These features are available to AWS Glue and other data-oriented services like Amazon EMR, Amazon Athena and Amazon Redshift.

When you create resources in the Data Catalog, you can access them from any SQL engine that supports the Apache Iceberg REST API. AWS Lake Formation manages permissions. Following configuration, you can leverage AWS Glue's capabilities to query disparate data by querying these metastore resources with familiar applications. These include Apache Spark and Trino.

How metadata resources are organized

Data is organized in a logical hierarchy of catalogs, databases and tables, using the AWS Glue Data Catalog:

- Catalog – A logical container that holds objects from a data store, such as schemas or tables.
- Database – Organizes data objects such as tables and views in a catalog.
- Tables and views – Data objects in a database that provide an abstraction layer with an understandable schema. They make it easy to access underlying data, which could be in various formats and in various locations.

Migrating from AWS Glue 4.0 to AWS Glue 5.0

All existing job parameters and major features that exist in AWS Glue 4.0 will exist in AWS Glue 5.0, except machine learning transforms.

The following new parameters were added:

- `--enable-lakeformation-fine-grained-access`: Enables the fine-grained access control (FGAC) feature in AWS Lake Formation tables.

Refer to the Spark migration documentation:

- Migration Guide: Spark Core
- Migration Guide: SQL, Datasets and DataFrame
- Migration Guide: Structured Streaming
- Upgrading PySpark

Migrating from AWS Glue 3.0 to AWS Glue 5.0

> **Note**
>
> For migration steps related to AWS Glue 4.0, see Migrating from AWS Glue 3.0 to AWS Glue 4.0.

All existing job parameters and major features that exist in AWS Glue 3.0 will exist in AWS Glue 5.0, except machine learning transforms.

Migrating from AWS Glue 2.0 to AWS Glue 5.0

> **Note**
>
> For migration steps related to AWS Glue 4.0 and a list of migration differences between AWS Glue version 3.0 and 4.0, see Migrating from AWS Glue 3.0 to AWS Glue 4.0.

Also note the following migration differences between AWS Glue versions 3.0 and 2.0:

- All existing job parameters and major features that exist in AWS Glue 2.0 will exist in AWS Glue 5.0, except machine learning transforms.
- Several Spark changes alone may require revision of your scripts to ensure removed features are not being referenced. For example, Spark 3.1.1 and later does not enable Scala-untyped UDFs but Spark 2.4 does allow them.
- Python 2.7 is not supported.
- Any extra jars supplied in existing AWS Glue 2.0 jobs may bring in conflicting dependencies since there were upgrades in several dependencies. You can avoid classpath conflicts with the `--user-jars-first` job parameter.
- Changes to the behavior of loading/saving of timestamps from/to parquet files. For more details, see Upgrading from Spark SQL 3.0 to 3.1.
- Different Spark task parallelism for driver/executor configuration. You can adjust task parallelism by passing the `--executor-cores` job argument.

Logging behavior changes in AWS Glue 5.0

The following are changes in logging behavior in AWS Glue 5.0. For more information, see Logging for AWS Glue jobs.

- All logs (system logs, Spark daemon logs, user logs, and Glue Logger logs) are now written to the `/aws-glue/jobs/error` log group by default.
- The `/aws-glue/jobs/logs-v2` log group used for continuous logging in previous versions is no longer used.
- You can no longer rename or customize the log group or log stream names using the removed continuous logging arguments. Instead, see the new job arguments in AWS Glue 5.0.

Two new job arguments are introduced in AWS Glue 5.0

- `--custom-logGroup-prefix`: Allows you to specify a custom prefix for the `/aws-glue/jobs/error` and `/aws-glue/jobs/output` log groups.
- `--custom-logStream-prefix`: Allows you to specify a custom prefix for the log stream names within the log groups.

  Validation rules and limitations for custom prefixes include:

  - The entire log stream name must be between 1 and 512 characters.
  - The custom prefix for log stream names is limited to 400 characters.
  - Allowed characters in prefixes include alphanumeric characters, underscores (`_`), hyphens (`-`), and forward slashes (`/`).

Deprecated continuous logging arguments in AWS Glue 5.0

The following job arguments for continuous logging have been deprecated in AWS Glue 5.0

- `--enable-continuous-cloudwatch-log`
- `--continuous-log-logGroup`
- `--continuous-log-logStreamPrefix`
- `--continuous-log-conversionPattern`
- `--enable-continuous-log-filter`

Connector and JDBC driver migration for AWS Glue 5.0

For the versions of JDBC and data lake connectors that were upgraded, see:

- Appendix B: JDBC driver upgrades
- Appendix C: Connector upgrades
- Appendix D: Open table format upgrades

The following changes apply to the connector or driver versions identified in the appendices for Glue 5.0.

Amazon Redshift

Note the following changes:

- Adds support for three-part table names to allow connector to query Redshift data sharing tables.
- Corrects mapping of Spark `ShortType` to use Redshift `SMALLINT` instead of `INTEGER` to better match expected data size.
- Added support for Custom Cluster Names (CNAME) for Amazon Redshift Serverless.

Apache Hudi

Note the following changes:

- Support record level index.
- Support auto generation of record keys. Now you don't have to specify the record key field.

Apache Iceberg

Note the following changes:

- Support fine-grained access control with AWS Lake Formation.
- Support branching and tagging which are named references to snapshots with their own independent lifecycles.
- Added a changelog view procedure which generates a view that contains the changes made to a table over a specified period or between specific snapshots.

Delta Lake

Note the following changes:

- Support Delta Universal Format (UniForm) which enables seamless access through Apache Iceberg and Apache Hudi.
- Support Deletion Vectors that implements a Merge-on-Read paradigm.

AzureCosmos

Note the following changes:

- Added hierarchical partition key support.
- Added option to use custom Schema with StringType (raw json) for a nested property.
- Added config option `spark.cosmos.auth.aad.clientCertPemBase64` to allow using SPN (ServicePrincipal name) authentication with certificate instead of client secret.

For more information, see the Azure Cosmos DB Spark connector change log.

Microsoft SQL Server

Note the following changes:

- TLS encryption is enabled by default.
- When encrypt = false but the server requires encryption, the certificate is validated based on the `trustServerCertificate` connection setting.
- `aadSecurePrincipalId` and `aadSecurePrincipalSecret` deprecated.
- `getAADSecretPrincipalId` API removed.
- Added CNAME resolution when realm is specified.

MongoDB

Note the following changes:

- Support for micro-batch mode with Spark Structured Streaming.
- Support for BSON data types.
- Added support for reading multiple collections when using micro-batch or continuous streaming modes.
  - If the name of a collection used in your `collection` configuration option contains a comma, the Spark Connector treats it as two different collections. To avoid this, you must escape the comma by preceding it with a backslash (\).
  - If the name of a collection used in your `collection` configuration option is "*", the Spark Connector interprets it as a specification to scan all collections. To avoid this, you must escape the asterisk by preceding it with a backslash (\).
  - If the name of a collection used in your `collection` configuration option contains a backslash (\), the Spark Connector treats the backslash as an escape character, which might change how it interprets the value. To avoid this, you must escape the backslash by preceding it with another backslash.

For more information, see the MongoDB connector for Spark release notes.

Snowflake

Note the following changes:

- Introduced a new `trim_space` parameter that you can use to trim values of `StringType` columns automatically when saving to a Snowflake table. Default: `false`.
- Disabled the `abort_detached_query` parameter at the session level by default.
- Removed the requirement of the SFUSER parameter when using OAUTH.
- Removed the Advanced Query Pushdown feature. Alternatives to the feature are available. For example, instead of loading data from Snowflake tables, users can directly load data from Snowflake SQL queries.

For more information, see the Snowflake Connector for Spark release notes.

Appendix A: Notable dependency upgrades

The following are dependency upgrades:

Dependency	Version in AWS Glue 5.0	Version in AWS Glue 4.0	Version in AWS Glue 3.0	Version in AWS Glue 2.0	Version in AWS Glue 1.0
Java	17	8	8	8	8
Spark	3.5.4	3.3.0-amzn-1	3.1.1-amzn-0	2.4.3	2.4.3
Hadoop	3.4.1	3.3.3-amzn-0	3.2.1-amzn-3	2.8.5-amzn-5	2.8.5-amzn-1
Scala	2.12.18	2.12	2.12	2.11	2.11
Jackson	2.15.2	2.12	2.12	2.11	2.11
Hive	2.3.9-amzn-4	2.3.9-amzn-2	2.3.7-amzn-4	1.2	1.2
EMRFS	2.69.0	2.54.0	2.46.0	2.38.0	2.30.0
Json4s	3.7.0-M11	3.7.0-M11	3.6.6	3.5.x	3.5.x

Dependency	Version in AWS Glue 5.0	Version in AWS Glue 4.0	Version in AWS Glue 3.0	Version in AWS Glue 2.0	Version in AWS Glue 1.0
Arrow	12.0.1	7.0.0	2.0.0	0.10.0	0.10.0
AWS Glue Data Catalog client	4.5.0	3.7.0	3.0.0	1.10.0	N/A
AWS SDK for Java	2.29.52	1.12	1.12		
Python	3.11	3.10	3.7	2.7 & 3.6	2.7 & 3.6
Boto	1.34.131	1.26	1.18	1.12	N/A
EMR DynamoDB connector	5.6.0	4.16.0			

Appendix B: JDBC driver upgrades

The following are JDBC driver upgrades:

Driver	JDBC driver version in AWS Glue 5.0	JDBC driver version in AWS Glue 4.0	JDBC driver version in AWS Glue 3.0	JDBC driver version in past AWS Glue versions
MySQL	8.0.33	8.0.23	8.0.23	5.1
Microsoft SQL Server	10.2.0	9.4.0	7.0.0	6.1.0
Oracle Databases	23.3.0.23.09	21.7	21.1	11.2
PostgreSQL	42.7.3	42.3.6	42.2.18	42.1.0

Driver	JDBC driver version in AWS Glue 5.0	JDBC driver version in AWS Glue 4.0	JDBC driver version in AWS Glue 3.0	JDBC driver version in past AWS Glue versions
Amazon Redshift	redshift-jdbc42-2.1.0.29	redshift-jdbc42-2.1.0.16	redshift-jdbc41-1.2.12.1017	redshift-jdbc41-1.2.12.1017
SAP Hana	2.20.17	2.17.12		
Teradata	20.00.00.33	20.00.00.06		

Appendix C: Connector upgrades

The following are connector upgrades:

Driver	Connector version in AWS Glue 5.0	Connector version in AWS Glue 4.0	Connector version in AWS Glue 3.0
EMR DynamoDB connector	5.6.0	4.16.0	
Amazon Redshift	6.4.0	6.1.3	
OpenSearch	1.2.0	1.0.1	
MongoDB	10.3.0	10.0.4	3.0.0
Snowflake	3.0.0	2.12.0	
Google BigQuery	0.32.2	0.32.2	
AzureCosmos	4.33.0	4.22.0	
AzureSQL	1.3.0	1.3.0	
Vertica	3.3.5	3.3.5	

Appendix D: Open table format upgrades

The following are open table format upgrades:

OTF	Connector version in AWS Glue 5.0	Connector version in AWS Glue 4.0	Connector version in AWS Glue 3.0
Hudi	0.15.0	0.12.1	0.10.1
Delta Lake	3.3.0	2.1.0	1.0.0
Iceberg	1.7.1	1.0.0	0.13.1

Migrating AWS Glue for Spark jobs to AWS Glue version 4.0

This topic describes the changes between AWS Glue versions 0.9, 1.0, 2.0, and 3.0 to allow you to migrate your Spark applications and ETL jobs to AWS Glue 4.0. It also describes the features in AWS Glue 4.0 and the advantages of using it.

To use this feature with your AWS Glue ETL jobs, choose **`4.0`** for the `Glue version` when creating your jobs.

Topics

- New features supported
- Actions to migrate to AWS Glue 4.0
- Migration checklist
- Migrating from AWS Glue 3.0 to AWS Glue 4.0
- Migrating from AWS Glue 2.0 to AWS Glue 4.0
- Migrating from AWS Glue 1.0 to AWS Glue 4.0
- Migrating from AWS Glue 0.9 to AWS Glue 4.0
- Connector and JDBC driver migration for AWS Glue 4.0
- Appendix A: Notable dependency upgrades
- Appendix B: JDBC driver upgrades
- Appendix C: Connector upgrades

New features supported

This section describes new features and advantages of AWS Glue version 4.0.

- It is based on Apache Spark 3.3.0, but includes optimizations in AWS Glue, and Amazon EMR, such as adaptive query runs, vectorized readers, and optimized shuffles and partition coalescing.
- Upgraded JDBC drivers for all AWS Glue native sources including MySQL, Microsoft SQL Server, Oracle, PostgreSQL, MongoDB, and upgraded Spark libraries and dependencies brought in by Spark 3.3.0.
- Updated with a new Amazon Redshift connector and JDBC driver.
- Optimized Amazon S3 access with upgraded EMR File System (EMRFS) and enabled Amazon S3-optimized output committers, by default.
- Optimized Data Catalog access with partition indexes, pushdown predicates, partition listing, and an upgraded Hive metastore client.
- Integration with Lake Formation for governed catalog tables with cell-level filtering and data lake transactions.
- Reduced startup latency to improve overall job completion times and interactivity.
- Spark jobs are billed in 1-second increments with a 10x lower minimum billing duration—from a 10-minute minimum to a 1-minute minimum.
- Native support for open-data lake frameworks with Apache Hudi, Delta Lake, and Apache Iceberg.
- Native support for the Amazon S3-based Cloud Shuffle Storage Plugin (an Apache Spark plugin) to use Amazon S3 for shuffling and elastic storage capacity.

Major enhancements from Spark 3.1.1 to Spark 3.3.0

Note the following enhancements:

- Row-level runtime filtering (SPARK-32268).
- ANSI enhancements (SPARK-38860).
- Error message improvements (SPARK-38781).
- Support complex types for Parquet vectorized reader (SPARK-34863).
- Hidden file metadata support for Spark SQL (SPARK-37273).
- Provide a profiler for Python/Pandas UDFs (SPARK-37443).

- Introduce Trigger.AvailableNow for running streaming queries like Trigger.Once in multiple batches (SPARK-36533).
- More comprehensive Datasource V2 pushdown capabilities (SPARK-38788).
- Migrating from log4j 1 to log4j 2 (SPARK-37814).

Other notable changes

Note the following changes:

- Breaking changes
  - Drop references to Python 3.6 support in docs and Python/docs (SPARK-36977).
  - Remove named tuple hack by replacing built-in pickle to cloudpickle (SPARK-32079).
  - Bump minimum pandas version to 1.0.5 (SPARK-37465).

Actions to migrate to AWS Glue 4.0

For existing jobs, change the `Glue version` from the previous version to `Glue 4.0` in the job configuration.

- In AWS Glue Studio, choose `Glue 4.0 - Supports Spark 3.3, Scala 2, Python 3` in `Glue version`.
- In the API, choose **`4.0`** in the `GlueVersion` parameter in the `UpdateJob` API operation.

For new jobs, choose `Glue 4.0` when you create a job.

- In the console, choose `Spark 3.3, Python 3 (Glue Version 4.0) or Spark 3.3, Scala 2 (Glue Version 3.0)` in `Glue version`.
- In AWS Glue Studio, choose `Glue 4.0 - Supports Spark 3.3, Scala 2, Python 3` in `Glue version`.
- In the API, choose **`4.0`** in the `GlueVersion` parameter in the `CreateJob` API operation.

To view Spark event logs of AWS Glue 4.0 coming from AWS Glue 2.0 or earlier, launch an upgraded Spark history server for AWS Glue 4.0 using CloudFormation or Docker.

Migration checklist

- Do your job's external Python libraries depend on Python 2.7/3.6?
  - Update the dependent libraries from Python 2.7/3.6 to Python 3.10 as Spark 3.3.0 completely removed Python 2.7 and 3.6 support.

Migrating from AWS Glue 3.0 to AWS Glue 4.0

Note the following changes when migrating:

- All existing job parameters and major features that exist in AWS Glue 3.0 will exist in AWS Glue 4.0.
- AWS Glue 3.0 uses Amazon EMR-optimized Spark 3.1.1, and AWS Glue 4.0 uses Amazon EMR-optimized Spark 3.3.0.

  Several Spark changes alone might require revision of your scripts to ensure that removed features are not being referenced.
- AWS Glue 4.0 also features an update to EMRFS and Hadoop. For the specific version, see Appendix A: Notable dependency upgrades.
- The AWS SDK provided in ETL jobs is now upgraded from 1.11 to 1.12.
- All Python jobs will be using Python version 3.10. Previously, Python 3.7 was used in AWS Glue 3.0.

  As a result, some pymodules brought out-of-the-box by AWS Glue are upgraded.
- Log4j has been upgraded to Log4j2.
  - For information on the Log4j2 migration path, see the Log4j documentation.
  - You must rename any custom log4j.properties file as a log4j2.properties file instead, with the appropriate log4j2 properties.
- For migrating certain connectors, see Connector and JDBC driver migration for AWS Glue 4.0.
- The AWS Encryption SDK is upgraded from 1.x to 2.x. AWS Glue jobs using AWS Glue security configurations and jobs dependent on the AWS Encryption SDK dependency provided in runtime are affected. See the instructions for AWS Glue job migration.

  You can safely upgrade an AWS Glue 2.0/3.0 job to an AWS Glue 4.0 job because AWS Glue 2.0/3.0 already contains the AWS Encryption SDK bridge version.

Refer to the Spark migration documentation:

- Upgrading from Spark SQL 3.1 to 3.2
- Upgrading from Spark SQL 3.2 to 3.3

Migrating from AWS Glue 2.0 to AWS Glue 4.0

Note the following changes when migrating:

> **Note**
>
> For migration steps related to AWS Glue 3.0, see Migrating from AWS Glue 3.0 to AWS Glue 4.0.

- All existing job parameters and major features that exist in AWS Glue 2.0 will exist in AWS Glue 4.0.
- The EMRFS S3-optimized committer for writing Parquet data into Amazon S3 is enabled by default since AWS Glue 3.0. However, you can still disable it by setting `--enable-s3-parquet-optimized-committer` to `false`.
- AWS Glue 2.0 uses open-source Spark 2.4 and AWS Glue 4.0 uses Amazon EMR-optimized Spark 3.3.0.
  - Several Spark changes alone may require revision of your scripts to ensure that removed features are not being referenced.
  - For example, Spark 3.3.0 does not enable Scala-untyped UDFs, but Spark 2.4 does allow them.
- The AWS SDK provided in ETL jobs is now upgraded from 1.11 to 1.12.
- AWS Glue 4.0 also features an update to EMRFS, updated JDBC drivers, and inclusions of additional optimizations onto Spark itself provided by AWS Glue.
- Scala is updated to 2.12 from 2.11, and Scala 2.12 is not backward compatible with Scala 2.11.
- Python 3.10 is the default version used for Python scripts, as AWS Glue 2.0 was only using Python 3.7 and 2.7.
  - Python 2.7 is not supported with Spark 3.3.0. Any job requesting Python 2 in the job configuration will fail with an IllegalArgumentException.
  - A new mechanism of installing additional Python modules is available since AWS Glue 2.0.
- Several dependency updates, highlighted in Appendix A: Notable dependency upgrades.

- Any extra JAR files supplied in existing AWS Glue 2.0 jobs might bring in conflicting dependencies because there were upgrades in several dependencies in 4.0 from 2.0. You can avoid classpath conflicts in AWS Glue 4.0 with the `--user-jars-first` AWS Glue job parameter.
- AWS Glue 4.0 uses Spark 3.3. Starting with Spark 3.1, there was a change in the behavior of loading/saving of timestamps from/to parquet files. For more details, see Upgrading from Spark SQL 3.0 to 3.1.

  We recommend to set the following parameters when reading/writing parquet data that contains timestamp columns. Setting those parameters can resolve the calendar incompatibility issue that occurs during the Spark 2 to Spark 3 upgrade, for both the AWS Glue Dynamic Frame and Spark Data Frame. Use the CORRECTED option to read the datetime value as it is; and the LEGACY option to rebase the datetime values with regard to the calendar difference during reading.

  ```
  - Key: --conf
  - Value: spark.sql.legacy.parquet.int96RebaseModeInRead=[CORRECTED|LEGACY] --
  conf spark.sql.legacy.parquet.int96RebaseModeInWrite=[CORRECTED|LEGACY] --conf
   spark.sql.legacy.parquet.datetimeRebaseModeInRead=[CORRECTED|LEGACY]
  ```
- For migrating certain connectors, see Connector and JDBC driver migration for AWS Glue 4.0.
- The AWS Encryption SDK is upgraded from 1.x to 2.x. AWS Glue jobs using AWS Glue security configurations and jobs dependent on the AWS Encryption SDK dependency provided in runtime are affected. See these instructions for AWS Glue job migration:
  - You can safely upgrade an AWS Glue 2.0 job to an AWS Glue 4.0 job because AWS Glue 2.0 already contains the AWS Encryption SDK bridge version.

Refer to the Spark migration documentation:

- Upgrading from Spark SQL 2.4 to 3.0
- Upgrading from Spark SQL 3.1 to 3.2
- Upgrading from Spark SQL 3.2 to 3.3
- Changes in Datetime behavior to be expected since Spark 3.0.

Migrating from AWS Glue 1.0 to AWS Glue 4.0

Note the following changes when migrating:

- AWS Glue 1.0 uses open-source Spark 2.4 and AWS Glue 4.0 uses Amazon EMR-optimized Spark 3.3.0.
  - Several Spark changes alone may require revision of your scripts to ensure that removed features are not being referenced.
  - For example, Spark 3.3.0 does not enable Scala-untyped UDFs, but Spark 2.4 does allow them.
- All jobs in AWS Glue 4.0 will be run with significantly improved startup times. Spark jobs will be billed in 1-second increments with a 10x lower minimum billing duration since startup latency will go from 10 minutes maximum to 1 minute maximum.
- Logging behavior has changed significantly in AWS Glue 4.0, Spark 3.3.0 has a minimum requirement of Log4j2.
- Several dependency updates, highlighted in the appendix.
- Scala is also updated to 2.12 from 2.11, and Scala 2.12 is not backward compatible with Scala 2.11.
- Python 3.10 is also the default version used for Python scripts, as AWS Glue 0.9 was only using Python 2.

  Python 2.7 is not supported with Spark 3.3.0. Any job requesting Python 2 in the job configuration will fail with an IllegalArgumentException.
- A new mechanism of installing additional Python modules through pip is available since AWS Glue 2.0. For more information, see Installing additional Python modules with pip in AWS Glue 2.0+.
- AWS Glue 4.0 does not run on Apache YARN, so YARN settings do not apply.
- AWS Glue 4.0 does not have a Hadoop Distributed File System (HDFS).
- Any extra JAR files supplied in existing AWS Glue 1.0 jobs might bring in conflicting dependencies because there were upgrades in several dependencies in 4.0 from 1.0. We enable AWS Glue 4.0 with the `--user-jars-first` AWS Glue job parameter by default, to avoid this problem.
- AWS Glue 4.0 supports auto scaling. Therefore, the ExecutorAllocationManager metric will be available when auto scaling is enabled.
- In AWS Glue version 4.0 jobs, you specify the number of workers and worker type, but do not specify a `maxCapacity`.
- AWS Glue 4.0 does not yet support machine learning transforms.
- For migrating certain connectors, see Connector and JDBC driver migration for AWS Glue 4.0.

- The AWS Encryption SDK is upgraded from 1.x to 2.x. AWS Glue jobs using AWS Glue security configurations and jobs dependent on the AWS Encryption SDK dependency provided in runtime are affected. See these instructions for AWS Glue job migration.
  - You cannot migrate an AWS Glue 0.9/1.0 job to an AWS Glue 4.0 job directly. This is because when upgrading directly to version 2.x or later and enabling all new features immediately, the AWS Encryption SDK won't be able to decrypt the ciphertext encrypted under earlier versions of the AWS Encryption SDK.
  - To safely upgrade, we first recommend that you migrate to an AWS Glue 2.0/3.0 job that contains the AWS Encryption SDK bridge version. Run the job once to utilize the AWS Encryption SDK bridge version.
  - Upon completion, you can safely migrate the AWS Glue 2.0/3.0 job to AWS Glue 4.0.

Refer to the Spark migration documentation:

- Upgrading from Spark SQL 2.4 to 3.0
- Upgrading from Spark SQL 3.0 to 3.1
- Upgrading from Spark SQL 3.1 to 3.2
- Upgrading from Spark SQL 3.2 to 3.3
- Changes in Datetime behavior to be expected since Spark 3.0.

Migrating from AWS Glue 0.9 to AWS Glue 4.0

Note the following changes when migrating:

- AWS Glue 0.9 uses open-source Spark 2.2.1 and AWS Glue 4.0 uses Amazon EMR-optimized Spark 3.3.0.
  - Several Spark changes alone might require revision of your scripts to ensure that removed features are not being referenced.
  - For example, Spark 3.3.0 does not enable Scala-untyped UDFs, but Spark 2.2 does allow them.
- All jobs in AWS Glue 4.0 will be run with significantly improved startup times. Spark jobs will be billed in 1-second increments with a 10x lower minimum billing duration because startup latency will go from 10 minutes maximum to 1 minute maximum.
- Logging behavior has changed significantly since AWS Glue 4.0, Spark 3.3.0 has a minimum requirement of Log4j2 as mentioned here (https://spark.apache.org/docs/latest/core-migration-guide.html#upgrading-from-core-32-to-33).

- Several dependency updates, highlighted in the appendix.
- Scala is also updated to 2.12 from 2.11, and Scala 2.12 is not backward compatible with Scala 2.11.
- Python 3.10 is also the default version used for Python scripts, as AWS Glue 0.9 was only using Python 2.
  - Python 2.7 is not supported with Spark 3.3.0. Any job requesting Python 2 in the job configuration will fail with an IllegalArgumentException.
  - A new mechanism of installing additional Python modules through pip is available.
- AWS Glue 4.0 does not run on Apache YARN, so YARN settings do not apply.
- AWS Glue 4.0 does not have a Hadoop Distributed File System (HDFS).
- Any extra JAR files supplied in existing AWS Glue 0.9 jobs might bring in conflicting dependencies because there were upgrades in several dependencies in 3.0 from 0.9. You can avoid classpath conflicts in AWS Glue 3.0 with the `--user-jars-first` AWS Glue job parameter.
- AWS Glue 4.0 supports auto scaling. Therefore, the ExecutorAllocationManager metric will be available when auto scaling is enabled.
- In AWS Glue version 4.0 jobs, you specify the number of workers and worker type, but do not specify a `maxCapacity`.
- AWS Glue 4.0 does not yet support machine learning transforms.
- For migrating certain connectors, see Connector and JDBC driver migration for AWS Glue 4.0.
- The AWS Encryption SDK is upgraded from 1.x to 2.x. AWS Glue jobs using AWS Glue security configurations and jobs dependent on the AWS Encryption SDK dependency provided in runtime are affected. See these instructions for AWS Glue job migration.
  - You cannot migrate an AWS Glue 0.9/1.0 job to an AWS Glue 4.0 job directly. This is because when upgrading directly to version 2.x or later and enabling all new features immediately, the AWS Encryption SDK won't be able to decrypt the ciphertext encrypted under earlier versions of the AWS Encryption SDK.
  - To safely upgrade, we first recommend that you migrate to an AWS Glue 2.0/3.0 job that contains the AWS Encryption SDK bridge version. Run the job once to utilize the AWS Encryption SDK bridge version.
  - Upon completion, you can safely migrate the AWS Glue 2.0/3.0 job to AWS Glue 4.0.

Refer to the Spark migration documentation:

- Upgrading from Spark SQL 2.2 to 2.3
- Upgrading from Spark SQL 2.3 to 2.4
- Upgrading from Spark SQL 2.4 to 3.0
- Upgrading from Spark SQL 3.0 to 3.1
- Upgrading from Spark SQL 3.1 to 3.2
- Upgrading from Spark SQL 3.2 to 3.3
- Changes in Datetime behavior to be expected since Spark 3.0.

Connector and JDBC driver migration for AWS Glue 4.0

For the versions of JDBC and data lake connectors that were upgraded, see:

- Appendix B: JDBC driver upgrades
- Appendix C: Connector upgrades

Hudi

- Spark SQL support improvements:
  - Through the `Call Procedure` command, there is added support for upgrade, downgrade, bootstrap, clean, and repair. `Create/Drop/Show/Refresh Index` syntax is possible in Spark SQL.
  - A performance gap has been closed between usage through a Spark DataSource as opposed to Spark SQL. Datasource writes in the past used to be faster than SQL.
  - All built-in key generators implement more performant Spark-specific API operations.
  - Replaced UDF transformation in the bulk `insert` operation with RDD transformations to cut down on costs of using SerDe.
  - Spark SQL with Hudi requires a `primaryKey` to be specified by `tblproperites` or options in the SQL statement. For update and delete operations, the `preCombineField` is required as well.
- Any Hudi table created before version 0.10.0 without a `primaryKey` needs to be recreated with a `primaryKey` field since version 0.10.0.

PostgreSQL

- Several vulnerabilities (CVEs) were addressed.
- Java 8 is natively supported.
- If the job is using Arrays of Arrays, with the exception of byte arrays, this scenario can be treated as multidimensional arrays.

MongoDB

- The current MongoDB connector supports Spark version 3.1 or later and MongoDB version 4.0 or later.
- Due to the connector upgrade, a few property names changed. For example, the URI property name changed to `connection.uri`. For more information on the current options, see the MongoDB Spark Connector blog.
- Using MongoDB 4.0 hosted by Amazon DocumentDB has some functional differences. For more information, see these topics:
  - Functional Differences: Amazon DocumentDB and MongoDB
  - Supported MongoDB APIs, Operations, and Data Types.
- The "partitioner" option is restricted to `ShardedPartitioner`, `PaginateIntoPartitionsPartitioner`, and `SinglePartitionPartitioner`. It cannot use default `SamplePartitioner` and `PaginateBySizePartitioner` for Amazon DocumentDB because the stage operator does not support the MongoDB API. For more information, see Supported MongoDB APIs, Operations, and Data Types.

Delta Lake

- Delta Lake now supports time travel in SQL to query older data easily. With this update, time travel is now available both in Spark SQL and through the DataFrame API. Support has been added for the current version of TIMESTAMP in SQL.
- Spark 3.3 introduces Trigger.AvailableNow for running streaming queries as an equivalent to `Trigger.Once` for batch queries. This support is also available when using Delta tables as a streaming source.
- Support for SHOW COLUMNS to return the list of columns in a table.
- Support for DESCRIBE DETAIL in the Scala and Python DeltaTable API. It retrieves detailed information about a Delta table using either the DeltaTable API or Spark SQL.

- Support for returning operation metrics from SQL Delete, Merge, and Update commands. Previously these SQL commands returned an empty DataFrame, now they return a DataFrame with useful metrics about the operation performed.
- Optimize performance improvements:
  - Set the configuration option `spark.databricks.delta.optimize.repartition.enabled=true` to use `repartition(1)` instead of `coalesce(1)` in the Optimize command for better performance when compacting many small files.
  - Improved performance by using a queue-based approach to parallelize compaction jobs.
- Other notable changes:
  - Support for using variables in the VACUUM and OPTIMIZE SQL commands.
  - Improvements for CONVERT TO DELTA with catalog tables including:
    - Autofill the partition schema from the catalog when it's not provided.
    - Use partition information from the catalog to find the data files to commit instead of doing a full directory scan. Instead of committing all data files in the table directory, only data files under the directories of active partitions will be committed.
  - Support for Change Data Feed (CDF) batch reads on column mapping enabled tables when DROP COLUMN and RENAME COLUMN have not been used. For more information, see the Delta Lake documentation.
  - Improve Update command performance by enabling schema pruning in the first pass.

Apache Iceberg

- Added several performance improvements for scan planning and Spark queries.
- Added a common REST catalog client that uses change-based commits to resolve commit conflicts on the service side.
- `AS OF` syntax for SQL time travel queries is supported.
- Added merge-on-read support for MERGE and UPDATE queries.
- Added support to rewrite partitions using Z-order.
- Added a spec and implementation for Puffin, a format for large stats and index blobs, like Theta sketches or bloom filters.
- Added new interfaces for consuming data incrementally (both append and changelog scans).
- Added support for bulk operations and ranged reads to FileIO interfaces.

- Added more metadata tables to show delete files in the metadata tree.
- The drop table behavior changed. In Iceberg 0.13.1, running `DROP TABLE` removes the table from the catalog and deletes the table contents as well. In Iceberg 1.0.0, `DROP TABLE` only removes the table from the catalog. To delete the table contents use `DROP TABLE PURGE`.
- Parquet vectorized reads are enabled by default in Iceberg 1.0.0. If you want to disable vectorized reads, set `read.parquet.vectorization.enabled` to `false`.

Oracle

Changes are minor.

MySQL

Changes are minor.

Amazon Redshift

AWS Glue 4.0 features a new Amazon Redshift connector with a new JDBC driver. For information about the enhancements and how to migrate from previous AWS Glue versions, see the section called “Redshift connections”.

Appendix A: Notable dependency upgrades

The following are dependency upgrades:

Dependency	Version in AWS Glue 4.0	Version in AWS Glue 3.0	Version in AWS Glue 2.0	Version in AWS Glue 1.0
Spark	3.3.0-amzn-1	3.1.1-amzn-0	2.4.3	2.4.3
Hadoop	3.3.3-amzn-0	3.2.1-amzn-3	2.8.5-amzn-5	2.8.5-amzn-1
Scala	2.12	2.12	2.11	2.11
Jackson	2.13.3	2.10.x	2.7.x	2.7.x
Hive	2.3.9-amzn-2	2.3.7-amzn-4	1.2	1.2
EMRFS	2.54.0	2.46.0	2.38.0	2.30.0

Dependency	Version in AWS Glue 4.0	Version in AWS Glue 3.0	Version in AWS Glue 2.0	Version in AWS Glue 1.0
Json4s	3.7.0-M11	3.6.6	3.5.x	3.5.x
Arrow	7.0.0	2.0.0	0.10.0	0.10.0
AWS Glue Data Catalog client	3.7.0	3.0.0	1.10.0	N/A
Python	3.10	3.7	2.7 & 3.6	2.7 & 3.6
Boto	1.26	1.18	1.12	N/A

Appendix B: JDBC driver upgrades

The following are JDBC driver upgrades:

Driver	JDBC driver version in past AWS Glue versions	JDBC driver version in AWS Glue 3.0	JDBC driver version in AWS Glue 4.0
MySQL	5.1	8.0.23	8.0.23
Microsoft SQL Server	6.1.0	7.0.0	9.4.0
Oracle Databases	11.2	21.1	21.7
PostgreSQL	42.1.0	42.2.18	42.3.6
MongoDB	2.0.0	4.0.0	4.7.2
Amazon Redshift	redshift-jdbc41-1.2.12.1017	redshift-jdbc41-1.2.12.1017	redshift-jdbc42-2.1.0.16

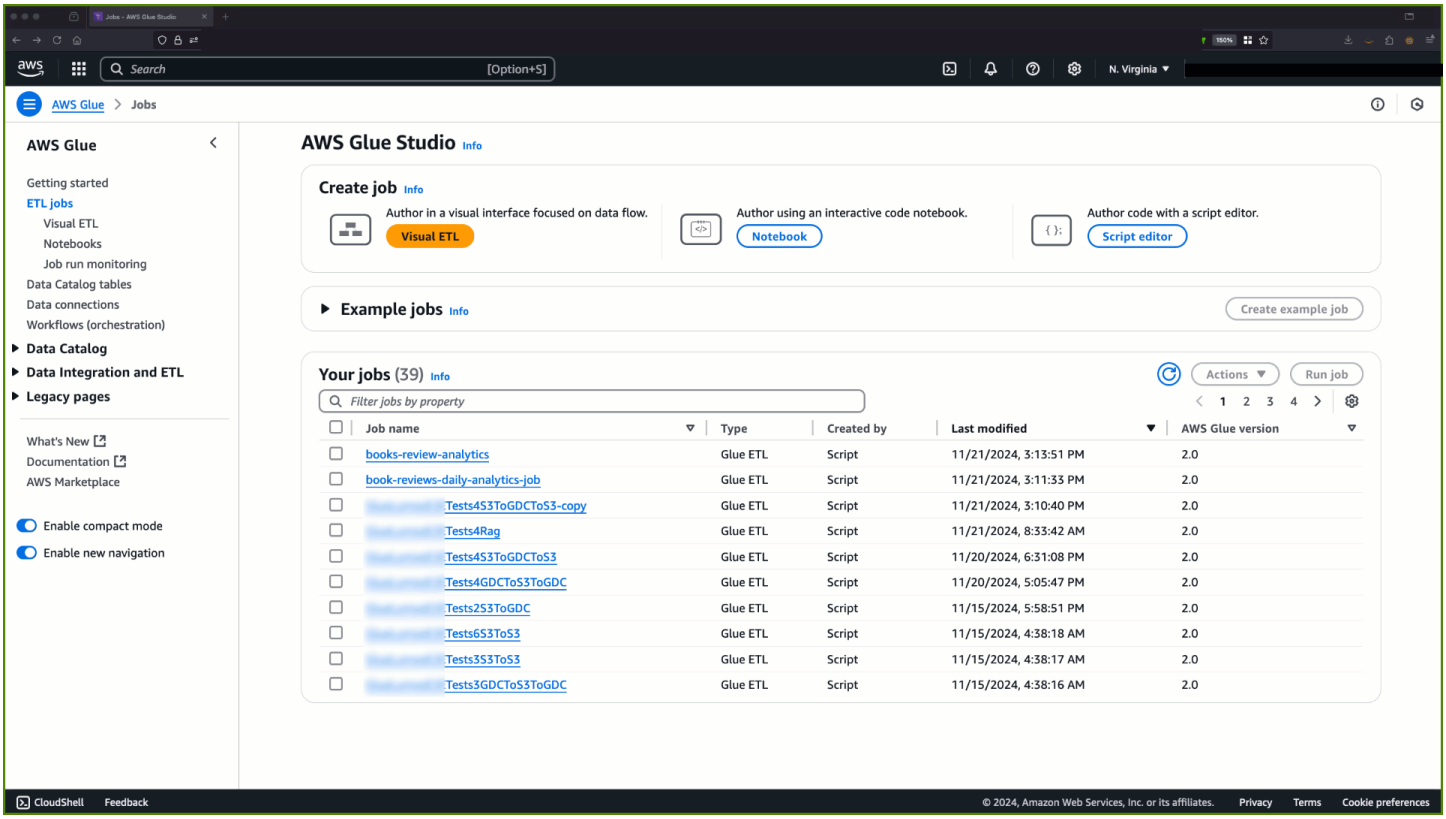
Appendix C: Connector upgrades

The following are connector upgrades:

Driver	Connector version in AWS Glue 3.0	Connector version in AWS Glue 4.0
MongoDB	3.0.0	10.0.4
Hudi	0.10.1	0.12.1
Delta Lake	1.0.0	2.1.0
Iceberg	0.13.1	1.0.0
DynamoDB	1.11	1.12

Generative AI upgrades for Apache Spark in AWS Glue

Spark Upgrades in AWS Glue enables data engineers and developers to upgrade and migrate their existing AWS Glue Spark jobs to the latest Spark releases using generative AI. Data engineers can use it to scan their AWS Glue Spark jobs, generate upgrade plans, execute plans, and validate outputs. It reduces the time and cost of Spark upgrades by automating the undifferentiated work of identifying and updating Spark scripts, configurations, dependencies, methods, and features.



How it works

When you use upgrade analysis, AWS Glue identifies differences between versions and configurations in your job's code to generate an upgrade plan. The upgrade plan details all code changes, and required migration steps. Next, AWS Glue builds and runs the upgraded application in an environment to validate changes and generates a list of code changes for you to migrate your job. You can view the updated script along with the summary that details the proposed changes. After running your own tests, accept the changes and the AWS Glue job will be updated automatically to the latest version with the new script.

The upgrade analysis process can take some time to complete, depending on the complexity of the job and the workload. The results of the upgrade analysis will be stored in the specified Amazon S3 path, which can be reviewed to understand the upgrade and any potential compatibility issues. After reviewing the upgrade analysis results, you can decide whether to proceed with the actual upgrade or make any necessary changes to the job before upgrading.

Prerequisites

The following prerequisites are required to use generative AI to upgrade jobs in AWS Glue:

- AWS Glue 2 PySpark jobs – only AWS Glue 2 jobs can be upgraded to AWS Glue 5.
- IAM permissions are required to start the analysis, review the results and upgrade your job. For more information, see the examples in the Permissions section below.
- If using AWS KMS to encrypt analysis artifacts, then additional AWS AWS KMS permissions are needed. For more information, see the examples in the AWS KMS policy section below.

Permissions

To start a new upgrade analysis, you need the following permissions:

1. Update the IAM policy of the caller with the following permission:

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "glue:StartJobUpgradeAnalysis",
                "glue:StartJobRun",
                "glue:GetJobRun",
                "glue:GetJob",
                "glue:BatchStopJobRun"
            ],
            "Resource": [
                "arn:aws:glue:us-east-1:111122223333:job/jobName"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": [
              "arn:aws:s3:::amzn-s3-demo-bucket/script-location/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
```

```
                "s3:PutObject",
                "s3:GetObject"
            ],
            "Resource": [
              "arn:aws:s3:::amzn-s3-demo-bucket/results/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "kms:Decrypt",
                "kms:GenerateDataKey"
            ],
            "Resource": "arn:aws:kms:us-east-1:111122223333:key/key-id"
        }
    ]
}
```

2. Update the Execution role of the job you are upgrading to include the following in-line policy:

```
    {
      "Effect": "Allow",
      "Action": ["s3:GetObject"],
      "Resource": [
        "ARN of the Amazon S3 path provided on API",
        "ARN of the Amazon S3 path provided on API/*"
      ]
    }
```

For example, if you are using the Amazon S3 path `s3://amzn-s3-demo-bucket/upgraded-result`, then the policy will be:

```
{
      "Effect": "Allow",
      "Action": ["s3:GetObject"],
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket/upgraded-result/",
        "arn:aws:s3:::amzn-s3-demo-bucket/upgraded-result/*"
      ]
    }
```

To retrieve the details of an analysis, you need the following permissions:

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:GetJobUpgradeAnalysis"
      ],
      "Resource": [
        "arn:aws:glue:us-east-1:111122223333:job/jobName"
      ]
    }
  ]
}
```

To stop an in-progress analysis, you need the following permissions:

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:StopJobUpgradeAnalysis",
        "glue:BatchStopJobRun"
      ],
      "Resource": [
        "arn:aws:glue:us-east-1:111122223333:job/jobName"
      ]
    }
  ]
}
```

To list all the analyses submitted on a specific job, you need the following permissions:

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:ListJobUpgradeAnalyses"
      ],
      "Resource": [
        "arn:aws:glue:us-east-1:111122223333:job/jobName"
      ]
    }
  ]
}
```

To accept the changes from an analysis and upgrade a job, you need the following permissions:

AWS KMS policy

To pass your own custom AWS KMS key when starting an analysis, please refer to the following section to configure appropriate permissions on the AWS KMS keys.

Configuring the result artifact encryption using a AWS KMS key:

This policy ensures that you have both the encryption and decryption permissions on the AWS KMS key.

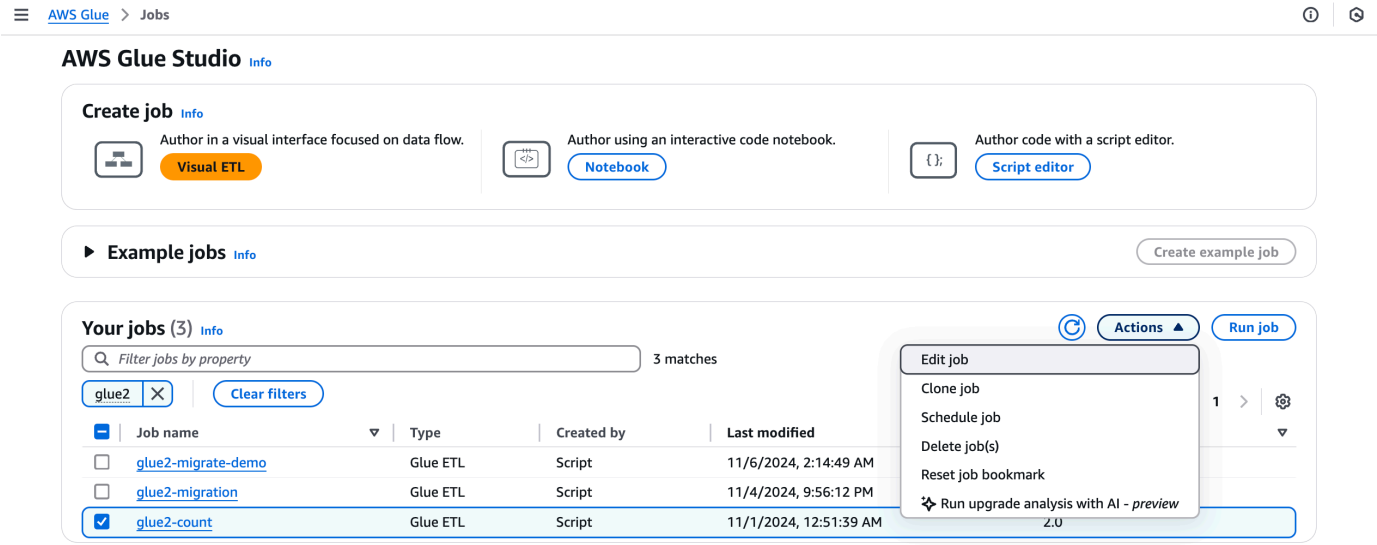
```
{
    "Effect": "Allow",
    "Principal":{
        "AWS": "<IAM Customer caller ARN>"
    },
    "Action": [
      "kms:Decrypt",
      "kms:GenerateDataKey",
    ],
    "Resource": "<key-arn-passed-on-start-api>"
```

```
}
```

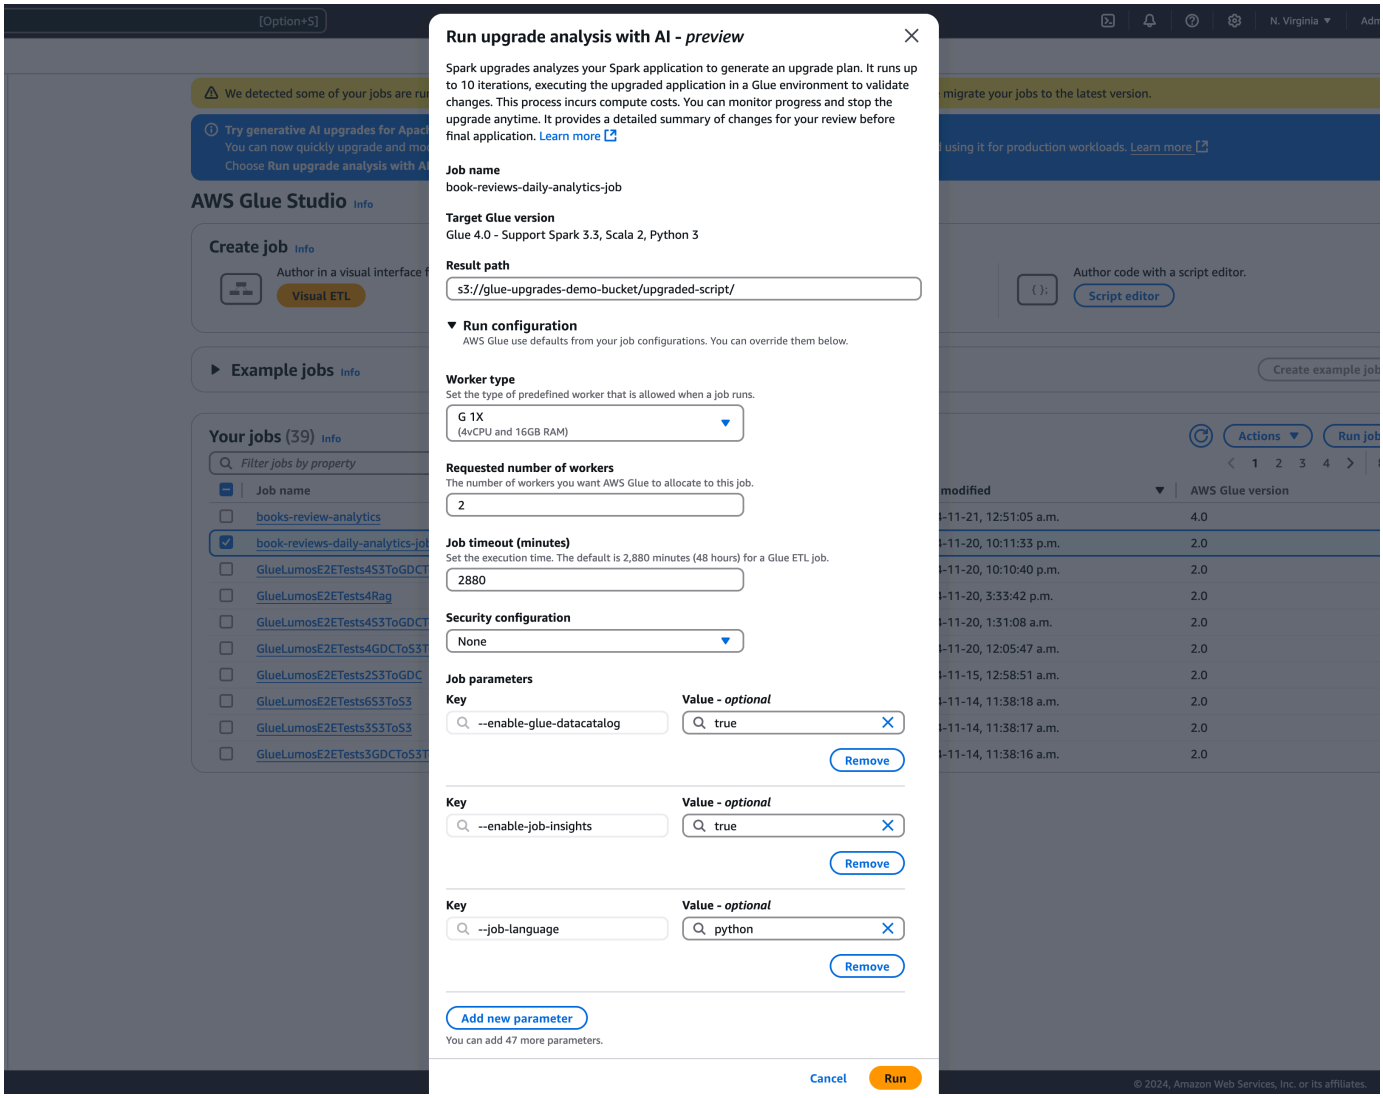
Running an upgrade analysis and applying the upgrade script

You can run an upgrade analysis, which will generate an upgrade plan on a job you select from the **Jobs** view.

1. From **Jobs**, select a AWS Glue 2.0 job, then choose **Run upgrade analysis** from the **Actions** menu.



2. In the modal, select a path to store your generated upgrade plan in the **Result path**. This must be an Amazon S3 bucket you can access and write to.



3. Configure additional options, if needed:

- **Run configuration** – optional: The run configuration is an optional setting that allows you to customize various aspects of the validation runs performed during the upgrade analysis. This configuration is utilized to execute the upgraded script and allows you to select the compute environment properties (worker type, number of workers, etc). Note you should use your non-production developer accounts to run the validations on sample datasets before reviewing, accepting the changes and applying them to production environments. The run configuration includes the following customizable parameters:
  - Worker type: You can specify the type of worker to be used for the validation runs, allowing you to choose appropriate compute resources based on your requirements.
  - Number of workers: You can define the number of workers to be provisioned for the validation runs, enabling you to scale resources according to your workload needs.

- Job timeout (in minutes): This parameter allows you to set a time limit for the validation runs, ensuring that the jobs terminate after a specified duration to prevent excessive resource consumption.
- Security configuration: You can configure security settings, such as encryption and access control, to ensure the protection of your data and resources during the validation runs.
- Additional job parameters: If needed, you can add new job parameters to further customize the execution environment for the validation runs.

By leveraging the run configuration, you can tailor the validation runs to suit your specific requirements. For example, you can configure the validation runs to use a smaller dataset, which allows the analysis to complete more quickly and optimizes costs. This approach ensures that the upgrade analysis is performed efficiently while minimizing resource utilization and associated costs during the validation phase.

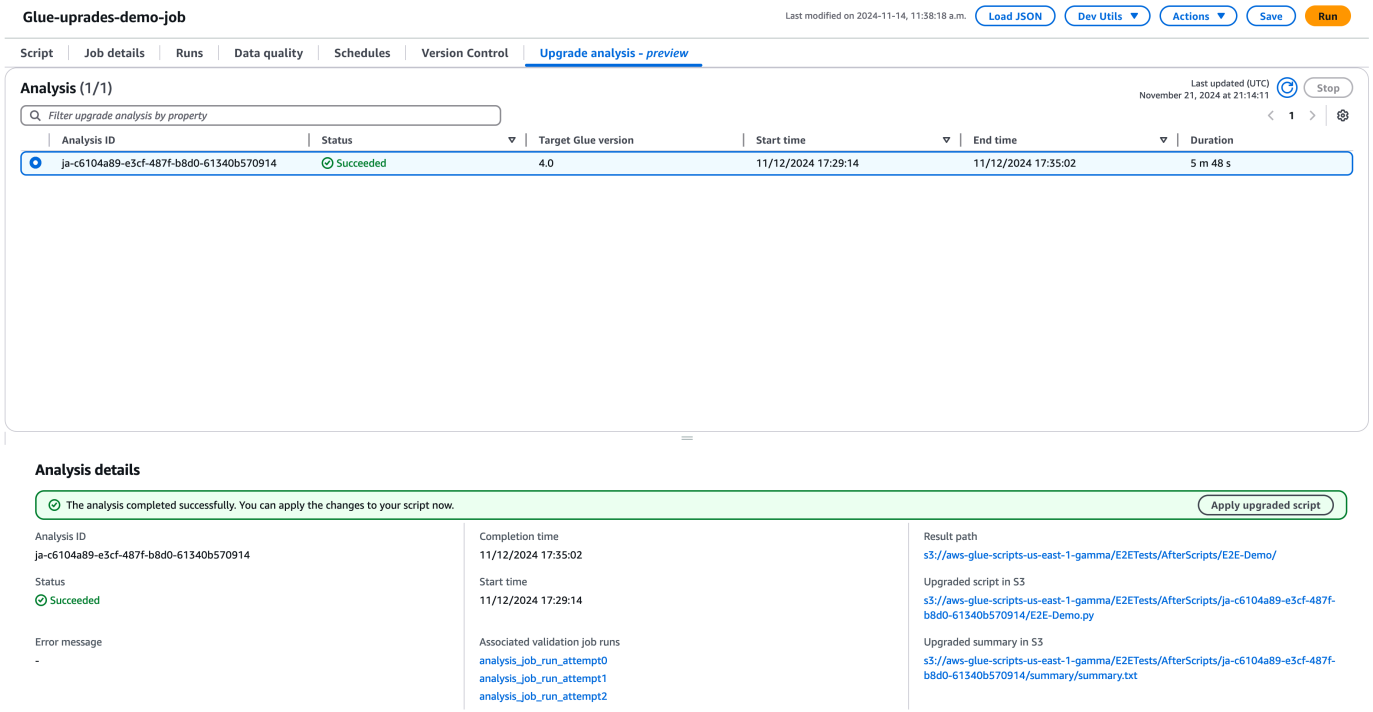
- **Encryption configuration** – optional:
  - **Enable upgrade artifacts encryption**: Enable at-rest encryption when writing data to the result path. If you don't want to encrypt your upgrade artifacts, leave this option unchecked.

4. Choose **Run** to start the upgrade analysis. While the analysis is running, you can view the results on the **Upgrade analysis** tab. The analysis details window will show you information about the analysis as well as links to the upgrade artifacts.

   - **Result path** – this is where the results summary and upgrade script are stored.
   - **Upgraded script in Amazon S3** – the location of the upgrade script in Amazon S3. You can view the script prior to applying the upgrade.
   - **Upgrade summary in Amazon S3** – the location of the upgrade summary in Amazon S3. You can view the upgrade summary prior to applying the upgrade.

5. When the upgrade analysis is completed successfully, you can apply the upgrade script to automatically upgrade your job by choosing **Apply upgraded script**.

   Once applied, the AWS Glue version will be updated to 4.0. You can view the new script in the **Script** tab.



Understanding your upgrade summary

This example demonstrates the process of upgrading a AWS Glue job from version 2.0 to version 4.0. The sample job reads product data from an Amazon S3 bucket, applies several transformations to the data using Spark SQL, and then saves the transformed results back to an Amazon S3 bucket.

Original code (AWS Glue 2.0) - before upgrade

```
from awsglue.transforms import *
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from pyspark.sql.types import *
from pyspark.sql.functions import *
from awsglue.job import Job
import json
from pyspark.sql.types import StructType

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
```

```
gdc_database = "s3://aws-glue-scripts-us-east-1-gamma/demo-database/"
schema_location = (
    "s3://aws-glue-scripts-us-east-1-gamma/DataFiles/"
)

products_schema_string = spark.read.text(
    f"{schema_location}schemas/products_schema"
).first()[0]

product_schema = StructType.fromJson(json.loads(products_schema_string))

products_source_df = (
    spark.read.option("header", "true")
    .schema(product_schema)
    .option(
        "path",
        f"{gdc_database}products/",
    )
    .csv(f"{gdc_database}products/")
)

products_source_df.show()
products_temp_view_name = "spark_upgrade_demo_product_view"
products_source_df.createOrReplaceTempView(products_temp_view_name)

query = f"select {products_temp_view_name}.*, format_string('%0$s-%0$s', category,
 subcategory) as unique_category from {products_temp_view_name}"
products_with_combination_df = spark.sql(query)
products_with_combination_df.show()

products_with_combination_df.createOrReplaceTempView(products_temp_view_name)
product_df_attribution = spark.sql(
    f"""
SELECT *,
unbase64(split(product_name, ' ')[0]) as product_name_decoded,
unbase64(split(unique_category, '-')[1]) as subcategory_decoded
FROM {products_temp_view_name}
"""
)
product_df_attribution.show()

product_df_attribution.write.mode("overwrite").option("header", "true").option(
    "path", f"{gdc_database}spark_upgrade_demo_product_agg/"
```

```
).saveAsTable("spark_upgrade_demo_product_agg", external=True)

spark_upgrade_demo_product_agg_table_df = spark.sql(
    f"SHOW TABLE EXTENDED in default like 'spark_upgrade_demo_product_agg'"
)
spark_upgrade_demo_product_agg_table_df.show()
job.commit()
```

New code (Glue 4.0) - after upgrade

```
from awsglue.transforms import *
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from pyspark.sql.types import *
from pyspark.sql.functions import *
from awsglue.job import Job
import json
from pyspark.sql.types import StructType

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
# change 1
spark.conf.set("spark.sql.adaptive.enabled", "false")
# change 2
spark.conf.set("spark.sql.legacy.pathOptionBehavior.enabled", "true")
job = Job(glueContext)

gdc_database = "s3://aws-glue-scripts-us-east-1-gamma/demo-database/"
schema_location = (
    "s3://aws-glue-scripts-us-east-1-gamma/DataFiles/"
)

products_schema_string = spark.read.text(
    f"{schema_location}schemas/products_schema"
).first()[0]

product_schema = StructType.fromJson(json.loads(products_schema_string))

products_source_df = (
    spark.read.option("header", "true")
    .schema(product_schema)
    .option(
```

```
        "path",
        f"{gdc_database}products/",
    )
    .csv(f"{gdc_database}products/")
)

products_source_df.show()
products_temp_view_name = "spark_upgrade_demo_product_view"
products_source_df.createOrReplaceTempView(products_temp_view_name)

# change 3
query = f"select {products_temp_view_name}.*, format_string('%1$s-%1$s', category,
 subcategory) as unique_category from {products_temp_view_name}"
products_with_combination_df = spark.sql(query)
products_with_combination_df.show()

products_with_combination_df.createOrReplaceTempView(products_temp_view_name)
# change 4
product_df_attribution = spark.sql(
    f"""
SELECT *,
try_to_binary(split(product_name, ' ')[0], 'base64') as product_name_decoded,
try_to_binary(split(unique_category, '-')[1], 'base64') as subcategory_decoded
FROM {products_temp_view_name}
"""
)
product_df_attribution.show()

product_df_attribution.write.mode("overwrite").option("header", "true").option(
    "path", f"{gdc_database}spark_upgrade_demo_product_agg/"
).saveAsTable("spark_upgrade_demo_product_agg", external=True)

spark_upgrade_demo_product_agg_table_df = spark.sql(
    f"SHOW TABLE EXTENDED in default like 'spark_upgrade_demo_product_agg'"
)
spark_upgrade_demo_product_agg_table_df.show()
job.commit()
```

Explanation of analysis summary

```
In Spark 3.2, spark.sql.adaptive.enabled is enabled by default. To restore the behavior before
Spark 3.2,
you can set spark.sql.adaptive.enabled to false.

In Spark 3.1, path option cannot coexist when the following methods are called with path
parameter(s): DataFrameReader.load(), DataFrameWriter.save(), DataStreamReader.load(), or
DataStreamWriter.start(). In addition, paths option cannot coexist for DataFrameReader.load().
For example, spark.read.format(csv).option(path, /tmp).load(/tmp2) or spark.read.option(path, /
tmp).csv(/tmp2) will throw org.apache.spark.sql.AnalysisException. In Spark version 3.0 and
below, path option is overwritten if one path parameter is passed to above methods; path option
is added to the overall paths if multiple path parameters are passed to DataFrameReader.load().
To restore the behavior before Spark 3.1, you can set
spark.sql.legacy.pathOptionBehavior.enabled to true.

Since Spark 3.3, the `strfmt` in `format_string(strfmt, obj, ...)` and `printf(strfmt,
obj, ...)` will no longer support to use 0$ to specify the first argument, the first argument
should always reference by 1$ when use argument index to indicating the position of the argument
in the argument list.

Since Spark 3.3, the unbase64 function throws error for a malformed str input. Use
try_to_binary(<str>, 'base64') to tolerate malformed input and return NULL instead. In Spark 3.2
and earlier, the unbase64 function returns a best-efforts result for a malformed str input.
```

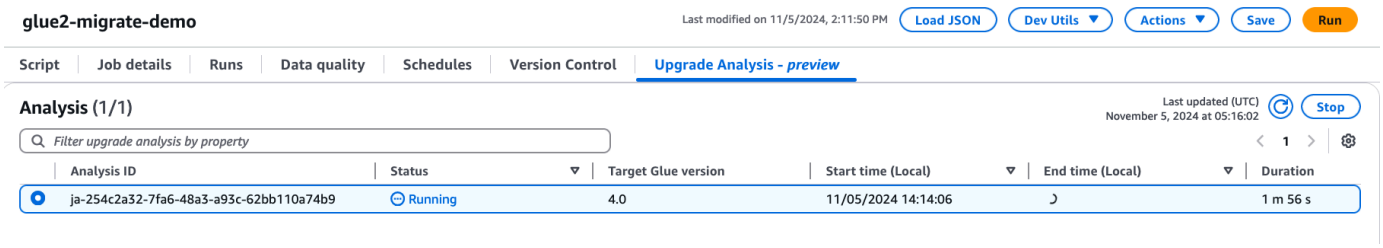
Based on the summary, there are four changes proposed by AWS Glue in order to successfully upgrade the script from AWS Glue 2.0 to AWS Glue 4.0:

1. **Spark SQL configuration (spark.sql.adaptive.enabled)**: This change is to restore the application behavior as a new feature for Spark SQL adaptive query execution is introduced starting Spark 3.2. You can inspect this configuration change and can further enable or disable it as per their preference.
2. **DataFrame API change**: The path option cannot coexist with other DataFrameReader operations like `load()`. To retain the previous behavior, AWS Glue updated the script to add a new SQL configuration **(spark.sql.legacy.pathOptionBehavior.enabled)**.
3. **Spark SQL API change**: The behavior of `strfmt` in `format_string(strfmt, obj, ...)` has been updated to disallow `0$` as the first argument. To ensure compatibility, AWS Glue has modified the script to use `1$` as the first argument instead.
4. **Spark SQL API change**: The `unbase64` function does not allow malformed string inputs. To retain the previous behavior, AWS Glue updated the script to use the `try_to_binary` function.

Stopping an upgrade analysis in progress

You can cancel an upgrade analysis in progress or just stop the analysis.

1. Choose the **Upgrade Analysis** tab.
2. Select the job that is running, then choose **Stop**. This will stop the analysis. You can then run another upgrade analysis on the same job.



Considerations

As you begin using Spark Upgrades, there are several important aspects to consider for optimal usage of the service.

- **Service Scope and Limitations**: The current release focuses on PySpark code upgrades from AWS Glue versions 2.0 to version 5.0. At this time, the service handles PySpark code that doesn't rely on additional library dependencies. You can run automated upgrades for up to 10 jobs concurrently in an AWS account, allowing you to efficiently upgrade multiple jobs while maintaining system stability.
  - Only PySpark jobs are supported.
  - Upgrade analysis will time out after 24 hours.
  - Only one active upgrade analysis can be run at a time for one job. On the account-level, up to 10 active upgrade analysis can be run at the same time.
- **Optimizing Costs During Upgrade Process**: Since Spark Upgrades use generative AI to validate the upgrade plan through multiple iterations, with each iteration running as a AWS Glue job in your account, it’s essential to optimize the validation job run configurations for cost efficiency. To achieve this, we recommend specifying a Run Configuration when starting an Upgrade Analysis as follows:
  - Use non-production developer accounts and select sample mock datasets that represent your production data but are smaller in size for validation with Spark Upgrades.

- Using right-sized compute resources, such as G.1X workers, and selecting an appropriate number of workers for processing your sample data.
- Enabling AWS Glue job auto-scaling when applicable to automatically adjust resources based on workload.

  For example, if your production job processes terabytes of data with 20 G.2X workers, you might configure the upgrade job to process a few gigabytes of representative data with 2 G.2X workers and auto-scaling enabled for validation.

- **Best Practices**: We strongly recommend starting your upgrade journey with non-production jobs. This approach allows you to familiarize yourself with the upgrade workflow, and understand how the service handles different types of Spark code patterns.
- **Alarms and notifications**: When utilizing the Generative AI upgrades feature on a job, ensure that alarms/notifications for failed job runs are turned off. During the upgrade process, there may be up to 10 failed job runs in your account before the upgraded artifacts are provided.
- **Anomaly detection rules**: Turn off any anomaly detection rules on the Job that is being upgraded as well, as the data written to output folders during intermediate job runs might not be in the expected format while the upgrade validation is in progress.
- **Use upgrade analysis with idempotent jobs**: Use upgrade analysis with idempotent jobs to ensure each subsequent validation job run attempt is similar to the previous one, and doesn't run into issues. Idempotent jobs are jobs that can be run multiple times with the same input data, and they will produce the same output each time. When using the Generative AI upgrades for Apache Spark in AWS Glue, the service will run multiple iterations of your job as part of the validation process. During each iteration, it will make changes to your Spark code and configurations to validate the upgrade plan. If your Spark job is not idempotent, running it multiple times with the same input data could lead to issues.

Supported regions

Generative AI upgrades for Apache Spark is available in the following regions:

- **Asia Pacific**: Tokyo (ap-northeast-1), Seoul (ap-northeast-2), Mumbai (ap-south-1), Singapore (ap-southeast-1), and Sydney (ap-southeast-2)
- **North America**: Canada (ca-central-1)
- **Europe**: Frankfurt (eu-central-1), Stockholm (eu-north-1), Ireland (eu-west-1), London (eu-west-2), and Paris (eu-west-3)

- **South America**: São Paulo (sa-east-1)
- **United States**: North Virginia (us-east-1), Ohio (us-east-2), and Oregon (us-west-2)

Cross-region inference in Spark Upgrades

Spark Upgrades is powered by Amazon Bedrock and leverages cross-region inference (CRIS). With CRIS, Spark Upgrades will automatically select the optimal region within your geography (as described in more detail here) to process your inference request, maximizing available compute resources and model availability, and providing the best customer experience. There's no additional cost for using cross-region inference.

Cross-region inference requests are kept within the AWS Regions that are part of the geography where the data originally resides. For example, a request made within the US is kept within the AWS Regions in the US. Although the data remains stored only in the primary region, when using cross-region inference, your input prompts and output results may move outside of your primary region. All data will be transmitted encrypted across Amazon's secure network.

Working with Spark jobs in AWS Glue

Provides information on AWS Glue for Spark ETL jobs.

Topics

- Using job parameters in AWS Glue jobs
- AWS Glue Spark and PySpark jobs
- AWS Glue worker types
- Streaming ETL jobs in AWS Glue
- Record matching with AWS Lake Formation FindMatches
- Migrate Apache Spark programs to AWS Glue

Using job parameters in AWS Glue jobs

When creating a AWS Glue job, you set some standard fields, such as `Role` and `WorkerType`. You can provide additional configuration information through the `Argument` fields (**Job Parameters** in the console). In these fields, you can provide AWS Glue jobs with the arguments (parameters) listed in this topic.

For more information about the AWS Glue Job API, see the section called "Jobs".

> **Note**
>
> Job arguments have a maximum size limit of 260KB. A validation check will raise an error if the argument size is greater than 260KB.

Setting job parameters

You can configure a job through the console on the **Job details** tab, under the **Job Parameters** heading. You can also configure a job through the AWS CLI by setting `DefaultArguments` or `NonOverridableArguments` on a job, or setting `Arguments` on a job run. Arguments set on the job will be passed in every time the job is run, while arguments set on the job run will only be passed in for that individual run.

For example, the following is the syntax for running a job using `--arguments` to set a job parameter.

```
$ aws glue start-job-run --job-name "CSV to CSV" --arguments='--scriptLocation="s3://
my_glue/libraries/test_lib.py"'
```

Accessing job parameters

When writing AWS Glue scripts, you may want to access job parameter values to alter the behavior of your own code. We provide helper methods to do so in our libraries. These methods resolve job run parameter values that override job parameter values. When resolving parameters set in multiple places, job `NonOverridableArguments` will override job run `Arguments`, which will override job `DefaultArguments`.

In Python:

In Python jobs, we provide a function named `getResolvedParameters`. For more information, see the section called "getResolvedOptions". Job parameters are available in the `sys.argv` variable.

In Scala:

In Scala jobs, we provide an object named `GlueArgParser`. For more information, see the section called "GlueArgParser". Job parameters are available in the `sysArgs` variable.

Job parameter reference

AWS Glue recognizes the following argument names that you can use to set up the script environment for your jobs and job runs:

`--additional-python-modules`

A comma delimited list representing a set of Python packages to be installed. You can install packages from PyPI or provide a custom distribution. A PyPI package entry will be in the format *`package`*==*`version`*, with the PyPI name and version of your target package. A custom distribution entry is the S3 path to the distribution.

Entries use Python version matching to match package and version. This means you will need to use two equals signs, such as ==. There are other version matching operators, for more information see PEP 440.

To pass module installation options to `pip3`, use the --python-modules-installer-option parameter.

`--auto-scale-within-microbatch`

The default value is true. This parameter can only be used for AWS Glue streaming jobs, which process the streaming data in a series of micro batches, and auto scaling must be enabled. When setting this value to false, it computes the exponential moving average of batch duration for completed micro-batches and compares this value with the window size to determine whether to scale up or scale down the number of executors. Scaling only happens when a micro batch is completed. When setting this value to true, during a micro-batch, it scales up when the number of Spark tasks remains the same for 30 seconds, or the current batch processing is greater than the window size. The number of executors will drop if an executor has been idle for more than 60 seconds, or the exponential moving average of batch duration is low.

`--class`

The Scala class that serves as the entry point for your Scala script. This applies only if your `--job-language` is set to `scala`.

`--continuous-log-conversionPattern`

Specifies a custom conversion log pattern for a job enabled for continuous logging. The conversion pattern applies only to driver logs and executor logs. It does not affect the AWS Glue progress bar.

`--continuous-log-logGroup`

Specifies a custom Amazon CloudWatch log group name for a job enabled for continuous logging.

`--continuous-log-logStreamPrefix`

Specifies a custom CloudWatch log stream prefix for a job enabled for continuous logging.

`--customer-driver-env-vars` and `--customer-executor-env-vars`

These parameters set environment variables on the operating system respectively for each worker (driver or executor). You can use these parameters when building platforms and custom frameworks on top of AWS Glue, to let your users write jobs on top of it. Enabling these two flags will allow you to set different environment variables on the driver and executor respectively without having to inject the same logic in the job script itself.

Example usage

The following is an example of using these parameters:

```
"–customer-driver-env-vars", "CUSTOMER_KEY1=VAL1,CUSTOMER_KEY2=\"val2,val2 val2\"",
"–customer-executor-env-vars", "CUSTOMER_KEY3=VAL3,KEY4=VAL4"
```

Setting these in the job run argument is equivalent to running the following commands:

In the driver:

- export CUSTOMER_KEY1=VAL1
- export CUSTOMER_KEY2="val2,val2 val2"

In the executor:

- export CUSTOMER_KEY3=VAL3

Then, in the job script itself, you can retrieve the environment variables using `os.environ.get("CUSTOMER_KEY1")` or `System.getenv("CUSTOMER_KEY1")`.

Enforced syntax

Observe the following standards when defining environment variables:

- Each key must have the `CUSTOMER_ prefix`.

  For example: for `"CUSTOMER_KEY3=VAL3,KEY4=VAL4"`, `KEY4=VAL4` will be ignored and not set.

- Each key and value pair must be delineated with a single comma.

  For example: `"CUSTOMER_KEY3=VAL3,CUSTOMER_KEY4=VAL4"`

- If the "value" has spaces or commas, then it must be defined within quotations.

  For example: `CUSTOMER_KEY2=\"val2,val2 val2\"`

This syntax closely models the standards of setting bash environment variables.

`--datalake-formats`

Supported in AWS Glue 3.0 and later versions.

Specifies the data lake framework to use. AWS Glue adds the required JAR files for the frameworks that you specify into the `classpath`. For more information, see Using data lake frameworks with AWS Glue ETL jobs.

You can specify one or more of the following values, separated by a comma:

- `hudi`
- `delta`
- `iceberg`

For example, pass the following argument to specify all three frameworks.

```
'--datalake-formats': 'hudi,delta,iceberg'
```

`--disable-proxy-v2`

Disable the service proxy to allow AWS service calls to Amazon S3, CloudWatch, and AWS Glue originating from your script through your VPC. For more information, see Configuring AWS calls to go through your VPC. To disable the service proxy, set the value of this paramater to `true`.

`--enable-auto-scaling`

Turns on auto scaling and per-worker billing when you set the value to `true`.

`--enable-continuous-cloudwatch-log`

Enables real-time continuous logging for AWS Glue jobs. You can view real-time Apache Spark job logs in CloudWatch.

`--enable-continuous-log-filter`

Specifies a standard filter (`true`) or no filter (`false`) when you create or edit a job enabled for continuous logging. Choosing the standard filter prunes out non-useful Apache Spark driver/executor and Apache Hadoop YARN heartbeat log messages. Choosing no filter gives you all the log messages.

`--enable-glue-datacatalog`

Enables you to use the AWS Glue Data Catalog as an Apache Spark Hive metastore. To enable this feature, set the value to `true`.

`--enable-job-insights`

Enables additional error analysis monitoring with AWS Glue job run insights. For details, see the section called "Monitoring with AWS Glue job run insights". By default, the value is set to `true` and job run insights are enabled.

This option is available for AWS Glue version 2.0 and 3.0.

`--enable-lakeformation-fine-grained-access`

Enables fine-grained access control for AWS Glue jobs. For more information, see the section called "Lake Formation for FGAC".

`--enable-metrics`

Enables the collection of metrics for job profiling for this job run. These metrics are available on the AWS Glue console and the Amazon CloudWatch console. The value of this parameter is not relevant. To enable this feature, you can provide this parameter with any value, but `true` is recommended for clarity. To disable this feature, remove this parameter from your job configuration.

`--enable-observability-metrics`

Enables a set of Observability metrics to generate insights into what is happening inside each job run on Job Runs Monitoring page under AWS Glue console and the Amazon CloudWatch console. To enable this feature, set the value of this parameter to true. To disable this feature, set it to `false` or remove this parameter from your job configuration.

`--enable-rename-algorithm-v2`

Sets the EMRFS rename algorithm version to version 2. When a Spark job uses dynamic partition overwrite mode, there is a possibility that a duplicate partition is created. For instance,

you can end up with a duplicate partition such as `s3://bucket/table/location/p1=1/p1=1`. Here, P1 is the partition that is being overwritten. Rename algorithm version 2 fixes this issue.

This option is only available on AWS Glue version 1.0.

`--enable-s3-parquet-optimized-committer`

Enables the EMRFS S3-optimized committer for writing Parquet data into Amazon S3. You can supply the parameter/value pair via the AWS Glue console when creating or updating an AWS Glue job. Setting the value to **`true`** enables the committer. By default, the flag is turned on in AWS Glue 3.0 and off in AWS Glue 2.0.

For more information, see Using the EMRFS S3-optimized Committer.

`--enable-spark-ui`

When set to `true`, turns on the feature to use the Spark UI to monitor and debug AWS Glue ETL jobs.

`--executor-cores`

Number of spark tasks that can run in parallel. This option is supported on AWS Glue 3.0+. The value should not exceed 2x the number of vCPUs on the worker type, which is 8 on `G.1X`, 16 on `G.2X`, 32 on `G.4X`, 64 on `G.8X`, 96 on `G.12X`, 128 on `G.16X`, and 8 on `R.1X`, 16 on `R.2X`, 32 on `R.4X`, 64 on `R.8X`. You should exercise caution while updating this configuration as it could impact job performance because increased task parallelism causes memory, disk pressure as well as it could throttle the source and target systems (for example: it would cause more concurrent connections on Amazon RDS).

`--extra-files`

The Amazon S3 paths to additional files, such as configuration files that AWS Glue copies to the working directory of your script on the driver node before running it. Multiple values must be complete paths separated by a comma (`,`). The value can be individual files or directory locations. This option is not supported for Python Shell job types.

`--extra-jars`

The Amazon S3 paths to additional files that AWS Glue copies to the driver and executors. AWS Glue also adds these files to the Java classpath before executing your script. Multiple values must be complete paths separated by a comma (`,`). The extension need not be `.jar`

`--extra-py-files`

The Amazon S3 paths to additional Python modules that AWS Glue adds to the Python path on the driver node before running your script. Multiple values must be complete paths separated by a comma (`,`). Only individual files are supported, not a directory path.

`--job-bookmark-option`

Controls the behavior of a job bookmark. The following option values can be set.

--job-bookmark-option value	Description
`job-bookmark-enable`	Keep track of previously processed data. When a job runs, process new data since the last checkpoint.
`job-bookmark-disable`	Always process the entire dataset. You are responsible for managing the output from previous job runs.
`job-bookmark-pause`	Process incremental data since the last successful run or the data in the range identified by the following suboptions, without updating the state of the last bookmark. You are responsible for managing the output from previous job runs. The two suboptions are as follows: • **`job-bookmark-from`** `<from-value>` is the run ID that represents all the input that was processed until the last successful run before and including the specified run ID. The corresponding input is ignored. • **`job-bookmark-to`** `<to-value>` is the run ID that represents all the input that was processed until the last successful run before and including the specified run ID. The corresponding input excluding the input identified by the `<from-value>` is processed by the job. Any input later than this input is also excluded for processing. The job bookmark state is not updated when this option set is specified.

--job-bookmark-option value	Description
	The suboptions are optional. However, when used, both suboptions must be provided.

For example, to enable a job bookmark, pass the following argument.

```
'--job-bookmark-option': 'job-bookmark-enable'
```

`--job-language`

The script programming language. This value must be either `scala` or `python`. If this parameter is not present, the default is `python`.

`--python-modules-installer-option`

A plaintext string that defines options to be passed to `pip3` when installing modules with `--additional-python-modules`. Provide options as you would in the command line, separated by spaces and prefixed by dashes. For more information about usage, see the section called "Installing additional Python modules with pip in AWS Glue 2.0 or later".

> **Note**
>
> This option is not supported for AWS Glue jobs when you use Python 3.9.

`--scriptLocation`

The Amazon Simple Storage Service (Amazon S3) location where your ETL script is located (in the form `s3://path/to/my/script.py`). This parameter overrides a script location set in the `JobCommand` object.

`--spark-event-logs-path`

Specifies an Amazon S3 path. When using the Spark UI monitoring feature, AWS Glue flushes the Spark event logs to this Amazon S3 path every 30 seconds to a bucket that can be used as a temporary directory for storing Spark UI events.

`--TempDir`

Specifies an Amazon S3 path to a bucket that can be used as a temporary directory for the job.

For example, to set a temporary directory, pass the following argument.

```
'--TempDir': 's3-path-to-directory'
```

> **Note**
>
> AWS Glue creates a temporary bucket for jobs if a bucket doesn't already exist in a Region. This bucket might permit public access. You can either modify the bucket in Amazon S3 to set the public access block, or delete the bucket later after all jobs in that Region have completed.

`--use-postgres-driver`

When setting this value to `true`, it prioritizes the Postgres JDBC driver in the class path to avoid a conflict with the Amazon Redshift JDBC driver. This option is only available in AWS Glue version 2.0.

`--user-jars-first`

When setting this value to `true`, it prioritizes the customer's extra JAR files in the classpath. This option is only available in AWS Glue version 2.0 or later.

`--conf`

Controls Spark config parameters. It is for advanced use cases.

`--encryption-type`

Legacy parameter. The corresponding behavior should be configured using security configurations. for more information about security configurations, see the section called “Encrypting data written by AWS Glue”.

AWS Glue uses the following arguments internally and you should never use them:

- `--debug` — Internal to AWS Glue. Do not set.
- `--mode` — Internal to AWS Glue. Do not set.
- `--JOB_NAME` — Internal to AWS Glue. Do not set.
- `--endpoint` — Internal to AWS Glue. Do not set.

AWS Glue supports bootstrapping an environment with Python's `site` module using `sitecustomize` to perform site-specific customizations. Bootstrapping your own initilization functions is recommended for advanced use cases only and is supported on a best-effort basis on AWS Glue 4.0.

The environment variable prefix, `GLUE_CUSTOMER`, is reserved for customer use.

AWS Glue Spark and PySpark jobs

AWS Glue support Spark and PySpark jobs. A Spark job is run in an Apache Spark environment managed by AWS Glue. It processes data in batches. A streaming ETL job is similar to a Spark job, except that it performs ETL on data streams. It uses the Apache Spark Structured Streaming framework. Some Spark job features are not available to streaming ETL jobs.

The following sections provide information on AWS Glue Spark and PySpark jobs.

Topics

- Configuring job properties for Spark jobs in AWS Glue
- Editing Spark scripts in the AWS Glue console
- Jobs (legacy)
- Tracking processed data using job bookmarks
- Storing Spark shuffle data
- Monitoring AWS Glue Spark jobs
- Generative AI troubleshooting for Apache Spark in AWS Glue
- Using materialized views with AWS Glue

Configuring job properties for Spark jobs in AWS Glue

When you define your job on the AWS Glue console, you provide values for properties to control the AWS Glue runtime environment.

Defining job properties for Spark jobs

The following list describes the properties of a Spark job. For the properties of a Python shell job, see Defining job properties for Python shell jobs. For properties of a streaming ETL job, see the section called “Defining job properties for a streaming ETL job”.

The properties are listed in the order in which they appear on the **Add job** wizard on AWS Glue console.

Name

Provide a UTF-8 string with a maximum length of 255 characters.

Description

Provide an optional description of up to 2048 characters.

IAM Role

Specify the IAM role that is used for authorization to resources used to run the job and access data stores. For more information about permissions for running jobs in AWS Glue, see Identity and access management for AWS Glue.

Type

The type of ETL job. This is set automatically based on the type of data sources you select.

- **Spark** runs an Apache Spark ETL script with the job command `glueetl`.
- **Spark Streaming** runs a Apache Spark streaming ETL script with the job command `gluestreaming`. For more information, see the section called "Streaming ETL jobs".
- **Python shell** run a Python script with the job command `pythonshell`. For more information, see Configuring job properties for Python shell jobs in AWS Glue.

AWS Glue version

AWS Glue version determines the versions of Apache Spark and Python that are available to the job, as specified in the following table.

AWS Glue version	Supported Spark and Python versions
5.1	• Spark 3.5.6 • Python 3.11
5.0	• Spark 3.5.4 • Python 3.11
4.0	• Spark 3.3.0 • Python 3.10

AWS Glue version	Supported Spark and Python versions
3.0	• Spark 3.1.1 • Python 3.7

Jobs that are created without specifying a AWS Glue version default to AWS Glue 5.1.

Language

The code in the ETL script defines your job's logic. The script can be coded in Python or Scala. You can choose whether the script that the job runs is generated by AWS Glue or provided by you. You provide the script name and location in Amazon Simple Storage Service (Amazon S3). Confirm that there isn't a file with the same name as the script directory in the path. To learn more about writing scripts, see AWS Glue programming guide.

Worker type

The following worker types are available:

The resources available on AWS Glue workers are measured in DPUs. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory.

- **`G.025X`** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 0.25 DPU (2 vCPUs, 4 GB of memory) with 84GB disk (approximately 34GB free). We recommend this worker type for low volume streaming jobs. This worker type is only available for AWS Glue version 3.0 or later streaming jobs.
- **`G.1X`** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 1 DPU (4 vCPUs, 16 GB of memory) with 94GB disk (approximately 44GB free). We recommend this worker type for workloads such as data transforms, joins, and queries, to offers a scalable and cost effective way to run most jobs.
- **`G.2X`** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 2 DPU (8 vCPUs, 32 GB of memory) with 138GB disk (approximately 78GB free). We recommend this worker type for workloads such as data transforms, joins, and queries, to offers a scalable and cost effective way to run most jobs.
- **`G.4X`** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 4 DPU (16 vCPUs, 64 GB of memory) with 256GB disk (approximately 230GB free). We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries.

- **G.8X** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 8 DPU (32 vCPUs, 128 GB of memory) with 512GB disk (approximately 485GB free). We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries.
- **G.12X** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 12 DPU (48 vCPUs, 192 GB of memory) with 768GB disk (approximately 741GB free). We recommend this worker type for jobs with very large and resource-intensive workloads that require significant compute capacity.
- **G.16X** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 16 DPU (64 vCPUs, 256 GB of memory) with 1024GB disk (approximately 996GB free). We recommend this worker type for jobs with the largest and most resource-intensive workloads that require maximum compute capacity.
- **R.1X** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 1 DPU with memory-optimized configuration. We recommend this worker type for memory-intensive workloads that frequently encounter out-of-memory errors or require high memory-to-CPU ratios.
- **R.2X** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 2 DPU with memory-optimized configuration. We recommend this worker type for memory-intensive workloads that frequently encounter out-of-memory errors or require high memory-to-CPU ratios.
- **R.4X** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 4 DPU with memory-optimized configuration. We recommend this worker type for large memory-intensive workloads that frequently encounter out-of-memory errors or require high memory-to-CPU ratios.
- **R.8X** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 8 DPU with memory-optimized configuration. We recommend this worker type for very large memory-intensive workloads that frequently encounter out-of-memory errors or require high memory-to-CPU ratios.

Worker Type Specifications

The following table provides detailed specifications for all available G worker types:

G Worker Type Specifications

Worker Type	DPU per Node	vCPU	Memory (GB)	Disk (GB)	Free Disk Space (GB)	Spark Executors per Node
G.025X	0.25	2	4	84	34	1
G.1X	1	4	16	94	44	1
G.2X	2	8	32	138	78	1
G.4X	4	16	64	256	230	1
G.8X	8	32	128	512	485	1
G.12X	**12**	**48**	**192**	**768**	**741**	**1**
G.16X	**16**	**64**	**256**	**1024**	**996**	**1**

Important: G.12X and G.16X worker types, as well as all R worker types (R.1X through R.8X), have higher startup latency.

You are charged an hourly rate based on the number of DPUs used to run your ETL jobs. For more information, see the AWS Glue pricing page.

For AWS Glue version 1.0 or earlier jobs, when you configure a job using the console and specify a **Worker type** of **Standard**, the **Maximum capacity** is set and the **Number of workers** becomes the value of **Maximum capacity** - 1. If you use the AWS Command Line Interface (AWS CLI) or AWS SDK, you can specify the **Max capacity** parameter, or you can specify both **Worker type** and the **Number of workers**.

For AWS Glue version 2.0 or later jobs, you cannot specify a **Maximum capacity**. Instead, you should specify a **Worker type** and the **Number of workers**.

`G.4X` and **`G.8X`** worker types are available only for AWS Glue version 3.0 or later Spark ETL jobs in the following AWS Regions: US East (Ohio), US East (N. Virginia), US West (N. California), US West (Oregon), Asia Pacific (Mumbai), Asia Pacific (Seoul), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), Canada (Central), Europe (Frankfurt), Europe (Ireland), Europe (London), Europe (Spain), Europe (Stockholm), and South America (São Paulo).

G.12X, **G.16X**, and **R.1X** through **R.8X** worker types are available only for AWS Glue version 4.0 or later Spark ETL jobs in the following AWS Regions: US East (N. Virginia), US West (Oregon), US East (Ohio), Europe (Ireland), and Europe (Frankfurt). Additional regions will be supported in future releases.

Requested number of workers

For most worker types, you must specify the number of workers that are allocated when the job runs.

Job bookmark

Specify how AWS Glue processes state information when the job runs. You can have it remember previously processed data, update state information, or ignore state information. For more information, see the section called “Tracking processed data using job bookmarks”.

Job run queuing

Specifies whether job runs are queued to run later when they cannot run immediately due to service quotas.

When checked, job run queuing is enabled for the job runs. If not populated, the job runs will not be considered for queueing.

If this setting does not match the value set in the job run, then the value from the job run field will be used.

Flex execution

When you configure a job using AWS Studio or the API you may specify a standard or flexible job execution class. Your jobs may have varying degrees of priority and time sensitivity. The standard execution-class is ideal for time-sensitive workloads that require fast job startup and dedicated resources.

The flexible execution class is appropriate for non-urgent jobs such as pre-production jobs, testing, and one-time data loads. Flexible job runs are supported for jobs using AWS Glue version 3.0 or later and `G.1X` or `G.2X` worker types. The new worker types (`G.12X`, `G.16X`, and `R.1X` through `R.8X`) do not support flexible execution.

Flex job runs are billed based on the number of workers running at any point in time. Number of workers may be added or removed for a running flexible job run. Instead of billing as a simple calculation of `Max Capacity * Execution Time`, each worker will contribute for the

time it ran during the job run. The bill is the sum of (`Number of DPUs per worker * time each worker ran`).

For more information, see the help panel in AWS Studio, or Jobs and Job runs.

Number of retries

Specify the number of times, from 0 to 10, that AWS Glue should automatically restart the job if it fails. Jobs that reach the timeout limit are not restarted.

Job timeout

Sets the maximum execution time in minutes. The maximum is 7 days or 10,080 minutes. Otherwise, the jobs will throw an exception.

When the value is left blank, the timeout is defaulted to 2,880 minutes for Glue version 4.0 and earlier, or 480 minutes for Glue version 5.0 and later.

Any existing AWS Glue jobs that had a timeout value greater than 7 days will be defaulted to 7 days. For instance if you specified a timeout of 20 days for a batch job, it will be stopped on the 7th day.

> **Best practices for job timeouts**
>
> Jobs are billed based on execution time. To avoid unexpected charges, configure timeout values appropriate for the expected execution time of your job.

Advanced Properties

Script filename

A unique script name for your job. Cannot be named **Untitled job**.

Script path

The Amazon S3 location of the script. The path must be in the form `s3://bucket/prefix/path/`. It must end with a slash (/) and not include any files.

Job metrics

Turn on or turn off the creation of Amazon CloudWatch metrics when this job runs. To see profiling data, you must enable this option. For more information about how to turn on and visualize metrics, see Job monitoring and debugging.

Job observability metrics

Turn on the creation of additional observability CloudWatch metrics when this job runs. For more information, see the section called “Monitoring with AWS Glue Observability metrics”.

Continuous logging

Turn on continuous logging to Amazon CloudWatch. If this option is not enabled, logs are available only after the job completes. For more information, see the section called “Logging for AWS Glue jobs”.

Spark UI

Turn on the use of Spark UI for monitoring this job. For more information, see Enabling the Apache Spark web UI for AWS Glue jobs.

Spark UI logs path

The path to write logs when Spark UI is enabled.

Spark UI logging and monitoring configuration

Choose one of the following options:

- *Standard*: write logs using the AWS Glue job run ID as the filename. Turn on Spark UI monitoring in the AWS Glue console.
- *Legacy*: write logs using 'spark-application-{timestamp}' as the filename. Do not turn on Spark UI monitoring.
- *Standard and legacy*: write logs to both the standard and legacy locations. Turn on Spark UI monitoring in the AWS Glue console.

Maximum concurrency

Sets the maximum number of concurrent runs that are allowed for this job. The default is 1. An error is returned when this threshold is reached. The maximum value you can specify is controlled by a service limit. For example, if a previous run of a job is still running when a new instance is started, you might want to return an error to prevent two instances of the same job from running concurrently.

Temporary path

Provide the location of a working directory in Amazon S3 where temporary intermediate results are written when AWS Glue runs the script. Confirm that there isn't a file with the

same name as the temporary directory in the path. This directory is used when AWS Glue reads and writes to Amazon Redshift and by certain AWS Glue transforms.

> **Note**
>
> AWS Glue creates a temporary bucket for jobs if a bucket doesn't already exist in a region. This bucket might permit public access. You can either modify the bucket in Amazon S3 to set the public access block, or delete the bucket later after all jobs in that region have completed.

Delay notification threshold (minutes)

Sets the threshold (in minutes) before a delay notification is sent. You can set this threshold to send notifications when a `RUNNING`, `STARTING`, or `STOPPING` job run takes more than an expected number of minutes.

Security configuration

Choose a security configuration from the list. A security configuration specifies how the data at the Amazon S3 target is encrypted: no encryption, server-side encryption with AWS KMS-managed keys (SSE-KMS), or Amazon S3-managed encryption keys (SSE-S3).

Server-side encryption

If you select this option, when the ETL job writes to Amazon S3, the data is encrypted at rest using SSE-S3 encryption. Both your Amazon S3 data target and any data that is written to an Amazon S3 temporary directory is encrypted. This option is passed as a job parameter. For more information, see Protecting Data Using Server-Side Encryption with Amazon S3-Managed Encryption Keys (SSE-S3) in the *Amazon Simple Storage Service User Guide*.

> **Important**
>
> This option is ignored if a security configuration is specified.

Use Glue data catalog as the Hive metastore

Select to use the AWS Glue Data Catalog as the Hive metastore. The IAM role used for the job must have the `glue:CreateDatabase` permission. A database called “default” is created in the Data Catalog if it does not exist.

Connections

Choose a VPC configuration to access Amazon S3 data sources located in your virtual private cloud (VPC). You can create and manage Network connection in AWS Glue. For more information, see Connecting to data.

Libraries

Python library path, Dependent JARs path, and Referenced files path

Specify these options if your script requires them. You can define the comma-separated Amazon S3 paths for these options when you define the job. You can override these paths when you run the job. For more information, see Providing your own custom scripts.

Job parameters

A set of key-value pairs that are passed as named parameters to the script. These are default values that are used when the script is run, but you can override them in triggers or when you run the job. You must prefix the key name with `--`; for example: `--myKey`. You pass job parameters as a map when using the AWS Command Line Interface.

For examples, see Python parameters in Passing and accessing Python parameters in AWS Glue.

Tags

Tag your job with a **Tag key** and an optional **Tag value**. After tag keys are created, they are read-only. Use tags on some resources to help you organize and identify them. For more information, see AWS tags in AWS Glue.

Restrictions for jobs that access Lake Formation managed tables

Keep in mind the following notes and restrictions when creating jobs that read from or write to tables managed by AWS Lake Formation:

- The following features are not supported in jobs that access tables with cell-level filters:
  - Job bookmarks and bounded execution
  - Push-down predicates
  - Server-side catalog partition predicates
  - enableUpdateCatalog

Editing Spark scripts in the AWS Glue console

A script contains the code that extracts data from sources, transforms it, and loads it into targets. AWS Glue runs a script when it starts a job.

AWS Glue ETL scripts can be coded in Python or Scala. Python scripts use a language that is an extension of the PySpark Python dialect for extract, transform, and load (ETL) jobs. The script contains *extended constructs* to deal with ETL transformations. When you automatically generate the source code logic for your job, a script is created. You can edit this script, or you can provide your own script to process your ETL work.

For information about defining and editing scripts in AWS Glue, see AWS Glue programming guide.

Additional libraries or files

If your script requires additional libraries or files, you can specify them as follows:

Python library path

Comma-separated Amazon Simple Storage Service (Amazon S3) paths to Python libraries that are required by the script.

> **Note**
>
> Only pure Python libraries can be used. Libraries that rely on C extensions, such as the pandas Python Data Analysis Library, are not yet supported.

Dependent jars path

Comma-separated Amazon S3 paths to JAR files that are required by the script.

> **Note**
>
> Currently, only pure Java or Scala (2.11) libraries can be used.

Referenced files path

Comma-separated Amazon S3 paths to additional files (for example, configuration files) that are required by the script.

Jobs (legacy)

A script contains the code that performs extract, transform, and load (ETL) work. You can provide your own script, or AWS Glue can generate a script with guidance from you. For information about creating your own scripts, see Providing your own custom scripts.

You can edit a script in the AWS Glue console. When you edit a script, you can add sources, targets, and transforms.

To edit a script

1. Sign in to the AWS Management Console and open the AWS Glue console at https://console.aws.amazon.com/glue/. Then choose the **Jobs** tab.
2. Choose a job in the list, and then choose **Action**, **Edit script** to open the script editor.

   You can also access the script editor from the job details page. Choose the **Script** tab, and then choose **Edit script**.

Script editor

The AWS Glue script editor lets you insert, modify, and delete sources, targets, and transforms in your script. The script editor displays both the script and a diagram to help you visualize the flow of data.

To create a diagram for the script, choose **Generate diagram**. AWS Glue uses annotation lines in the script beginning with **##** to render the diagram. To correctly represent your script in the diagram, you must keep the parameters in the annotations and the parameters in the Apache Spark code in sync.

The script editor lets you add code templates wherever your cursor is positioned in the script. At the top of the editor, choose from the following options:

- To add a source table to the script, choose **Source**.
- To add a target table to the script, choose **Target**.
- To add a target location to the script, choose **Target location**.
- To add a transform to the script, choose **Transform**. For information about the functions that are called in your script, see Program AWS Glue ETL scripts in PySpark.
- To add a Spigot transform to the script, choose **Spigot**.

In the inserted code, modify the `parameters` in both the annotations and Apache Spark code. For example, if you add a **Spigot** transform, verify that the `path` is replaced in both the `@args` annotation line and the `output` code line.

The **Logs** tab shows the logs that are associated with your job as it runs. The most recent 1,000 lines are displayed.

The **Schema** tab shows the schema of the selected sources and targets, when available in the Data Catalog.

Tracking processed data using job bookmarks

AWS Glue tracks data that has already been processed during a previous run of an ETL job by persisting state information from the job run. This persisted state information is called a *job bookmark*. Job bookmarks help AWS Glue maintain state information and prevent the reprocessing of old data. With job bookmarks, you can process new data when rerunning on a scheduled interval. A job bookmark is composed of the states for various elements of jobs, such as sources, transformations, and targets. For example, your ETL job might read new partitions in an Amazon S3 file. AWS Glue tracks which partitions the job has processed successfully to prevent duplicate processing and duplicate data in the job's target data store.

Job bookmarks are implemented for JDBC data sources, the Relationalize transform, and some Amazon Simple Storage Service (Amazon S3) sources. The following table lists the Amazon S3 source formats that AWS Glue supports for job bookmarks.

AWS Glue version	Amazon S3 source formats
Version 0.9	JSON, CSV, Apache Avro, XML
Version 1.0 and later	JSON, CSV, Apache Avro, XML, Parquet, ORC

For information about AWS Glue versions, see Defining job properties for Spark jobs.

The job bookmarks feature has additional functionalities when accessed through AWS Glue scripts. When browsing your generated script, you may see transformation contexts, which are related to this feature. For more information, see the section called “Using job bookmarks”.

Topics

- Using job bookmarks in AWS Glue

- Operational details of the job bookmarks feature

Using job bookmarks in AWS Glue

The job bookmark option is passed as a parameter when the job is started. The following table describes the options for setting job bookmarks on the AWS Glue console.

Job bookmark	Description
Enable	Causes the job to update the state after a run to keep track of previously processed data. If your job has a source with job bookmark support, it will keep track of processed data, and when a job runs, it processes new data since the last checkpoint.
Disable	Job bookmarks are not used, and the job always processes the entire dataset. You are responsible for managing the output from previous job runs. This is the default.
Pause	Process incremental data since the last successful run or the data in the range identified by the following sub-options, without updating the state of last bookmark. You are responsible for managing the output from previous job runs. The two sub-options are: • **job-bookmark-from** <from-value> is the run ID which represents all the input that was processed until the last successful run before and including the specified run ID. The corresponding input is ignored. • **job-bookmark-to** <to-value> is the run ID which represents all the input that was processed until the last successful run before and including the specified run ID. The corresponding input excluding the input identified by the <from-value> is processed by the job. Any input later than this input is also excluded for processing. The job bookmark state is not updated when this option set is specified . The sub-options are optional, however when used both the sub-options needs to be provided.

For details about the parameters passed to a job on the command line, and specifically for job bookmarks, see Using job parameters in AWS Glue jobs.

For Amazon S3 input sources, AWS Glue job bookmarks check the last modified time of the objects to verify which objects need to be reprocessed. If your input source data has been modified since your last job run, the files are reprocessed when you run the job again.

For JDBC sources, the following rules apply:

- For each table, AWS Glue uses one or more columns as bookmark keys to determine new and processed data. The bookmark keys combine to form a single compound key.
- AWS Glue by default uses the primary key as the bookmark key, provided that it is sequentially increasing or decreasing (with no gaps).
- You can specify the columns to use as bookmark keys in your AWS Glue script. For more information about using Job bookmarks in AWS Glue scripts, see the section called "Using job bookmarks".
- AWS Glue doesn't support using columns with case-sensitive names as job bookmark keys.

You can rewind your job bookmarks for your AWS Glue Spark ETL jobs to any previous job run. You can support data backfilling scenarios better by rewinding your job bookmarks to any previous job run, resulting in the subsequent job run reprocessing data only from the bookmarked job run.

If you intend to reprocess all the data using the same job, reset the job bookmark. To reset the job bookmark state, use the AWS Glue console, the ResetJobBookmark action (Python: reset_job_bookmark) API operation, or the AWS CLI. For example, enter the following command using the AWS CLI:

```
aws glue reset-job-bookmark --job-name my-job-name
```

When you rewind or reset a bookmark, AWS Glue does not clean the target files because there could be multiple targets and targets are not tracked with job bookmarks. Only source files are tracked with job bookmarks. You can create different output targets when rewinding and reprocessing the source files to avoid duplicate data in your output.

AWS Glue keeps track of job bookmarks by job. If you delete a job, the job bookmark is deleted.

In some cases, you might have enabled AWS Glue job bookmarks but your ETL job is reprocessing data that was already processed in an earlier run. For information about resolving common causes of this error, see Troubleshooting Glue common setup errors.

Operational details of the job bookmarks feature

This section describes more of the operational details of using job bookmarks.

Job bookmarks store the states for a job. Each instance of the state is keyed by a job name and a version number. When a script invokes `job.init`, it retrieves its state and always gets the latest version. Within a state, there are multiple state elements, which are specific to each source, transformation, and sink instance in the script. These state elements are identified by a transformation context that is attached to the corresponding element (source, transformation, or sink) in the script. The state elements are saved atomically when `job.commit` is invoked from the user script. The script gets the job name and the control option for the job bookmarks from the arguments.

The state elements in the job bookmark are source, transformation, or sink-specific data. For example, suppose that you want to read incremental data from an Amazon S3 location that is being constantly written to by an upstream job or process. In this case, the script must determine what has been processed so far. The job bookmark implementation for the Amazon S3 source saves information so that when the job runs again, it can filter only the new objects using the saved information and recompute the state for the next run of the job. A timestamp is used to filter the new files.

In addition to the state elements, job bookmarks have a *run number*, an *attempt number*, and a *version number*. The run number tracks the run of the job, and the attempt number records the attempts for a job run. The job run number is a monotonically increasing number that is incremented for every successful run. The attempt number tracks the attempts for each run, and is only incremented when there is a run after a failed attempt. The version number increases monotonically and tracks the updates to a job bookmark.

In the AWS Glue service database, the bookmark states for all the transformations are stored together as key-value pairs:

```
{
  "job_name" : ...,
  "run_id": ...,
  "run_number": ..,
  "attempt_number": ...
```

```
  "states": {
    "transformation_ctx1" : {
      bookmark_state1
    },
    "transformation_ctx2" : {
      bookmark_state2
    }
  }
}
```

Best practices

The following are best practices for using job bookmarks.

- *Do not change the data source property with the bookmark enabled*. For example, there is a datasource0 pointing to an Amazon S3 input path A, and the job has been reading from a source which has been running for several rounds with the bookmark enabled. If you change the input path of datasource0 to Amazon S3 path B without changing the `transformation_ctx`, the AWS Glue job will use the old bookmark state stored. That will result in missing or skipping files in the input path B as AWS Glue would assume that those files had been processed in previous runs.
- *Use a catalog table with bookmarks for better partition management*. Bookmarks works both for data sources from the Data Catalog or from options. However, it's difficult to remove/add new partitions with the from options approach. Using a catalog table with crawlers can provide better automation to track the newly added partitions and give you the flexibility to select particular partitions with a pushdown predicate.
- *Use the AWS Glue Amazon S3 file lister for large datasets*. A bookmark will list all files under each input partition and do the filering, so if there are too many files under a single partition the bookmark can run into driver OOM. Use the AWS Glue Amazon S3 file lister to avoid listing all files in memory at once.

Storing Spark shuffle data

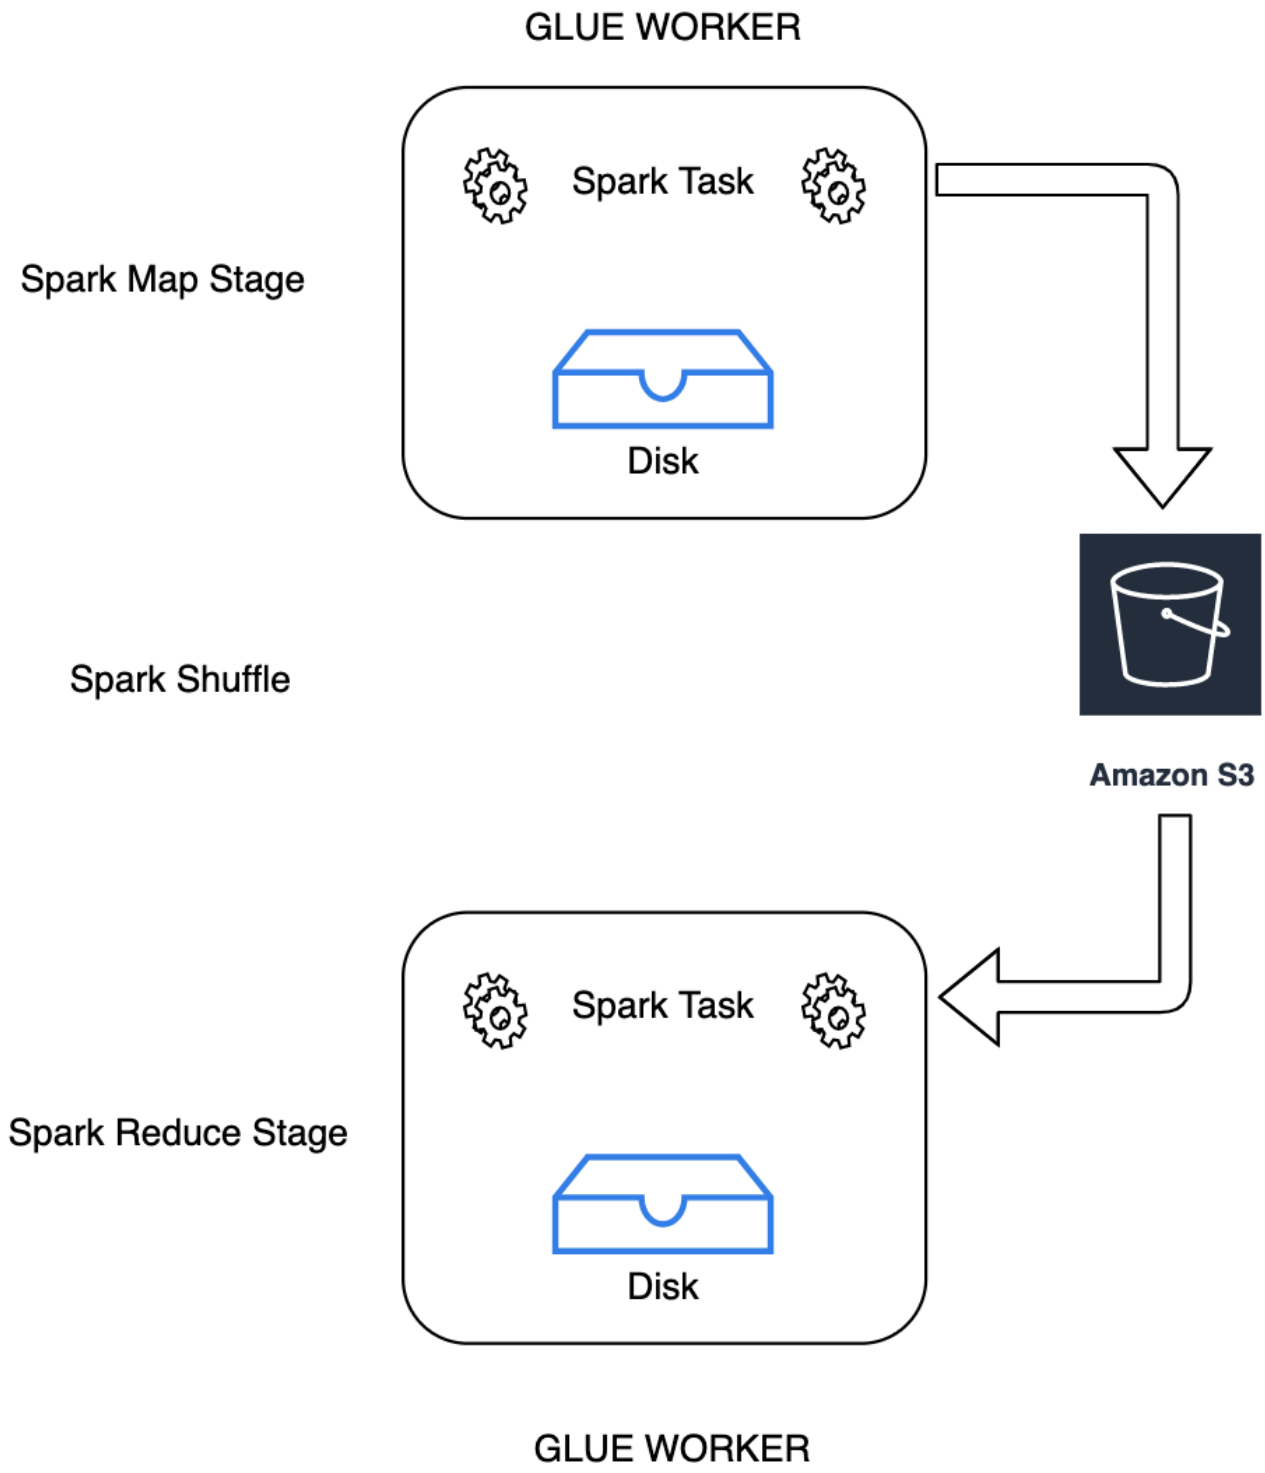
Shuffling is an important step in a Spark job whenever data is rearranged between partitions. This is required because wide transformations such as `join`, `groupByKey`, `reduceByKey`, and `repartition` require information from other partitions to complete processing. Spark gathers the required data from each partition and combines it into a new partition. During a shuffle, data is written to disk and transferred across the network. As a result, the shuffle

operation is bound to local disk capacity. Spark throws a `No space left on device` or `MetadataFetchFailedException` error when there is not enough disk space left on the executor and there is no recovery.

> **Note**
>
> AWS Glue Spark shuffle plugin with Amazon S3 is only supported for AWS Glue ETL jobs.

Solution

With AWS Glue, you can now use Amazon S3 to store Spark shuffle data using the Cloud Shuffle Storage Plugin. Amazon S3 is an object storage service that offers industry-leading scalability, data availability, security, and performance. This solution disaggregates compute and storage for your Spark jobs, and gives complete elasticity and low-cost shuffle storage, allowing you to run your most shuffle-intensive workloads reliably.



You can turn on Amazon S3 shuffling to run your AWS Glue jobs reliably without failures if they are known to be bound by the local disk capacity for large shuffle operations. In some cases, shuffling to Amazon S3 is marginally slower than local disk (or EBS) if you have a large number of small partitions or shuffle files written out to Amazon S3.

Prerequisites for using Cloud Shuffle Storage Plugin

In order to use the Cloud Shuffle Storage Plugin with AWS Glue ETL jobs, you need the following:

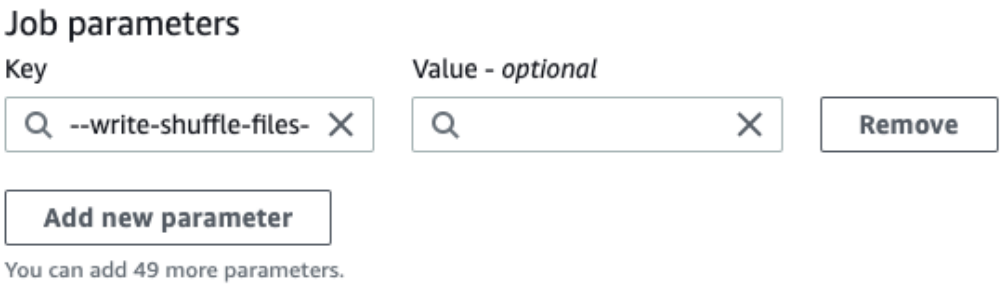
- An Amazon S3 bucket located in the same region as your job run, for storing the intermediate shuffle and spilled data. The Amazon S3 prefix of shuffle storage can be specified with `--conf spark.shuffle.glue.s3ShuffleBucket=s3://`*`shuffle-bucket`*`/`*`prefix`*`/`, as in the following example:

```
--conf spark.shuffle.glue.s3ShuffleBucket=s3://glue-shuffle-123456789-us-east-1/glue-shuffle-data/
```

- Set the Amazon S3 storage lifecycle policies on the *prefix* (such as `glue-shuffle-data`) as the shuffle manager does not clean the files after the job is done. The intermediate shuffle and spilled data should be deleted after a job is finished. Users can set a short lifecycle policies on the prefix. Instructions for setting up an Amazon S3 lifecycle policy are available at Setting lifecycle configuration on a bucket in the Amazon Simple Storage Service User Guide.

Using AWS Glue Spark shuffle manager from the AWS console

To set up the AWS Glue Spark shuffle manager using the AWS Glue console or AWS Glue Studio when configuring a job: choose the **--write-shuffle-files-to-s3** job parameter to turn on Amazon S3 shuffling for the job.



Using AWS Glue Spark shuffle plugin

The following job parameters turn on and tune the AWS Glue shuffle manager. These parameters are flags, so any values provided are not considered.

> **Important**
>
> To disable Amazon S3 shuffling, you must remove the `--write-shuffle-files-to-s3` parameter entirely from your job configuration. Setting the value to `false` does not disable Amazon S3 shuffling — the parameter acts as a presence-based flag, meaning that any value (including `false`) enables Amazon S3 shuffling when the parameter is present.

- `--write-shuffle-files-to-s3` — The main flag, which enables the AWS Glue Spark shuffle manager to use Amazon S3 buckets for writing and reading shuffle data. When the flag is not specified, the shuffle manager is not used.
- `--write-shuffle-spills-to-s3` — (Supported only on AWS Glue version 2.0). An optional flag that allows you to offload spill files to Amazon S3 buckets, which provides additional resiliency to your Spark job. This is only required for large workloads that spill a lot of data to disk. When the flag is not specified, no intermediate spill files are written.
- `--conf spark.shuffle.glue.s3ShuffleBucket=s3://<shuffle-bucket>` — Another optional flag that specifies the Amazon S3 bucket where you write the shuffle files. By default, `--TempDir`/shuffle-data. AWS Glue 3.0+ supports writing shuffle files to multiple buckets by specifying buckets with comma delimiter, as in `--conf spark.shuffle.glue.s3ShuffleBucket=s3://`*`shuffle-bucket-1`*`/`*`prefix`*`,s3://`*`shuffle-bucket-2`*`/`*`prefix`*`/`. Using multiple buckets improves performance.

You need to provide security configuration settings to enable encryption at-rest for the shuffle data. For more information about security configurations, see the section called "Setting up encryption". AWS Glue supports all other shuffle related configurations provided by Spark.

Software binaries for the Cloud Shuffle Storage plugin

You can also download the software binaries of the Cloud Shuffle Storage Plugin for Apache Spark under the Apache 2.0 license and run it on any Spark environment. The new plugin comes with out-of-the box support for Amazon S3, and can also be easily configured to use other forms of cloud storage such as Google Cloud Storage and Microsoft Azure Blob Storage. For more information, see Cloud Shuffle Storage Plugin for Apache Spark.

Notes and limitations

The following are notes or limitations for the AWS Glue shuffle manager:

- AWS Glue shuffle manager doesn't automatically delete the (temporary) shuffle data files stored in your Amazon S3 bucket after a job is completed. To ensure data protection, follow the instructions in Prerequisites for using Cloud Shuffle Storage Plugin before enabling the Cloud Shuffle Storage Plugin.
- You can use this feature if your data is skewed.

Cloud Shuffle Storage Plugin for Apache Spark

The Cloud Shuffle Storage Plugin is an Apache Spark plugin compatible with the `ShuffleDataIO` API which allows storing shuffle data on cloud storage systems (such as Amazon S3). It helps you to supplement or replace local disk storage capacity for large shuffle operations, commonly triggered by transformations such as `join`, `reduceByKey`, `groupByKey` and `repartition` in your Spark applications, thereby reducing common failures or price/performance dislocation of your serverless data analytics jobs and pipelines.

AWS Glue

AWS Glue versions 3.0 and 4.0 comes with the plugin pre-installed and ready to enable shuffling to Amazon S3 without any extra steps. For more information, see AWS Glue Spark shuffle plugin with Amazon S3 to enable the feature for your Spark applications.

Other Spark environments

The plugin requires the following Spark configurations to be set on other Spark environments:

- `--conf spark.shuffle.sort.io.plugin.class=com.amazonaws.spark.shuffle.io.cloud.Choppe` This informs Spark to use this plugin for Shuffle IO.
- `--conf spark.shuffle.storage.path=s3://`*`bucket-name`*`/`*`shuffle-file-dir`*: The path where your shuffle files will be stored.

> **Note**
>
> The plugin overwrites one Spark core class. As a result, the plugin jar needs to be loaded before Spark jars. You can do this using `userClassPathFirst` in on-prem YARN environments if the plugin is used outside AWS Glue.

Bundling the plugin with your Spark applications

You can bundle the plugin with your Spark applications and Spark distributions (versions 3.1 and above) by adding the plugin dependency in your Maven `pom.xml` while developing your Spark applications locally. For more information on the plugin and Spark versions, see Plugin versions.

```
<repositories>
   ...
    <repository>
        <id>aws-glue-etl-artifacts</id>
        <url>https://aws-glue-etl-artifacts.s3.amazonaws.com/release/ </url>
    </repository>
</repositories>
...
<dependency>
    <groupId>com.amazonaws</groupId>
    <artifactId>chopper-plugin</artifactId>
    <version>3.1-amzn-LATEST</version>
</dependency>
```

You can alternatively download the binaries from AWS Glue Maven artifacts directly and include them in your Spark application as follows.

```
#!/bin/bash
sudo wget -v https://aws-glue-etl-artifacts.s3.amazonaws.com/release/com/amazonaws/
chopper-plugin/3.1-amzn-LATEST/chopper-plugin-3.1-amzn-LATEST.jar -P /usr/lib/spark/
jars/
```

Example spark-submit

```
spark-submit --deploy-mode cluster \
--conf spark.shuffle.storage.s3.path=s3://<ShuffleBucket>/<shuffle-dir> \
--conf spark.driver.extraClassPath=<Path to plugin jar> \
--conf spark.executor.extraClassPath=<Path to plugin jar> \
--class <your test class name> s3://<ShuffleBucket>/<Your application jar> \
```

Optional configurations

These are optional configuration values that control Amazon S3 shuffle behavior.

- `spark.shuffle.storage.s3.enableServerSideEncryption`: Enable/disable S3 SSE for shuffle and spill files. Default value is `true`.

- `spark.shuffle.storage.s3.serverSideEncryption.algorithm`: The SSE algorithm to be used. Default value is AES256.
- `spark.shuffle.storage.s3.serverSideEncryption.kms.key`: The KMS key ARN when SSE aws:kms is enabled.

Along with these configurations, you may need to set configurations such as `spark.hadoop.fs.s3.enableServerSideEncryption` and **other environment-specific configurations** to ensure appropriate encryption is applied for your use case.

Plugin versions

This plugin is supported for the Spark versions associated with each AWS Glue version. The following table shows the AWS Glue version, Spark version and associated plugin version with Amazon S3 location for the plugin's software binary.

AWS Glue version	Spark version	Plugin version	Amazon S3 location
3.0	3.1	3.1-amzn-LATEST	s3://aws-glue-etl-artifacts/release/com/amazonaws/chopper-plugin/3.1-amzn-0/chopper-plugin-3.1-amzn-LATEST.jar
4.0	3.3	3.3-amzn-LATEST	s3://aws-glue-etl-artifacts/release/com/amazonaws/chopper-plugin/3.3-amzn-0/chopper-plugin-3.3-amzn-LATEST.jar

License

The software binary for this plugin is licensed under the Apache-2.0 License.

Monitoring AWS Glue Spark jobs

Topics

- Spark Metrics available in AWS Glue Studio
- Monitoring jobs using the Apache Spark web UI
- Monitoring with AWS Glue job run insights
- Monitoring with Amazon CloudWatch
- Job monitoring and debugging

Spark Metrics available in AWS Glue Studio

The **Metrics** tab shows metrics collected when a job runs and profiling is turned on. The following graphs are shown in Spark jobs:

- ETL Data Movement
- Memory Profile: Driver and Executors

Choose **View additional metrics** to show the following graphs:

- ETL Data Movement
- Memory Profile: Driver and Executors
- Data Shuffle Across Executors
- CPU Load: Driver and Executors
- Job Execution: Active Executors, Completed Stages & Maximum Needed Executors

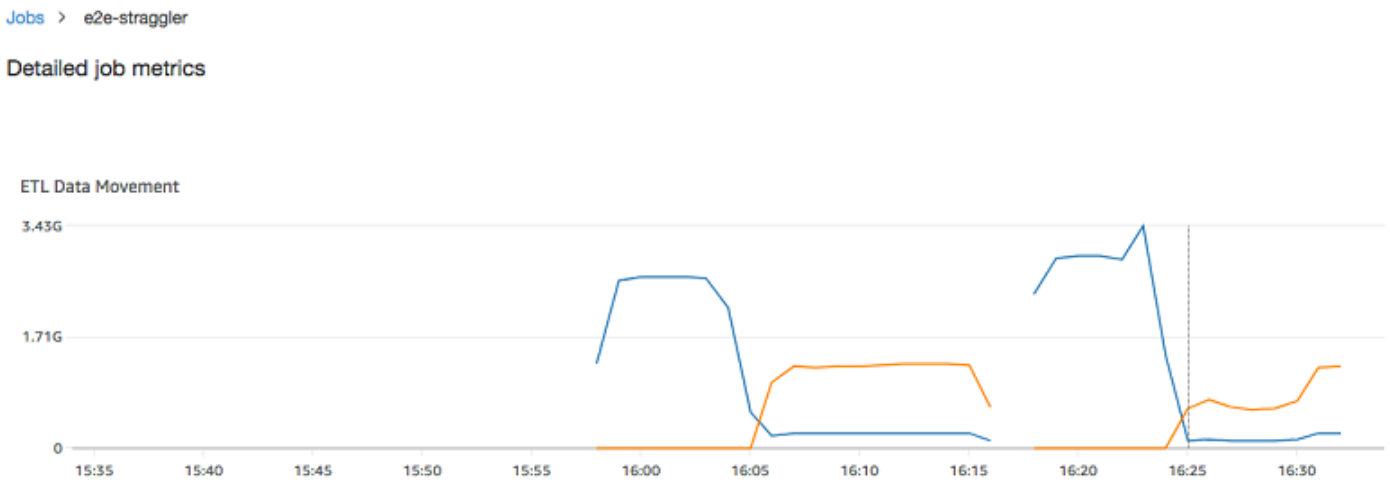
Data for these graphs is pushed to CloudWatch metrics if the job is configured to collect metrics. For more information about how to turn on metrics and interpret the graphs, see Job monitoring and debugging.

Example ETL data movement graph

The ETL Data Movement graph shows the following metrics:

- The number of bytes read from Amazon S3 by all executors —`glue.ALL.s3.filesystem.read_bytes`

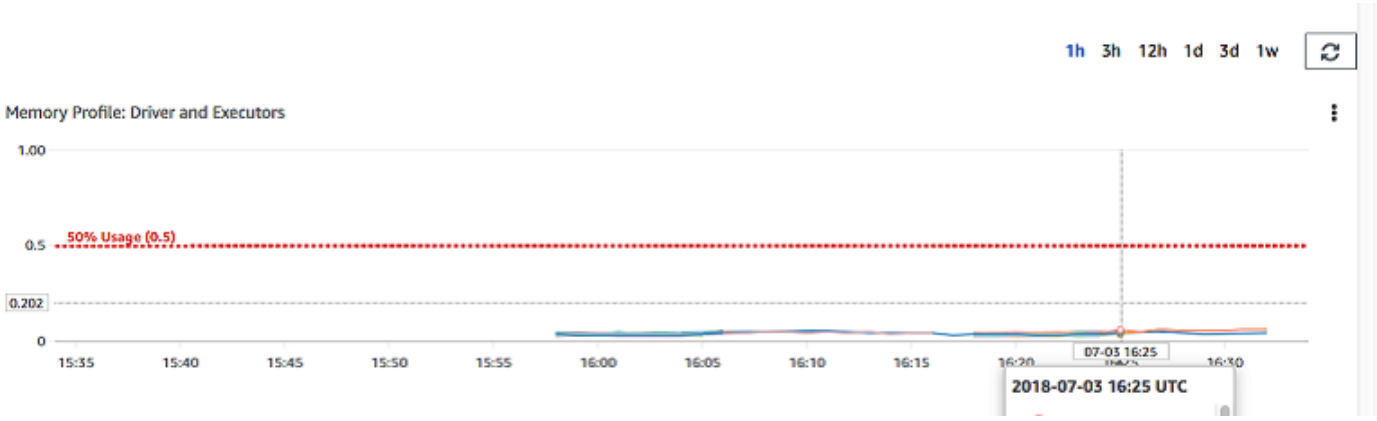
- The number of bytes written to Amazon S3 by all executors —glue.ALL.s3.filesystem.write_bytes



Example Memory profile graph

The Memory Profile graph shows the following metrics:

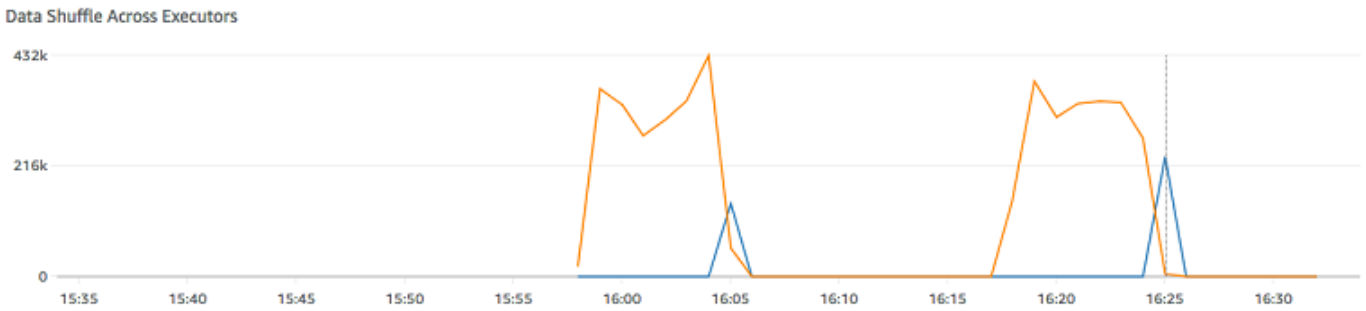
- The fraction of memory used by the JVM heap for this driver (scale: 0–1) by the driver, an executor identified by *executorId*, or all executors—
  - glue.driver.jvm.heap.usage
  - glue.*executorId*.jvm.heap.usage
  - glue.ALL.jvm.heap.usage



Example Data shuffle across executors graph

The Data Shuffle Across Executors graph shows the following metrics:

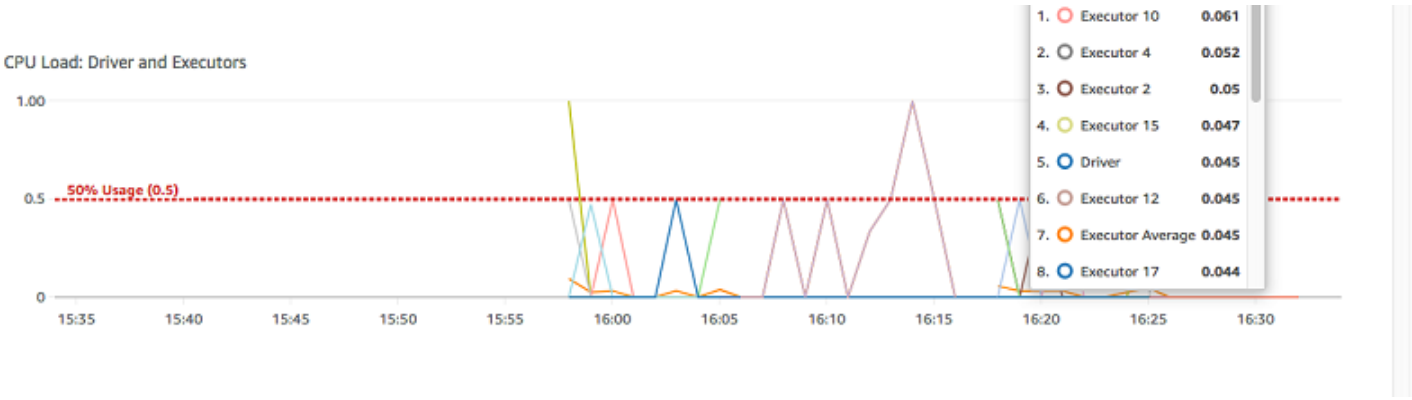
- The number of bytes read by all executors to shuffle data between them —glue.driver.aggregate.shuffleLocalBytesRead
- The number of bytes written by all executors to shuffle data between them —glue.driver.aggregate.shuffleBytesWritten



Example CPU load graph

The CPU Load graph shows the following metrics:

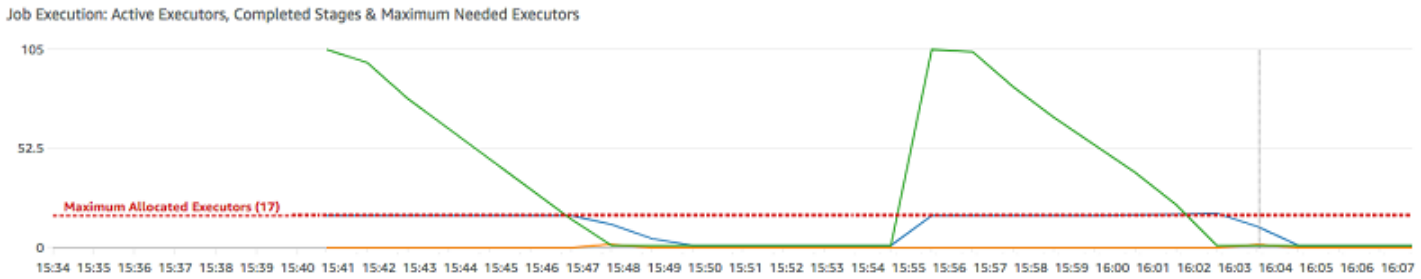
- The fraction of CPU system load used (scale: 0–1) by the driver, an executor identified by *executorId*, or all executors—
  - glue.driver.system.cpuSystemLoad
  - glue.*executorId*.system.cpuSystemLoad
  - glue.ALL.system.cpuSystemLoad



Example Job execution graph

The Job Execution graph shows the following metrics:

- The number of actively running executors —glue.driver.ExecutorAllocationManager.executors.numberAllExecutors
- The number of completed stages—glue.aggregate.numCompletedStages
- The number of maximum needed executors —glue.driver.ExecutorAllocationManager.executors.numberMaxNeededExecutors



Monitoring jobs using the Apache Spark web UI

You can use the Apache Spark web UI to monitor and debug AWS Glue ETL jobs running on the AWS Glue job system, and also Spark applications running on AWS Glue development endpoints. The Spark UI enables you to check the following for each job:

- The event timeline of each Spark stage
- A directed acyclic graph (DAG) of the job
- Physical and logical plans for SparkSQL queries
- The underlying Spark environmental variables for each job

For more information about using the Spark Web UI, see Web UI in the Spark documentation. For guidance on how to interpret Spark UI results to improve the performance of your job, see Best practices for performance tuning AWS Glue for Apache Spark jobs in AWS Prescriptive Guidance.

You can see the Spark UI in the AWS Glue console. This is available when an AWS Glue job runs on AWS Glue 3.0 or later versions with logs generated in the Standard (rather than legacy) format, which is the default for newer jobs. If you have log files greater than 0.5 GB, you can enable rolling

log support for job runs on AWS Glue 4.0 or later versions to simplify log archiving, analysis, and troubleshooting.

You can enable the Spark UI by using the AWS Glue console or the AWS Command Line Interface (AWS CLI). When you enable the Spark UI, AWS Glue ETL jobs and Spark applications on AWS Glue development endpoints can back up Spark event logs to a location that you specify in Amazon Simple Storage Service (Amazon S3). You can use the backed up event logs in Amazon S3 with the Spark UI, both in real time as the job is operating and after the job is complete. While the logs remain in Amazon S3, the Spark UI in the AWS Glue console can view them.

Permissions

In order to use the Spark UI in the AWS Glue console, you can use `UseGlueStudio` or add all the individual service APIs. All APIs are needed to use the Spark UI completely, however users can access SparkUI features by adding its service APIs in their IAM permission for fine-grained access.

`RequestLogParsing` is the most critical as it performs the parsing of logs. The remaining APIs are for reading the respective parsed data. For example, `GetStages` provides access to the data about all stages of a Spark job.

The list of Spark UI service APIs mapped to `UseGlueStudio` are below in the sample policy. The policy below provides access to use only Spark UI features. To add more permissions like Amazon S3 and IAM see Creating Custom IAM Policies for AWS Glue Studio.

The list of Spark UI service APIs mapped to `UseGlueStudio` is below in the sample policy. When using a Spark UI service API, use the following namespace: `glue:<ServiceAPI>`.

JSON

      ],
      "Resource": [
        "*"
      ]
    }
  ]
}
```

Limitations

- Spark UI in the AWS Glue console is not available for job runs that occurred before 20 Nov 2023 because they are in the legacy log format.
- Spark UI in the AWS Glue console supports rolling logs for AWS Glue 4.0, such as those generated by default in streaming jobs. The maximum sum of all generated rolled log event files is 2 GB. For AWS Glue jobs without rolled log support, the maximum log event file size supported for SparkUI is 0.5 GB.
- Serverless Spark UI is not available for Spark event logs stored in an Amazon S3 bucket that can only be accessed by your VPC.

Example: Apache Spark web UI

This example shows you how to use the Spark UI to understand your job performance. Screen shots show the Spark web UI as provided by a self-managed Spark history server. Spark UI in the AWS Glue console provides similar views. For more information about using the Spark Web UI, see Web UI in the Spark documentation.

The following is an example of a Spark application that reads from two data sources, performs a join transform, and writes it out to Amazon S3 in Parquet format.

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from pyspark.sql.functions import count, when, expr, col, sum, isnull
from pyspark.sql.functions import countDistinct
from awsglue.dynamicframe import DynamicFrame

args = getResolvedOptions(sys.argv, ['JOB_NAME'])

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

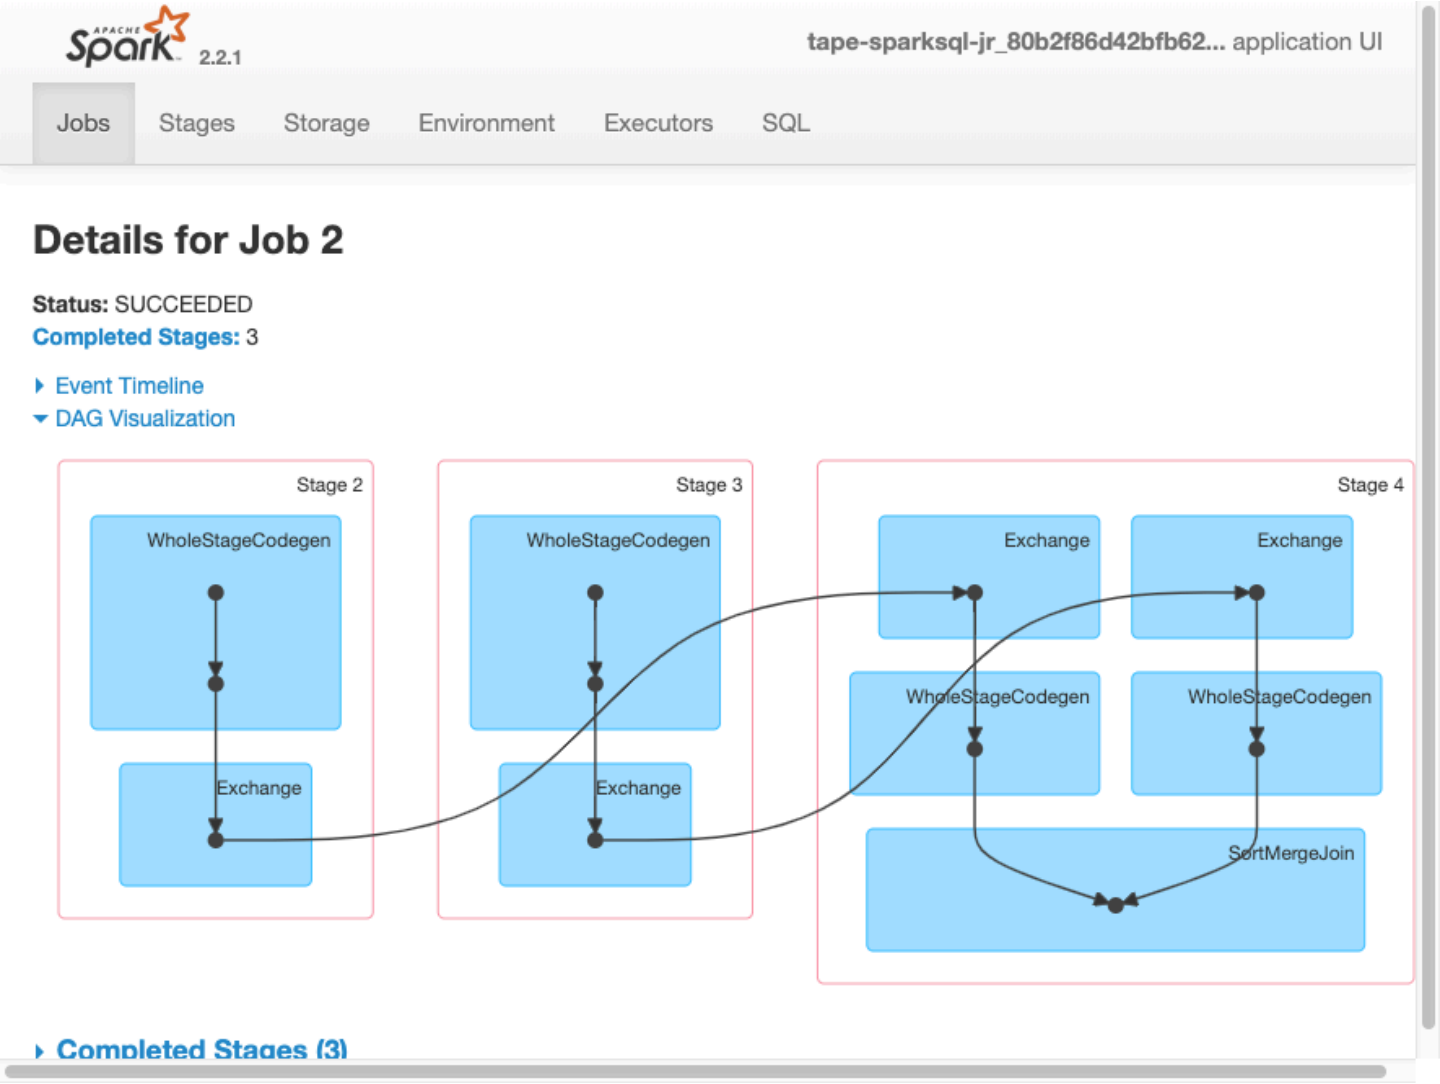
job = Job(glueContext)
job.init(args['JOB_NAME'])

df_persons = spark.read.json("s3://awsglue-datasets/examples/us-legislators/all/
persons.json")
df_memberships = spark.read.json("s3://awsglue-datasets/examples/us-legislators/all/
memberships.json")

df_joined = df_persons.join(df_memberships, df_persons.id == df_memberships.person_id,
 'fullouter')
df_joined.write.parquet("s3://aws-glue-demo-sparkui/output/")

job.commit()
```

The following DAG visualization shows the different stages in this Spark job.



The following event timeline for a job shows the start, execution, and termination of different Spark executors.

Topics

- Enabling the Apache Spark web UI for AWS Glue jobs
- Launching the Spark history server

Enabling the Apache Spark web UI for AWS Glue jobs

You can use the Apache Spark web UI to monitor and debug AWS Glue ETL jobs running on the AWS Glue job system. You can configure the Spark UI using the AWS Glue console or the AWS Command Line Interface (AWS CLI).

Every 30 seconds, AWS Glue backs up the Spark event logs to the Amazon S3 path that you specify.

Topics

- Configuring the Spark UI (console)
- Configuring the Spark UI (AWS CLI)
- Configuring the Spark UI for sessions using Notebooks
- Enable rolling logs

Configuring the Spark UI (console)

Follow these steps to configure the Spark UI by using the AWS Management Console. When creating an AWS Glue job, Spark UI is enabled by default.

To turn on the Spark UI when you create or edit a job

1. Sign in to the AWS Management Console and open the AWS Glue console at https://console.aws.amazon.com/glue/.
2. In the navigation pane, choose **Jobs**.
3. Choose **Add job**, or select an existing one.
4. In **Job details**, open the **Advanced properties**.
5. Under the **Spark UI** tab, choose **Write Spark UI logs to Amazon S3**.
6. Specify an Amazon S3 path for storing the Spark event logs for the job. Note that if you use a security configuration in the job, the encryption also applies to the Spark UI log file. For more information, see Encrypting data written by AWS Glue.
7. Under **Spark UI logging and monitoring configuration**:

- Select **Standard** if you are generating logs to view in the AWS Glue console.
- Select **Legacy** if you are generating logs to view on a Spark history server.
- You can also choose to generate both.

Configuring the Spark UI (AWS CLI)

To generate logs for viewing with Spark UI, in the AWS Glue console, use the AWS CLI to pass the following job parameters to AWS Glue jobs. For more information, see the section called “Job parameters”.

```
'--enable-spark-ui': 'true',
'--spark-event-logs-path': 's3://s3-event-log-path'
```

To distribute logs to their legacy locations, set the `--enable-spark-ui-legacy-path` parameter to `"true"`. If you do not want to generate logs in both formats, remove the `--enable-spark-ui` parameter.

Configuring the Spark UI for sessions using Notebooks

> **Warning**
>
> AWS Glue interactive sessions do not currently support Spark UI in the console. Configure a Spark history server.

If you use AWS Glue notebooks, set up SparkUI config before starting the session. To do this, use the `%%configure` cell magic:

```
%%configure { “--enable-spark-ui”: “true”, “--spark-event-logs-path”: “s3://path” }
```

Enable rolling logs

Enabling SparkUI and rolling log event files for AWS Glue jobs provides several benefits:

- Rolling Log Event Files – With rolling log event files enabled, AWS Glue generates separate log files for each step of the job execution, making it easier to identify and troubleshoot issues specific to a particular stage or transformation.

- Better Log Management – Rolling log event files help in managing log files more efficiently. Instead of having a single, potentially large log file, the logs are split into smaller, more manageable files based on the job execution stages. This can simplify log archiving, analysis, and troubleshooting.
- Improved Fault Tolerance – If a AWS Glue job fails or is interrupted, the rolling log event files can provide valuable information about the last successful stage, making it easier to resume the job from that point rather than starting from scratch.
- Cost Optimization – By enabling rolling log event files, you can save on storage costs associated with log files. Instead of storing a single, potentially large log file, you store smaller, more manageable log files, which can be more cost-effective, especially for long-running or complex jobs.

In a new environment, users can explicitly enable rolling logs through:

```
'–conf': 'spark.eventLog.rolling.enabled=true'
```

or

```
'–conf': 'spark.eventLog.rolling.enabled=true –conf
spark.eventLog.rolling.maxFileSize=128m'
```

When rolling logs are activated, `spark.eventLog.rolling.maxFileSize` specifies the maximum size of the event log file before it rolls over. The default value of this optional parameter if not specified is 128 MB. Minimum is 10 MB.

The maximum sum of all generated rolled log event files is 2 GB. For AWS Glue jobs without rolling log support, the maximum log event file size supported for SparkUI is 0.5 GB.

You can turn off rolling logs for a streaming job by passing an additional configuration. Note that very large log files may be costly to maintain.

To turn off rolling logs, provide the following configuration:

```
'--spark-ui-event-logs-path': 'true',
'--conf': 'spark.eventLog.rolling.enabled=false'
```

Launching the Spark history server

You can use a Spark history server to visualize Spark logs on your own infrastructure. You can see the same visualizations in the AWS Glue console for AWS Glue job runs on AWS Glue 4.0 or later versions with logs generated in the Standard (rather than legacy) format. For more information, see the section called “Monitoring with the Spark UI”.

You can launch the Spark history server using a AWS CloudFormation template that hosts the server on an EC2 instance, or launch locally using Docker.

Topics

- Launching the Spark history server and viewing the Spark UI using AWS CloudFormation
- Launching the Spark history server and viewing the Spark UI using Docker

Launching the Spark history server and viewing the Spark UI using AWS CloudFormation

You can use an AWS CloudFormation template to start the Apache Spark history server and view the Spark web UI. These templates are samples that you should modify to meet your requirements.

To start the Spark history server and view the Spark UI using CloudFormation

1. Choose one of the **Launch Stack** buttons in the following table. This launches the stack on the CloudFormation console.

Region	Launch
US East (Ohio)	
US East (N. Virginia)	
US West (N. California)	
US West (Oregon)	
Africa (Cape Town)	

Region	Launch
Asia Pacific (Hong Kong)	Asia Pacific (Mumbai)	
Asia Pacific (Osaka)	
Asia Pacific (Seoul)	
Asia Pacific (Singapore)	Asia Pacific (Sydney)	
Asia Pacific (Tokyo)	
Canada (Central)	
Europe (Frankfurt)	
Europe (Ireland)	
Europe (London)	Europe (Milan)	
Europe (Paris)	
Europe (Stockholm)	
Middle East (Bahrain)	
Region	Launch
South America (São Paulo)	Launch Stack

2. On the **Specify template** page, choose **Next**.
3. On the **Specify stack details** page, enter the **Stack name**. Enter additional information under **Parameters**.

   a. **Spark UI configuration**

   Provide the following information:

   - **IP address range** — The IP address range that can be used to view the Spark UI. If you want to restrict access from a specific IP address range, you should use a custom value.
   - **History server port** — The port for the Spark UI. You can use the default value.
   - **Event log directory** — Choose the location where Spark event logs are stored from the AWS Glue job or development endpoints. You must use **`s3a://`** for the event logs path scheme.
   - **Spark package location** — You can use the default value.
   - **Keystore path** — SSL/TLS keystore path for HTTPS. If you want to use a custom keystore file, you can specify the S3 path `s3://path_to_your_keystore_file` here. If you leave this parameter empty, a self-signed certificate based keystore is generated and used.
   - **Keystore password** — Enter a SSL/TLS keystore password for HTTPS.

   b. **EC2 instance configuration**

   Provide the following information:

   - **Instance type** — The type of Amazon EC2 instance that hosts the Spark history server. Because this template launches Amazon EC2 instance in your account, Amazon EC2 cost will be charged in your account separately.
   - **Latest AMI ID** — The AMI ID of Amazon Linux 2 for the Spark history server instance. You can use the default value.
   - **VPC ID** — The virtual private cloud (VPC) ID for the Spark history server instance. You can use any of the VPCs available in your account Using a default VPC with a default

Network ACL is not recommended. For more information, see Default VPC and Default Subnets and Creating a VPC in the *Amazon VPC User Guide*.

- **Subnet ID** — The ID for the Spark history server instance. You can use any of the subnets in your VPC. You must be able to reach the network from your client to the subnet. If you want to access via the internet, you must use a public subnet that has the internet gateway in the route table.

c. Choose **Next**.

4. On the **Configure stack options** page, to use the current user credentials for determining how CloudFormation can create, modify, or delete resources in the stack, choose **Next**. You can also specify a role in the **Permissions** section to use instead of the current user permissions, and then choose **Next**.
5. On the **Review** page, review the template.

   Select **I acknowledge that CloudFormation might create IAM resources**, and then choose **Create stack**.
6. Wait for the stack to be created.
7. Open the **Outputs** tab.

   a. Copy the URL of **SparkUiPublicUrl** if you are using a public subnet.

   b. Copy the URL of **SparkUiPrivateUrl** if you are using a private subnet.
8. Open a web browser, and paste in the URL. This lets you access the server using HTTPS on the specified port. Your browser may not recognize the server's certificate, in which case you have to override its protection and proceed anyway.

Launching the Spark history server and viewing the Spark UI using Docker

If you prefer local access (not to have an EC2 instance for the Apache Spark history server), you can also use Docker to start the Apache Spark history server and view the Spark UI locally. This Dockerfile is a sample that you should modify to meet your requirements.

Prerequisites

For information about how to install Docker on your laptop see the Docker Engine community.

To start the Spark history server and view the Spark UI locally using Docker

1. Download files from GitHub.

Download the Dockerfile and `pom.xml` from AWS Glue code samples.

2. Determine if you want to use your user credentials or federated user credentials to access AWS.

   - To use the current user credentials for accessing AWS, get the values to use for `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY` in the `docker run` command. For more information, see Managing access keys for IAM users in the *IAM User Guide*.
   - To use SAML 2.0 federated users for accessing AWS, get the values for `AWS_ACCESS_KEY_ID`, `AWS_SECRET_ACCESS_KEY`, and `AWS_SESSION_TOKEN`. For more information, see Requesting temporary security credentials

3. Determine the location of your event log directory, to use in the `docker run` command.
4. Build the Docker image using the files in the local directory, using the name `glue/sparkui`, and the tag `latest`.

   ```
   $ docker build -t glue/sparkui:latest .
   ```

5. Create and start the docker container.

   In the following commands, use the values obtained previously in steps 2 and 3.

   a. To create the docker container using your user credentials, use a command similar to the following

      ```
      docker run -itd -e SPARK_HISTORY_OPTS="$SPARK_HISTORY_OPTS -
      Dspark.history.fs.logDirectory=s3a://path_to_eventlog
       -Dspark.hadoop.fs.s3a.access.key=AWS_ACCESS_KEY_ID -
      Dspark.hadoop.fs.s3a.secret.key=AWS_SECRET_ACCESS_KEY"
       -p 18080:18080 glue/sparkui:latest "/opt/spark/bin/spark-class
       org.apache.spark.deploy.history.HistoryServer"
      ```

   b. To create the docker container using temporary credentials, use `org.apache.hadoop.fs.s3a.TemporaryAWSCredentialsProvider` as the provider, and provide the credential values obtained in step 2. For more information, see Using Session Credentials with TemporaryAWSCredentialsProvider in the *Hadoop: Integration with Amazon Web Services* documentation.

      ```
      docker run -itd -e SPARK_HISTORY_OPTS="$SPARK_HISTORY_OPTS -
      Dspark.history.fs.logDirectory=s3a://path_to_eventlog
      ```

```
 -Dspark.hadoop.fs.s3a.access.key=AWS_ACCESS_KEY_ID -
Dspark.hadoop.fs.s3a.secret.key=AWS_SECRET_ACCESS_KEY
 -Dspark.hadoop.fs.s3a.session.token=AWS_SESSION_TOKEN
 -
Dspark.hadoop.fs.s3a.aws.credentials.provider=org.apache.hadoop.fs.s3a.TemporaryAWSCred
 -p 18080:18080 glue/sparkui:latest "/opt/spark/bin/spark-class
 org.apache.spark.deploy.history.HistoryServer"
```

> **Note**
>
> These configuration parameters come from the Hadoop-AWS Module. You may need to add specific configuration based on your use case. For example: users in isolated regions will need to configure the `spark.hadoop.fs.s3a.endpoint`.

6. Open `http://localhost:18080` in your browser to view the Spark UI locally.

Monitoring with AWS Glue job run insights

AWS Glue job run insights is a feature in AWS Glue that simplifies job debugging and optimization for your AWS Glue jobs. AWS Glue provides Spark UI, and CloudWatch logs and metrics for monitoring your AWS Glue jobs. With this feature, you get this information about your AWS Glue job's execution:

- Line number of your AWS Glue job script that had a failure.
- Spark action that executed last in the Spark query plan just before the failure of your job.
- Spark exception events related to the failure presented in a time-ordered log stream.
- Root cause analysis and recommended action (such as tuning your script) to fix the issue.
- Common Spark events (log messages relating to a Spark action) with a recommended action that addresses the root cause.

All these insights are available to you using two new log streams in the CloudWatch logs for your AWS Glue jobs.

Requirements

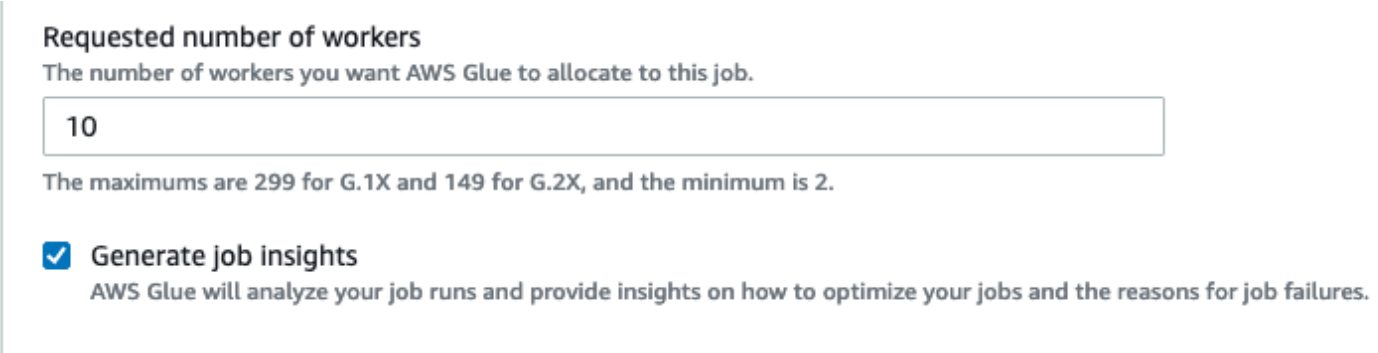
The AWS Glue job run insights feature is available for AWS Glue versions 2.0 and above. You can follow the migration guide for your existing jobs to upgrade them from older AWS Glue versions.

Enabling job run insights for an AWS Glue ETL job

You can enable job run insights through AWS Glue Studio or the CLI.

AWS Glue Studio

When creating a job via AWS Glue Studio, you can enable or disable job run insights under the **Job Details** tab. Check that the **Generate job insights** box is selected.



Command line

If creating a job via the CLI, you can start a job run with a single new job parameter: `--enable-job-insights = true`.

By default, the job run insights log streams are created under the same default log group used by AWS Glue continuous logging, that is, `/aws-glue/jobs/logs-v2/`. You may set up custom log group name, log filters and log group configurations using the same set of arguments for continuous logging. For more information, see Enabling Continuous Logging for AWS Glue Jobs.

Accessing the job run insights log streams in CloudWatch

With the job run insights feature enabled, there may be two log streams created when a job run fails. When a job finishes successfully, neither of the streams are generated.

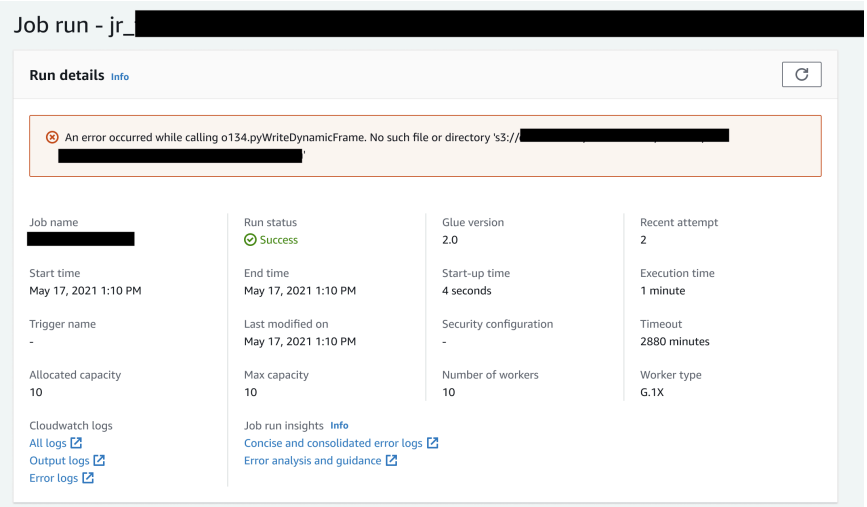
1. *Exception analysis log stream*: `<job-run-id>-job-insights-rca-driver`. This stream provides the following:
   - Line number of your AWS Glue job script that caused the failure.
   - Spark action that executed last in the Spark query plan (DAG).
   - Concise time-ordered events from the Spark driver and executors that are related to the exception. You can find details such as complete error messages, the failed Spark task and its executors ID that help you to focus on the specific executor's log stream for a deeper investigation if needed.

2. *Rule-based insights stream*:

- Root cause analysis and recommendations on how to fix the errors (such as using a specific job parameter to optimize the performance).
- Relevant Spark events serving as the basis for root cause analysis and a recommended action.

> **Note**
>
> The first stream will exist only if any exception Spark events are available for a failed job run, and the second stream will exist only if any insights are available for the failed job run. For example, if your job finishes successfully, neither of the streams will be generated; if your job fails but there isn't a service-defined rule that can match with your failure scenario, then only the first stream will be generated.

If the job is created from AWS Glue Studio, the links to the above streams are also available under the job run details tab (Job run insights) as "Concise and consolidated error logs" and "Error analysis and guidance".



Example for AWS Glue job run insights

In this section we present an example of how the job run insights feature can help you resolve an issue in your failed job. In this example, a user forgot to import the required module (tensorflow) in an AWS Glue job to analyze and build a machine learning model on their data.

```
import sys
from awsglue.transforms import *
```

```
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from pyspark.sql.types import *
from pyspark.sql.functions import udf,col

args = getResolvedOptions(sys.argv, ['JOB_NAME'])

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
job.init(args['JOB_NAME'], args)

data_set_1 = [1, 2, 3, 4]
data_set_2 = [5, 6, 7, 8]

scoresDf = spark.createDataFrame(data_set_1, IntegerType())

def data_multiplier_func(factor, data_vector):
    import tensorflow as tf
    with tf.compat.v1.Session() as sess:
        x1 = tf.constant(factor)
        x2 = tf.constant(data_vector)
        result = tf.multiply(x1, x2)
        return sess.run(result).tolist()

data_multiplier_udf = udf(lambda x:data_multiplier_func(x, data_set_2),
 ArrayType(IntegerType(),False))
factoredDf = scoresDf.withColumn("final_value", data_multiplier_udf(col("value")))
print(factoredDf.collect())
```

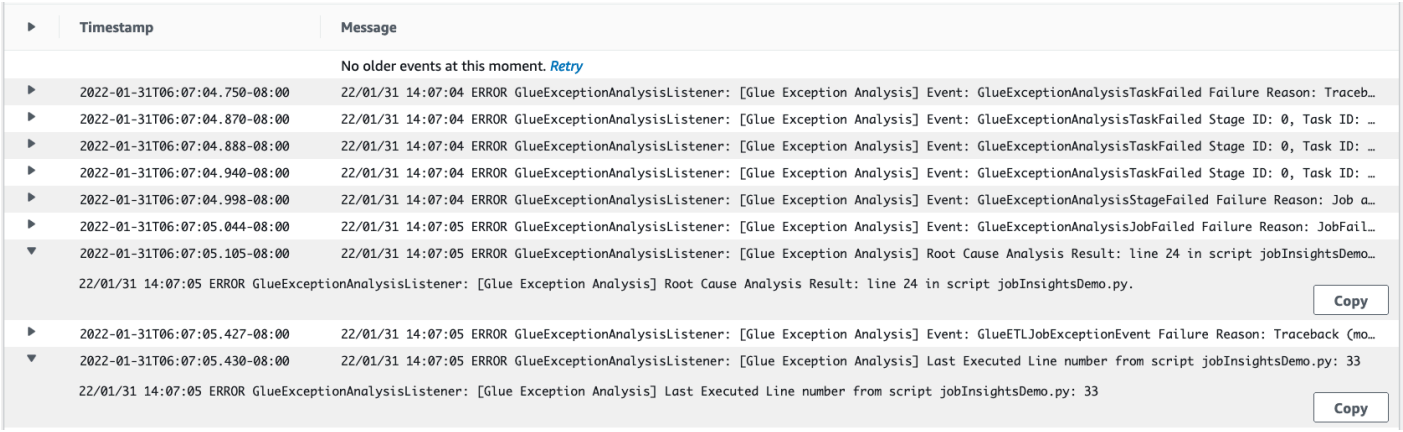
Without the job run insights feature, as the job fails, you only see this message thrown by Spark:

```
An error occurred while calling o111.collectToPython. Traceback (most
recent call last):
```

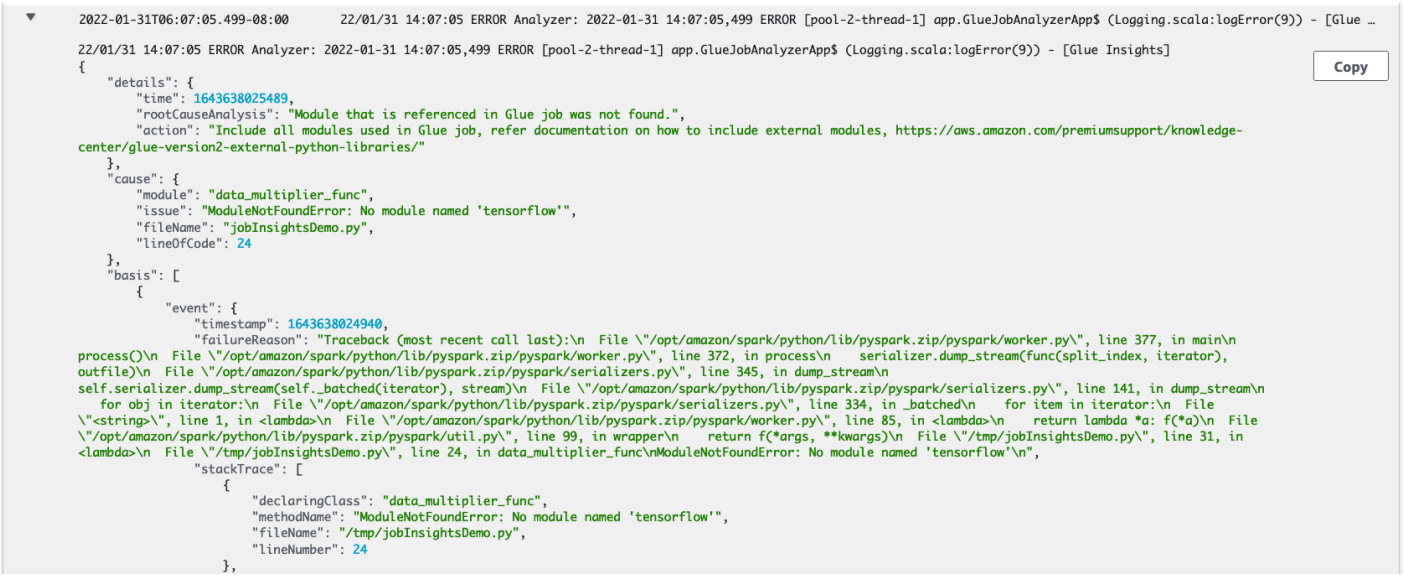
The message is ambiguous and limits your debugging experience. In this case, this feature provides with you additional insights in two CloudWatch log streams:

1. The `job-insights-rca-driver` log stream:

- *Exception events*: This log stream provides you the Spark exception events related to the failure collected from the Spark driver and different distributed workers. These events help you understand the time-ordered propagation of the exception as faulty code executes across Spark tasks, executors, and stages distributed across the AWS Glue workers.
- *Line numbers*: This log stream identifies line 21, which made the call to import the missing Python module that caused the failure; it also identifies line 24, the call to Spark Action `collect()`, as the last executed line in your script.



2. The `job-insights-rule-driver` log stream:
   - *Root cause and recommendation*: In addition to the line number and last executed line number for the fault in your script, this log stream shows the root cause analysis and recommendation for you to follow the AWS Glue doc and set up the necessary job parameters in order to use an additional Python module in your AWS Glue job.
   - *Basis event*: This log stream also shows the Spark exception event that was evaluated with the service-defined rule to infer the root cause and provide a recommendation.



Monitoring with Amazon CloudWatch

You can monitor AWS Glue using Amazon CloudWatch, which collects and processes raw data from AWS Glue into readable, near-real-time metrics. These statistics are recorded for a period of two weeks so that you can access historical information for a better perspective on how your web application or service is performing. By default, AWS Glue metrics data is sent to CloudWatch automatically. For more information, see What Is Amazon CloudWatch? in the *Amazon CloudWatch User Guide*, and AWS Glue metrics.

Continous logging

AWS Glue also supports real-time continuous logging for AWS Glue jobs. When continuous logging is enabled for a job, you can view the real-time logs on the AWS Glue console or the CloudWatch console dashboard. For more information, see Logging for AWS Glue jobs.

Observability metrics

When **Job observability metrics** is enabled, additional Amazon CloudWatch metrics are generated when the job is run. Use AWS Glue Observability metrics to generate insights into what is happening inside your AWS Glue to improve triaging and analysis of issues.

Topics

- Monitoring AWS Glue using Amazon CloudWatch metrics
- Setting up Amazon CloudWatch alarms on AWS Glue job profiles
- Logging for AWS Glue jobs
- Monitoring with AWS Glue Observability metrics

Monitoring AWS Glue using Amazon CloudWatch metrics

You can profile and monitor AWS Glue operations using AWS Glue job profiler. It collects and processes raw data from AWS Glue jobs into readable, near real-time metrics stored in Amazon CloudWatch. These statistics are retained and aggregated in CloudWatch so that you can access historical information for a better perspective on how your application is performing.

> **Note**
>
> You may incur additional charges when you enable job metrics and CloudWatch custom metrics are created. For more information, see Amazon CloudWatch pricing .

AWS Glue metrics overview

When you interact with AWS Glue, it sends metrics to CloudWatch. You can view these metrics using the AWS Glue console (the preferred method), the CloudWatch console dashboard, or the AWS Command Line Interface (AWS CLI).

To view metrics using the AWS Glue console dashboard

You can view summary or detailed graphs of metrics for a job, or detailed graphs for a job run.

1. Sign in to the AWS Management Console and open the AWS Glue console at https://console.aws.amazon.com/glue/.
2. In the navigation pane, choose **Job run monitoring**.
3. In **Job runs** choose **Actions** to stop a job that is currently running, view a job, or rewind job bookmark.
4. Select a job, then choose **View run details** to view additional information about the job run.

To view metrics using the CloudWatch console dashboard

Metrics are grouped first by the service namespace, and then by the various dimension combinations within each namespace.

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the **Glue** namespace.

To view metrics using the AWS CLI

- At a command prompt, use the following command.

```
aws cloudwatch list-metrics --namespace Glue
```

AWS Glue reports metrics to CloudWatch every 30 seconds, and the CloudWatch metrics dashboards are configured to display them every minute. The AWS Glue metrics represent delta values from the previously reported values. Where appropriate, metrics dashboards aggregate (sum) the 30-second values to obtain a value for the entire last minute.

AWS Glue metrics behavior for Spark jobs

AWS Glue metrics are enabled at initialization of a `GlueContext` in a script and are generally updated only at the end of an Apache Spark task. They represent the aggregate values across all completed Spark tasks so far.

However, the Spark metrics that AWS Glue passes on to CloudWatch are generally absolute values representing the current state at the time they are reported. AWS Glue reports them to CloudWatch every 30 seconds, and the metrics dashboards generally show the average across the data points received in the last 1 minute.

AWS Glue metrics names are all preceded by one of the following types of prefix:

- `glue.driver.` – Metrics whose names begin with this prefix either represent AWS Glue metrics that are aggregated from all executors at the Spark driver, or Spark metrics corresponding to the Spark driver.
- `glue.`*executorId*`.` – The *executorId* is the number of a specific Spark executor. It corresponds with the executors listed in the logs.
- `glue.ALL.` – Metrics whose names begin with this prefix aggregate values from all Spark executors.

AWS Glue metrics

AWS Glue profiles and sends the following metrics to CloudWatch every 30 seconds, and the AWS Glue Metrics Dashboard report them once a minute:

Metric	Description
`glue.driver.aggregate.bytesRead`	The number of bytes read from all data sources by all completed Spark tasks running in all executors. Valid dimensions: `JobName` (the name of the AWS Glue Job), `JobRunId` (the JobRun ID. or `ALL`), and `Type` (count). Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the AWS Glue Metrics Dashboard, a SUM statistic is used for aggregation.

Metric	Description
	Unit: Bytes Can be used to monitor: • Bytes read. • Job progress. • JDBC data sources. • Job Bookmark Issues. • Variance across Job Runs. This metric can be used the same way as the `glue.ALL.s3.filesystem.read_bytes` metric, with the difference that this metric is updated at the end of a Spark task and captures non-S3 data sources as well.

Metric	Description
`glue.driver.aggregate.elapsedTime`	The ETL elapsed time in milliseconds (does not include the job bootstrap times). Valid dimensions: `JobName` (the name of the AWS Glue Job), `JobRunId` (the JobRun ID. or `ALL`), and `Type` (count). Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the AWS Glue Metrics Dashboard, a SUM statistic is used for aggregation. Unit: Milliseconds Can be used to determine how long it takes a job run to run on average. Some ways to use the data: • Set alarms for stragglers. • Measure variance across job runs.

Metric	Description
`glue.driver.aggregate.numCompletedStages`	The number of completed stages in the job. Valid dimensions: `JobName` (the name of the AWS Glue Job), `JobRunId` (the JobRun ID. or `ALL`), and `Type` (count). Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the AWS Glue Metrics Dashboard, a SUM statistic is used for aggregation. Unit: Count Can be used to monitor: • Job progress. • Per-stage timeline of job execution,when correlated with other metrics. Some ways to use the data: • Identify demanding stages in the execution of a job. • Set alarms for correlated spikes (demanding stages) across job runs.

Metric	Description
`glue.driver.aggregate.numCompletedTasks`	The number of completed tasks in the job. Valid dimensions: `JobName` (the name of the AWS Glue Job), `JobRunId` (the JobRun ID. or `ALL`), and `Type` (count). Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the AWS Glue Metrics Dashboard, a SUM statistic is used for aggregation. Unit: Count Can be used to monitor: • Job progress. • Parallelism within a stage.

Metric	Description
`glue.driver.aggregate.numFailedTasks`	The number of failed tasks. Valid dimensions: `JobName` (the name of the AWS Glue Job), `JobRunId` (the JobRun ID. or `ALL`), and `Type` (count). Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the AWS Glue Metrics Dashboard, a SUM statistic is used for aggregation. Unit: Count Can be used to monitor: • Data abnormalities that cause job tasks to fail. • Cluster abnormalities that cause job tasks to fail. • Script abnormalities that cause job tasks to fail. The data can be used to set alarms for increased failures that might suggest abnormalities in data, cluster or scripts.

Metric	Description
`glue.driver.aggregate.numKilledTasks`	The number of tasks killed. Valid dimensions: `JobName` (the name of the AWS Glue Job), `JobRunId` (the JobRun ID. or `ALL`), and `Type` (count). Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the AWS Glue Metrics Dashboard, a SUM statistic is used for aggregation. Unit: Count Can be used to monitor: • Abnormalities in Data Skew that result in exceptions (OOMs) that kill tasks. • Script abnormalities that result in exceptions (OOMs) that kill tasks. Some ways to use the data: • Set alarms for increased failures indicating data abnormalities. • Set alarms for increased failures indicating cluster abnormalities. • Set alarms for increased failures indicating script abnormalities.

Metric	Description
`glue.driver.aggregate.recordsRead`	The number of records read from all data sources by all completed Spark tasks running in all executors. Valid dimensions: `JobName` (the name of the AWS Glue Job), `JobRunId` (the JobRun ID. or `ALL`), and `Type` (count). Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the AWS Glue Metrics Dashboard, a SUM statistic is used for aggregation. Unit: Count Can be used to monitor: • Records read. • Job progress. • JDBC data sources. • Job Bookmark Issues. • Skew in Job Runs over days. This metric can be used in a similar way to the `glue.ALL.s3.filesystem.read_bytes` metric, with the difference that this metric is updated at the end of a Spark task.

Metric	Description
`glue.driver.aggregate.shuffleBytesWritten`	The number of bytes written by all executors to shuffle data between them since the previous report (aggregated by the AWS Glue Metrics Dashboard as the number of bytes written for this purpose during the previous minute). Valid dimensions: `JobName` (the name of the AWS Glue Job), `JobRunId` (the JobRun ID. or `ALL`), and `Type` (count). Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the AWS Glue Metrics Dashboard, a SUM statistic is used for aggregation. Unit: Bytes Can be used to monitor: Data shuffle in jobs (large joins, groupBy, repartition, coalesce). Some ways to use the data: • Repartition or decompress large input files before further processing. • Repartition data more uniformly to avoid hot keys. • Pre-filter data before joins or groupBy operations.

Metric	Description
`glue.driver.aggregate.shuffleLocalBytesRead`	The number of bytes read by all executors to shuffle data between them since the previous report (aggregated by the AWS Glue Metrics Dashboard as the number of bytes read for this purpose during the previous minute). Valid dimensions: `JobName` (the name of the AWS Glue Job), `JobRunId` (the JobRun ID. or `ALL`), and `Type` (count). Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the AWS Glue Metrics Dashboard, a SUM statistic is used for aggregation. Unit: Bytes Can be used to monitor: Data shuffle in jobs (large joins, groupBy, repartition, coalesce). Some ways to use the data: • Repartition or decompress large input files before further processing. • Repartition data more uniformly using hot keys. • Pre-filter data before joins or groupBy operations.

Metric	Description
`glue.driver.BlockManager.disk.diskSpaceUsed_MB`	The number of megabytes of disk space used across all executors. Valid dimensions: `JobName` (the name of the AWS Glue Job), `JobRunId` (the JobRun ID. or `ALL`), and `Type` (gauge). Valid Statistics: Average. This is a Spark metric, reported as an absolute value. Unit: Megabytes Can be used to monitor: • Disk space used for blocks that represent cached RDD partitions. • Disk space used for blocks that represent intermediate shuffle outputs. • Disk space used for blocks that represent broadcasts. Some ways to use the data: • Identify job failures due to increased disk usage. • Identify large partitions resulting in spilling or shuffling. • Increase provisioned DPU capacity to correct these issues.

Metric	Description
`glue.driver.ExecutorAllocationManager.executors.numberAllExecutors`	The number of actively running job executors. Valid dimensions: `JobName` (the name of the AWS Glue Job), `JobRunId` (the JobRun ID. or `ALL`), and `Type` (gauge). Valid Statistics: Average. This is a Spark metric, reported as an absolute value. Unit: Count Can be used to monitor: • Job activity. • Straggling executors (with a few executors running only) • Current executor-level parallelism. Some ways to use the data: • Repartition or decompress large input files beforehand if cluster is under-utilized. • Identify stage or job execution delays due to straggler scenarios. • • Compare with numberMaxNeededExecutors to understand backlog for provisioning more DPUs.

Metric	Description
`glue.driver.ExecutorAllocationManager.executors.numberMaxNeededExecutors`	The number of maximum (actively running and pending) job executors needed to satisfy the current load. Valid dimensions: `JobName` (the name of the AWS Glue Job), `JobRunId` (the JobRun ID. or `ALL`), and `Type` (gauge). Valid Statistics: Maximum. This is a Spark metric, reported as an absolute value. Unit: Count Can be used to monitor: • Job activity. • Current executor-level parallelism and backlog of pending tasks not yet scheduled because of unavailable executors due to DPU capacity or killed/failed executors. Some ways to use the data: • Identify pending/backlog of scheduling queue. • Identify stage or job execution delays due to straggler scenarios. • Compare with numberAllExecutors to understand backlog for provisioning more DPUs. • Increase provisioned DPU capacity to correct the pending executor backlog.

Metric	Description

`glue.driver.jvm.heap.usage`
 	
`glue.`*executorId*`.jvm.heap.usage`
 	
`glue.ALL.jvm.heap.usage`
	The fraction of memory used by the JVM heap for this driver (scale: 0-1) for driver, executor identified by executorId, or ALL executors.
	
	Valid dimensions: `JobName` (the name of the AWS Glue Job), `JobRunId` (the JobRun ID. or `ALL`), and `Type` (gauge).
	
	Valid Statistics: Average. This is a Spark metric, reported as an absolute value.
	
	Unit: Percentage
	
	Can be used to monitor:
	
	• Driver out-of-memory conditions (OOM) using `glue.driver.jvm.heap.usage` .
	• Executor out-of-memory conditions (OOM) using `glue.ALL.jvm.heap.usage` .
	
	Some ways to use the data:
	
	• Identify memory-consuming executor ids and stages.
	• Identify straggling executor ids and stages.
	• Identify a driver out-of-memory condition (OOM).
	• Identify an executor out-of-memory condition (OOM) and obtain the corresponding executor ID so as to be able to get a stack trace from the executor log.
	• Identify files or partitions that may have data skew resulting in stragglers or out-of-memory conditions (OOMs).

Metric	Description

`glue.driver.jvm.heap.used`
 	
`glue.`*executorId*`.jvm.heap.used`
 	
`glue.ALL.jvm.heap.used`
	The number of memory bytes used by the JVM heap for the driver, the executor identified by *executorId*, or ALL executors.
	
	Valid dimensions: `JobName` (the name of the AWS Glue Job), `JobRunId` (the JobRun ID. or `ALL`), and `Type` (gauge).
	
	Valid Statistics: Average. This is a Spark metric, reported as an absolute value.
	
	Unit: Bytes
	
	Can be used to monitor:
	
	• Driver out-of-memory conditions (OOM).
	• Executor out-of-memory conditions (OOM).
	
	Some ways to use the data:
	
	• Identify memory-consuming executor ids and stages.
	• Identify straggling executor ids and stages.
	• Identify a driver out-of-memory condition (OOM).
	• Identify an executor out-of-memory condition (OOM) and obtain the corresponding executor ID so as to be able to get a stack trace from the executor log.
	• Identify files or partitions that may have data skew resulting in stragglers or out-of-memory conditions (OOMs).

Metric	Description

`glue.driver.s3.filesystem.read_bytes`
 	
`glue.`*executorId*`.s3.filesystem.read_bytes`
 	
`glue.ALL.s3.filesystem.read_bytes`
	The number of bytes read from Amazon S3 by the driver, an executor identified by *executorId*, or ALL executors since the previous report (aggregated by the AWS Glue Metrics Dashboard as the number of bytes read during the previous minute).
	
	Valid dimensions: `JobName`, `JobRunId`, and `Type` (gauge).
	
	Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the AWS Glue Metrics Dashboard a SUM statistic is used for aggregation. The area under the curve on the AWS Glue Metrics Dashboard can be used to visually compare bytes read by two different job runs.
	
	Unit: Bytes.
	
	Can be used to monitor:
	
	• ETL data movement.
	• Job progress.
	• Job bookmark issues (data processed, reprocessed, and skipped).
	• Comparison of reads to ingestion rate from external data sources.
	• Variance across job runs.
	
	Resulting data can be used for:
	
	• DPU capacity planning.
	• Setting alarms for large spikes or dips in data read for job runs and job stages.

Metric	Description

`glue.driver.s3.filesystem.write_bytes`
 	
`glue.`*executorId*`.s3.filesystem.write_bytes`
 	
`glue.ALL.s3.filesystem.write_bytes`
	The number of bytes written to Amazon S3 by the driver, an executor identified by *executorId*, or ALL executors since the previous report (aggregated by the AWS Glue Metrics Dashboard as the number of bytes written during the previous minute).
	
	Valid dimensions: `JobName`, `JobRunId`, and `Type` (gauge).
	
	Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the AWS Glue Metrics Dashboard a SUM statistic is used for aggregation. The area under the curve on the AWS Glue Metrics Dashboard can be used to visually compare bytes written by two different job runs.
	
	Unit: Bytes
	
	Can be used to monitor:
	
	• ETL data movement.
	• Job progress.
	• Job bookmark issues (data processed, reprocessed, and skipped).
	• Comparison of reads to ingestion rate from external data sources.
	• Variance across job runs.
	
	Some ways to use the data:
	
	• DPU capacity planning.
	• Setting alarms for large spikes or dips in data read for job runs and job stages.

Metric	Description
glue.driver.streaming.numRecords	The number of records that are received in a micro-batch. This metric is only available for AWS Glue streaming jobs with AWS Glue version 2.0 and above. Valid dimensions: JobName (the name of the AWS Glue job), JobRunId (the JobRun ID. or ALL), and Type (count). Valid Statistics: Sum, Maximum, Minimum, Average, Percentile Unit: Count Can be used to monitor: • Records read. • Job progress.
glue.driver.streaming.batchProcessingTimeInMs	The time it takes to process the batches in milliseconds. This metric is only available for AWS Glue streaming jobs with AWS Glue version 2.0 and above. Valid dimensions: JobName (the name of the AWS Glue job), JobRunId (the JobRun ID. or ALL), and Type (count). Valid Statistics: Sum, Maximum, Minimum, Average, Percentile Unit: Count Can be used to monitor: • Job progress. • Script performance.

Metric	Description

`glue.driver.system.cpuSystemLoad`
 	
`glue.`*executorId*`.system.cpuSystemLoad`
 	
`glue.ALL.system.cpuSystemLoad`
	The fraction of CPU system load used (scale: 0-1) by the driver, an executor identified by *executorId*, or ALL executors.
	
	Valid dimensions: `JobName` (the name of the AWS Glue job), `JobRunId` (the JobRun ID. or `ALL`), and `Type` (gauge).
	
	Valid Statistics: Average. This metric is reported as an absolute value.
	
	Unit: Percentage
	
	Can be used to monitor:
	
	• Driver CPU load.
	• Executor CPU load.
	• Detecting CPU-bound or IO-bound executors or stages in a Job.
	
	Some ways to use the data:
	
	• DPU capacity Planning along with IO Metrics (Bytes Read/Shuffle Bytes, Task Parallelism) and the number of maximum needed executors metric.
	• Identify the CPU/IO-bound ratio. This allows for repartitionioning and increasing provisioned capacity for long-running jobs with splittable datasets having lower CPU utilization.

Dimensions for AWS Glue Metrics

AWS Glue metrics use the AWS Glue namespace and provide metrics for the following dimensions:

Dimension	Description
`JobName`	This dimension filters for metrics of all job runs of a specific AWS Glue job.
`JobRunId`	This dimension filters for metrics of a specific AWS Glue job run by a JobRun ID, or `ALL`.
`Type`	This dimension filters for metrics by either `count` (an aggregate number) or `gauge` (a value at a point in time).

For more information, see the Amazon CloudWatch User Guide.

Setting up Amazon CloudWatch alarms on AWS Glue job profiles

AWS Glue metrics are also available in Amazon CloudWatch. You can set up alarms on any AWS Glue metric for scheduled jobs.

A few common scenarios for setting up alarms are as follows:

- Jobs running out of memory (OOM): Set an alarm when the memory usage exceeds the normal average for either the driver or an executor for an AWS Glue job.
- Straggling executors: Set an alarm when the number of executors falls below a certain threshold for a large duration of time in an AWS Glue job.
- Data backlog or reprocessing: Compare the metrics from individual jobs in a workflow using a CloudWatch math expression. You can then trigger an alarm on the resulting expression value (such as the ratio of bytes written by a job and bytes read by a following job).

For detailed instructions on setting alarms, see Create or Edit a CloudWatch Alarm in the *Amazon CloudWatch Events User Guide*.

For monitoring and debugging scenarios using CloudWatch, see Job monitoring and debugging.

Logging for AWS Glue jobs

In AWS Glue 5.0, all jobs have real-time logging capabilities. Additionally, you can specify custom configuration options to tailor the logging behavior. These options include setting the Amazon

CloudWatch log group name, the Amazon CloudWatch log stream prefix (which will precede the AWS Glue job run ID and driver/executor ID), and the log conversion pattern for log messages. These configurations allow you to aggregate logs in custom Amazon CloudWatch log groups with different expiration policies. Furthermore, you can analyze the logs more effectively by using custom log stream prefixes and conversion patterns. This level of customization enables you to optimize log management and analysis according to your specific requirements.

Logging behavior in AWS Glue 5.0

By default, system logs, Spark daemon logs, and user AWS Glue Logger logs are written to the `/aws-glue/jobs/error` log group in Amazon CloudWatch. On the other hand, user stdout (standard output) and stderr (standard error) logs are written to the `/aws-glue/jobs/output` log group by default.

Custom logging

You can customize the default log group and log stream prefixes using the following job arguments:

- `--custom-logGroup-prefix`: Allows you to specify a custom prefix for the `/aws-glue/jobs/error` and `/aws-glue/jobs/output` log groups. If you provide a custom prefix, the log group names will be in the following format:
  - `/aws-glue/jobs/error` will be *`<customer prefix>`*`/error`
  - `/aws-glue/jobs/output` will be *`<customer prefix>`*`/output`
- `--custom-logStream-prefix`: Allows you to specify a custom prefix for the log stream names within the log groups. If you provide a custom prefix, the log stream names will be in the following format:
  - `jobrunid-driver` will be *`<customer log stream>`*`-driver`
  - `jobrunid-executorNum` will be *`<customer log stream>`*`-executorNum`

Validation rules and limitations for custom prefixes:

- The entire log stream name must be between 1 and 512 characters long.
- The custom prefix itself is restricted to 400 characters.
- The custom prefix must match the regular expression pattern `[^:*]*` (special characters allowed are '_', '-', and '/').

Logging application-specific messages using the custom script logger

You can use the AWS Glue logger to log any application-specific messages in the script that are sent in real time to the driver log stream.

The following example shows a Python script.

```
from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)
logger = glueContext.get_logger()
logger.info("info message")
logger.warn("warn message")
logger.error("error message")
```

The following example shows a Scala script.

```
import com.amazonaws.services.glue.log.GlueLogger

object GlueApp {
  def main(sysArgs: Array[String]) {
    val logger = new GlueLogger
    logger.info("info message")
    logger.warn("warn message")
    logger.error("error message")
  }
}
```

Enabling the progress bar to show job progress

AWS Glue provides a real-time progress bar under the `JOB_RUN_ID-progress-bar` log stream to check AWS Glue job run status. Currently it supports only jobs that initialize `glueContext`. If you run a pure Spark job without initializing `glueContext`, the AWS Glue progress bar does not appear.

The progress bar shows the following progress update every 5 seconds.

```
Stage Number (Stage Name): > (numCompletedTasks + numActiveTasks) /
 totalNumOfTasksInThisStage]
```

Security configuration with Amazon CloudWatch logging

When a security configuration is enabled for Amazon CloudWatch logs, AWS Glue creates log groups with specific naming patterns that incorporate the security configuration name.

Log group naming with security configuration

The default and custom log groups will be as follows:

- **Default error log group:** `/aws-glue/jobs/`*`Security-Configuration-Name`*`-role/`*`glue-job-role`*`/error`
- **Default output log group:** `/aws-glue/jobs/`*`Security-Configuration-Name`*`-role/`*`glue-job-role`*`/output`
- **Custom error log group (AWS Glue 5.0):** *`custom-log-group-prefix`*`/`*`Security-Configuration-Name`*`-role/`*`glue-job-role`*`/error`
- **Custom output log group (AWS Glue 5.0):** *`custom-log-group-prefix`*`/`*`Security-Configuration-Name`*`-role/`*`glue-job-role`*`/output`

Required IAM Permissions

You need to add the `logs:AssociateKmsKey` permission to your IAM role permissions, if you enable a security configuration with Amazon CloudWatch Logs. If that permission is not included, continuous logging will be disabled.

Also, to configure the encryption for the Amazon CloudWatch Logs, follow the instructions at Encrypt Log Data in Amazon CloudWatch Logs Using AWS Key Management Service in the Amazon Amazon CloudWatch Logs User Guide.

Additional Information

For more information on creating security configurations, see Managing security configurations on the AWS Glue console.

- Enabling continuous logging for AWS Glue 4.0 and earlier jobs
- Viewing logs for AWS Glue jobs

Enabling continuous logging for AWS Glue 4.0 and earlier jobs

> **Note**
>
> In AWS Glue 4.0 and earlier versions, continuous logging was an available feature. However, with the introduction of AWS Glue 5.0, all jobs have real-time logging capability. For more details on the logging capabilities and configuration options in AWS Glue 5.0, see Logging for AWS Glue jobs.

You can enable continuous logging using the AWS Glue console or through the AWS Command Line Interface (AWS CLI).

You can enable continuous logging when you create a new job, edit an existing job, or enable it through the AWS CLI.

You can also specify custom configuration options such as the Amazon CloudWatch log group name, CloudWatch log stream prefix before the AWS Glue job run ID driver/executor ID, and log conversion pattern for log messages. These configurations help you to set aggregate logs in custom CloudWatch log groups with different expiration policies, and analyze them further with custom log stream prefixes and conversions patterns.

Topics

- Using the AWS Management Console
- Logging application-specific messages using the custom script logger
- Enabling the progress bar to show job progress
- Security configuration with continuous logging

Using the AWS Management Console

Follow these steps to use the console to enable continuous logging when creating or editing an AWS Glue job.

To create a new AWS Glue job with continuous logging

1. Sign in to the AWS Management Console and open the AWS Glue console at https://console.aws.amazon.com/glue/.
2. In the navigation pane, choose **ETL jobs**.

3. Choose **Visual ETL**.
4. In the **Job details** tab, expand the **Advanced properties** section.
5. Under **Continuous logging** select **Enable logs in CloudWatch**.

To enable continuous logging for an existing AWS Glue job

1. Open the AWS Glue console at https://console.aws.amazon.com/glue/.
2. In the navigation pane, choose **Jobs**.
3. Choose an existing job from the **Jobs** list.
4. Choose **Action**, **Edit job**.
5. In the **Job details** tab, expand the **Advanced properties** section.
6. Under **Continuous logging** select **Enable logs in CloudWatch**.

Using the AWS CLI

To enable continuous logging, you pass in job parameters to an AWS Glue job. Pass the following special job parameters similar to other AWS Glue job parameters. For more information, see Using job parameters in AWS Glue jobs.

```
'--enable-continuous-cloudwatch-log': 'true'
```

You can specify a custom Amazon CloudWatch log group name. If not specified, the default log group name is `/aws-glue/jobs/logs-v2`.

```
'--continuous-log-logGroup': 'custom_log_group_name'
```

You can specify a custom Amazon CloudWatch log stream prefix. If not specified, the default log stream prefix is the job run ID.

```
'--continuous-log-logStreamPrefix': 'custom_log_stream_prefix'
```

You can specify a custom continuous logging conversion pattern. If not specified, the default conversion pattern is `%d{yy/MM/dd HH:mm:ss} %p %c{1}: %m%n`. Note that the conversion pattern only applies to driver logs and executor logs. It does not affect the AWS Glue progress bar.

```
'--continuous-log-conversionPattern': 'custom_log_conversion_pattern'
```

Logging application-specific messages using the custom script logger

You can use the AWS Glue logger to log any application-specific messages in the script that are sent in real time to the driver log stream.

The following example shows a Python script.

```
from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)
logger = glueContext.get_logger()
logger.info("info message")
logger.warn("warn message")
logger.error("error message")
```

The following example shows a Scala script.

```
import com.amazonaws.services.glue.log.GlueLogger

object GlueApp {
  def main(sysArgs: Array[String]) {
    val logger = new GlueLogger
    logger.info("info message")
    logger.warn("warn message")
    logger.error("error message")
  }
}
```

Enabling the progress bar to show job progress

AWS Glue provides a real-time progress bar under the `JOB_RUN_ID-progress-bar` log stream to check AWS Glue job run status. Currently it supports only jobs that initialize `glueContext`. If you run a pure Spark job without initializing `glueContext`, the AWS Glue progress bar does not appear.

The progress bar shows the following progress update every 5 seconds.

```
Stage Number (Stage Name): > (numCompletedTasks + numActiveTasks) /
 totalNumOfTasksInThisStage]
```

Security configuration with continuous logging

If a security configuration is enabled for CloudWatch logs, AWS Glue will create a log group named as follows for continuous logs:

```
<Log-Group-Name>-<Security-Configuration-Name>
```

The default and custom log groups will be as follows:

- The default continuous log group will be `/aws-glue/jobs/error-`*`<Security-Configuration-Name>`*
- The custom continuous log group will be *`<custom-log-group-name>`*`-`*`<Security-Configuration-Name>`*

You need to add the `logs:AssociateKmsKey` to your IAM role permissions, if you enable a security configuration with CloudWatch Logs. If that permission is not included, continuous logging will be disabled. Also, to configure the encryption for the CloudWatch Logs, follow the instructions at Encrypt Log Data in CloudWatch Logs Using AWS Key Management Service in the *Amazon CloudWatch Logs User Guide*.

For more information on creating security configurations, see Managing security configurations on the AWS Glue console.

> **Note**
>
> You may incur additional charges when you enable logging and additional CloudWatch log events are created. For more information, see Amazon CloudWatch pricing .

Viewing logs for AWS Glue jobs

You can view real-time logs using the AWS Glue console or the Amazon CloudWatch console.

To view real-time logs using the AWS Glue console dashboard

1. Sign in to the AWS Management Console and open the AWS Glue console at https://console.aws.amazon.com/glue/.
2. In the navigation pane, choose **Jobs**.

3. Add or start an existing job. Choose **Action**, **Run job**.

   When you start running a job, you navigate to a page that contains information about the running job:

   - The **Logs** tab shows the older aggregated application logs.
   - The **Logs** tab shows a real-time progress bar when the job is running with `glueContext` initialized.
   - The **Logs** tab also contains the **Driver logs**, which capture real-time Apache Spark driver logs, and application logs from the script logged using the AWS Glue application logger when the job is running.
4. For older jobs, you can also view the real-time logs under the **Job History** view by choosing **Logs**. This action takes you to the CloudWatch console that shows all Spark driver, executor, and progress bar log streams for that job run.

To view real-time logs using the CloudWatch console dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Log**.
3. Choose the **/aws-glue/jobs/error/** log group.
4. In the **Filter** box, paste the job run ID.

   You can view the driver logs, executor logs, and progress bar (if using the **Standard filter**).

Monitoring with AWS Glue Observability metrics

> **Note**
>
> AWS Glue Observability metrics is available on AWS Glue 4.0 and later versions.

Use AWS Glue Observability metrics to generate insights into what is happening inside your AWS Glue for Apache Spark jobs to improve triaging and analysis of issues. Observability metrics are visualized through Amazon CloudWatch dashboards and can be used to help perform root cause analysis for errors and for diagnosing performance bottlenecks. You can reduce the time spent debugging issues at scale so you can focus on resolving issues faster and more effectively.

AWS Glue Observability provides Amazon CloudWatch metrics categorized in following four groups:

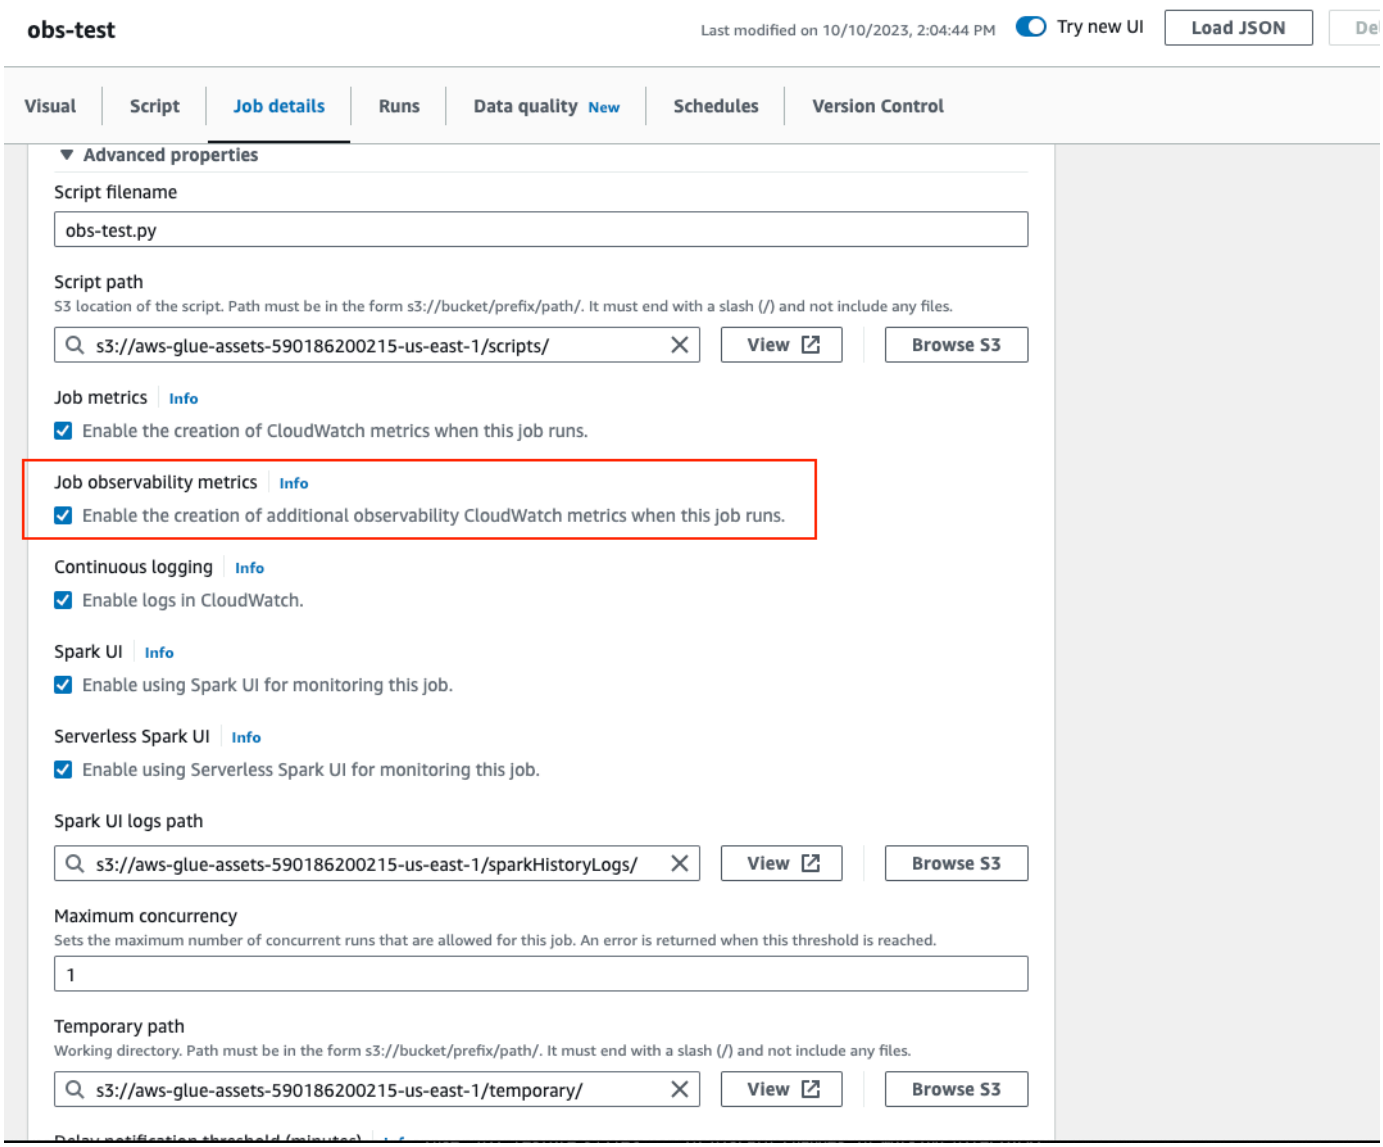
- **Reliability (i.e., Errors Classes)** – easily identify the most common failure reasons at given time range that you may want to address.
- **Performance (i.e., Skewness)** – identify a performance bottleneck and apply tuning techniques. For example, when you experience degraded performance due to job skewness, you may want to enable Spark Adaptive Query Execution and fine-tune the skew join threshold.
- **Throughput (i.e., per source/sink throughput)** – monitor trends of data reads and writes. You can also configure Amazon CloudWatch alarms for anomalies.
- **Resource Utilization (i.e., workers, memory and disk utilization)** – efficiently find the jobs with low capacity utilization. You may want to enable AWS Glue auto-scaling for those jobs.

Getting started with AWS Glue Observability metrics

> **Note**
>
> The new metrics are enabled by default in the AWS Glue Studio console.

To configure observability metrics in AWS Glue Studio:

1. Log in to the AWS Glue console and choose **ETL jobs** from the console menu.
2. Choose a job by clicking on the job name in the **Your jobs** section.
3. Choose the **Job details** tab.
4. Scroll to the bottom and choose **Advanced properties**, then **Job observability metrics**.



To enable AWS Glue Observability metrics using AWS CLI:

- Add to the `--default-arguments` map the following key-value in the input JSON file:

```
--enable-observability-metrics, true
```

Using AWS Glue observability

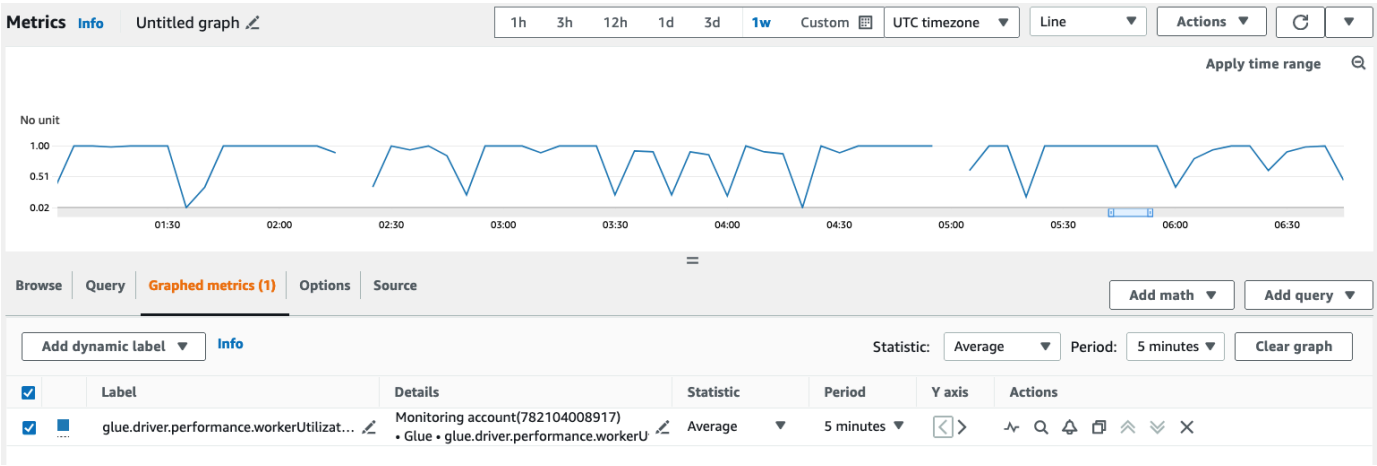
Because the AWS Glue observability metrics is provided through Amazon CloudWatch, you can use the Amazon CloudWatch console, AWS CLI, SDK or API to query the observability metrics

datapoints. See Using Glue Observability for monitoring resource utilization to reduce cost for an example use case when to use AWS Glue observability metrics.

Using AWS Glue observability in the Amazon CloudWatch console

To query and visualize metrics in the Amazon CloudWatch console:

1. Open the Amazon CloudWatch console and choose **All metrics**.
2. Under custom namespaces, choose **AWS Glue**.
3. Choose **Job Observability Metrics, Observability Metrics Per Source, or Observability Metrics Per Sink** .
4. Search for the specific metric name, job name, job run ID, and select them.
5. Under the **Graphed metrics** tab, configure your preferred statistic, period, and other options.



To query an Observability metric using AWS CLI:

1. Create a metric definition JSON file and replace `your-Glue-job-name`and `your-Glue-job-run-id` with yours.

```
$ cat multiplequeries.json
[
    {
        "Id": "avgWorkerUtil_0",
        "MetricStat": {
            "Metric": {
                "Namespace": "Glue",
                "MetricName": "glue.driver.workerUtilization",
                "Dimensions": [
```

```
                    {
                        "Name": "JobName",
                        "Value": "<your-Glue-job-name-A>"
                    },
                    {
                        "Name": "JobRunId",
                        "Value": "<your-Glue-job-run-id-A>"
                    },
                    {
                        "Name": "Type",
                        "Value": "gauge"
                    },
                    {
                        "Name": "ObservabilityGroup",
                        "Value": "resource_utilization"
                    }
                ]
            },
            "Period": 1800,
            "Stat": "Minimum",
            "Unit": "None"
        }
    },
    {
        "Id": "avgWorkerUtil_1",
        "MetricStat": {
            "Metric": {
                "Namespace": "Glue",
                "MetricName": "glue.driver.workerUtilization",
                "Dimensions": [
                    {
                        "Name": "JobName",
                        "Value": "<your-Glue-job-name-B>"
                    },
                    {
                        "Name": "JobRunId",
                        "Value": "<your-Glue-job-run-id-B>"
                    },
                    {
                        "Name": "Type",
                        "Value": "gauge"
                    },
                    {
                        "Name": "ObservabilityGroup",
```

```
                        "Value": "resource_utilization"
                    }
                ]
            },
            "Period": 1800,
            "Stat": "Minimum",
            "Unit": "None"
        }
    }
]
```

2. Run the `get-metric-data` command:

```
$ aws cloudwatch get-metric-data --metric-data-queries file: //multiplequeries.json
 \
     --start-time '2023-10-28T18: 20' \
     --end-time '2023-10-28T19: 10'  \
     --region us-east-1
{
    "MetricDataResults": [
        {
            "Id": "avgWorkerUtil_0",
            "Label": "<your-label-for-A>",
            "Timestamps": [
                "2023-10-28T18:20:00+00:00"
            ],
            "Values": [
                0.06718750000000001
            ],
            "StatusCode": "Complete"
        },
        {
            "Id": "avgWorkerUtil_1",
            "Label": "<your-label-for-B>",
            "Timestamps": [
                "2023-10-28T18:50:00+00:00"
            ],
            "Values": [
                0.5959183673469387
            ],
            "StatusCode": "Complete"
        }
```

```
    ],
    "Messages": []
}
```

Observability metrics

AWS Glue Observability profiles and sends the following metrics to Amazon CloudWatch every 30 seconds, and some of these metrics can be visible in the AWS Glue Studio Job Runs Monitoring Page.

Metric	Description	Category
glue.driver.skewness.stage	Metric Category: job_performance The spark stages execution Skewness: this metric is an indicator of how long the maximum task duration time in a certain stage is compared to the median task duration in this stage. It captures execution skewness, which might be caused by input data skewness or by a transformation (e.g., skewed join). The values of this metric falls into the range of [0, infinity[, where 0 means the ratio of the maximum to median tasks' execution time, among all tasks in the stage is less than a certain stage skewness factor. The default stage skewness factor is `5` and it can be overwritten via	job_performance

Metric	Description	Category
	spark conf: spark.metrics.conf.driver.source.glue.jobPerformance.skewnessFactor A stage skewness value of 1 means the ratio is twice the stage skewness factor. The value of stage skewness is updated every 30 seconds to reflect the current skewness. The value at the end of the stage reflects the final stage skewness. This stage-level metric is used to calculate the job-level metric `glue.driver.skewness.job` . Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (job_performance) Valid Statistics: Average, Maximum, Minimum, Percentile Unit: Count	

Metric	Description	Category
glue.driver.skewness.job	Metric Category: job_performance Job skewness is the maximum of weighted skewness of all stages. The stage skewness (glue.driver.skewness.stage) is weighted with stage duration. This is to avoid the corner case when a very skewed stage is actually running for very short time relative to other stages (and thus its skewness is not significant for the overall job performance and does not worth the effort to try to address its skewness). This metric is updated upon completion of each stage, and thus the last value reflects the actual overall job skewness. Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (job_performance) Valid Statistics: Average, Maximum, Minimum, Percentile Unit: Count	job_performance

Metric	Description	Category
glue.succeed.ALL	Metric Category: error Total number of successfu l job runs, to complete the picture of failures categories Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (count), and ObservabilityGroup (error) Valid Statistics: SUM Unit: Count	error
glue.error.ALL	Metric Category: error Total number of job run errors, to complete the picture of failures categories Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (count), and ObservabilityGroup (error) Valid Statistics: SUM Unit: Count	error

Metric	Description	Category
glue.error.[error category]	Metric Category: error This is actually a set of metrics, that are updated only when a job run fails. The error categorization helps with triaging and debugging. When a job run fails, the error causing the failure is categorized and the corresponding error category metric is set to 1. This helps to perform over time failures analysis, as well as over all jobs error analysis to identify most common failure categories to start addressing them. AWS Glue has 28 error categorie s, including OUT_OF_ME MORY (driver and executor) , PERMISSION, SYNTAX and THROTTLING error categories. Error categories also include COMPILATION, LAUNCH and TIMEOUT error categories. Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (count), and ObservabilityGroup (error) Valid Statistics: SUM	error

Metric	Description	Category
	Unit: Count	
glue.driver.workerUtilization	Metric Category: resource_utilization The percentage of the allocated workers which are actually used. If not good, auto scaling can help. Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (resource_utilization) Valid Statistics: Average, Maximum, Minimum, Percentile Unit: Percentage	resource_utilization

Metric	Description	Category
glue.driver.memory.heap.[available | used]	Metric Category: resource_utilization The driver's available / used heap memory during the job run. This helps to understand memory usage trends, especially over time, which can help avoid potential failures, in addition to debugging memory related failures. Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (resource_utilization) Valid Statistics: Average Unit: Bytes	resource_utilization

Metric	Description	Category
glue.driver.memory.heap.used.percentage	Metric Category: resource_utilization The driver's used (%) heap memory during the job run. This helps to understand memory usage trends, especially over time, which can help avoid potential failures, in addition to debugging memory related failures. Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (resource_utilization) Valid Statistics: Average Unit: Percentage	resource_utilization

Metric	Description	Category
glue.driver.memory.non-heap .[available | used]	Metric Category: resource_ utilization The driver's available / used non-heap memory during the job run. This helps to understand memory usage trensd, especially over time, which can help avoid potential failures, in addition to debugging memory related failures. Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (resource _utilization) Valid Statistics: Average Unit: Bytes	resource_utilization

Metric	Description	Category
glue.driver.memory.non-heap.used.percentage	Metric Category: resource_utilization The driver's used (%) non-heap memory during the job run. This helps to understand memory usage trends, especially over time, which can help avoid potential failures, in addition to debugging memory related failures. Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (resource_utilization) Valid Statistics: Average Unit: Percentage	resource_utilization

Metric	Description	Category
glue.driver.memory.total.[available | used]	Metric Category: resource_utilization The driver's available / used total memory during the job run. This helps to understand memory usage trends, especially over time, which can help avoid potential failures, in addition to debugging memory related failures. Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (resource_utilization) Valid Statistics: Average Unit: Bytes	resource_utilization

Metric	Description	Category
glue.driver.memory.total.used.percentage	Metric Category: resource_utilization The driver's used (%) total memory during the job run. This helps to understand memory usage trends, especially over time, which can help avoid potential failures, in addition to debugging memory related failures. Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (resource_utilization) Valid Statistics: Average Unit: Percentage	resource_utilization

Metric	Description	Category
glue.ALL.memory.heap.[available | used]	Metric Category: resource_utilization The executors' available/used heap memory. ALL means all executors. Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (resource_utilization) Valid Statistics: Average Unit: Bytes	resource_utilization
glue.ALL.memory.heap.used.percentage	Metric Category: resource_utilization The executors' used (%) heap memory. ALL means all executors. Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (resource_utilization) Valid Statistics: Average Unit: Percentage	resource_utilization

Metric	Description	Category
glue.ALL.memory.non-heap.[available | used]	Metric Category: resource_utilization The executors' available/used non-heap memory. ALL means all executors. Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (resource_utilization) Valid Statistics: Average Unit: Bytes	resource_utilization
glue.ALL.memory.non-heap.used.percentage	Metric Category: resource_utilization The executors' used (%) non-heap memory. ALL means all executors. Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (resource_utilization) Valid Statistics: Average Unit: Percentage	resource_utilization

Metric	Description	Category
glue.ALL.memory.total.[available | used]	Metric Category: resource_utilization The executors' available/used total memory. ALL means all executors. Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (resource_utilization) Valid Statistics: Average Unit: Bytes	resource_utilization
glue.ALL.memory.total.used.percentage	Metric Category: resource_utilization The executors' used (%) total memory. ALL means all executors. Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (resource_utilization) Valid Statistics: Average Unit: Percentage	resource_utilization

Metric	Description	Category
glue.driver.disk.[available_GB | used_GB]	Metric Category: resource_utilization The driver's available/used disk space during the job run. This helps to understand disk usage trends, especially over time, which can help avoid potential failures, in addition to debugging not enought disk space related failures. Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (resource_utilization) Valid Statistics: Average Unit: Gigabytes	resource_utilization

Metric	Description	Category
glue.driver.disk.used.percentage]	Metric Category: resource_utilization The driver's available/used disk space during the job run. This helps to understand disk usage trends, especially over time, which can help avoid potential failures, in addition to debugging not enought disk space related failures. Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (resource_utilization) Valid Statistics: Average Unit: Percentage	resource_utilization

Metric	Description	Category
glue.ALL.disk.[available_GB | used_GB]	Metric Category: resource_utilization The executors' available/used disk space. ALL means all executors. Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (resource_utilization) Valid Statistics: Average Unit: Gigabytes	resource_utilization
glue.ALL.disk.used.percentage	Metric Category: resource_utilization The executors' available/used/used(%) disk space. ALL means all executors. Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (resource_utilization) Valid Statistics: Average Unit: Percentage	resource_utilization

Metric	Description	Category
glue.driver.bytesRead	Metric Category: throughput The number of bytes read per input source in this job run, as well as well as for ALL sources. This helps understand the data volume and its changes over time, which helps addressing issues such as data skewness. Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), ObservabilityGroup (resource_utilization), and Source (source data location) Valid Statistics: Average Unit: Bytes	throughput

Metric	Description	Category
glue.driver.[recordsRead | filesRead]	Metric Category: throughput The number of records/files read per input source in this job run, as well as well as for ALL sources. This helps understand the data volume and its changes over time, which helps addressing issues such as data skewness. Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), ObservabilityGroup (resource _utilization), and Source (source data location) Valid Statistics: Average Unit: Count	throughput

Metric	Description	Category
glue.driver.partitionsRead	Metric Category: throughput The number of partitions read per Amazon S3 input source in this job run, as well as well as for ALL sources. Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), ObservabilityGroup (resource _utilization), and Source (source data location) Valid Statistics: Average Unit: Count	throughput

Metric	Description	Category
glue.driver.bytesWrittten	Metric Category: throughput The number of bytes written per output sink in this job run, as well as well as for ALL sinks. This helps understan d the data volume and how it evolves over time, which helps addressing issues such as processing skewness. Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), ObservabilityGroup (resource _utilization), and Sink (sink data location) Valid Statistics: Average Unit: Bytes	throughput

Metric	Description	Category
glue.driver.[recordsWritten | filesWritten]	Metric Category: throughput The nnumber of records/files written per output sink in this job run, as well as well as for ALL sinks. This helps understand the data volume and how it evolves over time, which helps addressing issues such as processing skewness. Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), ObservabilityGroup (resource_utilization), and Sink (sink data location) Valid Statistics: Average Unit: Count	throughput

Error categories

Error categories	Description
COMPILATION_ERROR	Errors arise during the compilation of Scala code.
CONNECTION_ERROR	Errors arise during connecting to a service/remote host/database service, etc.
DISK_NO_SPACE_ERROR	Errors arise when there is no space left in disk on driver/executor.

Error categories	Description
OUT_OF_MEMORY_ERROR	Errors arise when there is no space left in memory on driver/executor.
IMPORT_ERROR	Errors arise when import dependencies.
INVALID_ARGUMENT_ERROR	Errors arise when the input arguments are invalid/illegal.
PERMISSION_ERROR	Errors arise when lacking the permission to service, data, etc.
RESOURCE_NOT_FOUND_ERROR	Errors arise when data, location, etc does not exit.
QUERY_ERROR	Errors arise from Spark SQL query execution.
SYNTAX_ERROR	Errors arise when there is syntax error in the script.
THROTTLING_ERROR	Errors arise when hitting service concurrency limitation or exceeding service quota limitaion .
DATA_LAKE_FRAMEWORK_ERROR	Errors arise from AWS Glue native-supported data lake framework like Hudi, Iceberg, etc.
UNSUPPORTED_OPERATION_ERROR	Errors arise when making unsupported operation.
RESOURCES_ALREADY_EXISTS_ERROR	Errors arise when a resource to be created or added already exists.
GLUE_INTERNAL_SERVICE_ERROR	Errors arise when there is a AWS Glue internal service issue.
GLUE_OPERATION_TIMEOUT_ERROR	Errors arise when a AWS Glue operation is timeout.

Error categories	Description
GLUE_VALIDATION_ERROR	Errors arise when a required value could not be validated for AWS Glue job.
GLUE_JOB_BOOKMARK_VERSION_MISMATCH_ERROR	Errors arise when same job exon the same source bucket and write to the same/different destination concurrently (concurrency >1)
LAUNCH_ERROR	Errors arise during the AWS Glue job launch phase.
DYNAMODB_ERROR	Generic errors arise from Amazon DynamoDB service.
GLUE_ERROR	Generic Errors arise from AWS Glue service.
LAKEFORMATION_ERROR	Generic Errors arise from AWS Lake Formation service.
REDSHIFT_ERROR	Generic Errors arise from Amazon Redshift service.
S3_ERROR	Generic Errors arise from Amazon S3 service.
SYSTEM_EXIT_ERROR	Generic system exit error.
TIMEOUT_ERROR	Generic errors arise when job failed by operation time out.
UNCLASSIFIED_SPARK_ERROR	Generic errors arise from Spark.
UNCLASSIFIED_ERROR	Default error category.

Limitations

Note

`glueContext` must be initialized to publish the metrics.

In the Source Dimension, the value is either Amazon S3 path or table name, depending on the source type. In addition, if the source is JDBC and the query option is used, the query string is set in the source dimension. If the value is longer than 500 characters, it is trimmed within 500 characters.The following are limitations in the value:

- Non-ASCII characters will be removed.
- If the source name doesn't contain any ASCII character, it is converted to <non-ASCII input>.

Limitations and considerations for throughput metrics

- DataFrame and DataFrame-based DynamicFrame (e.g. JDBC, reading from parquet on Amazon S3) are supported, however, RDD-based DynamicFrame (e.g. reading csv, json on Amazon S3, etc.) is not supported. Technically, all reads and writes visible on Spark UI are supported.
- The `recordsRead` metric will be emitted if the data source is catalog table and the format is JSON, CSV, text, or Iceberg.
- `glue.driver.throughput.recordsWritten`, `glue.driver.throughput.bytesWritten`, and `glue.driver.throughput.filesWritten` metrics are not available in JDBC and Iceberg tables.
- Metrics may be delayed. If the job finishes in about one minute, there may be no throughput metrics in Amazon CloudWatch Metrics.

Job monitoring and debugging

You can collect metrics about AWS Glue jobs and visualize them on the AWS Glue and Amazon CloudWatch consoles to identify and fix issues. Profiling your AWS Glue jobs requires the following steps:

1. Enable metrics:

    a. Enable the **Job metrics** option in the job definition. You can enable profiling in the AWS Glue console or as a parameter to the job. For more information see Defining job properties for Spark jobs or Using job parameters in AWS Glue jobs.

    b. Enable the **AWS Glue Observability metrics** option in the job definition. You can enable Observability in the AWS Glue console or as a parameter to the job. For more information see Monitoring with AWS Glue Observability metrics.

2. Confirm that the job script initializes a `GlueContext`. For example, the following script snippet initializes a `GlueContext` and shows where profiled code is placed in the script. This general format is used in the debugging scenarios that follow.

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
import time

## @params: [JOB_NAME]

job.commit()
```

3. Run the job.
4. Visualize the metrics:
   a. Visualize job metrics on the AWS Glue console and identify abnormal metrics for the driver or an executor.
   b. Check observability metrics in the Job run monitoring page, job run details page, or on Amazon CloudWatch. For more information, see Monitoring with AWS Glue Observability metrics.
5. Narrow down the root cause using the identified metric.
6. Optionally, confirm the root cause using the log stream of the identified driver or job executor.

Use cases for AWS Glue observability metrics

- Debugging OOM exceptions and job abnormalities
- Debugging demanding stages and straggler tasks
- Monitoring the progress of multiple jobs
- Monitoring for DPU capacity planning
- Using AWS Glue Observability for monitoring resource utilization to reduce cost

Debugging OOM exceptions and job abnormalities

You can debug out-of-memory (OOM) exceptions and job abnormalities in AWS Glue. The following sections describe scenarios for debugging out-of-memory exceptions of the Apache Spark driver or a Spark executor.

- Debugging a driver OOM exception
- Debugging an executor OOM exception

Debugging a driver OOM exception

In this scenario, a Spark job is reading a large number of small files from Amazon Simple Storage Service (Amazon S3). It converts the files to Apache Parquet format and then writes them out to Amazon S3. The Spark driver is running out of memory. The input Amazon S3 data has more than 1 million files in different Amazon S3 partitions.

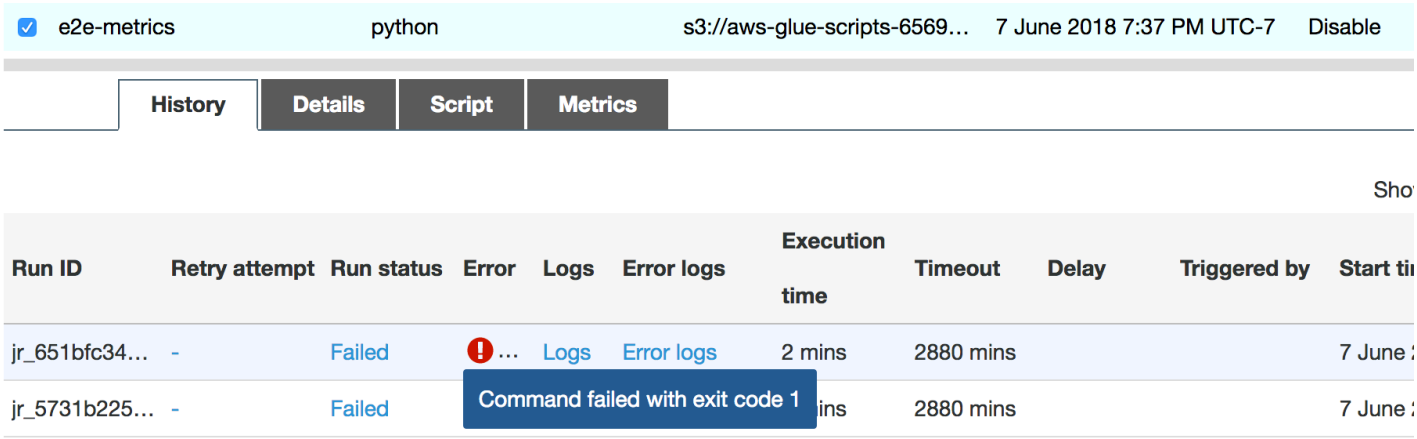
The profiled code is as follows:

```
data = spark.read.format("json").option("inferSchema", False).load("s3://input_path")
data.write.format("parquet").save(output_path)
```

Visualize the profiled metrics on the AWS Glue console

The following graph shows the memory usage as a percentage for the driver and executors. This usage is plotted as one data point that is averaged over the values reported in the last minute. You can see in the memory profile of the job that the driver memory crosses the safe threshold of 50 percent usage quickly. On the other hand, the average memory usage across all executors is still less than 4 percent. This clearly shows abnormality with driver execution in this Spark job.

The job run soon fails, and the following error appears in the **History** tab on the AWS Glue console: Command Failed with Exit Code 1. This error string means that the job failed due to a systemic error—which in this case is the driver running out of memory.



On the console, choose the **Error logs** link on the **History** tab to confirm the finding about driver OOM from the CloudWatch Logs. Search for "**`Error`**" in the job's error logs to confirm that it was indeed an OOM exception that failed the job:

```
# java.lang.OutOfMemoryError: Java heap space
# -XX:OnOutOfMemoryError="kill -9 %p"
# Executing /bin/sh -c "kill -9 12039"...
```

On the **History** tab for the job, choose **Logs**. You can find the following trace of driver execution in the CloudWatch Logs at the beginning of the job. The Spark driver tries to list all the files in all the directories, constructs an `InMemoryFileIndex`, and launches one task per file. This in turn results in the Spark driver having to maintain a large amount of state in memory to track all the tasks. It caches the complete list of a large number of files for the in-memory index, resulting in a driver OOM.

Fix the processing of multiple files using grouping

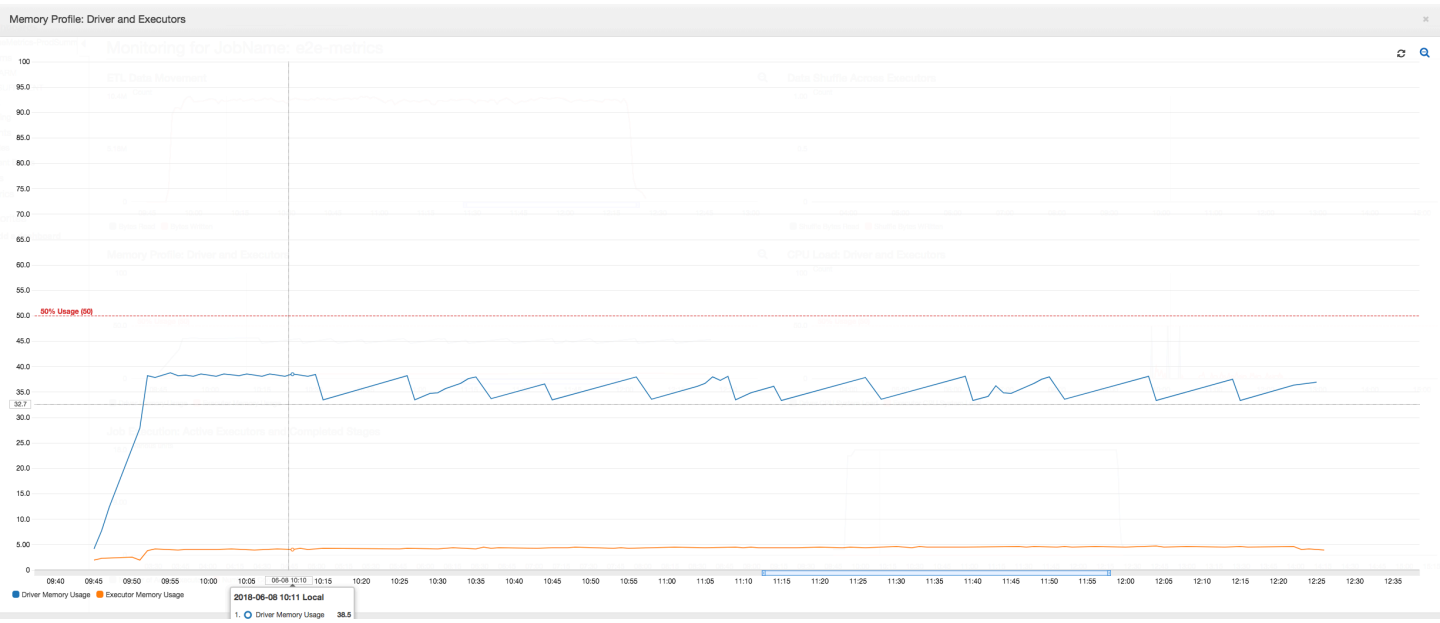
You can fix the processing of the multiple files by using the *grouping* feature in AWS Glue. Grouping is automatically enabled when you use dynamic frames and when the input dataset has a large number of files (more than 50,000). Grouping allows you to coalesce multiple files together into a group, and it allows a task to process the entire group instead of a single file. As a result, the Spark driver stores significantly less state in memory to track fewer tasks. For more information about manually enabling grouping for your dataset, see Reading input files in larger groups.

To check the memory profile of the AWS Glue job, profile the following code with grouping enabled:

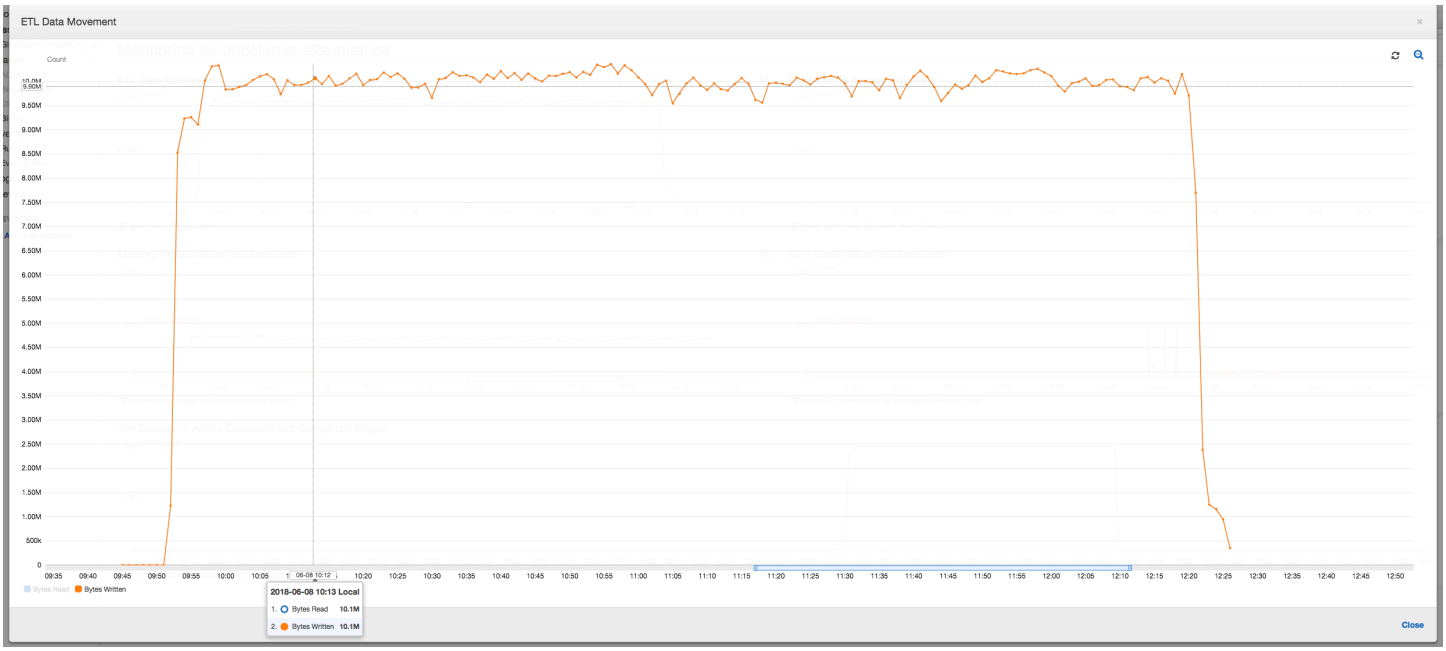
```
df = glueContext.create_dynamic_frame_from_options("s3", {'paths': ["s3://input_path"],
 "recurse":True, 'groupFiles': 'inPartition'}, format="json")
datasink = glueContext.write_dynamic_frame.from_options(frame = df, connection_type
 = "s3", connection_options = {"path": output_path}, format = "parquet",
 transformation_ctx = "datasink")
```

You can monitor the memory profile and the ETL data movement in the AWS Glue job profile.

The driver runs below the threshold of 50 percent memory usage over the entire duration of the AWS Glue job. The executors stream the data from Amazon S3, process it, and write it out to Amazon S3. As a result, they consume less than 5 percent memory at any point in time.



The data movement profile below shows the total number of Amazon S3 bytes that are read and written in the last minute by all executors as the job progresses. Both follow a similar pattern as the data is streamed across all the executors. The job finishes processing all one million files in less than three hours.



Debugging an executor OOM exception

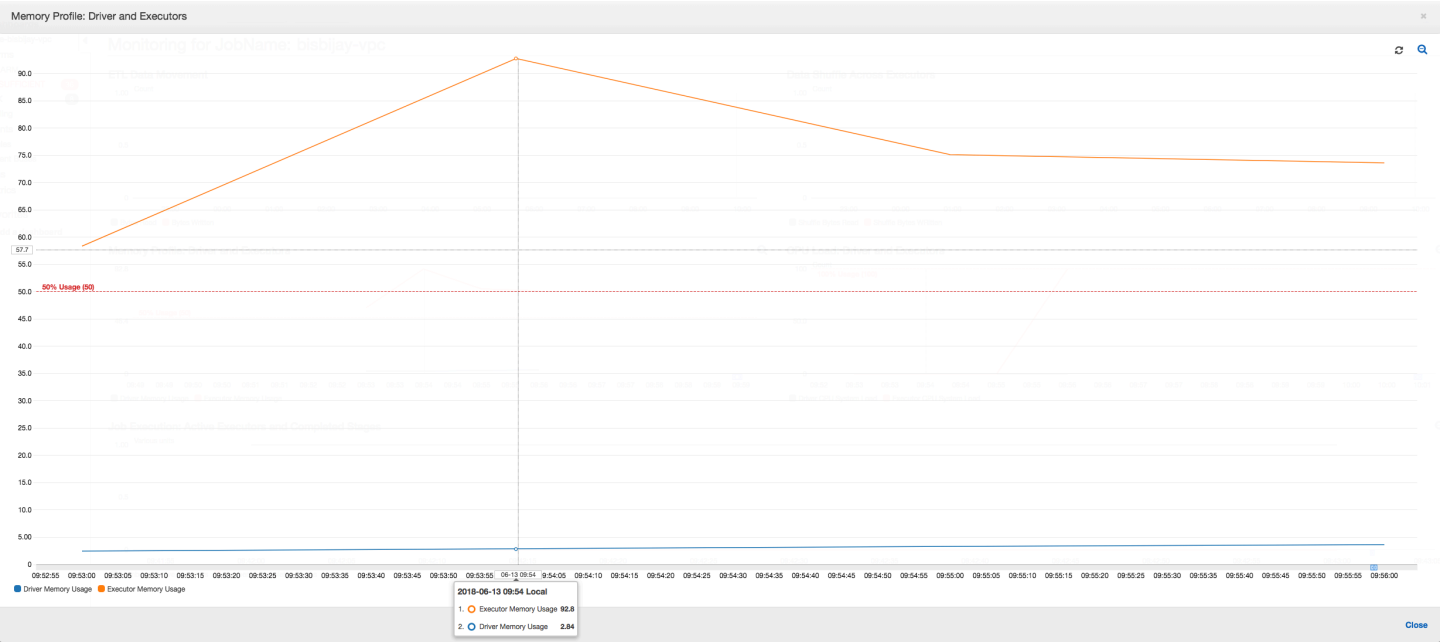
In this scenario, you can learn how to debug OOM exceptions that could occur in Apache Spark executors. The following code uses the Spark MySQL reader to read a large table of about 34

million rows into a Spark dataframe. It then writes it out to Amazon S3 in Parquet format. You can provide the connection properties and use the default Spark configurations to read the table.

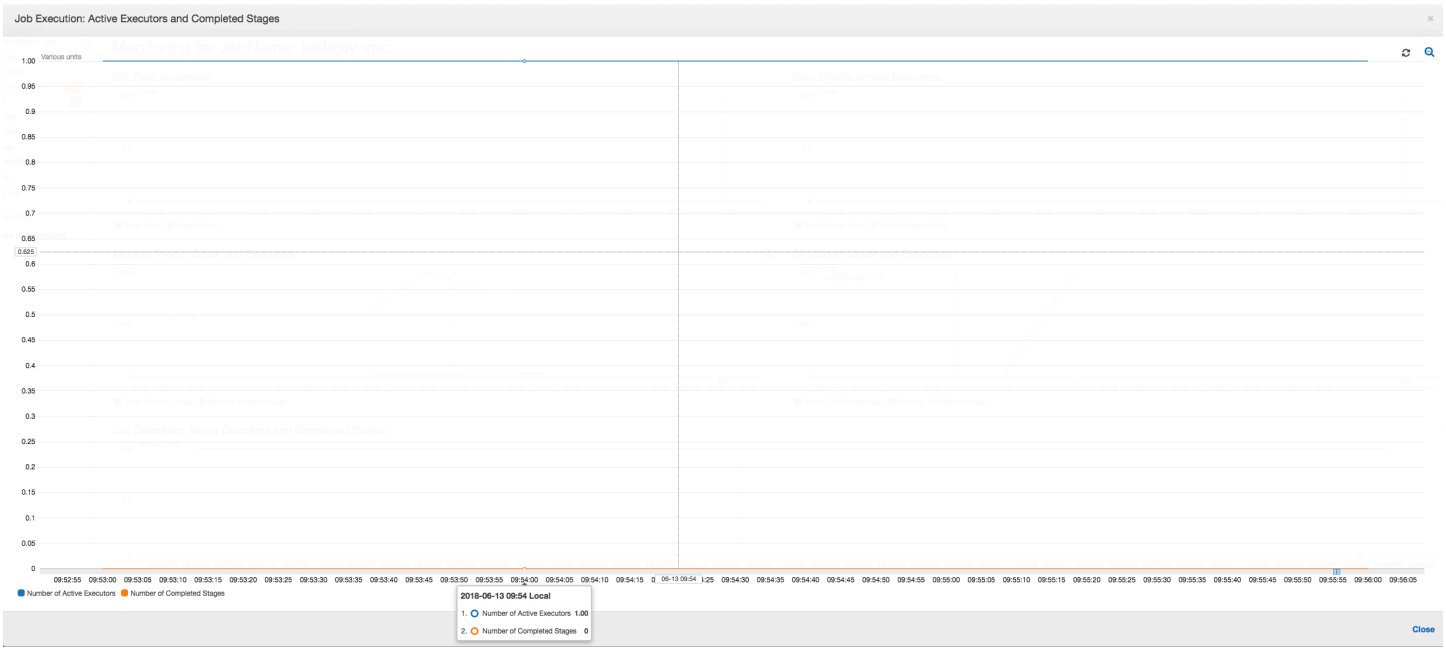
```
val connectionProperties = new Properties()
connectionProperties.put("user", user)
connectionProperties.put("password", password)
connectionProperties.put("Driver", "com.mysql.jdbc.Driver")
val sparkSession = glueContext.sparkSession
val dfSpark = sparkSession.read.jdbc(url, tableName, connectionProperties)
dfSpark.write.format("parquet").save(output_path)
```

Visualize the profiled metrics on the AWS Glue console

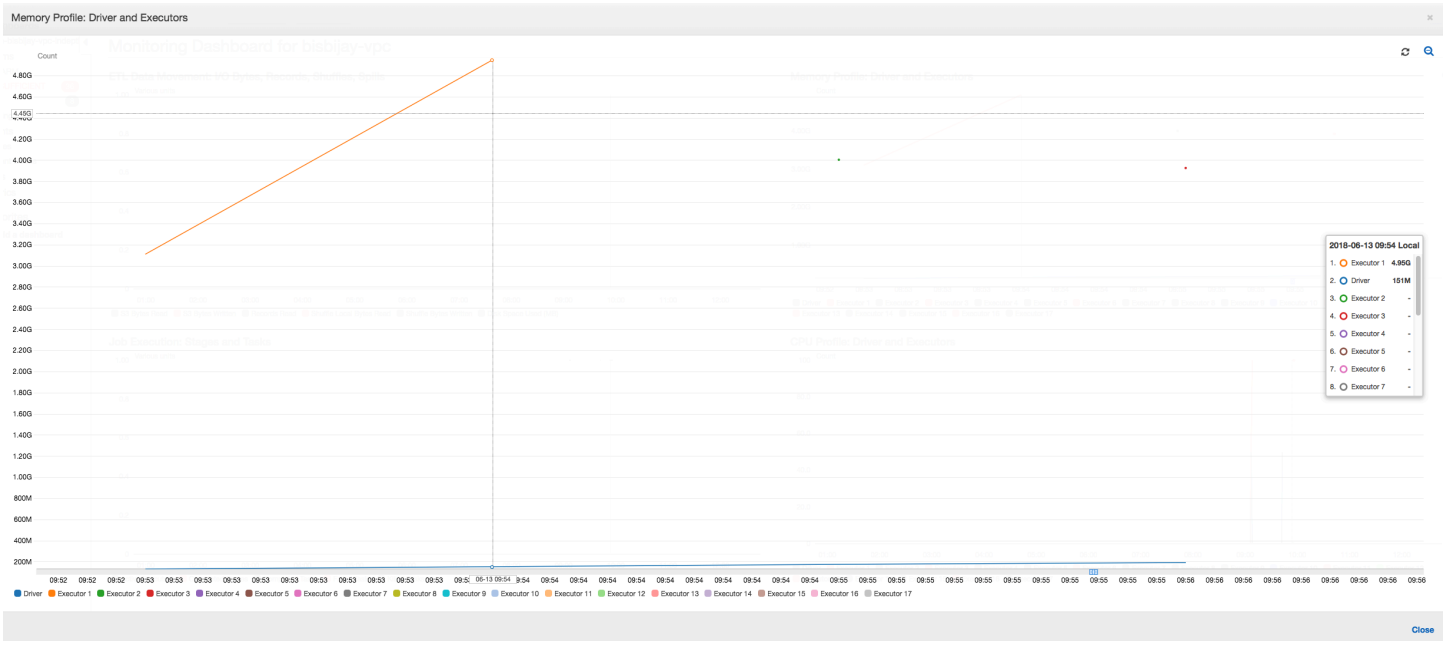
If the slope of the memory usage graph is positive and crosses 50 percent, then if the job fails before the next metric is emitted, then memory exhaustion is a good candidate for the cause. The following graph shows that within a minute of execution, the average memory usage across all executors spikes up quickly above 50 percent. The usage reaches up to 92 percent and the container running the executor is stopped by Apache Hadoop YARN.



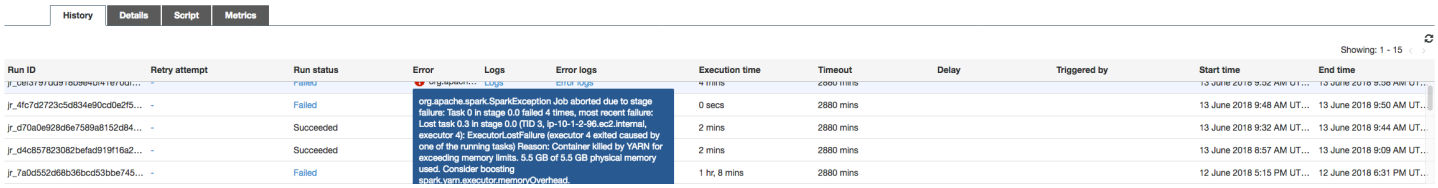
As the following graph shows, there is always a single executor running until the job fails. This is because a new executor is launched to replace the stopped executor. The JDBC data source reads are not parallelized by default because it would require partitioning the table on a column and opening multiple connections. As a result, only one executor reads in the complete table sequentially.



As the following graph shows, Spark tries to launch a new task four times before failing the job. You can see the memory profile of three executors. Each executor quickly uses up all of its memory. The fourth executor runs out of memory, and the job fails. As a result, its metric is not reported immediately.



You can confirm from the error string on the AWS Glue console that the job failed due to OOM exceptions, as shown in the following image.



Job output logs: To further confirm your finding of an executor OOM exception, look at the CloudWatch Logs. When you search for **`Error`**, you find the four executors being stopped in roughly the same time windows as shown on the metrics dashboard. All are terminated by YARN as they exceed their memory limits.

```

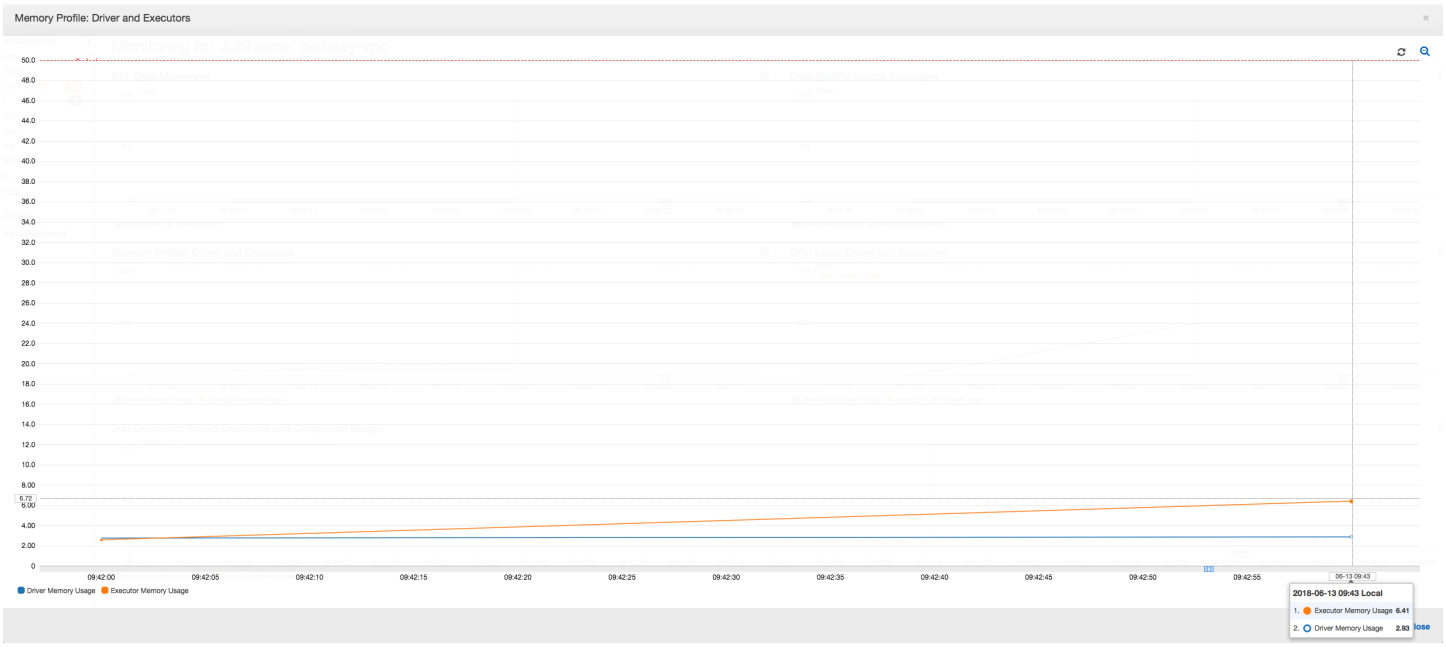
Fix the fetch size setting using AWS Glue dynamic frames

The executor ran out of memory while reading the JDBC table because the default configuration for the Spark JDBC fetch size is zero. This means that the JDBC driver on the Spark executor tries to fetch the 34 million rows from the database together and cache them, even though Spark streams through the rows one at a time. With Spark, you can avoid this scenario by setting the fetch size parameter to a non-zero default value.

You can also fix this issue by using AWS Glue dynamic frames instead. By default, dynamic frames use a fetch size of 1,000 rows that is a typically sufficient value. As a result, the executor does not take more than 7 percent of its total memory. The AWS Glue job finishes in less than two minutes with only a single executor. While using AWS Glue dynamic frames is the recommended approach, it is also possible to set the fetch size using the Apache Spark `fetchsize` property. See the Spark SQL, DataFrames and Datasets Guide.

```
val (url, database, tableName) = {
 ("jdbc_url", "db_name", "table_name")
 }
val source = glueContext.getSource(format, sourceJson)
val df = source.getDynamicFrame
glueContext.write_dynamic_frame.from_options(frame = df, connection_type = "s3",
 connection_options = {"path": output_path}, format = "parquet", transformation_ctx =
 "datasink")
```

Normal profiled metrics: The executor memory with AWS Glue dynamic frames never exceeds the safe threshold, as shown in the following image. It streams in the rows from the database and caches only 1,000 rows in the JDBC driver at any point in time. An out of memory exception does not occur.



Debugging demanding stages and straggler tasks

You can use AWS Glue job profiling to identify demanding stages and straggler tasks in your extract, transform, and load (ETL) jobs. A straggler task takes much longer than the rest of the tasks in a stage of an AWS Glue job. As a result, the stage takes longer to complete, which also delays the total execution time of the job.

Coalescing small input files into larger output files

A straggler task can occur when there is a non-uniform distribution of work across the different tasks, or a data skew results in one task processing more data.

You can profile the following code—a common pattern in Apache Spark—to coalesce a large number of small files into larger output files. For this example, the input dataset is 32 GB of JSON Gzip compressed files. The output dataset has roughly 190 GB of uncompressed JSON files.

The profiled code is as follows:

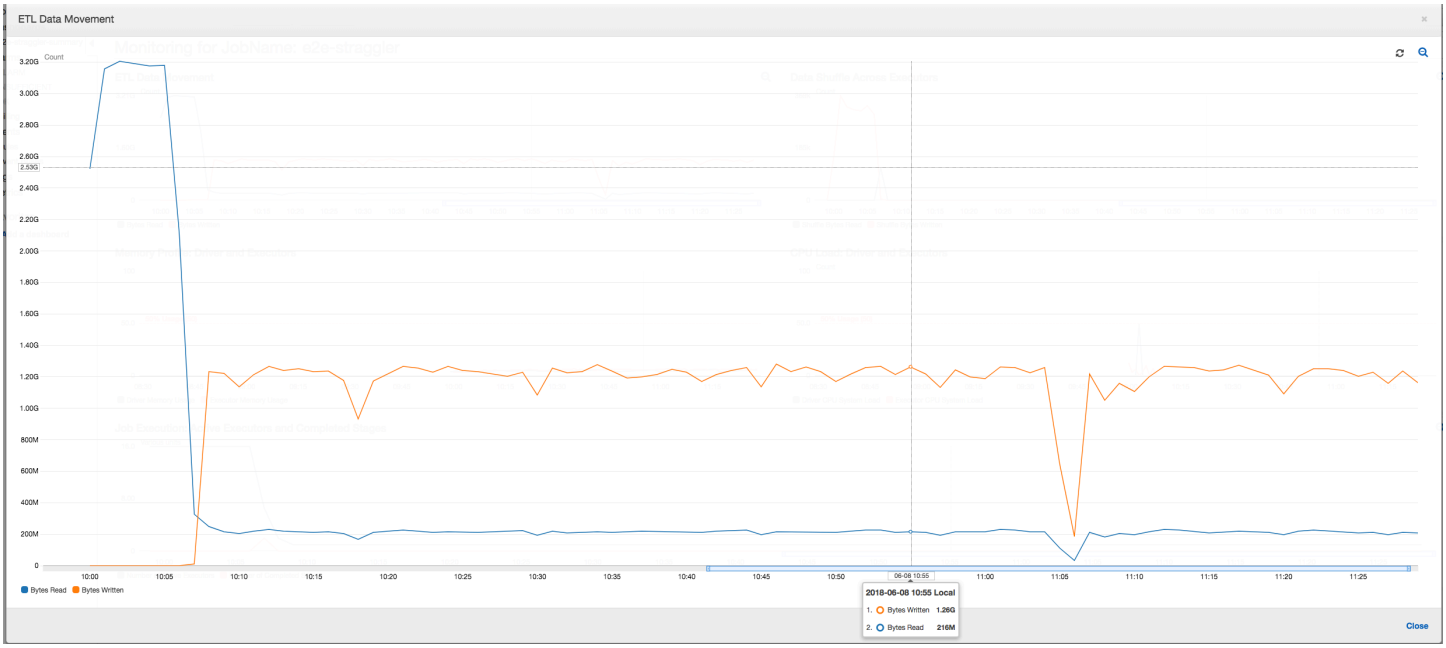
```
datasource0 = spark.read.format("json").load("s3://input_path")
df = datasource0.coalesce(1)
df.write.format("json").save(output_path)
```

Visualize the profiled metrics on the AWS Glue console

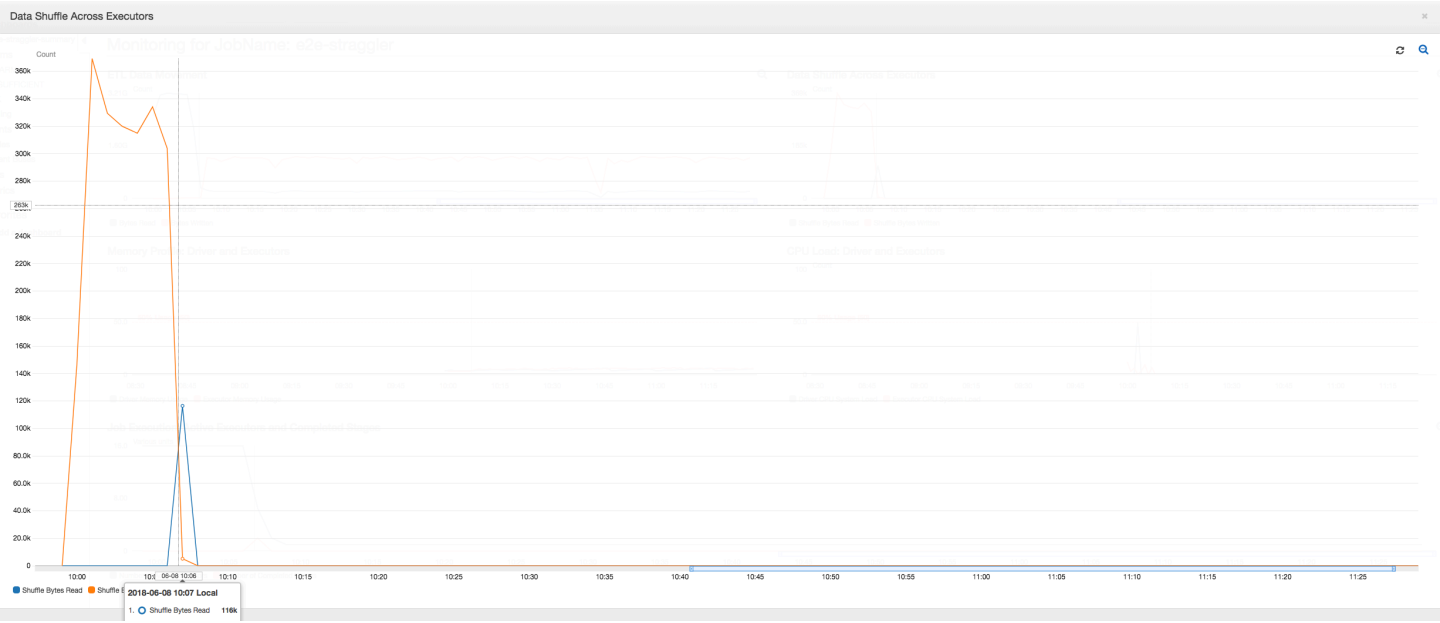
You can profile your job to examine four different sets of metrics:

- ETL data movement
- Data shuffle across executors
- Job execution
- Memory profile

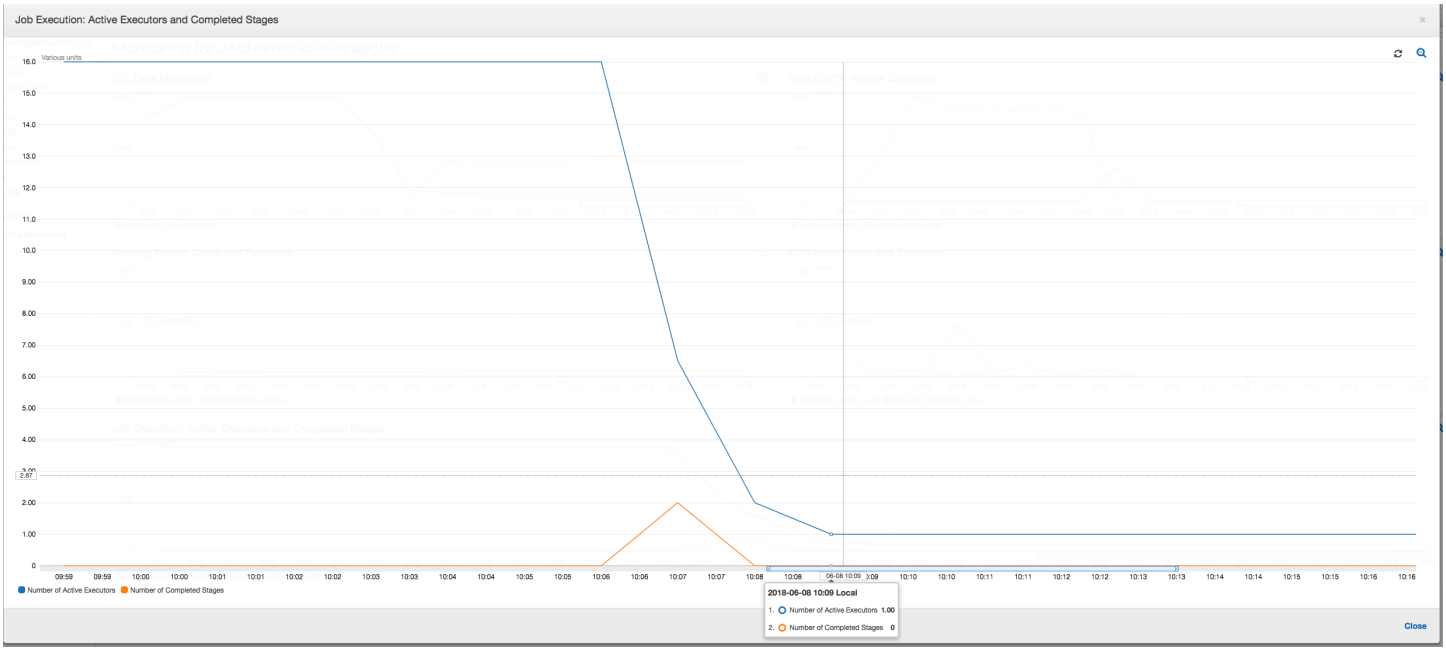
ETL data movement: In the **ETL Data Movement** profile, the bytes are read fairly quickly by all the executors in the first stage that completes within the first six minutes. However, the total job execution time is around one hour, mostly consisting of the data writes.



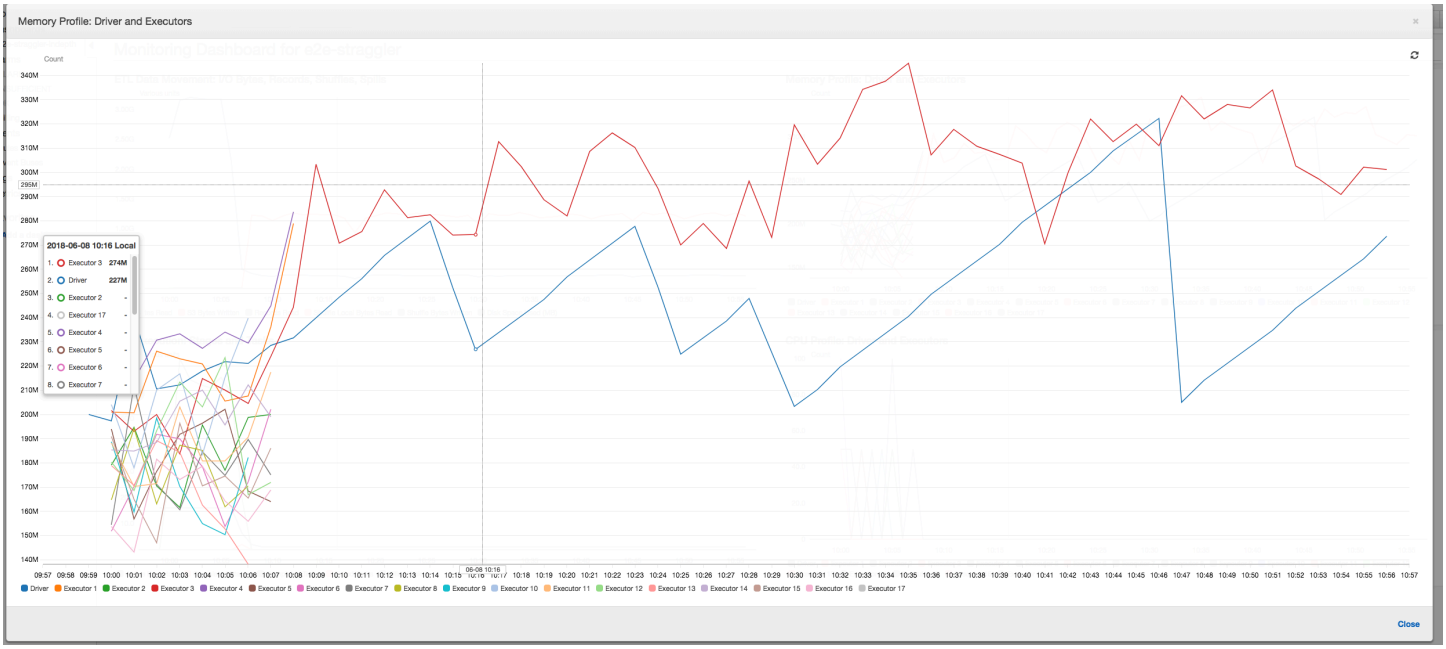
Data shuffle across executors: The number of bytes read and written during shuffling also shows a spike before Stage 2 ends, as indicated by the **Job Execution** and **Data Shuffle** metrics. After the data shuffles from all executors, the reads and writes proceed from executor number 3 only.



Job execution: As shown in the graph below, all other executors are idle and are eventually relinquished by the time 10:09. At that point, the total number of executors decreases to only one. This clearly shows that executor number 3 consists of the straggler task that is taking the longest execution time and is contributing to most of the job execution time.



Memory profile: After the first two stages, only executor number 3 is actively consuming memory to process the data. The remaining executors are simply idle or have been relinquished shortly after the completion of the first two stages.



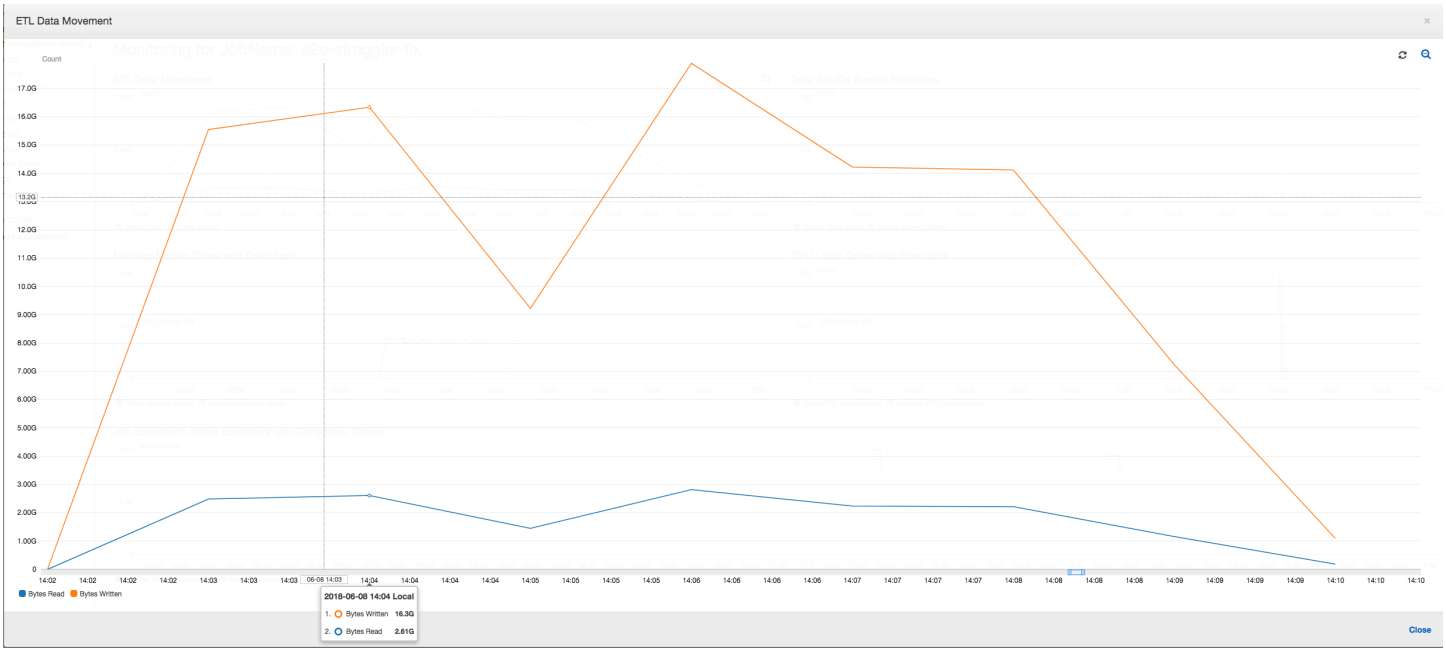
Fix straggling executors using grouping

You can avoid straggling executors by using the *grouping* feature in AWS Glue. Use grouping to distribute the data uniformly across all the executors and coalesce files into larger files using all the available executors on the cluster. For more information, see Reading input files in larger groups.

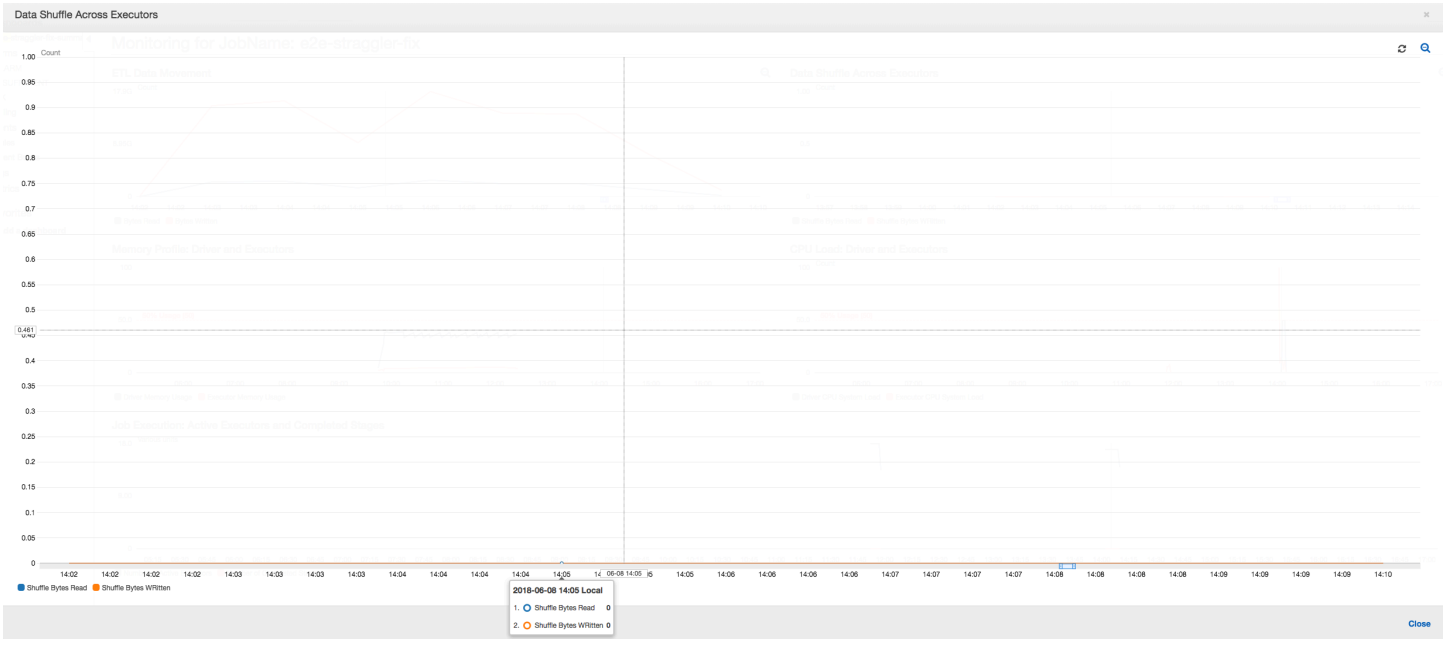
To check the ETL data movements in the AWS Glue job, profile the following code with grouping enabled:

```
df = glueContext.create_dynamic_frame_from_options("s3", {'paths': ["s3://input_path"],
 "recurse":True, 'groupFiles': 'inPartition'}, format="json")
datasink = glueContext.write_dynamic_frame.from_options(frame = df, connection_type =
 "s3", connection_options = {"path": output_path}, format = "json", transformation_ctx
 = "datasink4")
```

ETL data movement: The data writes are now streamed in parallel with the data reads throughout the job execution time. As a result, the job finishes within eight minutes—much faster than previously.

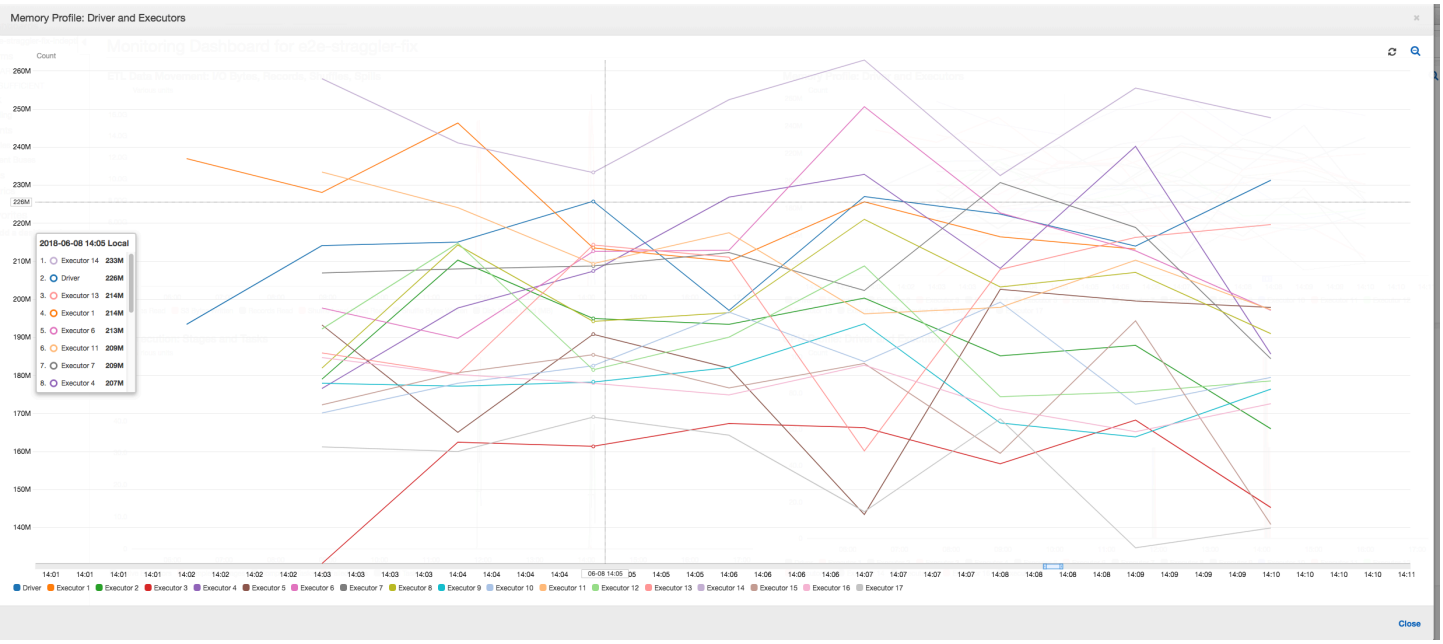


Data shuffle across executors: As the input files are coalesced during the reads using the grouping feature, there is no costly data shuffle after the data reads.



Job execution: The job execution metrics show that the total number of active executors running and processing data remains fairly constant. There is no single straggler in the job. All executors are active and are not relinquished until the completion of the job. Because there is no intermediate shuffle of data across the executors, there is only a single stage in the job.

Memory profile: The metrics show the active memory consumption across all executors—reconfirming that there is activity across all executors. As data is streamed in and written out in parallel, the total memory footprint of all executors is roughly uniform and well below the safe threshold for all executors.



Monitoring the progress of multiple jobs

You can profile multiple AWS Glue jobs together and monitor the flow of data between them. This is a common workflow pattern, and requires monitoring for individual job progress, data processing backlog, data reprocessing, and job bookmarks.

Topics

- Profiled code
- Visualize the profiled metrics on the AWS Glue console
- Fix the processing of files

Profiled code

In this workflow, you have two jobs: an Input job and an Output job. The Input job is scheduled to run every 30 minutes using a periodic trigger. The Output job is scheduled to run after each successful run of the Input job. These scheduled jobs are controlled using job triggers.

Input job: This job reads in data from an Amazon Simple Storage Service (Amazon S3) location, transforms it using `ApplyMapping`, and writes it to a staging Amazon S3 location. The following code is profiled code for the Input job:

```
datasource0 = glueContext.create_dynamic_frame.from_options(connection_type="s3",
 connection_options = {"paths": ["s3://input_path"],
 "useS3ListImplementation":True,"recurse":True}, format="json")
applymapping1 = ApplyMapping.apply(frame = datasource0, mappings = [map_spec])
datasink2 = glueContext.write_dynamic_frame.from_options(frame = applymapping1,
 connection_type = "s3", connection_options = {"path": staging_path, "compression":
 "gzip"}, format = "json")
```

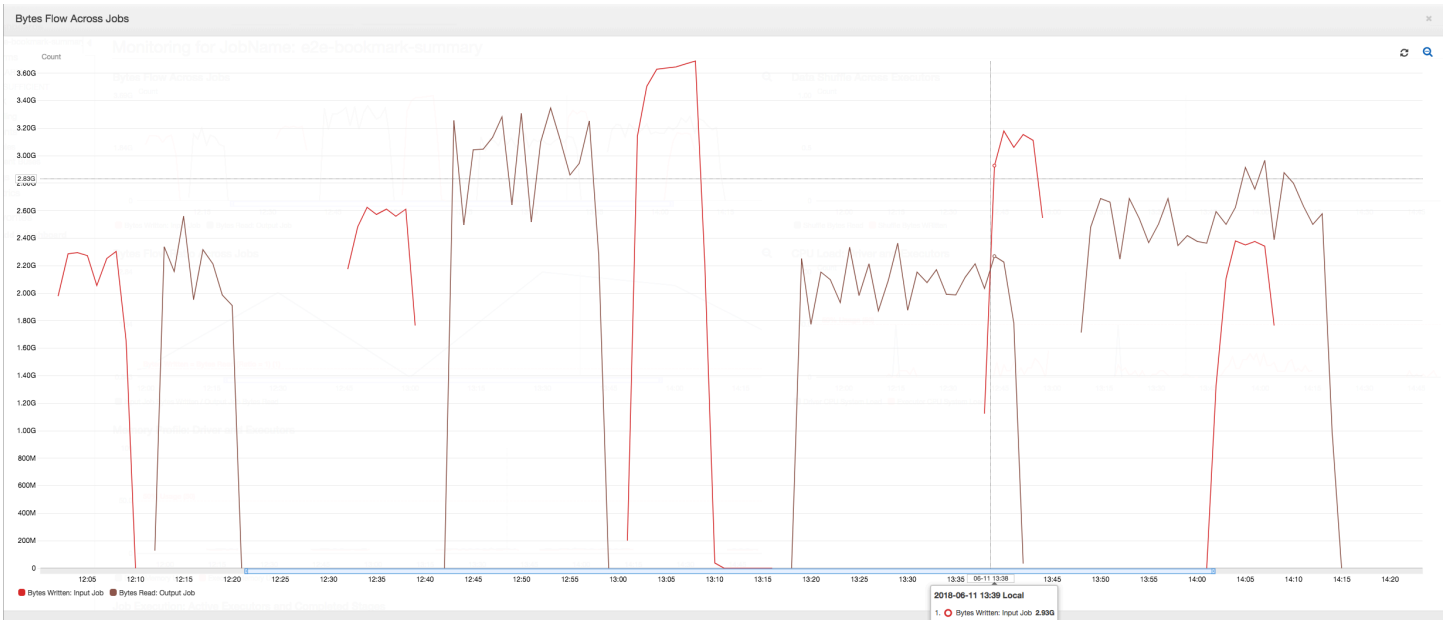
Output job: This job reads the output of the Input job from the staging location in Amazon S3, transforms it again, and writes it to a destination:

```
datasource0 = glueContext.create_dynamic_frame.from_options(connection_type="s3",
 connection_options = {"paths": [staging_path],
 "useS3ListImplementation":True,"recurse":True}, format="json")
```

```
applymapping1 = ApplyMapping.apply(frame = datasource0, mappings = [map_spec])
datasink2 = glueContext.write_dynamic_frame.from_options(frame = applymapping1,
 connection_type = "s3", connection_options = {"path": output_path}, format = "json")
```

Visualize the profiled metrics on the AWS Glue console

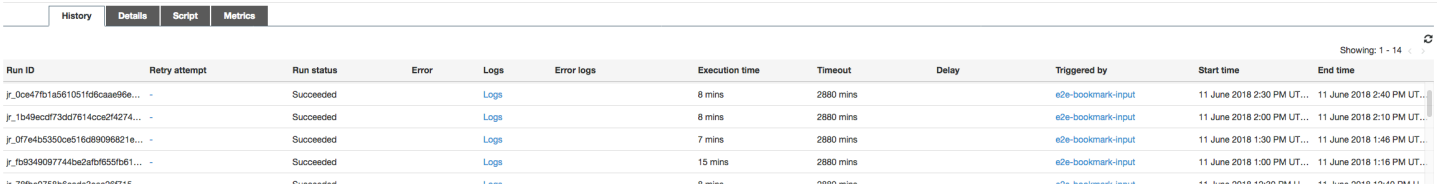
The following dashboard superimposes the Amazon S3 bytes written metric from the Input job onto the Amazon S3 bytes read metric on the same timeline for the Output job. The timeline shows different job runs of the Input and Output jobs. The Input job (shown in red) starts every 30 minutes. The Output Job (shown in brown) starts at the completion of the Input Job, with a Max Concurrency of 1.



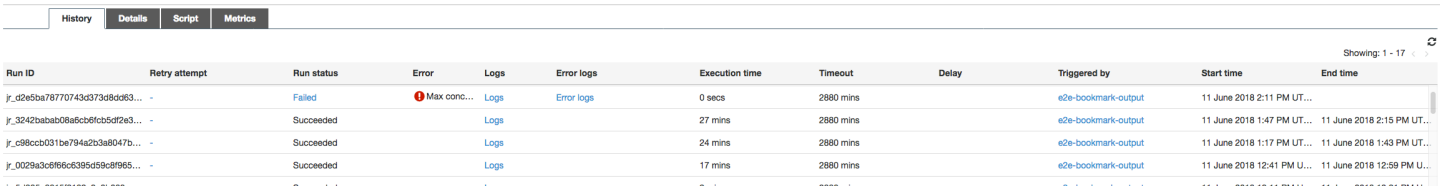
In this example, job bookmarks are not enabled. No transformation contexts are used to enable job bookmarks in the script code.

Job History: The Input and Output jobs have multiple runs, as shown on the **History** tab, starting from 12:00 PM.

The Input job on the AWS Glue console looks like this:

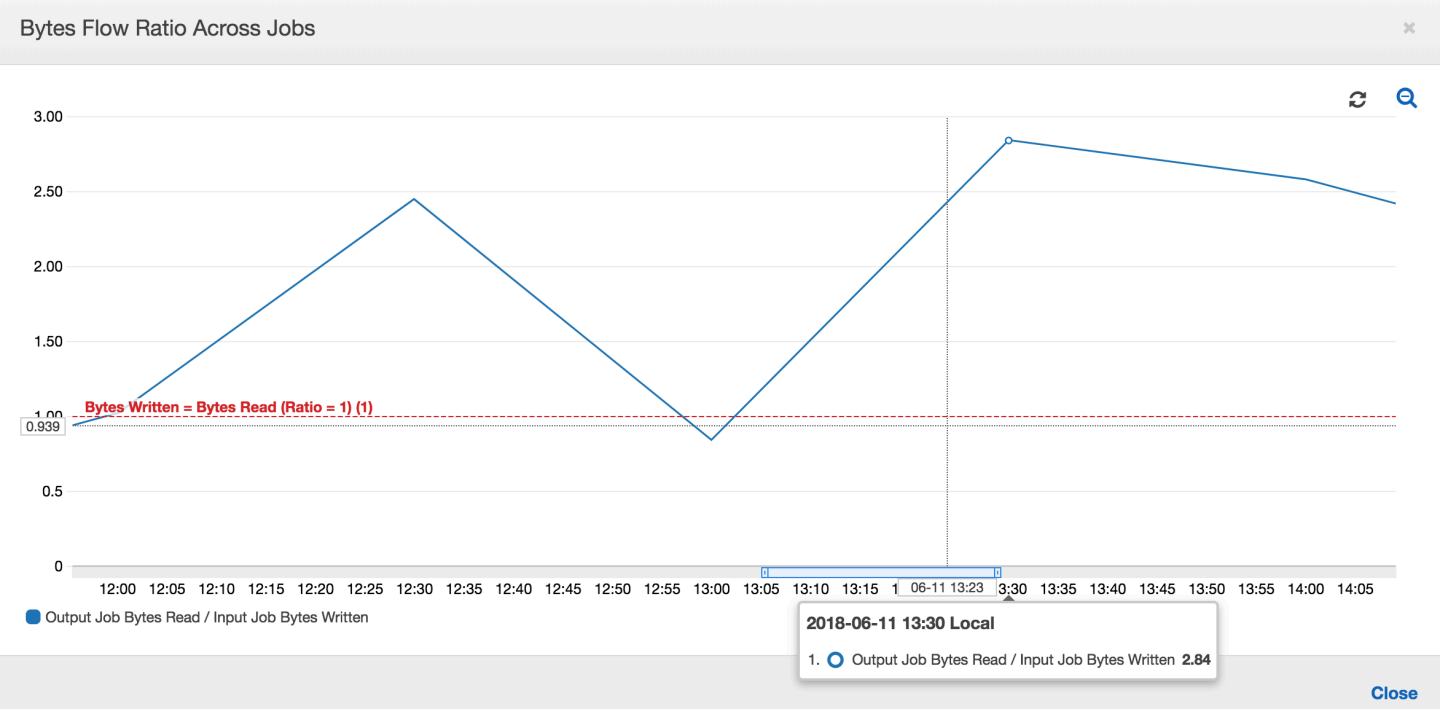


The following image shows the Output job:



First job runs: As shown in the Data Bytes Read and Written graph below, the first job runs of the Input and Output jobs between 12:00 and 12:30 show roughly the same area under the curves. Those areas represent the Amazon S3 bytes written by the Input job and the Amazon S3 bytes read by the Output job. This data is also confirmed by the ratio of Amazon S3 bytes written (summed over 30 minutes – the job trigger frequency for the Input job). The data point for the ratio for the Input job run that started at 12:00PM is also 1.

The following graph shows the data flow ratio across all the job runs:



Second job runs: In the second job run, there is a clear difference in the number of bytes read by the Output job compared to the number of bytes written by the Input job. (Compare the area under the curve across the two job runs for the Output job, or compare the areas in the second run of the Input and Output jobs.) The ratio of the bytes read and written shows that the Output Job read about 2.5x the data written by the Input job in the second span of 30 minutes from 12:30 to 13:00. This is because the Output Job reprocessed the output of the first job run of the Input job because job bookmarks were not enabled. A ratio above 1 shows that there is an additional backlog of data that was processed by the Output job.

Third job runs: The Input job is fairly consistent in terms of the number of bytes written (see the area under the red curves). However, the third job run of the Input job ran longer than expected (see the long tail of the red curve). As a result, the third job run of the Output job started late. The third job run processed only a fraction of the data accumulated in the staging location in the remaining 30 minutes between 13:00 and 13:30. The ratio of the bytes flow shows that it only processed 0.83 of data written by the third job run of the Input job (see the ratio at 13:00).

Overlap of Input and Output jobs: The fourth job run of the Input job started at 13:30 as per the schedule, before the third job run of the Output job finished. There is a partial overlap between these two job runs. However, the third job run of the Output job captures only the files that it listed in the staging location of Amazon S3 when it began around 13:17. This consists of all data output from the first job runs of the Input job. The actual ratio at 13:30 is around 2.75. The third job run of the Output job processed about 2.75x of data written by the fourth job run of the Input job from 13:30 to 14:00.

As these images show, the Output job is reprocessing data from the staging location from all prior job runs of the Input job. As a result, the fourth job run for the Output job is the longest and overlaps with the entire fifth job run of the Input job.

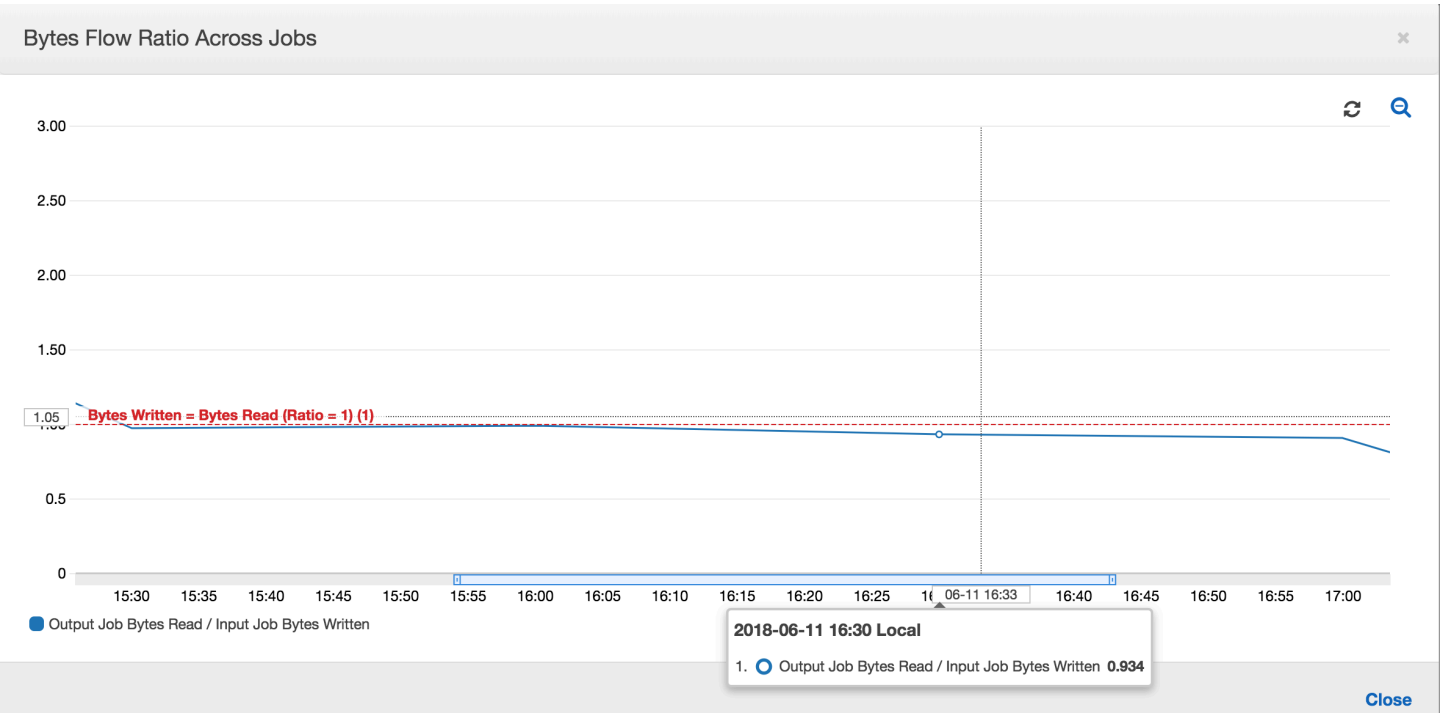
Fix the processing of files

You should ensure that the Output job processes only the files that haven't been processed by previous job runs of the Output job. To do this, enable job bookmarks and set the transformation context in the Output job, as follows:

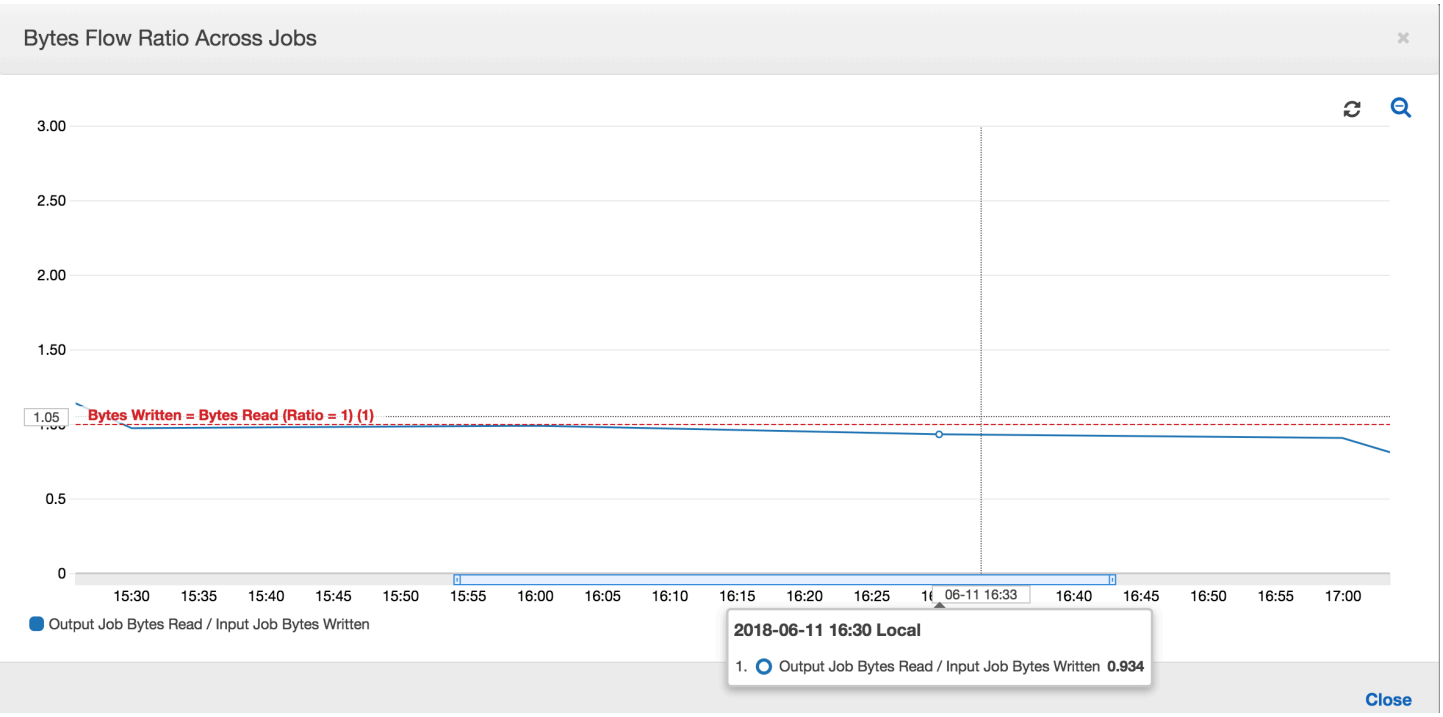
```
datasource0 = glueContext.create_dynamic_frame.from_options(connection_type="s3",
 connection_options = {"paths": [staging_path],
 "useS3ListImplementation":True,"recurse":True}, format="json", transformation_ctx =
 "bookmark_ctx")
```

With job bookmarks enabled, the Output job doesn't reprocess the data in the staging location from all the previous job runs of the Input job. In the following image showing the data read and written, the area under the brown curve is fairly consistent and similar with the red curves.

The ratios of byte flow also remain roughly close to 1 because there is no additional data processed.



A job run for the Output job starts and captures the files in the staging location before the next Input job run starts putting more data into the staging location. As long as it continues to do this, it processes only the files captured from the previous Input job run, and the ratio stays close to 1.



Suppose that the Input job takes longer than expected, and as a result, the Output job captures files in the staging location from two Input job runs. The ratio is then higher than 1 for that Output job run. However, the following job runs of the Output job don't process any files that are already processed by the previous job runs of the Output job.

Monitoring for DPU capacity planning

You can use job metrics in AWS Glue to estimate the number of data processing units (DPUs) that can be used to scale out an AWS Glue job.

> **Note**
>
> This page is only applicable to AWS Glue versions 0.9 and 1.0. Later versions of AWS Glue contain cost-saving features that introduce additional considerations when capacity planning.

Topics

- Profiled code
- Visualize the profiled metrics on the AWS Glue console
- Determine the optimal DPU capacity

Profiled code

The following script reads an Amazon Simple Storage Service (Amazon S3) partition containing 428 gzipped JSON files. The script applies a mapping to change the field names, and converts and writes them to Amazon S3 in Apache Parquet format. You provision 10 DPUs as per the default and run this job.

```
datasource0 = glueContext.create_dynamic_frame.from_options(connection_type="s3",
 connection_options = {"paths": [input_path],
 "useS3ListImplementation":True,"recurse":True}, format="json")
applymapping1 = ApplyMapping.apply(frame = datasource0, mappings = [(map_spec])
datasink2 = glueContext.write_dynamic_frame.from_options(frame = applymapping1,
 connection_type = "s3", connection_options = {"path": output_path}, format =
 "parquet")
```

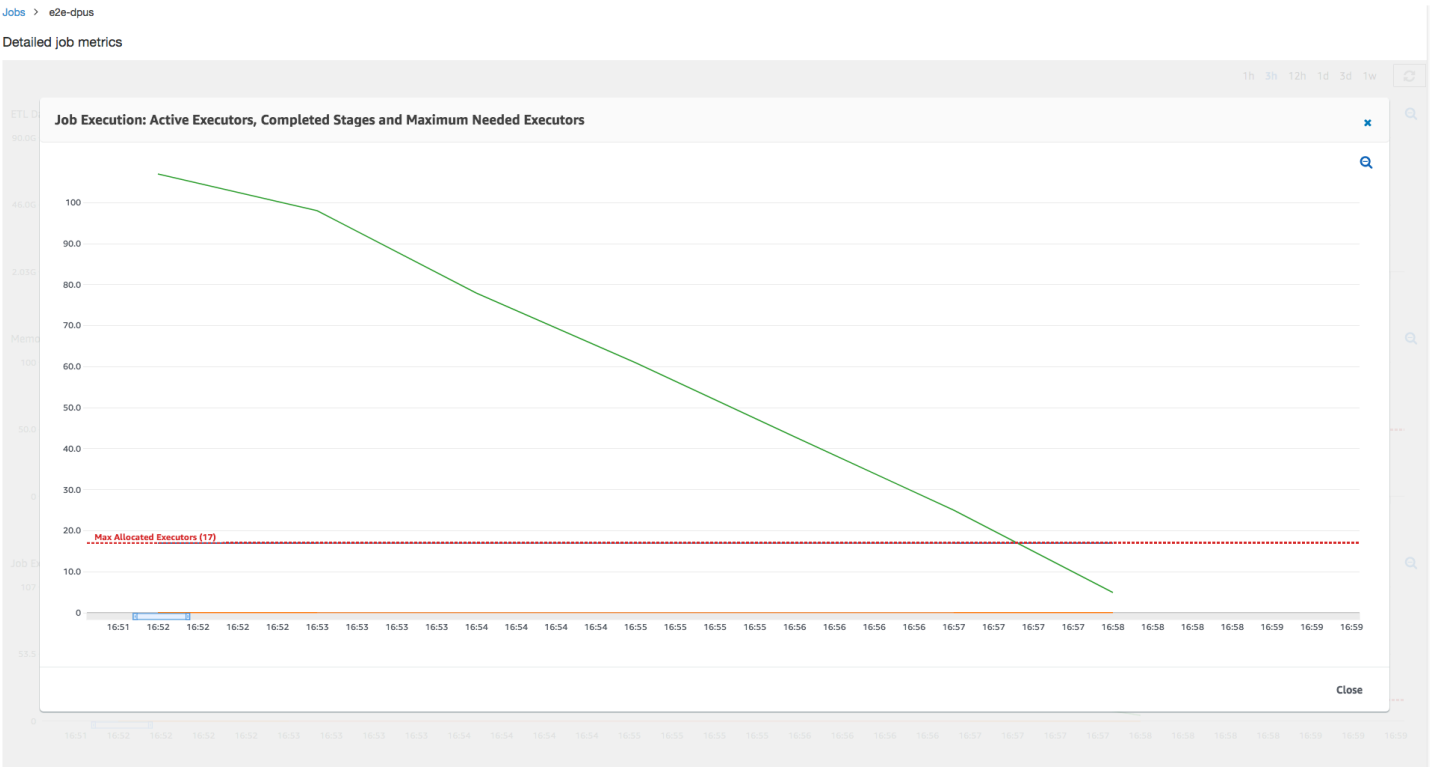
Visualize the profiled metrics on the AWS Glue console

Job run 1: In this job run we show how to find if there are under-provisioned DPUs in the cluster. The job execution functionality in AWS Glue shows the total number of actively running executors, the number of completed stages, and the number of maximum needed executors.

The number of maximum needed executors is computed by adding the total number of running tasks and pending tasks, and dividing by the tasks per executor. This result is a measure of the total number of executors required to satisfy the current load.

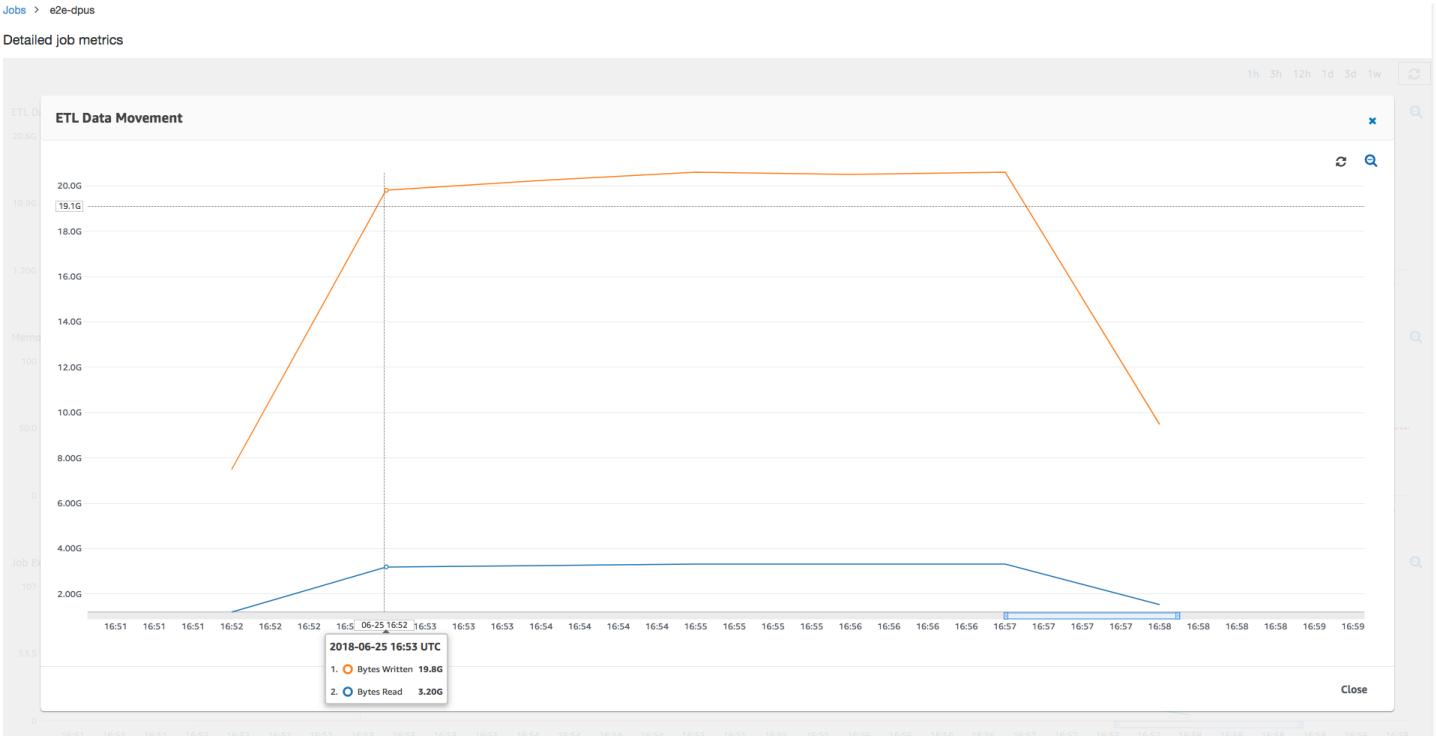
In contrast, the number of actively running executors measures how many executors are running active Apache Spark tasks. As the job progresses, the maximum needed executors can change and typically goes down towards the end of the job as the pending task queue diminishes.

The horizontal red line in the following graph shows the number of maximum allocated executors, which depends on the number of DPUs that you allocate for the job. In this case, you allocate 10 DPUs for the job run. One DPU is reserved for management. Nine DPUs run two executors each and one executor is reserved for the Spark driver. The Spark driver runs inside the primary application. So, the number of maximum allocated executors is 2*9 - 1 = 17 executors.



As the graph shows, the number of maximum needed executors starts at 107 at the beginning of the job, whereas the number of active executors remains 17. This is the same as the number of maximum allocated executors with 10 DPUs. The ratio between the maximum needed executors and maximum allocated executors (adding 1 to both for the Spark driver) gives you the under-provisioning factor: 108/18 = 6x. You can provision 6 (under provisioning ratio) *9 (current DPU capacity - 1) + 1 DPUs = 55 DPUs to scale out the job to run it with maximum parallelism and finish faster.

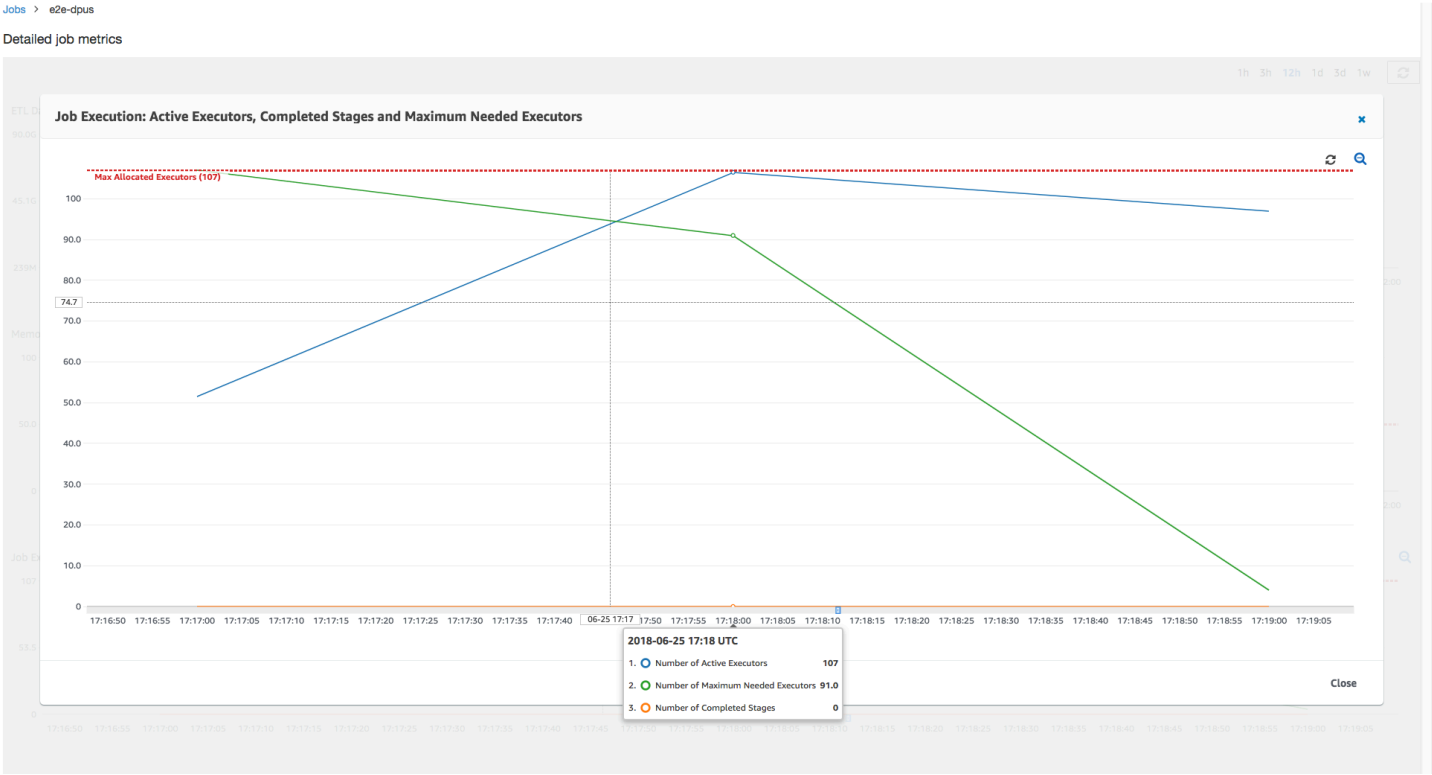
The AWS Glue console displays the detailed job metrics as a static line representing the original number of maximum allocated executors. The console computes the maximum allocated executors from the job definition for the metrics. By constrast, for detailed job run metrics, the console computes the maximum allocated executors from the job run configuration, specifically the DPUs allocated for the job run. To view metrics for an individual job run, select the job run and choose **View run metrics**.



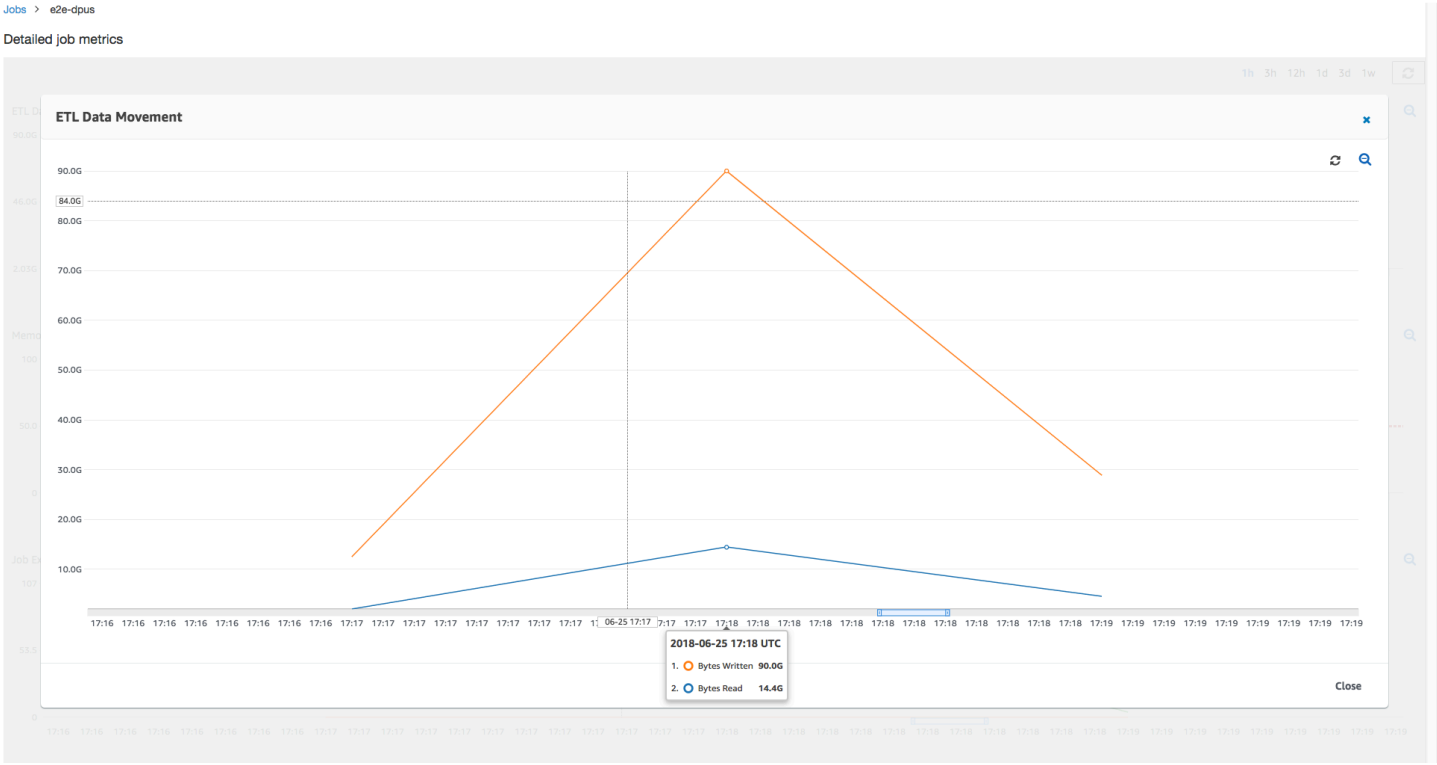
Looking at the Amazon S3 bytes read and written, notice that the job spends all six minutes streaming in data from Amazon S3 and writing it out in parallel. All the cores on the allocated DPUs are reading and writing to Amazon S3. The maximum number of needed executors being 107 also matches the number of files in the input Amazon S3 path—428. Each executor can launch four Spark tasks to process four input files (JSON gzipped).

Determine the optimal DPU capacity

Based on the results of the previous job run, you can increase the total number of allocated DPUs to 55, and see how the job performs. The job finishes in less than three minutes—half the time it required previously. The job scale-out is not linear in this case because it is a short running job. Jobs with long-lived tasks or a large number of tasks (a large number of max needed executors) benefit from a close-to-linear DPU scale-out performance speedup.



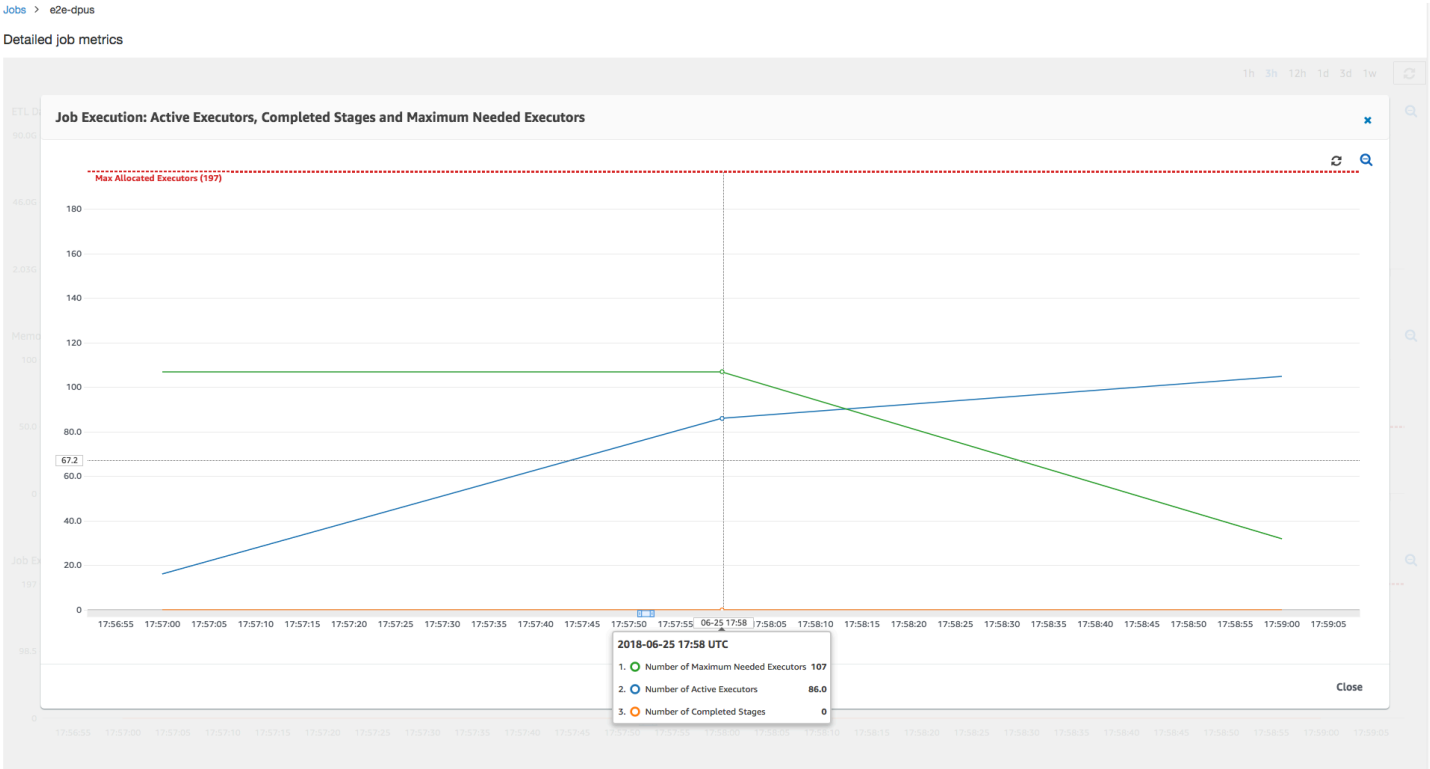
As the above image shows, the total number of active executors reaches the maximum allocated—107 executors. Similarly, the maximum needed executors is never above the maximum allocated executors. The maximum needed executors number is computed from the actively running and pending task counts, so it might be smaller than the number of active executors. This is because there can be executors that are partially or completely idle for a short period of time and are not yet decommissioned.



This job run uses 6x more executors to read and write from Amazon S3 in parallel. As a result, this job run uses more Amazon S3 bandwidth for both reads and writes, and finishes faster.

Identify overprovisioned DPUs

Next, you can determine whether scaling out the job with 100 DPUs (99 * 2 = 198 executors) helps to scale out any further. As the following graph shows, the job still takes three minutes to finish. Similarly, the job does not scale out beyond 107 executors (55 DPUs configuration), and the remaining 91 executors are overprovisioned and not used at all. This shows that increasing the number of DPUs might not always improve performance, as evident from the maximum needed executors.



Compare time differences

The three job runs shown in the following table summarize the job execution times for 10 DPUs, 55 DPUs, and 100 DPUs. You can find the DPU capacity to improve the job execution time using the estimates you established by monitoring the first job run.

Job ID	Number of DPUs	Execution time
jr_c894524c8ef5048a4d9...	10	6 min.
jr_1a466cf2575e7ffe6856...	55	3 min.
jr_34fa1ed4c6aa9ff0a814...	100	3 min.

Generative AI troubleshooting for Apache Spark in AWS Glue

Generative AI Troubleshooting for Apache Spark jobs in AWS Glue is a new capability that helps data engineers and scientists diagnose and fix issues in their Spark applications with ease. Utilizing machine learning and generative AI technologies, this feature analyzes issues in Spark jobs and provides detailed root cause analysis along with actionable recommendations to resolve those

issues. The generative AI troubleshooting for Apache Spark is available for jobs running on AWS Glue version 4.0 and above.

Transform your Apache Spark troubleshooting with our AI-powered Troubleshooting Agent, now supporting all major deployment modes including AWS Glue, Amazon EMR-EC2, Amazon EMR-Serverless and Amazon SageMaker AI Notebooks. This powerful agent eliminates complex debugging processes by combining natural language interactions, real-time workload analysis, and smart code recommendations into a seamless experience. For implementation details, refer to What is Apache Spark Troubleshooting Agent for Amazon EMR. View the second demonstra tion in Using the Troubleshooting Agent for AWS Glue troubleshooting examples.

How does Generative AI Troubleshooting for Apache Spark work?

For your failed Spark jobs, Generative AI Troubleshooting analyzes the job metadata and the precise metrics and logs associated with the error signature of your job to generate a root cause analysis, and recommends specific solutions and best practices to help address job failures.

Setting up Generative AI Troubleshooting for Apache Spark for your jobs

Configuring IAM permissions

Granting permissions to the APIs used by Spark Troubleshooting for your jobs in AWS Glue requires appropriate IAM permissions. You can obtain permissions by attaching the following custom AWS policy to your IAM identity (such as a user, role, or group).

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:StartCompletion",
        "glue:GetCompletion"
      ],
      "Resource": [
        "arn:aws:glue:*:*:completion/*",
        "arn:aws:glue:*:*:job/*"
```

```
      ]
    }
  ]
}
```

> **Note**
>
> The following two APIs are used in the IAM policy for enabling this experience through the AWS Glue Studio Console: `StartCompletion` and `GetCompletion`.

Assigning permissions

To provide access, add permissions to your users, groups, or roles:

- For users and groups in IAM Identity Center: Create a permission set. Follow the instructions in Create a permission set in the IAM Identity Center User Guide.
- For users managed in IAM through an identity provider: Create a role for identity federation. Follow the instructions in Creating a role for a third-party identity provider (federation) in the IAM User Guide.
- For IAM users: Create a role that your user can assume. Follow the instructions in Creating a role for an IAM user in the IAM User Guide.

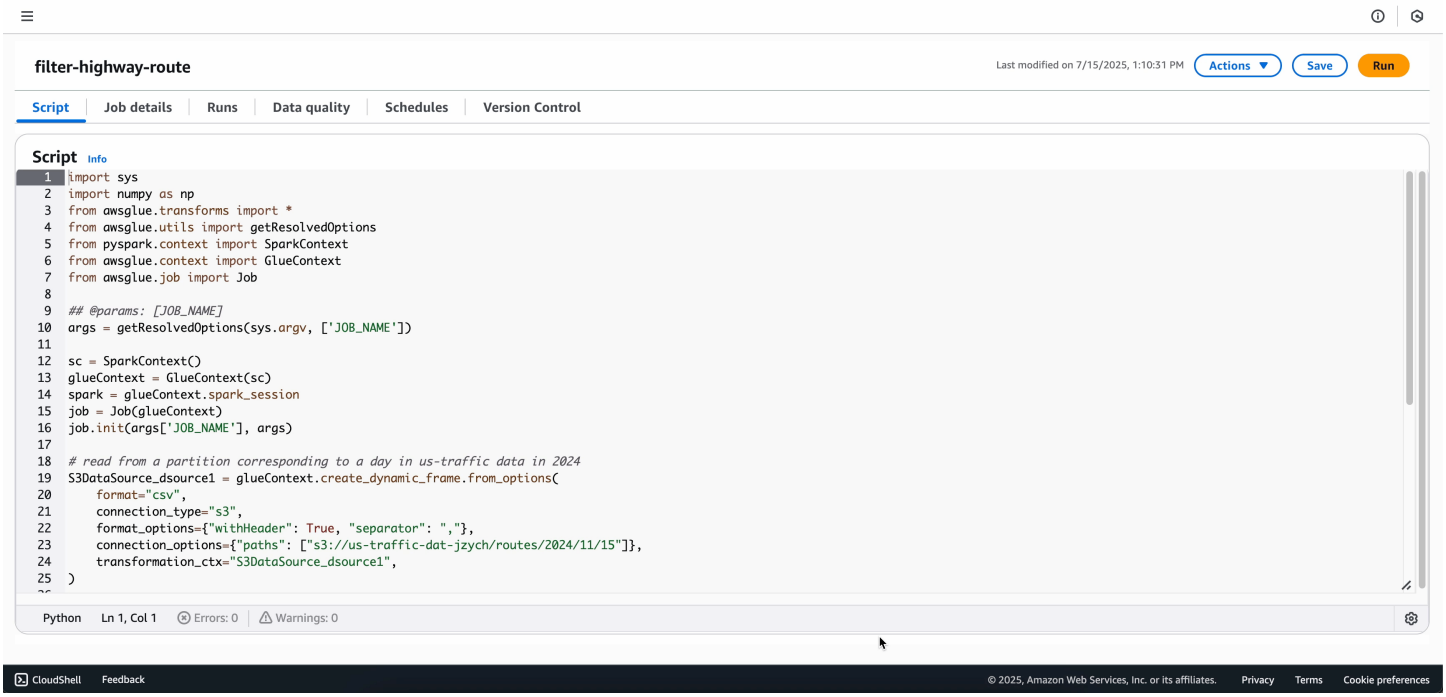
Running troubleshooting analysis from a failed job run

You can access the troubleshooting feature through multiple paths in the AWS Glue console. Here's how to get started:

Option 1: From the Jobs List page

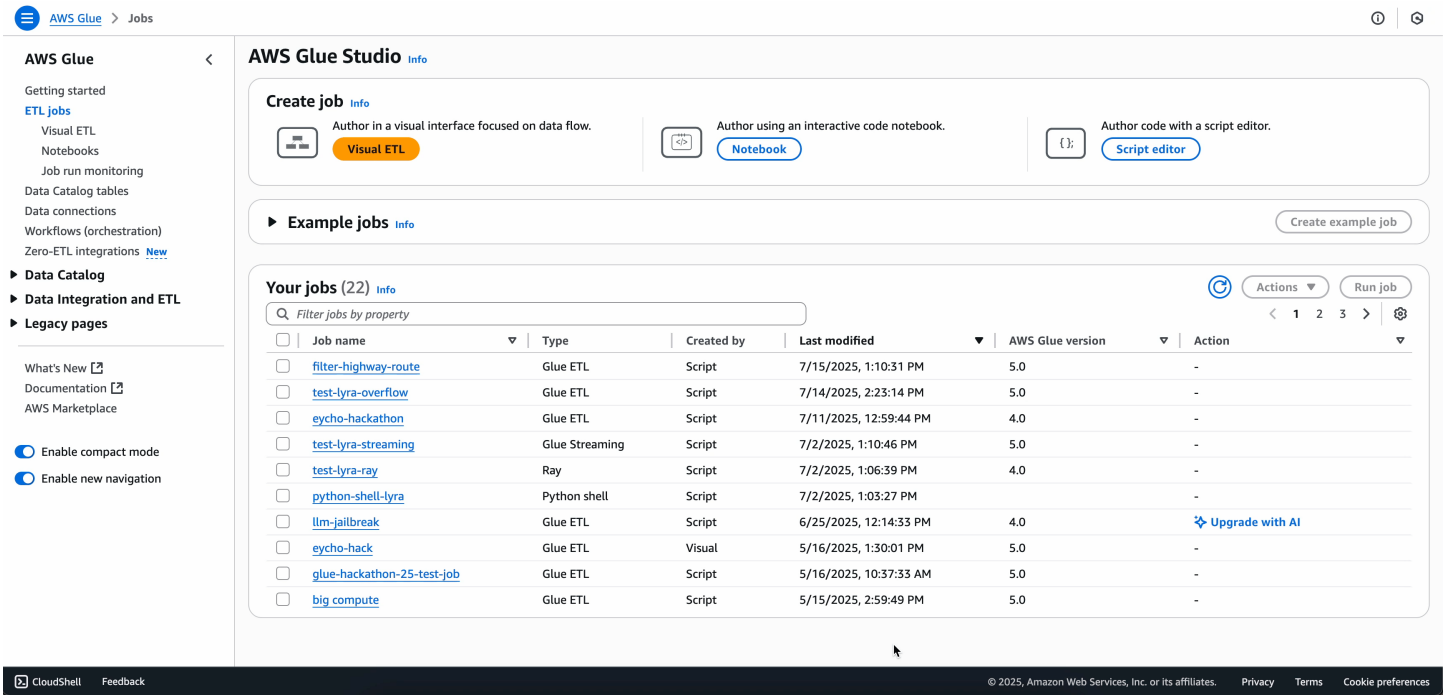
1. Open the AWS Glue console at https://console.aws.amazon.com/glue/.
2. In the navigation pane, choose **ETL Jobs**.
3. Locate your failed job in the jobs list.
4. Select the **Runs** tab in the job details section.
5. Click on the failed job run you want to analyze.
6. Choose **Troubleshoot with AI** to start the analysis.

7. When the troubleshooting analysis is complete, you can view the root-cause analysis and recommendations in the **Troubleshooting analysis** tab at the bottom of the screen.



Option 2: Using the Job Run Monitoring page

1. Navigate to the **Job run monitoring** page.
2. Locate your failed job run.
3. Choose the **Actions** drop-down menu.
4. Choose **Troubleshoot with AI**.



Option 3: From the Job Run Details page

1. Navigate to your failed job run's details page by either clicking **View details** on a failed run from the **Runs** tab or selecting the job run from the **Job run monitoring** page.
2. In the job run details page, find the **Troubleshooting analysis** tab.

Supported troubleshooting categories

This service focuses on three primary categories of issues that data engineers and developers frequently encounter in their Spark applications:

- **Resource setup and access errors:** When running Spark applications in AWS Glue, resource setup and access errors are among the most common yet challenging issues to diagnose. These errors often occur when your Spark application attempts to interact with AWS resources but encounters permission issues, missing resources, or configuration problems.
- **Spark driver and executor memory issues:** Memory-related errors in Apache Spark jobs can be complex to diagnose and resolve. These errors often manifest when your data processing requirements exceed the available memory resources, either on the driver node or executor nodes.
- **Spark disk capacity issues:** Storage-related errors in AWS Glue Spark jobs often emerge during shuffle operations, data spilling, or when dealing with large-scale data transformations. These

errors can be particularly tricky because they might not manifest until your job has been running for a while, potentially wasting valuable compute time and resources.

- **Query execution errors:** Query failures in Spark SQL and DataFrame operations can be difficult to troubleshoot because error messages may not clearly point to the root cause, and queries that work fine with small datasets can suddenly fail at scale. These errors become even more challenging when they occur deep within complex transformation pipelines, where the actual issue may stem from data quality problems in earlier stages rather than the query logic itself.

> **Note**
>
> Before implementing any suggested changes in your production environment, review the suggested changes thoroughly. The service provides recommendations based on patterns and best practices, but your specific use case might require additional considerations.

Supported regions

Generative AI troubleshooting for Apache Spark is available in the following regions:

- **Africa**: Cape Town (af-south-1)
- **Asia Pacific**: Hong Kong (ap-east-1), Tokyo (ap-northeast-1), Seoul (ap-northeast-2), Osaka (ap-northeast-3), Mumbai (ap-south-1), Singapore (ap-southeast-1), Sydney (ap-southeast-2), and Jakarta (ap-southeast-3)
- **Europe**: Frankfurt (eu-central-1), Stockholm (eu-north-1), Milan (eu-south-1), Ireland (eu-west-1), London (eu-west-2), and Paris (eu-west-3)
- **Middle East**: Bahrain (me-south-1) and UAE (me-central-1)
- **North America**: Canada (ca-central-1)
- **South America**: São Paulo (sa-east-1)
- **United States**: North Virginia (us-east-1), Ohio (us-east-2), North California (us-west-1), and Oregon (us-west-2)

Using materialized views with AWS Glue

AWS Glue version 5.1 and later supports creating and managing Apache Iceberg materialized views in the AWS Glue Data Catalog. A materialized view is a managed table that stores the precomputed

result of a SQL query in Apache Iceberg format and incrementally updates as the underlying source tables change. You can use materialized views to simplify data transformation pipelines and accelerate query performance for complex analytical workloads.

When you create a materialized view using Spark in AWS Glue, the view definition and metadata are stored in the AWS Glue Data Catalog. The precomputed results are stored as Apache Iceberg tables in Amazon S3 Tables buckets or Amazon S3 general purpose buckets within your account. The AWS Glue Data Catalog automatically monitors source tables and refreshes materialized views using managed compute infrastructure.

Topics

- How materialized views work with AWS Glue
- Prerequisites
- Configuring Spark to use materialized views
- Creating materialized views
- Querying materialized views
- Refreshing materialized views
- Managing materialized views
- Permissions for materialized views
- Monitoring materialized view operations
- Example: Complete workflow
- Considerations and limitations

How materialized views work with AWS Glue

Materialized views integrate with AWS Glue through Apache Spark's Iceberg support in AWS Glue jobs and AWS Glue Studio notebooks. When you configure your Spark session to use the AWS Glue Data Catalog, you can create materialized views using standard SQL syntax. The Spark optimizer can automatically rewrite queries to use materialized views when they provide better performance, eliminating the need to manually modify application code.

The AWS Glue Data Catalog handles all operational aspects of materialized view maintenance, including:

- Detecting changes in source tables using Apache Iceberg's metadata layer
- Scheduling and executing refresh operations using managed Spark compute

- Determining whether to perform full or incremental refresh based on the data changes
- Storing precomputed results in Apache Iceberg format for multi-engine access

You can query materialized views from AWS Glue using the same Spark SQL interfaces you use for regular tables. The precomputed data is also accessible from other services including Amazon Athena and Amazon Redshift.

Prerequisites

To use materialized views with AWS Glue, you need:

- An account
- AWS Glue version 5.1 or later
- Source tables in Apache Iceberg format registered in the AWS Glue Data Catalog
- AWS Lake Formation permissions configured for source tables and target databases
- An S3 Tables bucket or S3 general purpose bucket registered with AWS Lake Formation for storing materialized view data
- An IAM role with permissions to access AWS Glue Data Catalog and Amazon S3

Configuring Spark to use materialized views

To create and manage materialized views in AWS Glue, configure your Spark session with the required Iceberg extensions and catalog settings. The configuration method varies depending on whether you're using AWS Glue jobs or AWS Glue Studio notebooks.

Configuring AWS Glue jobs

When creating or updating an AWS Glue job, add the following configuration parameters as job parameters:

For S3 Tables buckets

```
job = glue.create_job(
    Name='materialized-view-job',
    Role='arn:aws:iam::111122223333:role/GlueServiceRole',
    Command={
        'Name': 'glueetl',
```

```
        'ScriptLocation': 's3://amzn-s3-demo-bucket/scripts/mv-script.py',
        'PythonVersion': '3'
    },
    DefaultArguments={
        '--enable-glue-datacatalog': 'true',
        '--conf':
 'spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions
 '
        '--conf spark.sql.catalog.glue_catalog=org.apache.iceberg.spark.SparkCatalog '
                  '--conf spark.sql.catalog.glue_catalog.type=glue '
                  '--conf spark.sql.catalog.glue_catalog.warehouse=s3://amzn-s3-demo-
bucket/warehouse '
                  '--conf spark.sql.catalog.glue_catalog.glue.region=us-east-1 '
                  '--conf spark.sql.catalog.glue_catalog.glue.id=111122223333 '
                  '--conf spark.sql.catalog.glue_catalog.glue.account-id=111122223333
 ',
                  '--conf spark.sql.catalog.glue_catalog.glue.lakeformation-
enabled=true ',
                  '--conf
 spark.sql.catalog.s3t_catalog=org.apache.iceberg.spark.SparkCatalog '
                  '--conf spark.sql.catalog.s3t_catalog.type=glue '
                  '--conf
 spark.sql.catalog.s3t_catalog.glue.id=111122223333:s3tablescatalog/my-table-bucket ',
                  '--conf spark.sql.catalog.s3t_catalog.glue.account-id=111122223333 ',
                  '--conf spark.sql.catalog.s3t_catalog.glue.lakeformation-enabled=true
 ',
                  '--conf spark.sql.catalog.s3t_catalog.warehouse=s3://amzn-s3-demo-
bucket/mv-warehouse '
                  '--conf spark.sql.catalog.s3t_catalog.glue.region=us-east-1 '
                  '--conf spark.sql.defaultCatalog=s3t_catalog '
                  '--conf spark.sql.optimizer.answerQueriesWithMVs.enabled=true '
                  '--conf spark.sql.materializedViews.metadataCache.enabled=true'
    },
    GlueVersion='5.1'
)
```

For S3 general purpose buckets

```
job = glue.create_job(
    Name='materialized-view-job',
    Role='arn:aws:iam::111122223333:role/GlueServiceRole',
    Command={
```

```
        'Name': 'glueetl',
        'ScriptLocation': 's3://amzn-s3-demo-bucket/scripts/mv-script.py',
        'PythonVersion': '3'
    },
    DefaultArguments={
        '--enable-glue-datacatalog': 'true',
        '--conf':
 'spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions
 '
                  '--conf
 spark.sql.catalog.glue_catalog=org.apache.iceberg.spark.SparkCatalog '
                  '--conf spark.sql.catalog.glue_catalog.type=glue '
                  '--conf spark.sql.catalog.glue_catalog.warehouse=s3://amzn-s3-demo-
bucket/warehouse '
                  '--conf spark.sql.catalog.glue_catalog.glue.region=us-east-1 '
                  '--conf spark.sql.catalog.glue_catalog.glue.id=111122223333 ',
                  '--conf spark.sql.catalog.glue_catalog.glue.account-id=111122223333
 ',
                  '--conf spark.sql.catalog.glue_catalog.glue.lakeformation-
enabled=true ',
                  '--conf spark.sql.defaultCatalog=glue_catalog '
                  '--conf spark.sql.optimizer.answerQueriesWithMVs.enabled=true '
                  '--conf spark.sql.materializedViews.metadataCache.enabled=true'
    },
    GlueVersion='5.1'
)
```

Configuring AWS Glue Studio notebooks

In AWS Glue Studio notebooks, configure your Spark session using the %%configure magic command at the beginning of your notebook:

```
%%configure
{
    "conf": {
        "spark.sql.extensions":
 "org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions",
        "spark.sql.catalog.glue_catalog": "org.apache.iceberg.spark.SparkCatalog",
        "spark.sql.catalog.glue_catalog.type": "glue",
        "spark.sql.catalog.glue_catalog.warehouse": "s3://amzn-s3-demo-bucket/
warehouse",
        "spark.sql.catalog.glue_catalog.glue.region": "us-east-1",
        "spark.sql.catalog.glue_catalog.glue.id": "111122223333",
```

```
        "spark.sql.catalog.glue_catalog.glue.account-id": "111122223333",
        "spark.sql.catalog.glue_catalog.glue.lakeformation-enabled": "true",
        "spark.sql.defaultCatalog": "glue_catalog",
        "spark.sql.optimizer.answerQueriesWithMVs.enabled": "true",
        "spark.sql.materializedViews.metadataCache.enabled": "true"
    }
}
```

Enabling incremental refresh

To enable incremental refresh optimization, add the following configuration properties to your job parameters or notebook configuration:

```
--conf spark.sql.optimizer.incrementalMVRefresh.enabled=true
--conf spark.sql.optimizer.incrementalMVRefresh.deltaThresholdCheckEnabled=false
```

Configuration parameters

The following configuration parameters control materialized view behavior:

- `spark.sql.extensions` – Enables Iceberg Spark session extensions required for materialized view support.
- `spark.sql.optimizer.answerQueriesWithMVs.enabled` – Enables automatic query rewrite to use materialized views. Set to true to activate this optimization.
- `spark.sql.materializedViews.metadataCache.enabled` – Enables caching of materialized view metadata for query optimization. Set to true to improve query rewrite performance.
- `spark.sql.optimizer.incrementalMVRefresh.enabled` – Enables incremental refresh optimization. Set to true to process only changed data during refresh operations.
- `spark.sql.optimizer.answerQueriesWithMVs.decimalAggregateCheckEnabled` – Controls validation of decimal aggregate operations in query rewrite. Set to false to disable certain decimal overflow checks.

Creating materialized views

You create materialized views using the CREATE MATERIALIZED VIEW SQL statement in AWS Glue jobs or notebooks. The view definition specifies the transformation logic as a SQL query that references one or more source tables.

Creating a basic materialized view in AWS Glue jobs

The following example demonstrates creating a materialized view in a AWS Glue job script, use fully qualified table names with three part naming convention in view definition:

```
from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

# Create materialized view
spark.sql("""
    CREATE MATERIALIZED VIEW customer_orders
    AS
    SELECT
        customer_name,
        COUNT(*) as order_count,
        SUM(amount) as total_amount
    FROM glue_catalog.sales.orders
    GROUP BY customer_name
""")
```

Creating a materialized view with automatic refresh

To configure automatic refresh, specify a refresh schedule when creating the view, using fully qualified table names with three part naming convention in view definition:

```
spark.sql("""
    CREATE MATERIALIZED VIEW customer_orders
    SCHEDULE REFRESH EVERY 1 HOUR
    AS
    SELECT
        customer_name,
        COUNT(*) as order_count,
        SUM(amount) as total_amount
    FROM glue_catalog.sales.orders
    GROUP BY customer_name
""")
```

Creating a materialized view with cross-catalog references

When your source tables are in a different catalog than your materialized view, use fully qualified table names with three-part naming convention in both view name and view definition:

```
spark.sql("""
    CREATE MATERIALIZED VIEW s3t_catalog.analytics.customer_summary
    AS
    SELECT
        customer_name,
        COUNT(*) as order_count,
        SUM(amount) as total_amount
    FROM glue_catalog.sales.orders
    GROUP BY customer_name
""")
```

Creating materialized views in AWS Glue Studio notebooks

In AWS Glue Studio notebooks, you can use the %%sql magic command to create materialized views, using fully qualified table names with three part naming convention in view definition:

```
%%sql
CREATE MATERIALIZED VIEW customer_orders
AS
SELECT
    customer_name,
    COUNT(*) as order_count,
    SUM(amount) as total_amount
FROM glue_catalog.sales.orders
GROUP BY customer_name
```

Querying materialized views

After creating a materialized view, you can query it like any other table using standard SQL SELECT statements in your AWS Glue jobs or notebooks.

Querying in AWS Glue jobs

```
from awsglue.context import GlueContext
from pyspark.context import SparkContext
```

```
sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

# Query materialized view
result = spark.sql("SELECT * FROM customer_orders")
result.show()
```

Querying in AWS Glue Studio notebooks

```
%%sql
SELECT * FROM customer_orders
```

Automatic query rewrite

When automatic query rewrite is enabled, the Spark optimizer analyzes your queries and automatically uses materialized views when they can improve performance. For example, if you execute the following query:

```
result = spark.sql("""
    SELECT
        customer_name,
        COUNT(*) as order_count,
        SUM(amount) as total_amount
    FROM orders
    GROUP BY customer_name
""")
```

The Spark optimizer automatically rewrites this query to use the customer_orders materialized view instead of processing the base orders table, provided the materialized view is current.

Verifying automatic query rewrite

To verify whether a query uses automatic query rewrite, use the EXPLAIN EXTENDED command:

```
spark.sql("""
    EXPLAIN EXTENDED
    SELECT customer_name, COUNT(*) as order_count, SUM(amount) as total_amount
    FROM orders
    GROUP BY customer_name
""").show(truncate=False)
```

In the execution plan, look for the materialized view name in the BatchScan operation. If the plan shows BatchScan glue_catalog.analytics.customer_orders instead of BatchScan glue_catalog.sales.orders, the query has been automatically rewritten to use the materialized view.

Note that automatic query rewrite requires time for the Spark metadata cache to populate after creating a materialized view. This process typically completes within 30 seconds.

Refreshing materialized views

You can refresh materialized views using two methods: full refresh or incremental refresh. Full refresh recomputes the entire materialized view from all base table data, while incremental refresh processes only the data that has changed since the last refresh.

Manual full refresh in AWS Glue jobs

To perform a full refresh of a materialized view:

```
spark.sql("REFRESH MATERIALIZED VIEW customer_orders FULL")

# Verify updated results
result = spark.sql("SELECT * FROM customer_orders")
result.show()
```

Manual incremental refresh in AWS Glue jobs

To perform an incremental refresh, ensure incremental refresh is enabled in your Spark session configuration, then execute:

```
spark.sql("REFRESH MATERIALIZED VIEW customer_orders")

# Verify updated results
result = spark.sql("SELECT * FROM customer_orders")
result.show()
```

The AWS Glue Data Catalog automatically determines whether incremental refresh is applicable based on the view definition and the amount of changed data. If incremental refresh is not possible, the operation falls back to full refresh.

Refreshing in AWS Glue Studio notebooks

In notebooks, use the %%sql magic command:

```
%%sql
REFRESH MATERIALIZED VIEW customer_orders FULL
```

Verifying incremental refresh execution

To confirm that incremental refresh executed successfully, enable debug logging in your AWS Glue job:

```
from awsglue.context import GlueContext
from pyspark.context import SparkContext
import logging

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

# Enable debug logging
logger = logging.getLogger('org.apache.spark.sql')
logger.setLevel(logging.DEBUG)

# Execute refresh
spark.sql("REFRESH MATERIALIZED VIEW customer_orders")
```

Search for the following message in the AWS Glue job logs:

```
DEBUG RefreshMaterializedViewExec: Executed Incremental Refresh
```

Managing materialized views

AWS Glue provides SQL commands for managing the lifecycle of materialized views in your jobs and notebooks.

Describing a materialized view

To view metadata about a materialized view, including its definition, refresh status, and last refresh timestamp:

```
spark.sql("DESCRIBE EXTENDED customer_orders").show(truncate=False)
```

Altering a materialized view

To modify the refresh schedule of an existing materialized view:

```
spark.sql("""
    ALTER MATERIALIZED VIEW customer_orders
    ADD SCHEDULE REFRESH EVERY 2 HOURS
""")
```

To remove automatic refresh:

```
spark.sql("""
    ALTER MATERIALIZED VIEW customer_orders
    DROP SCHEDULE
""")
```

Dropping a materialized view

To delete a materialized view:

```
spark.sql("DROP MATERIALIZED VIEW customer_orders")
```

This command removes the materialized view definition from the AWS Glue Data Catalog and deletes the underlying Iceberg table data from your S3 bucket.

Listing materialized views

To list all materialized views in a database:

```
spark.sql("SHOW VIEWS FROM analytics").show()
```

Permissions for materialized views

To create and manage materialized views, you must configure AWS Lake Formation permissions. The IAM role creating the materialized view (the definer role) requires specific permissions on source tables and target databases.

Required permissions for the definer role

The definer role must have the following Lake Formation permissions:

- On source tables – SELECT or ALL permissions without row, column, or cell filters
- On the target database – CREATE_TABLE permission
- On the AWS Glue Data Catalog – GetTable and CreateTable API permissions

When you create a materialized view, the definer role's ARN is stored in the view definition. The AWS Glue Data Catalog assumes this role when executing automatic refresh operations. If the definer role loses access to source tables, refresh operations will fail until permissions are restored.

IAM permissions for AWS Glue jobs

Your AWS Glue job's IAM role requires the following permissions:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "glue:GetCatalog",
                "glue:GetCatalogs",
                "glue:GetTable",
                "glue:GetTables",
                "glue:CreateTable",
                "glue:UpdateTable",
                "glue:DeleteTable",
                "glue:GetDatabase",
                "glue:GetDatabases",
                "cloudwatch:PutMetricData"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:PutObject",
                "s3:DeleteObject"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListBucket"
            ],
```

```
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "logs:CreateLogGroup",
                "logs:CreateLogStream",
                "logs:PutLogEvents"
            ],
            "Resource": [
                "arn:aws:logs:*:*:*:/aws-glue/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "lakeformation:GetDataAccess"
            ],
            "Resource": "*"
        }
    ]
}
```

The role you use for Materialized View auto-refresh must have the iam:PassRole permission on the role.

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:PassRole"
      ],
      "Resource": [
        "arn:aws:iam::111122223333:role/materialized-view-role-name"
      ]
    }
  ]
}
```

To let Glue automatically refresh the materialized view for you, the role must also have the following trust policy that enables the service to assume the role.

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:PassRole"
      ],
      "Resource": [
        "arn:aws:iam::111122223333:role/materialized-view-role-name"
      ]
    }
  ]
}
```

If the Materialized View is stored in S3 Tables Buckets, you also need to add the following permission to the role.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3tables:PutTableMaintenanceConfiguration"
      ],
      "Resource": "arn:aws:s3tables:*:123456789012:*"
    }
  ]
}
```

Granting access to materialized views

To grant other users access to query a materialized view, use AWS Lake Formation to grant SELECT permission on the materialized view table. Users can query the materialized view without requiring direct access to the underlying source tables.

For detailed information about configuring Lake Formation permissions, see Granting and revoking permissions on Data Catalog resources in the AWS Lake Formation Developer Guide.

Monitoring materialized view operations

The AWS Glue Data Catalog publishes metrics and logs for materialized view refresh operations to Amazon CloudWatch. You can monitor refresh status, duration, and data volume processed through CloudWatch metrics.

Viewing job logs

To view logs for AWS Glue jobs that create or refresh materialized views:

1. Open the AWS Glue console.
2. Choose Jobs from the navigation pane.
3. Select your job and choose Runs.
4. Select a specific run and choose Logs to view CloudWatch logs.

Setting up alarms

To receive notifications when refresh operations fail or exceed expected duration, create CloudWatch alarms on materialized view metrics. You can also configure Amazon EventBridge rules to trigger automated responses to refresh events.

Example: Complete workflow

The following example demonstrates a complete workflow for creating and using a materialized view in AWS Glue.

Example AWS Glue job script

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
```

```
from awsglue.context import GlueContext
from awsglue.job import Job

args = getResolvedOptions(sys.argv, ['JOB_NAME'])
sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
job.init(args['JOB_NAME'], args)

# Create database and base table
spark.sql("CREATE DATABASE IF NOT EXISTS sales")
spark.sql("USE sales")

spark.sql("""
    CREATE TABLE IF NOT EXISTS orders (
        id INT,
        customer_name STRING,
        amount DECIMAL(10,2),
        order_date DATE
    )
""")

# Insert sample data
spark.sql("""
    INSERT INTO orders VALUES
        (1, 'John Doe', 150.00, DATE('2024-01-15')),
        (2, 'Jane Smith', 200.50, DATE('2024-01-16')),
        (3, 'Bob Johnson', 75.25, DATE('2024-01-17'))
""")

# Create materialized view
spark.sql("""
    CREATE MATERIALIZED VIEW customer_summary
    AS
    SELECT
        customer_name,
        COUNT(*) as order_count,
        SUM(amount) as total_amount
    FROM glue_catalog.sales.orders
    GROUP BY customer_name
""")

# Query the materialized view
```

```
print("Initial materialized view data:")
spark.sql("SELECT * FROM customer_summary").show()

# Insert additional data
spark.sql("""
    INSERT INTO orders VALUES
        (4, 'Jane Smith', 350.00, DATE('2024-01-18')),
        (5, 'Bob Johnson', 100.25, DATE('2024-01-19'))
""")

# Refresh the materialized view
spark.sql("REFRESH MATERIALIZED VIEW customer_summary FULL")

# Query updated results
print("Updated materialized view data:")
spark.sql("SELECT * FROM customer_summary").show()

job.commit()
```

Example AWS Glue Studio notebook

```
%%configure
{
    "conf": {
        "spark.sql.extensions":
 "org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions",
        "spark.sql.catalog.glue_catalog": "org.apache.iceberg.spark.SparkCatalog",
        "spark.sql.catalog.glue_catalog.type": "glue",
        "spark.sql.catalog.glue_catalog.warehouse": "s3://amzn-s3-demo-bucket/
warehouse",
        "spark.sql.catalog.glue_catalog.glue.region": "us-east-1",
        "spark.sql.catalog.glue_catalog.glue.id": "111122223333",
        "spark.sql.catalog.glue_catalog.glue.account-id": "111122223333",
        "spark.sql.catalog.glue_catalog.glue.lakeformation-enabled": "true",
        "spark.sql.defaultCatalog": "glue_catalog",
        "spark.sql.optimizer.answerQueriesWithMVs.enabled": "true",
        "spark.sql.materializedViews.metadataCache.enabled": "true"
    }
}
```

```
%%sql
CREATE DATABASE IF NOT EXISTS sales
```

```
%%sql
USE sales
```

```
%%sql
CREATE TABLE IF NOT EXISTS orders (
    id INT,
    customer_name STRING,
    amount DECIMAL(10,2),
    order_date DATE
)
```

```
%%sql
INSERT INTO orders VALUES
    (1, 'John Doe', 150.00, DATE('2024-01-15')),
    (2, 'Jane Smith', 200.50, DATE('2024-01-16')),
    (3, 'Bob Johnson', 75.25, DATE('2024-01-17'))
```

```
%%sql
CREATE MATERIALIZED VIEW customer_summary
AS
SELECT
    customer_name,
    COUNT(*) as order_count,
    SUM(amount) as total_amount
FROM glue_catalog.sales.orders
GROUP BY customer_name
```

```
%%sql
SELECT * FROM customer_summary
```

```
%%sql
INSERT INTO orders VALUES
    (4, 'Jane Smith', 350.00, DATE('2024-01-18')),
    (5, 'Bob Johnson', 100.25, DATE('2024-01-19'))
```

```
%%sql
REFRESH MATERIALIZED VIEW customer_summary FULL
```

```
%%sql
```

```
SELECT * FROM customer_summary
```

Considerations and limitations

Consider the following when using materialized views with AWS Glue:

- Materialized views require AWS Glue version 5.1 or later.
- Source tables must be Apache Iceberg tables registered in the AWS Glue Data Catalog. Apache Hive, Apache Hudi, and Linux Foundation Delta Lake tables are not supported at launch.
- Source tables must reside in the same Region and account as the materialized view.
- All source tables must be governed by AWS Lake Formation. IAM-only permissions and hybrid access are not supported.
- Materialized views cannot reference AWS Glue Data Catalog views, multi-dialect views, or other materialized views as source tables.
- The view definer role must have full read access (SELECT or ALL permission) on all source tables without row, column, or cell filters applied.
- Materialized views are eventually consistent with source tables. During the refresh window, queries may return stale data. Execute manual refresh for immediate consistency.
- The minimum automatic refresh interval is one hour.
- Incremental refresh supports a restricted subset of SQL operations. The view definition must be a single SELECT-FROM-WHERE-GROUP BY-HAVING block and cannot contain set operations, subqueries, the DISTINCT keyword in SELECT or aggregate functions, window functions, or joins other than INNER JOIN.
- Incremental refresh does not support user-defined functions or certain built-in functions. Only a subset of Spark SQL built-in functions are supported.
- Query automatic rewrite only considers materialized views whose definitions belong to a restricted SQL subset similar to incremental refresh restrictions.
- Identifiers containing special characters other than alphanumeric characters and underscores are not supported in CREATE MATERIALIZED VIEW queries. This applies to all identifier types including catalog/namespace/table names, column and struct field names, CTEs, and aliases.
- Materialized view columns starting with the __ivm prefix are reserved for system use. Amazon reserves the right to modify or remove these columns in future releases.
- The SORT BY, LIMIT, OFFSET, CLUSTER BY, and ORDER BY clauses are not supported in materialized view definitions.
- Cross-Region and cross-account source tables are not supported.

- Tables referenced in the view query must use three-part naming convention (e.g., glue_catalog.my_db.my_table) because automatic refresh does not use default catalog and database settings.
- Full refresh operations override the entire table and make previous snapshots unavailable.
- Non-deterministic functions such as rand() or current_timestamp() are not supported in materialized view definitions.

AWS Glue worker types

Overview

AWS Glue provides multiple worker types to accommodate different workload requirements, from small streaming jobs to large-scale, memory-intensive data processing tasks. This section provides comprehensive information about all available worker types, their specifications, and usage recommendations.

Worker type categories

AWS Glue offers two main categories of worker types:

- **G Worker Types**: General-purpose compute workers optimized for standard ETL workloads
- **R Worker Types**: Memory-optimized workers designed for memory-intensive Spark applications

Data Processing Units (DPUs)

The resources available on AWS Glue workers are measured in DPUs. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory.

Memory-Optimized DPUs (M-DPUs): R type workers use M-DPUs, which provide double the memory allocation for a given size compared to standard DPUs. This means that while a standard DPU provides 16 GB of memory, an M-DPU in R type workers provides 32GB of memory optimized for memory-intensive Spark applications.

Available worker types

G.1X

- **DPU**: 1 DPU (4 vCPUs, 16 GB memory)

- **Storage**: 94GB disk (approximately 44GB free)
- **Use Case**: Data transforms, joins, and queries - scalable and cost-effective for most jobs

G.2X

- **DPU**: 2 DPU (8 vCPUs, 32 GB memory)
- **Storage**: 138GB disk (approximately 78GB free)
- **Use Case**: Data transforms, joins, and queries - scalable and cost-effective for most jobs

G.4X

- **DPU**: 4 DPU (16 vCPUs, 64 GB memory)
- **Storage**: 256GB disk (approximately 230GB free)
- **Use Case**: Demanding transforms, aggregations, joins, and queries

G.8X

- **DPU**: 8 DPU (32 vCPUs, 128 GB memory)
- **Storage**: 512GB disk (approximately 485GB free)
- **Use Case**: Demanding transforms, aggregations, joins, and queries

G.12X

- **DPU**: 12 DPU (48 vCPUs, 192 GB memory)
- **Storage**: 768GB disk (approximately 741GB free)
- **Use Case**: Very large and resource-intensive workloads requiring significant compute capacity

G.16X

- **DPU**: 16 DPU (64 vCPUs, 256 GB memory)
- **Storage**: 1024GB disk (approximately 996GB free)
- **Use Case**: Largest and most resource-intensive workloads requiring maximum compute capacity

R.1X - Memory-Optimized*

- **DPU**: 1 M-DPU (4 vCPUs, 32 GB memory)
- **Use Case**: Memory-intensive workloads with frequent out-of-memory errors or high memory-to-CPU ratio requirements

R.2X - Memory-Optimized*

- **DPU**: 2 M-DPU (8 vCPUs, 64 GB memory)
- **Use Case**: Memory-intensive workloads with frequent out-of-memory errors or high memory-to-CPU ratio requirements

R.4X - Memory-Optimized*

- **DPU**: 4 M-DPU (16 vCPUs, 128 GB memory)
- **Use Case**: Large memory-intensive workloads with frequent out-of-memory errors or high memory-to-CPU ratio requirements

R.8X - Memory-Optimized*

- **DPU**: 8 M-DPU (32 vCPUs, 256 GB memory)
- **Use Case**: Very large memory-intensive workloads with frequent out-of-memory errors or high memory-to-CPU ratio requirements

***** You may encounter higher startup latency with these workers. To resolve the issue, try the following:

- Wait a few minutes and then submit your job again.
- Submit a new job with a reduced number of workers.
- Submit a new job using a different worker type or size.

Worker type specifications table

Worker Type Specifications

Worker Type	DPU per Node	vCPU	Memory (GB)	Disk (GB)	Approximate Free Disk Space (GB)	Spark Executors per Node
G.1X	1	4	16	94	44	1
G.2X	2	8	32	138	78	1
G.4X	4	16	64	256	230	1
G.8X	8	32	128	512	485	1
G.12X	12	48	192	768	741	1
G.16X	16	64	256	1024	996	1
R.1X	1	4	32	94	44	1
R.2X	2	8	64	138	78	1
R.4X	4	16	128	256	230	1
R.8X	8	32	256	512	485	1

Note: R worker types have memory-optimized configurations with specifications optimized for memory-intensive workloads.

Important considerations

Startup latency

Important

G.12X and G.16X worker types, as well as all R worker types (R.1X through R.8X), may encounter higher startup latency. To resolve the issue, try the following:

- Wait a few minutes and then submit your job again.
- Submit a new job with a reduced number of workers.
- Submit a new job using a different worker type and size.

Choosing the right worker type

For standard ETL workloads

- **G.1X or G.2X**: Most cost-effective for typical data transforms, joins, and queries
- **G.4X or G.8X**: For more demanding workloads with larger datasets

For large-scale workloads

- **G.12X**: Very large datasets requiring significant compute resources
- **G.16X**: Maximum compute capacity for the most demanding workloads

For memory-intensive workloads

- **R.1X or R.2X**: Small to medium memory-intensive jobs
- **R.4X or R.8X**: Large memory-intensive workloads with frequent OOM errors

Cost Optimization Considerations

- **Standard G workers**: Provide a balance of compute, memory and networking resources, and can be used for a variety of diverse workloads at lower cost
- **R workers**: Specialized for memory-intensive tasks with fast performance for workloads that process large data sets in memory

Best practices

Worker selection guidelines

1. **Start with standard workers** (G.1X, G.2X) for most workloads

2. **Use R workers** when experiencing frequent out-of-memory errors or workloads with memory-intensive operations like caching, shuffling, and aggregating
3. **Consider G.12X/G.16X** for compute-intensive workloads requiring maximum resources
4. **Account for capacity constraints** when using new worker types in time-sensitive workflows

Performance optimization

- Monitor CloudWatch metrics to understand resource utilization
- Use appropriate worker counts based on data size and complexity
- Consider data partitioning strategies to optimize worker efficiency

Streaming ETL jobs in AWS Glue

You can create streaming extract, transform, and load (ETL) jobs that run continuously, consume data from streaming sources like Amazon Kinesis Data Streams, Apache Kafka, and Amazon Managed Streaming for Apache Kafka (Amazon MSK). The jobs cleanse and transform the data, and then load the results into Amazon S3 data lakes or JDBC data stores.

Additionally, you can produce data for Amazon Kinesis Data Streams streams. This feature is only available when writing AWS Glue scripts. For more information, see the section called “Kinesis connections”.

By default, AWS Glue processes and writes out data in 100-second windows. This allows data to be processed efficiently and permits aggregations to be performed on data arriving later than expected. You can modify this window size to increase timeliness or aggregation accuracy. AWS Glue streaming jobs use checkpoints rather than job bookmarks to track the data that has been read.

> **Note**
>
> AWS Glue bills hourly for streaming ETL jobs while they are running.

This video discusses streaming ETL cost challenges, and cost-saving features in AWS Glue.

Creating a streaming ETL job involves the following steps:

1. For an Apache Kafka streaming source, create an AWS Glue connection to the Kafka source or the Amazon MSK cluster.
2. Manually create a Data Catalog table for the streaming source.
3. Create an ETL job for the streaming data source. Define streaming-specific job properties, and supply your own script or optionally modify the generated script.

For more information, see Streaming ETL in AWS Glue.

When creating a streaming ETL job for Amazon Kinesis Data Streams, you don't have to create an AWS Glue connection. However, if there is a connection attached to the AWS Glue streaming ETL job that has Kinesis Data Streams as a source, then a virtual private cloud (VPC) endpoint to Kinesis is required. For more information, see Creating an interface endpoint in the *Amazon VPC User Guide*. When specifying a Amazon Kinesis Data Streams stream in another account, you must setup the roles and policies to allow cross-account access. For more information, see Example: Read From a Kinesis Stream in a Different Account.

AWS Glue streaming ETL jobs can auto-detect compressed data, transparently decompress the streaming data, perform the usual transformations on the input source, and load to the output store.

AWS Glue supports auto-decompression for the following compression types given the input format:

Compression type	Avro file	Avro datum	JSON	CSV	Grok
BZIP2	Yes	Yes	Yes	Yes	Yes
GZIP	No	Yes	Yes	Yes	Yes
SNAPPY	Yes (raw Snappy)	Yes (framed Snappy)	Yes (framed Snappy)	Yes (framed Snappy)	Yes (framed Snappy)
XZ	Yes	Yes	Yes	Yes	Yes
ZSTD	Yes	No	No	No	No
DEFLATE	Yes	Yes	Yes	Yes	Yes

Topics

- Creating an AWS Glue connection for an Apache Kafka data stream

- Notes and restrictions for Avro streaming sources
- Applying grok patterns to streaming sources
- Defining job properties for a streaming ETL job
- Streaming ETL notes and restrictions

Creating an AWS Glue connection for an Apache Kafka data stream

To read from an Apache Kafka stream, you must create an AWS Glue connection.

To create an AWS Glue connection for a Kafka source (Console)

1. Open the AWS Glue console at https://console.aws.amazon.com/glue/.
2. In the navigation pane, under **Data catalog**, choose **Connections**.
3. Choose **Add connection**, and on the **Set up your connection's properties** page, enter a connection name.

   > **Note**
   >
   > For more information about specifying connection properties, see AWS Glue connection properties..

4. For **Connection type**, choose **Kafka**.
5. For **Kafka bootstrap servers URLs**, enter the host and port number for the bootstrap brokers for your Amazon MSK cluster or Apache Kafka cluster. Use only Transport Layer Security (TLS) endpoints for establishing the initial connection to the Kafka cluster. Plaintext endpoints are not supported.

   The following is an example list of hostname and port number pairs for an Amazon MSK cluster.

   ```
   myserver1.kafka.us-east-1.amazonaws.com:9094,myserver2.kafka.us-
   east-1.amazonaws.com:9094,
   myserver3.kafka.us-east-1.amazonaws.com:9094
   ```

For more information about getting the bootstrap broker information, see Getting the Bootstrap Brokers for an Amazon MSK Cluster in the *Amazon Managed Streaming for Apache Kafka Developer Guide*.

6. If you want a secure connection to the Kafka data source, select **Require SSL connection**, and for **Kafka private CA certificate location**, enter a valid Amazon S3 path to a custom SSL certificate.

   For an SSL connection to self-managed Kafka, the custom certificate is mandatory. It's optional for Amazon MSK.

   For more information about specifying a custom certificate for Kafka, see the section called "SSL connection properties".

7. Use AWS Glue Studio or the AWS CLI to specify a Kafka client authentication method. To access AWS Glue Studio select **AWS Glue** from the **ETL** menu in the left navigation pane.

   For more information about Kafka client authentication methods, see AWS Glue Kafka connection properties for client authentication.

8. Optionally enter a description, and then choose **Next**.
9. For an Amazon MSK cluster, specify its virtual private cloud (VPC), subnet, and security group. The VPC information is optional for self-managed Kafka.
10. Choose **Next** to review all connection properties, and then choose **Finish**.

For more information about AWS Glue connections, see Connecting to data.

AWS Glue Kafka connection properties for client authentication

SASL/GSSAPI (Kerberos) authentication

Choosing this authentication method will allow you to specify Kerberos properties.

Kerberos Keytab

Choose the location of the keytab file. A keytab stores long-term keys for one or more principals. For more information, see MIT Kerberos Documentation: Keytab .

Kerberos krb5.conf file

Choose the krb5.conf file. This contains the default realm (a logical network, similar to a domain, that defines a group of systems under the same KDC) and the location of the KDC server. For more information, see MIT Kerberos Documentation: krb5.conf .

Kerberos principal and Kerberos service name

Enter the Kerberos principal and service name. For more information, see MIT Kerberos Documentation: Kerberos principal .

SASL/SCRAM-SHA-512 authentication

Choosing this authentication method will allow you to specify authentication credentials.

AWS Secrets Manager

Search for your token in the Search box by typing the name or ARN.

Provider username and password directly

Search for your token in the Search box by typing the name or ARN.

SSL client authentication

Choosing this authentication method allows you to select the location of the Kafka client keystore by browsing Amazon S3. Optionally, you can enter the Kafka client keystore password and Kafka client key password.

IAM authentication

This authentication method does not require any additional specifications and is only applicable when the Streaming source is MSK Kafka.

SASL/PLAIN authentication

Choosing this authentication method allows you to specify authentication credentials.

Creating a Data Catalog table for a streaming source

A Data Catalog table that specifies source data stream properties, including the data schema can be manually created for a streaming source. This table is used as the data source for the streaming ETL job.

If you don't know the schema of the data in the source data stream, you can create the table without a schema. Then when you create the streaming ETL job, you can turn on the AWS Glue schema detection function. AWS Glue determines the schema from the streaming data.

Use the AWS Glue console, the AWS Command Line Interface (AWS CLI), or the AWS Glue API to create the table. For information about creating a table manually with the AWS Glue console, see the section called "Creating tables".

> **Note**
>
> You can't use the AWS Lake Formation console to create the table; you must use the AWS Glue console.

Also consider the following information for streaming sources in Avro format or for log data that you can apply Grok patterns to.

- the section called "Notes and restrictions for Avro streaming sources"
- the section called "Applying grok patterns to streaming sources"

Topics

- Kinesis data source
- Kafka data source
- AWS Glue Schema Registry table source

Kinesis data source

When creating the table, set the following streaming ETL properties (console).

Type of Source

Kinesis

For a Kinesis source in the same account:

Region

The AWS Region where the Amazon Kinesis Data Streams service resides. The Region and Kinesis stream name are together translated to a Stream ARN.

Example: https://kinesis.us-east-1.amazonaws.com

Kinesis stream name

Stream name as described in Creating a Stream in the *Amazon Kinesis Data Streams Developer Guide*.

For a Kinesis source in another account, refer to this example to set up the roles and policies to allow cross-account access. Configure these settings:

Stream ARN

The ARN of the Kinesis data stream that the consumer is registered with. For more information, see Amazon Resource Names (ARNs) and AWS Service Namespaces in the *AWS General Reference*.

Assumed Role ARN

The Amazon Resource Name (ARN) of the role to assume.

Session name (optional)

An identifier for the assumed role session.

Use the role session name to uniquely identify a session when the same role is assumed by different principals or for different reasons. In cross-account scenarios, the role session name is visible to, and can be logged by the account that owns the role. The role session name is also used in the ARN of the assumed role principal. This means that subsequent cross-account API requests that use the temporary security credentials will expose the role session name to the external account in their AWS CloudTrail logs.

To set streaming ETL properties for Amazon Kinesis Data Streams (AWS Glue API or AWS CLI)

- To set up streaming ETL properties for a Kinesis source in the same account, specify the `streamName` and `endpointUrl` parameters in the `StorageDescriptor` structure of the `CreateTable` API operation or the `create_table` CLI command.

```
"StorageDescriptor": {
 "Parameters": {
  "typeOfData": "kinesis",
  "streamName": "sample-stream",
  "endpointUrl": "https://kinesis.us-east-1.amazonaws.com"
 }
```

```
 ...
}
```

Or, specify the `streamARN`.

Example

```
"StorageDescriptor": {
 "Parameters": {
  "typeOfData": "kinesis",
  "streamARN": "arn:aws:kinesis:us-east-1:123456789:stream/sample-stream"
 }
 ...
}
```

- To set up streaming ETL properties for a Kinesis source in another account, specify the `streamARN`, `awsSTSRoleARN` and `awsSTSSessionName` (optional) parameters in the `StorageDescriptor` structure in the `CreateTable` API operation or the `create_table` CLI command.

```
"StorageDescriptor": {
 "Parameters": {
  "typeOfData": "kinesis",
  "streamARN": "arn:aws:kinesis:us-east-1:123456789:stream/sample-stream",
  "awsSTSRoleARN": "arn:aws:iam::123456789:role/sample-assume-role-arn",
  "awsSTSSessionName": "optional-session"
 }
 ...
}
```

Kafka data source

When creating the table, set the following streaming ETL properties (console).

Type of Source

Kafka

For a Kafka source:

Topic name

Topic name as specified in Kafka.

Connection

An AWS Glue connection that references a Kafka source, as described in the section called "Creating a connection for a Kafka data stream".

AWS Glue Schema Registry table source

To use AWS Glue Schema Registry for streaming jobs, follow the instructions at Use case: AWS Glue Data Catalog to create or update a Schema Registry table.

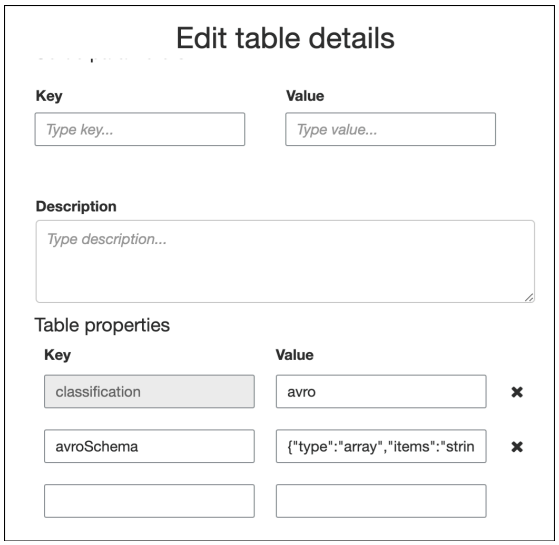
Currently, AWS Glue Streaming supports only Glue Schema Registry Avro format with schema inference set to `false`.

Notes and restrictions for Avro streaming sources

The following notes and restrictions apply for streaming sources in the Avro format:

- When schema detection is turned on, the Avro schema must be included in the payload. When turned off, the payload should contain only data.
- Some Avro data types are not supported in dynamic frames. You can't specify these data types when defining the schema with the **Define a schema** page in the create table wizard in the AWS Glue console. During schema detection, unsupported types in the Avro schema are converted to supported types as follows:
  - `EnumType => StringType`
  - `FixedType => BinaryType`
  - `UnionType => StructType`
- If you define the table schema using the **Define a schema** page in the console, the implied root element type for the schema is `record`. If you want a root element type other than `record`, for example `array` or `map`, you can't specify the schema using the **Define a schema** page. Instead you must skip that page and specify the schema either as a table property or within the ETL script.

- To specify the schema in the table properties, complete the create table wizard, edit the table details, and add a new key-value pair under **Table properties**. Use the key `avroSchema`, and enter a schema JSON object for the value, as shown in the following screenshot.



- To specify the schema in the ETL script, modify the `datasource0` assignment statement and add the `avroSchema` key to the `additional_options` argument, as shown in the following Python and Scala examples.

  Python

```
SCHEMA_STRING = ‘{"type":"array","items":"string"}’
datasource0 = glueContext.create_data_frame.from_catalog(database =
 "database", table_name = "table_name", transformation_ctx = "datasource0",
 additional_options = {"startingPosition": "TRIM_HORIZON", "inferSchema":
 "false", "avroSchema": SCHEMA_STRING})
```

  Scala

```
val SCHEMA_STRING = """{"type":"array","items":"string"}"""
val datasource0 = glueContext.getCatalogSource(database = "database", tableName
 = "table_name", redshiftTmpDir = "", transformationContext = "datasource0",
 additionalOptions = JsonOptions(s"""{"startingPosition": "TRIM_HORIZON",
 "inferSchema": "false", "avroSchema":"$SCHEMA_STRING"}""")).getDataFrame()
```

Applying grok patterns to streaming sources

You can create a streaming ETL job for a log data source and use Grok patterns to convert the logs to structured data. The ETL job then processes the data as a structured data source. You specify the Grok patterns to apply when you create the Data Catalog table for the streaming source.

For information about Grok patterns and custom pattern string values, see Writing grok custom classifiers.

To add grok patterns to the Data Catalog table (console)

- Use the create table wizard, and create the table with the parameters specified in the section called "Creating a Data Catalog table for a streaming source". Specify the data format as Grok, fill in the **Grok pattern** field, and optionally add custom patterns under **Custom patterns (optional)**.

  Press **Enter** after each custom pattern.

To add grok patterns to the Data Catalog table (AWS Glue API or AWS CLI)

- Add the `GrokPattern` parameter and optionally the `CustomPatterns` parameter to the `CreateTable` API operation or the `create_table` CLI command.

```
 "Parameters": {
...
    "grokPattern": "string",
    "grokCustomPatterns": "string",
...
},
```

Express `grokCustomPatterns` as a string and use "\n" as the separator between patterns.

The following is an example of specifying these parameters.

Example

```
"parameters": {
...
    "grokPattern": "%{USERNAME:username} %{DIGIT:digit:int}",
    "grokCustomPatterns": "digit \d",
...
}
```

Defining job properties for a streaming ETL job

When you define a streaming ETL job in the AWS Glue console, provide the following streams-specific properties. For descriptions of additional job properties, see Defining job properties for Spark jobs.

IAM role

Specify the AWS Identity and Access Management (IAM) role that is used for authorization to resources that are used to run the job, access streaming sources, and access target data stores.

For access to Amazon Kinesis Data Streams, attach the `AmazonKinesisFullAccess` AWS managed policy to the role, or attach a similar IAM policy that permits more fine-grained access. For sample policies, see Controlling Access to Amazon Kinesis Data Streams Resources Using IAM.

For more information about permissions for running jobs in AWS Glue, see Identity and access management for AWS Glue.

Type

Choose **Spark streaming**.

AWS Glue version

The AWS Glue version determines the versions of Apache Spark, and Python or Scala, that are available to the job. Choose a selection that specifies the version of Python or Scala available to the job. AWS Glue Version 2.0 with Python 3 support is the default for streaming ETL jobs.

Maintenance window

Specifies a window where a streaming job can be restarted. See the section called "Maintenance windows".

Job timeout

Optionally enter a duration in minutes. The default value is blank.

- Streaming jobs must have a timeout value less than 7 days or 10080 minutes.
- When the value is left blank, the job will be restarted after 7 days, if you have not set up a maintenance window. If you have set up a maintenance window, the job will be restarted during the maintenance window after 7 days.

Data source

Specify the table that you created in the section called "Creating a Data Catalog table for a streaming source".

Data target

Do one of the following:

- Choose **Create tables in your data target** and specify the following data target properties.

  Data store

  Choose Amazon S3 or JDBC.

  Format

  Choose any format. All are supported for streaming.

- Choose **Use tables in the data catalog and update your data target**, and choose a table for a JDBC data store.

Output schema definition

Do one of the following:

- Choose **Automatically detect schema of each record** to turn on schema detection. AWS Glue determines the schema from the streaming data.
- Choose **Specify output schema for all records** to use the Apply Mapping transform to define the output schema.

Script

Optionally supply your own script or modify the generated script to perform operations that the Apache Spark Structured Streaming engine supports. For information on the available operations, see Operations on streaming DataFrames/Datasets.

Streaming ETL notes and restrictions

Keep in mind the following notes and restrictions:

- Auto-decompression for AWS Glue streaming ETL jobs is only available for the supported compression types. Also note the following:
  - Framed Snappy refers to the official framing format for Snappy.
  - Deflate is supported in Glue version 3.0, not Glue version 2.0.
- When using schema detection, you cannot perform joins of streaming data.
- AWS Glue streaming ETL jobs do not support the Union data type for AWS Glue Schema Registry with Avro format.
- Your ETL script can use AWS Glue's built-in transforms and the transforms native to Apache Spark Structured Streaming. For more information, see Operations on streaming DataFrames/Datasets on the Apache Spark website or AWS Glue PySpark transforms reference.
- AWS Glue streaming ETL jobs use checkpoints to keep track of the data that has been read. Therefore, a stopped and restarted job picks up where it left off in the stream. If you want to reprocess data, you can delete the checkpoint folder referenced in the script.
- Job bookmarks aren't supported.
- To use enhanced fan-out feature of Kinesis Data Streams in your job, consult the section called "Using enhanced fan-out in Kinesis streaming jobs".
- If you use a Data Catalog table created from AWS Glue Schema Registry, when a new schema version becomes available, to reflect the new schema, you need to do the following:

1. Stop the jobs associated with the table.
2. Update the schema for the Data Catalog table.
3. Restart the jobs associated with the table.

Record matching with AWS Lake Formation FindMatches

> **Note**
>
> Record matching is currently unavailable in the following Regions in the AWS Glue console: Middle East (UAE), Europe (Spain), Asia Pacific (Jakarta), and Europe (Zurich).

AWS Lake Formation provides machine learning capabilities to create custom transforms to cleanse your data. There is currently one available transform named FindMatches. The FindMatches transform enables you to identify duplicate or matching records in your dataset, even when the records do not have a common unique identifier and no fields match exactly. This will not require writing any code or knowing how machine learning works. FindMatches can be useful in many different problems, such as:

- **Matching customers**: Linking customer records across different customer databases, even when many customer fields do not match exactly across the databases (e.g. different name spelling, address differences, missing or inaccurate data, etc).
- **Matching products**: Matching products in your catalog against other product sources, such as product catalog against a competitor's catalog, where entries are structured differently.
- **Improving fraud detection**: Identifying duplicate customer accounts, determining when a newly created account is (or might be) a match for a previously known fraudulent user.
- **Other matching problems**: Match addresses, movies, parts lists, etc etc. In general, if a human being could look at your database rows and determine that they were a match, there is a really good chance that the FindMatches transform can help you.

You can create these transforms when you create a job. The transform that you create is based on a source data store schema and example data from the source data set that you label (we call this process "teaching" a transform). The records that you label must be present in the source dataset. In this process we generate a file which you label and then upload back which the transform would

in a manner learn from. After you teach your transform, you can call it from your Spark-based AWS Glue job (PySpark or Scala Spark) and use it in other scripts with a compatible source data store.

After the transform is created, it is stored in AWS Glue. On the AWS Glue console, you can manage the transforms that you create. In the navigation pane under **Data Integration and ETL**, **Data classification tools > Record Matching**, you can edit and continue to teach your machine learning transform. For more information about managing transforms on the console, see Working with machine learning transforms.

> **Note**
>
> AWS Glue version 2.0 FindMatches jobs use the Amazon S3 bucket `aws-glue-temp-<accountID>-<region>` to store temporary files while the transform is processing data. You can delete this data after the run has completed, either manually or by setting an Amazon S3 Lifecycle rule.

Types of machine learning transforms

You can create machine learning transforms to cleanse your data. You can call these transforms from your ETL script. Your data passes from transform to transform in a data structure called a *DynamicFrame*, which is an extension to an Apache Spark SQL `DataFrame`. The `DynamicFrame` contains your data, and you reference its schema to process your data.

The following types of machine learning transforms are available:

Find matches

Finds duplicate records in the source data. You teach this machine learning transform by labeling example datasets to indicate which rows match. The machine learning transform learns which rows should be matches the more you teach it with example labeled data. Depending on how you configure the transform, the output is one of the following:

- A copy of the input table plus a `match_id` column filled in with values that indicate matching sets of records. The `match_id` column is an arbitrary identifier. Any records which have the same `match_id` have been identified as matching to each other. Records with different `match_id`'s do not match.
- A copy of the input table with duplicate rows removed. If multiple duplicates are found, then the record with the lowest primary key is kept.

Find incremental matches

The Find matches transform can also be configured to find matches across the existing and incremental frames and return as output a column containing a unique ID per match group.

For more information, see: Finding incremental matches

Using the FindMatches transform

You can use the `FindMatches` transform to find duplicate records in the source data. A labeling file is generated or provided to help teach the transform.

> **Note**
>
> Currently, `FindMatches` transforms that use a custom encryption key aren't supported in the following Regions:
>
> - Asia Pacific (Osaka) - `ap-northeast-3`

To get started with the FindMatches transform, you can follow the steps below. For a more advanced and detailed example, see the **AWS Big Data Blog**: Harmonize data using AWS Glue and AWS Lake Formation FindMatches ML to build a customer 360 view .

Getting started using the Find Matches transform

Follow these steps to get started with the `FindMatches` transform:

1. Create a table in the AWS Glue Data Catalog for the source data that is to be cleaned. For information about how to create a crawler, see Working with Crawlers on the AWS Glue Console.

   If your source data is a text-based file such as a comma-separated values (CSV) file, consider the following:

   - Keep your input record CSV file and labeling file in separate folders. Otherwise, the AWS Glue crawler might consider them as multiple parts of the same table and create tables in the Data Catalog incorrectly.
   - Unless your CSV file includes ASCII characters only, ensure that UTF-8 without BOM (byte order mark) encoding is used for the CSV files. Microsoft Excel often adds a BOM in the beginning of UTF-8 CSV files. To remove it, open the CSV file in a text editor, and resave the file as **UTF-8 without BOM**.

2. On the AWS Glue console, create a job, and choose the **Find matches** transform type.

> **Important**
>
> The data source table that you choose for the job can't have more than 100 columns.

3. Tell AWS Glue to generate a labeling file by choosing **Generate labeling file**. AWS Glue takes the first pass at grouping similar records for each `labeling_set_id` so that you can review those groupings. You label matches in the `label` column.
   - If you already have a labeling file, that is, an example of records that indicate matching rows, upload the file to Amazon Simple Storage Service (Amazon S3). For information about the format of the labeling file, see Labeling file format. Proceed to step 4.
4. Download the labeling file and label the file as described in the Labeling section.
5. Upload the corrected labelled file. AWS Glue runs tasks to teach the transform how to find matches.

   On the **Machine learning transforms** list page, choose the **History** tab. This page indicates when AWS Glue performs the following tasks:
   - **Import labels**
   - **Export labels**
   - **Generate labels**
   - **Estimate quality**
6. To create a better transform, you can iteratively download, label, and upload the labelled file. In the initial runs, a lot more records might be mismatched. But AWS Glue learns as you continue to teach it by verifying the labeling file.
7. Evaluate and tune your transform by evaluating performance and results of finding matches. For more information, see Tuning machine learning transforms in AWS Glue.

Labeling

When `FindMatches` generates a labeling file, records are selected from your source table. Based on previous training, `FindMatches` identifies the most valuable records to learn from.

The act of *labeling* is editing a labeling file (we suggest using a spreadsheet such as Microsoft Excel) and adding identifiers, or labels, into the `label` column that identifies matching and nonmatching records. It is important to have a clear and consistent definition of a match in your source data.

`FindMatches` learns from which records you designate as matches (or not) and uses your decisions to learn how to find duplicate records.

When a labeling file is generated by `FindMatches`, approximately 100 records are generated. These 100 records are typically divided into 10 *labeling sets*, where each labeling set is identified by a unique `labeling_set_id` generated by `FindMatches`. Each labeling set should be viewed as a separate labeling task independent of the other labeling sets. Your task is to identify matching and non-matching records within each labeling set.

Tips for editing labeling files in a spreadsheet

When editing the labeling file in a spreadsheet application, consider the following:

- The file might not open with column fields fully expanded. You might need to expand the `labeling_set_id` and `label` columns to see content in those cells.
- If the primary key column is a number, such as a `long` data type, the spreadsheet might interpret it as a number and change the value. This key value must be treated as text. To correct this problem, format all the cells in the primary key column as **Text data**.

Labeling file format

The labeling file that is generated by AWS Glue to teach your `FindMatches` transform uses the following format. If you generate your own file for AWS Glue, it must follow this format as well:

- It is a comma-separated values (CSV) file.
- It must be encoded in `UTF-8`. If you edit the file using Microsoft Windows, it might be encoded with `cp1252`.
- It must be in an Amazon S3 location to pass it to AWS Glue.
- Use a moderate number of rows for each labeling task. 10–20 rows per task are recommended, although 2–30 rows per task are acceptable. Tasks larger than 50 rows are not recommended and may cause poor results or system failure.
- If you have already-labeled data consisting of pairs of records labeled as a "match" or a "no-match", this is fine. These labeled pairs can be represented as labeling sets of size 2. In this case label both records with, for instance, a letter "A" if they match, but label one as "A" and one as "B" if they do not match.

> **Note**
>
> Because it has additional columns, the labeling file has a different schema from a file that contains your source data. Place the labeling file in a different folder from any transform input CSV file so that the AWS Glue crawler does not consider it when it creates tables in the Data Catalog. Otherwise, the tables created by the AWS Glue crawler might not correctly represent your data.

- The first two columns (`labeling_set_id`, `label`) are required by AWS Glue. The remaining columns must match the schema of the data that is to be processed.
- For each `labeling_set_id`, you identify all matching records by using the same label. A label is a unique string placed in the `label` column. We recommend using labels that contain simple characters, such as A, B, C, and so on. Labels are case sensitive and are entered in the `label` column.
- Rows that contain the same `labeling_set_id` and the same label are understood to be labeled as a match.
- Rows that contain the same `labeling_set_id` and a different label are understood to be labeled as *not* a match
- Rows that contain a different `labeling_set_id` are understood to be conveying no information for or against matching.

The following is an example of labeling the data:

labeling_set_id	label	first_name	last_name	Birthday
ABC123	A	John	Doe	04/01/1980
ABC123	B	Jane	Smith	04/03/1980
ABC123	A	Johnny	Doe	04/01/1980
ABC123	A	Jon	Doe	04/01/1980
DEF345	A	Richard	Jones	12/11/1992
DEF345	A	Rich	Jones	11/12/1992

labeling_set_id	label	first_name	last_name	Birthday
DEF345	B	Sarah	Jones	12/11/1992
DEF345	C	Richie	Jones Jr.	05/06/2017
DEF345	B	Sarah	Jones-Walker	12/11/1992
GHI678	A	Robert	Miller	1/3/1999
GHI678	A	Bob	Miller	1/3/1999
XYZABC	A	William	Robinson	2/5/2001
XYZABC	B	Andrew	Robinson	2/5/1971

- In the above example we identify John/Johnny/Jon Doe as being a match and we teach the system that these records do not match Jane Smith. Separately, we teach the system that Richard and Rich Jones are the same person, but that these records are not a match to Sarah Jones/Jones-Walker and Richie Jones Jr.
- As you can see, the scope of the labels is limited to the `labeling_set_id`. So labels do not cross `labeling_set_id` boundaries. For example, a label "A" in `labeling_set_id` 1 does not have any relation to label "A" in `labeling_set_id` 2.
- If a record does not have any matches within a labeling set, then assign it a unique label. For instance, Jane Smith does not match any record in labeling set ABC123, so it is the only record in that labeling set with the label of B.
- The labeling set "GHI678" shows that a labeling set can consist of just two records which are given the same label to show that they match. Similarly, "XYZABC" shows two records given different labels to show that they do not match.
- Note that sometimes a labeling set may contain no matches (that is, you give every record in the labeling set a different label) or a labeling set might all be "the same" (you gave them all the same label). This is okay as long as your labeling sets collectively contain examples of records that are and are not "the same" by your criteria.

Important

Confirm that the IAM role that you pass to AWS Glue has access to the Amazon S3 bucket that contains the labeling file. By convention, AWS Glue policies grant permission to

Amazon S3 buckets or folders whose names are prefixed with **aws-glue-**. If your labeling files are in a different location, add permission to that location in the IAM role.

Tuning machine learning transforms in AWS Glue

You can tune your machine learning transforms in AWS Glue to improve the results of your data-cleansing jobs to meet your objectives. To improve your transform, you can teach it by generating a labeling set, adding labels, and then repeating these steps several times until you get your desired results. You can also tune by changing some machine learning parameters.

For more information about machine learning transforms, see Record matching with AWS Lake Formation FindMatches.

Topics

- Machine learning measurements
- Deciding between precision and recall
- Deciding Between accuracy and cost
- Estimating the quality of matches using match confidence scores
- Teaching the Find Matches transform

Machine learning measurements

To understand the measurements that are used to tune your machine learning transform, you should be familiar with the following terminology:

True positive (TP)

A match in the data that the transform correctly found, sometimes called a *hit*.

True negative (TN)

A nonmatch in the data that the transform correctly rejected.

False positive (FP)

A nonmatch in the data that the transform incorrectly classified as a match, sometimes called a *false alarm*.

False negative (FN)

A match in the data that the transform didn't find, sometimes called a *miss*.

For more information about the terminology that is used in machine learning, see Confusion matrix in Wikipedia.

To tune your machine learning transforms, you can change the value of the following measurements in the **Advanced properties** of the transform.

- **Precision** measures how well the transform finds true positives among the total number of records that it identifies as positive (true positives and false positives). For more information, see Precision and recall in Wikipedia.
- **Recall** measures how well the transform finds true positives from the total records in the source data. For more information, see Precision and recall in Wikipedia.
- **Accuracy** measures how well the transform finds true positives and true negatives. Increasing accuracy requires more machine resources and cost. But it also results in increased recall. For more information, see Accuracy and precision in Wikipedia.
- **Cost** measures how many compute resources (and thus money) are consumed to run the transform.

Deciding between precision and recall

Each `FindMatches` transform contains a `precision-recall` parameter. You use this parameter to specify one of the following:

- If you are more concerned about the transform falsely reporting that two records match when they actually don't match, then you should emphasize *precision*.
- If you are more concerned about the transform failing to detect records that really do match, then you should emphasize *recall*.

You can make this trade-off on the AWS Glue console or by using the AWS Glue machine learning API operations.

When to favor precision

Favor precision if you are more concerned about the risk that `FindMatches` results in a pair of records matching when they don't actually match. To favor precision, choose a *higher* precision-

recall trade-off value. With a higher value, the `FindMatches` transform requires more evidence to decide that a pair of records should be matched. The transform is tuned to bias toward saying that records do not match.

For example, suppose that you're using `FindMatches` to detect duplicate items in a video catalog, and you provide a higher precision-recall value to the transform. If your transform incorrectly detects that *Star Wars: A New Hope* is the same as *Star Wars: The Empire Strikes Back*, a customer who wants *A New Hope* might be shown *The Empire Strikes Back*. This would be a poor customer experience.

However, if the transform fails to detect that *Star Wars: A New Hope* and *Star Wars: Episode IV —A New Hope* are the same item, the customer might be confused at first but might eventually recognize them as the same. It would be a mistake, but not as bad as the previous scenario.

When to favor recall

Favor recall if you are more concerned about the risk that the `FindMatches` transform results might fail to detect a pair of records that actually do match. To favor recall, choose a *lower* precision-recall trade-off value. With a lower value, the `FindMatches` transform requires less evidence to decide that a pair of records should be matched. The transform is tuned to bias toward saying that records do match.

For example, this might be a priority for a security organization. Suppose that you are matching customers against a list of known defrauders, and it is important to determine whether a customer is a defrauder. You are using `FindMatches` to match the defrauder list against the customer list. Every time `FindMatches` detects a match between the two lists, a human auditor is assigned to verify that the person is, in fact, a defrauder. Your organization might prefer to choose recall over precision. In other words, you would rather have the auditors manually review and reject some cases when the customer is not a defrauder than fail to identify that a customer is, in fact, on the defrauder list.

How to favor both precision and recall

The best way to improve both precision and recall is to label more data. As you label more data, the overall accuracy of the `FindMatches` transform improves, thus improving both precision and recall. Nevertheless, even with the most accurate transform, there is always a gray area where you need to experiment with favoring precision or recall, or choose a value in the middle.

Deciding Between accuracy and cost

Each `FindMatches` transform contains an `accuracy-cost` parameter. You can use this parameter to specify one of the following:

- If you are more concerned with the transform accurately reporting that two records match, then you should emphasize *accuracy*.
- If you are more concerned about the cost or speed of running the transform, then you should emphasize *lower cost*.

You can make this trade-off on the AWS Glue console or by using the AWS Glue machine learning API operations.

When to favor accuracy

Favor accuracy if you are more concerned about the risk that the `find matches` results won't contain matches. To favor accuracy, choose a *higher* accuracy-cost trade-off value. With a higher value, the `FindMatches` transform requires more time to do a more thorough search for correctly matching records. Note that this parameter doesn't make it less likely to falsely call a nonmatching record pair a match. The transform is tuned to bias towards spending more time finding matches.

When to favor cost

Favor cost if you are more concerned about the cost of running the `find matches` transform and less about how many matches are found. To favor cost, choose a *lower* accuracy-cost trade-off value. With a lower value, the `FindMatches` transform requires fewer resources to run. The transform is tuned to bias towards finding fewer matches. If the results are acceptable when favoring lower cost, use this setting.

How to favor both accuracy and lower cost

It takes more machine time to examine more pairs of records to determine whether they might be matches. If you want to reduce cost without reducing quality, here are some steps you can take:

- Eliminate records in your data source that you aren't concerned about matching.
- Eliminate columns from your data source that you are sure aren't useful for making a match/no-match decision. A good way of deciding this is to eliminate columns that you don't think affect your own decision about whether a set of records is “the same.”

Estimating the quality of matches using match confidence scores

Match confidence scores provide an estimate of the quality of matches found by FindMatches to distinguish between matched records in which the machine learning model is highly confident, uncertain, or unlikely. A match confidence score will be between 0 and 1, where a higher score means higher similarity. Examining match confidence scores lets you distinguish between clusters of matches in which the system is highly confident (which you may decide to merge), clusters about which the system is uncertain (which you may decide to have reviewed by a human), and clusters that the system deems to be unlikely (which you may decide to reject).

You may want to adjust your training data in situations where you see a high match confidence score, but determine there are not matches, or where you see a low score but determine there are, in fact, matches.

Confidence scores are particularly useful when there are large sized industrial datasets, where it is infeasible to review every FindMatches decision.

Match confidence scores are available in AWS Glue version 2.0 or later.

Generating match confidence scores

You can generate match confidence scores by setting the Boolean value of `computeMatchConfidenceScores` to True when calling the `FindMatches` or `FindIncrementalMatches` API.

AWS Glue adds a new `column match_confidence_score` to the output.

Match scoring examples

For example, consider the following matched records:

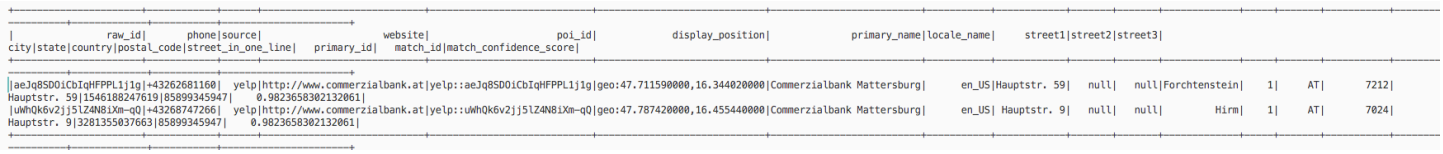
Score >= 0.9

Summary of matched records:

```
  primary_id  |   match_id  | match_confidence_score

3281355037663    85899345947   0.9823658302132061
1546188247619    85899345947   0.9823658302132061
```

Details:



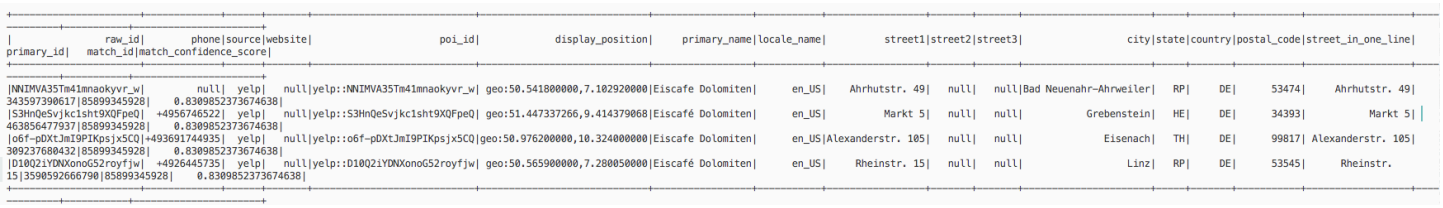
From this example, we can see that two records are very similar and share `display_position`, `primary_name`, and `street name`.

Score >= 0.8 and score < 0.9

Summary of matched records:

primary_id	match_id	match_confidence_score
309237680432	85899345928	0.8309852373674638
3590592666790	85899345928	0.8309852373674638
343597390617	85899345928	0.8309852373674638
249108124906	85899345928	0.8309852373674638
463856477937	85899345928	0.8309852373674638

Details:



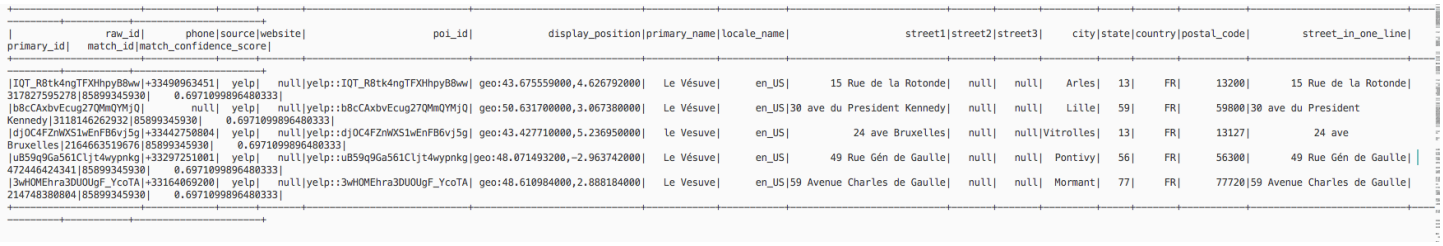
From this example, we can see that these records share the same `primary_name`, and `country`.

Score >= 0.6 and score < 0.7

Summary of matched records:

primary_id	match_id	match_confidence_score
2164663519676	85899345930	0.6971099896480333
317827595278	85899345930	0.6971099896480333
472446424341	85899345930	0.6971099896480333
3118146262932	85899345930	0.6971099896480333
214748380804	85899345930	0.6971099896480333

Details:



```

```

From this example, we can see that these records share only the same `primary_name`.

For more information, see:

- Step 5: Add and run a job with your machine learning transform
- PySpark: FindMatches class
- PySpark: FindIncrementalMatches class
- Scala: FindMatches class
- Scala: FindIncrementalMatches class

Teaching the Find Matches transform

Each `FindMatches` transform must be taught what should be considered a match and what should not be considered a match. You teach your transform by adding labels to a file and uploading your choices to AWS Glue.

You can orchestrate this labeling on the AWS Glue console or by using the AWS Glue machine learning API operations.

How many times should I add labels? How many labels do I need?

The answers to these questions are mostly up to you. You must evaluate whether `FindMatches` is delivering the level of accuracy that you need and whether you think the extra labeling effort is worth it for you. The best way to decide this is to look at the “Precision,” “Recall,” and “Area under the precision recall curve” metrics that you can generate when you choose **Estimate quality** on the AWS Glue console. After you label more sets of tasks, rerun these metrics and verify whether they have improved. If, after labeling a few sets of tasks, you don't see improvement on the metric that you are focusing on, the transform quality might have reached a plateau.

Why are both true positive and true negative labels needed?

The `FindMatches` transform needs both positive and negative examples to learn what you think is a match. If you are labeling `FindMatches`-generated training data (for example, using the **I do**

not have labels option), `FindMatches` tries to generate a set of "label set ids" for you. Within each task, you give the same "label" to some records and different "labels" to other records. In other words, the tasks generally are not either all the same or all different (but it's okay if a particular task is all "the same" or all "not the same").

If you are teaching your `FindMatches` transform using the **Upload labels from S3** option, try to include both examples of matching and nonmatching records. It's acceptable to have only one type. These labels help you build a more accurate `FindMatches` transform, but you still need to label some records that you generate using the **Generate labeling file** option.

How can I enforce that the transform matches exactly as I taught it?

The `FindMatches` transform learns from the labels that you provide, so it might generate records pairs that don't respect the provided labels. To enforce that the `FindMatches` transform respects your labels, select **EnforceProvidedLabels** in **FindMatchesParameter**.

What techniques can you use when an ML transform identifies items as matches that are not true matches?

You can use the following techniques:

- Increase the `precisionRecallTradeoff` to a higher value. This eventually results in finding fewer matches, but it should also break up your big cluster when it reaches a high enough value.
- Take the output rows corresponding to the incorrect results and reformat them as a labeling set (removing the `match_id` column and adding a `labeling_set_id` and `label` column). If necessary, break up (subdivide) into multiple labeling sets to ensure that the labeler can keep each labeling set in mind while assigning labels. Then, correctly label the matching sets and upload the label file and append it to your existing labels. This might teach your transformer enough about what it is looking for to understand the pattern.
- (Advanced) Finally, look at that data to see if there is a pattern that you can detect that the system is not noticing. Preprocess that data using standard AWS Glue functions to *normalize* the data. Highlight what you want the algorithm to learn from by separating data that you know to be differently important into their own columns. Or construct combined columns from columns whose data you know to be related.

Working with machine learning transforms

You can use AWS Glue to create custom machine learning transforms that can be used to cleanse your data. You can use these transforms when you create a job on the AWS Glue console.

For information about how to create a machine learning transform, see Record matching with AWS Lake Formation FindMatches.

Topics

- Transform properties
- Adding and editing machine learning transforms
- Viewing transform details
- Teach transforms using labels

Transform properties

To view an existing machine learning transform, sign in to the AWS Management Console, and open the AWS Glue console at https://console.aws.amazon.com/glue/. In the navigation pane under **Data Integration and ETL**, choose **Data classification tools > Record Matching**.

The properties for each transform:

Transform name

The unique name you gave the transform when you created it.

ID

A unique identifier of the transform.

Label count

The number of labels in the labeling file that was provided to help teach the transform.

Status

Indicates whether the transform is **Ready** or **Needs training**. To run a machine learning transform successfully in a job, it must be **Ready**.

Created

The date the transform was created.

Modified

The date the transform was last updated.

Description

The description supplied for the transform, if one was provided.

AWS Glue version

The version of AWS Glue used.

Run ID

The unique name you gave the transform when you created it.

Task type

The type of machine learning transform; for example, **Find matching records**.

Status

Indicates the status of the task run. Possible statuses include:

- Starting
- Running
- Stopping
- Stopped
- Succeeded
- Failed
- Timeout

Error

If the status is Failed, an error message is displayed describing the reason for the failure.

Adding and editing machine learning transforms

You can view, delete, set up and teach, or tune a transform on the AWS Glue console. Select the check box next to the transform in the list, choose **Action**, and then choose the action that you want to take.

Creating a new ML transform

To add a new machine learning transform, choose **Create transform**. Follow the instructions in the **Add job** wizard. For more information, see Record matching with AWS Lake Formation FindMatches.

Step 1. Set transform properties.

1. Enter the name and description (optional).

2. Optionally, set security configuration. See Using data encryption with machine learning transforms.
3. Optionally, set Task execution settings. Task execution settings allow you to customize how the task is run. Select the Worker type, number of workers, task timeout (in minutes), the number of retries, and the AWS Glue version.
4. Optionally, set Tags. Tags are labels that you can assign to an AWS resource. Each tag consists of a key and an optional value. Tags can be used to search and filter your resource or track your AWS costs.

Step 2. Choose table and primary key.

1. Choose the AWS Glue Catalog database and table.
2. Choose a primary key from the selected table. The primary key column typically contains a unique identifier for every record in the data source.

Step 3. Select tuning options.

1. For **Recall vs. precision**, choose the tuning value to tune the transform to favor recall or precision. By default, **Balanced** is selected, but you can choose to favor recall or favor precision, or choose **Custom** and enter a value between 0.0 and 1.0 (inclusive).
2. For **Lower cost vs. accuracy**, choose the tuning value to favor lower cost or accuracy, or choose **Custom** and enter a value between 0.0 and 1.0 (inclusive).
3. For **Match enforcement**, choose **Force output to match labels** if you want to teach the ML transform by forcing the output to match the labels used.

Step 4. Review and create.

1. Review the options for steps 1 – 3.
2. Choose **Edit** for any step that needs to be modified. Choose **Create transform** to complete the create transform wizard.

Using data encryption with machine learning transforms

When adding a machine learning transform to AWS Glue, you can optionally specify a security configuration that is associated with the data source or data target. If the Amazon S3 bucket used

to store the data is encrypted with a security configuration, specify the same security configuration when creating the transform.

You can also choose to use server-side encryption with AWS KMS (SSE-KMS) to encrypt the model and labels to prevent unauthorized persons from inspecting it. If you choose this option, you're prompted to choose the AWS KMS key by name, or you can choose **Enter a key ARN**. If you choose to enter the ARN for the KMS key, a second field appears where you can enter the KMS key ARN.

> **Note**
>
> Currently, ML transforms that use a custom encryption key aren't supported in the following Regions:
>
> - Asia Pacific (Osaka) - `ap-northeast-3`

Viewing transform details

Viewing transform properties

The **Transform properties** page includes attributes of your transform. It shows you the details about the transform definition, including the following:

- **Transform name** shows the name of the transform.
- **Type** lists the type of the transform.
- **Status** displays whether the transform is ready to be used in a script or job.
- **Force output to match labels** displays whether the transform forces the output to match the labels provided by the user.
- **Spark version** is related to the AWS Glue version you chose in the **Task run properties** when adding the transform. AWS Glue 1.0 and Spark 2.4 is recommended for most customers. For more information, see AWS Glue Versions.

History, Estimate quality and Tags tabs

Transform details include the information that you defined when you created the transform. To view the details of a transform, select the transform in the **Machine learning transforms** list, and review the information on the following tabs:

- History

- Estimate quality
- Tags

History

The **History** tab shows your transform task run history. Several types of tasks are run to teach a transform. For each task, the run metrics include the following:

- **Run ID** is an identifier created by AWS Glue for each run of this task.
- **Task type** shows the type of task run.
- **Status** shows the success of each task listed with the most recent run at the top.
- **Error** shows the details of an error message if the run was not successful.
- **Start time** shows the date and time (local time) that the task started.
- **End time** shows the date and time (local time) that the task ended.
- **Logs** links to the logs written to `stdout` for this job run.

  The **Logs** link takes you to Amazon CloudWatch Logs. There you can view the details about the tables that were created in the AWS Glue Data Catalog and any errors that were encountered. You can manage your log retention period on the CloudWatch console. The default log retention is `Never Expire`. For more information about how to change the retention period, see Change Log Data Retention in CloudWatch Logs in the *Amazon CloudWatch Logs User Guide*.
- **Label file** shows a link to Amazon S3 for a generated labeling file.

Estimate quality

The **Estimate quality** tab shows the metrics that you use to measure the quality of the transform. Estimates are calculated by comparing the transform match predictions using a subset of your labeled data against the labels you have provided. These estimates are approximate. You can invoke an **Estimate quality** task run from this tab.

The **Estimate quality** tab shows the metrics from the last **Estimate quality** run including the following properties:

- **Area under the Precision-Recall curve** is a single number estimating the upper bound of the overall quality of the transform. It is independent of the choice made for the precision-recall parameter. Higher values indicate that you have a more attractive precision-recall tradeoff.

- **Precision** estimates how often the transform is correct when it predicts a match.
- **Recall upper limit** estimates that for an actual match, how often the transform predicts the match.
- **F1** estimates the transform's accuracy between 0 and 1, where 1 is the best accuracy. For more information, see F1 score in Wikipedia.
- The **Column importance** table show the column names and importance score for each column. Column importance helps you understand how columns contribute to your model, by identifying which columns in your records are being used the most to do the matching. This data may prompt you to add to or change your labelset to raise or lower the importance of columns.

  The Importance column provides a numerical score for each column, as a decimal not greater than 1.0.

For information about understanding quality estimates versus true quality, see Quality estimates versus end-to-end (true) quality.

For more information about tuning your transform, see Tuning machine learning transforms in AWS Glue.

Quality estimates versus end-to-end (true) quality

AWS Glue estimates the quality of your transform by presenting the internal machine-learned model with a number of pairs of records that you provided matching labels for but that the model has not seen before. These quality estimates are a function of the quality of the machine-learned model (which is influenced by the number of records that you label to “teach” the transform). The end-to-end, or *true* recall (which is not automatically calculated by the `ML transform`) is also influenced by the `ML transform` filtering mechanism that proposes a wide variety of possible matches to the machine-learned model.

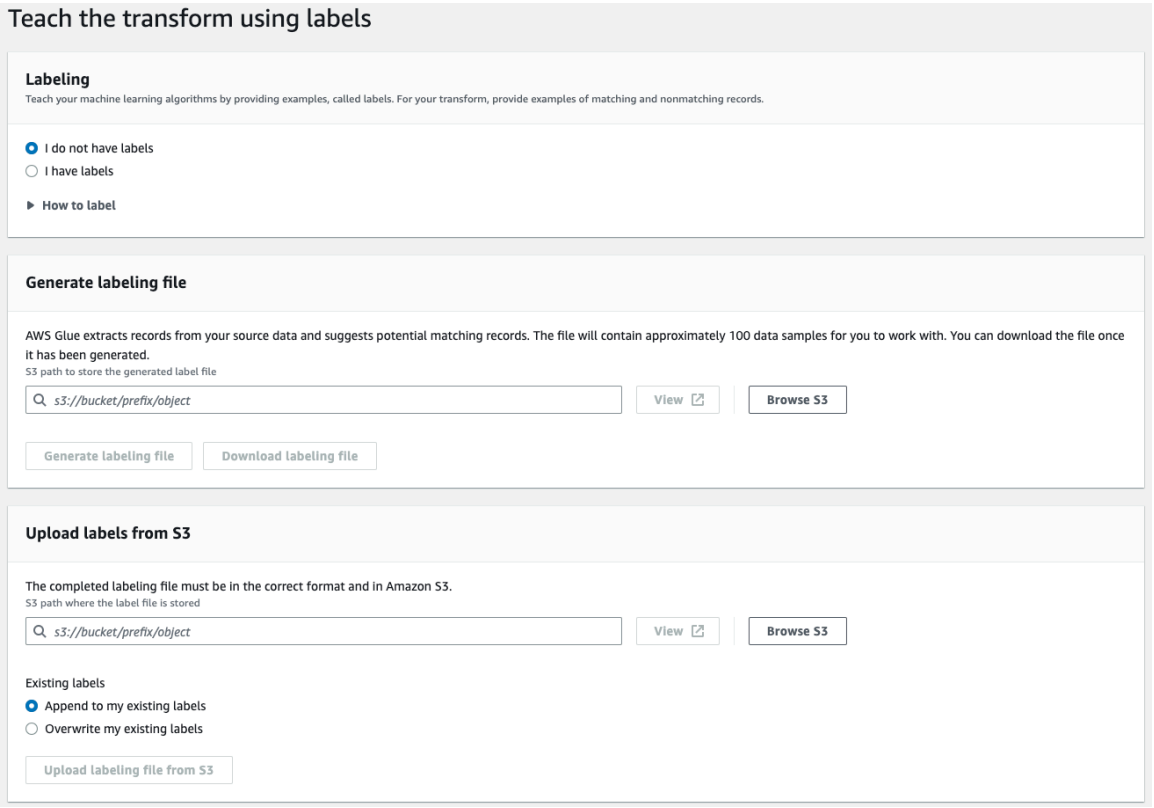
You can tune this filtering method primarily by specifying the **Lower Cost-Accuracy** tuning value. As the tuning value gets closer to favor **Accuracy**, the system does a more thorough and expensive search for pairs of records that might be matches. More pairs of records are fed to your machine-learned model, and your `ML transform`'s end-to-end or true recall gets closer to the estimated recall metric. As a result, changes in the end-to-end quality of your matches as a result of changes in the cost/accuracy tradeoff for your matches will typically not be reflected in the quality estimate.

Tags

Tags are labels that you can assign to an AWS resource. Each tag consists of a key and an optional value. Tags can be used to search and filter your resource or track your AWS costs.

Teach transforms using labels

You can teach your ML transform using labels (examples) by choosing **Teach transform** from the ML transform details page. When you teach your machine learning algorithm by providing examples (called labels), you can choose existing labels to use, or create a labeling file.



- **Labeling** – If you have labels, choose **I have labels**. If you do not have labels, you can still continue with the next step in generating a labeling file.
- **Generate labeling file** – AWS Glue extracts records from your source data and suggest potential matching records. You choose the Amazon S3 bucket to store the generated label file. Choose **Generate labeling file** to start the process. When done, choose **Download labeling file**. The downloaded file will have a column for labels where you can fill in the labels.
- **Upload labels from Amazon S3** – Choose the completed labeling file from the Amazon S3 bucket where the label file is stored. Then, choose to either append the labels to your existing labels or to overwrite your existing labels. Choose **Upload labeling file from Amazon S3**.

Tutorial: Creating a machine learning transform with AWS Glue

This tutorial guides you through the actions to create and manage a machine learning (ML) transform using AWS Glue. Before using this tutorial, you should be familiar with using the AWS Glue console to add crawlers and jobs and edit scripts. You should also be familiar with finding and downloading files on the Amazon Simple Storage Service (Amazon S3) console.

In this example, you create a `FindMatches` transform to find matching records, teach it how to identify matching and nonmatching records, and use it in an AWS Glue job. The AWS Glue job writes a new Amazon S3 file with an additional column named `match_id`.

The source data used by this tutorial is a file named `dblp_acm_records.csv`. This file is a modified version of academic publications (DBLP and ACM) available from the original DBLP ACM dataset. The `dblp_acm_records.csv` file is a comma-separated values (CSV) file in UTF-8 format with no byte-order mark (BOM).

A second file, `dblp_acm_labels.csv`, is an example labeling file that contains both matching and nonmatching records used to teach the transform as part of the tutorial.

Topics

- Step 1: Crawl the source data
- Step 2: Add a machine learning transform
- Step 3: Teach your machine learning transform
- Step 4: Estimate the quality of your machine learning transform
- Step 5: Add and run a job with your machine learning transform
- Step 6: Verify output data from Amazon S3

Step 1: Crawl the source data

First, crawl the source Amazon S3 CSV file to create a corresponding metadata table in the Data Catalog.

> **Important**
>
> To direct the crawler to create a table for only the CSV file, store the CSV source data in a different Amazon S3 folder from other files.

1. Sign in to the AWS Management Console and open the AWS Glue console at https://console.aws.amazon.com/glue/.
2. In the navigation pane, choose **Crawlers**, **Add crawler**.
3. Follow the wizard to create and run a crawler named `demo-crawl-dblp-acm` with output to database `demo-db-dblp-acm`. When running the wizard, create the database `demo-db-dblp-acm` if it doesn't already exist. Choose an Amazon S3 include path to sample data in the current AWS Region. For example, for `us-east-1`, the Amazon S3 include path to the source file is `s3://ml-transforms-public-datasets-us-east-1/dblp-acm/records/dblp_acm_records.csv`.

   If successful, the crawler creates the table `dblp_acm_records_csv` with the following columns: id, title, authors, venue, year, and source.

Step 2: Add a machine learning transform

Next, add a machine learning transform that is based on the schema of your data source table created by the crawler named `demo-crawl-dblp-acm`.

1. On the AWS Glue console, in the navigation pane under **Data Integration and ETL**, choose **Data classification tools > Record Matching**, then **Add transform**. Follow the wizard to create a `Find matches` transform with the following properties.

   a. For **Transform name**, enter **`demo-xform-dblp-acm`**. This is the name of the transform that is used to find matches in the source data.

   b. For **IAM role**, choose an IAM role that has permission to the Amazon S3 source data, labeling file, and AWS Glue API operations. For more information, see Create an IAM Role for AWS Glue in the *AWS Glue Developer Guide*.

   c. For **Data source**, choose the table named **dblp_acm_records_csv** in database **demo-db-dblp-acm**.

   d. For **Primary key**, choose the primary key column for the table, **id**.
2. In the wizard, choose **Finish** and return to the **ML transforms** list.

Step 3: Teach your machine learning transform

Next, you teach your machine learning transform using the tutorial sample labeling file.

You can't use a machine language transform in an extract, transform, and load (ETL) job until its status is **Ready for use**. To get your transform ready, you must teach it how to identify matching and nonmatching records by providing examples of matching and nonmatching records. To teach your transform, you can **Generate a label file**, add labels, and then **Upload label file**. In this tutorial, you can use the example labeling file named `dblp_acm_labels.csv`. For more information about the labeling process, see Labeling.

1. On the AWS Glue console, in the navigation pane, choose **Record Matching**.
2. Choose the `demo-xform-dblp-acm` transform, and then choose **Action**, **Teach**. Follow the wizard to teach your `Find matches` transform.
3. On the transform properties page, choose **I have labels**. Choose an Amazon S3 path to the sample labeling file in the current AWS Region. For example, for `us-east-1`, upload the provided labeling file from the Amazon S3 path `s3://ml-transforms-public-datasets-us-east-1/dblp-acm/labels/dblp_acm_labels.csv` with the option to **overwrite** existing labels. The labeling file must be located in Amazon S3 in the same Region as the AWS Glue console.

   When you upload a labeling file, a task is started in AWS Glue to add or overwrite the labels used to teach the transform how to process the data source.
4. On the final page of the wizard, choose **Finish**, and return to the **ML transforms** list.

Step 4: Estimate the quality of your machine learning transform

Next, you can estimate the quality of your machine learning transform. The quality depends on how much labeling you have done. For more information about estimating quality, see Estimate quality.

1. On the AWS Glue console, in the navigation pane under **Data Integration and ETL**, choose **Data classification tools > Record Matching**.
2. Choose the `demo-xform-dblp-acm` transform, and choose the **Estimate quality** tab. This tab displays the current quality estimates, if available, for the transform.
3. Choose **Estimate quality** to start a task to estimate the quality of the transform. The accuracy of the quality estimate is based on the labeling of the source data.
4. Navigate to the **History** tab. In this pane, task runs are listed for the transform, including the **Estimating quality** task. For more details about the run, choose **Logs**. Check that the run status is **Succeeded** when it finishes.

Step 5: Add and run a job with your machine learning transform

In this step, you use your machine learning transform to add and run a job in AWS Glue. When the transform `demo-xform-dblp-acm` is **Ready for use**, you can use it in an ETL job.

1. On the AWS Glue console, in the navigation pane, choose **Jobs**.
2. Choose **Add job**, and follow the steps in the wizard to create an ETL Spark job with a generated script. Choose the following property values for your transform:
   a. For **Name**, choose the example job in this tutorial, **demo-etl-dblp-acm**.
   b. For **IAM role**, choose an IAM role with permission to the Amazon S3 source data, labeling file, and AWS Glue API operations. For more information, see Create an IAM Role for AWS Glue in the *AWS Glue Developer Guide*.
   c. For **ETL language**, choose **Scala**. This is the programming language in the ETL script.
   d. For **Script file name**, choose **demo-etl-dblp-acm**. This is the file name of the Scala script (same as the job name).
   e. For **Data source**, choose **dblp_acm_records_csv**. The data source you choose must match the machine learning transform data source schema.
   f. For **Transform type**, choose **Find matching records** to create a job using a machine learning transform.
   g. Clear **Remove duplicate records**. You don't want to remove duplicate records because the output records written have an additional `match_id` field added.
   h. For **Transform**, choose **demo-xform-dblp-acm**, the machine learning transform used by the job.
   i. For **Create tables in your data target**, choose to create tables with the following properties:
      - **Data store type** — **`Amazon S3`**
      - **Format** — **CSV**
      - **Compression type** — **None**
      - **Target path** — The Amazon S3 path where the output of the job is written (in the current console AWS Region)
3. Choose **Save job and edit script** to display the script editor page.

4. Edit the script to add a statement to cause the job output to the **Target path** to be written to a single partition file. Add this statement immediately following the statement that runs the `FindMatches` transform. The statement is similar to the following.

```
val single_partition = findmatches1.repartition(1)
```

   You must modify the `.writeDynamicFrame(findmatches1)` statement to write the output as `.writeDynamicFrame(single_partion)`.

5. After you edit the script, choose **Save**. The modified script looks similar to the following code, but customized for your environment.

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.ml.FindMatches
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._

object GlueApp {
  def main(sysArgs: Array[String]) {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    // @params: [JOB_NAME]
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)
    // @type: DataSource
    // @args: [database = "demo-db-dblp-acm", table_name = "dblp_acm_records_csv",
 transformation_ctx = "datasource0"]
    // @return: datasource0
    // @inputs: []
    val datasource0 = glueContext.getCatalogSource(database = "demo-db-dblp-acm",
 tableName = "dblp_acm_records_csv", redshiftTmpDir = "", transformationContext =
 "datasource0").getDynamicFrame()
    // @type: FindMatches
    // @args: [transformId = "tfm-123456789012", emitFusion = false,
 survivorComparisonField = "<primary_id>", transformation_ctx = "findmatches1"]
    // @return: findmatches1
    // @inputs: [frame = datasource0]
```

```
    val findmatches1 = FindMatches.apply(frame = datasource0, transformId
 = "tfm-123456789012", transformationContext = "findmatches1",
 computeMatchConfidenceScores = true)

    // Repartition the previous DynamicFrame into a single partition.
    val single_partition = findmatches1.repartition(1)

    // @type: DataSink
    // @args: [connection_type = "s3", connection_options = {"path": "s3://aws-
glue-ml-transforms-data/sal"}, format = "csv", transformation_ctx = "datasink2"]
    // @return: datasink2
    // @inputs: [frame = findmatches1]
    val datasink2 = glueContext.getSinkWithFormat(connectionType =
 "s3", options = JsonOptions("""{"path": "s3://aws-glue-ml-transforms-
data/sal"}"""), transformationContext = "datasink2", format =
 "csv").writeDynamicFrame(single_partition)
    Job.commit()
  }
}
```

6. Choose **Run job** to start the job run. Check the status of the job in the jobs list. When the job finishes, in the **ML transform**, **History** tab, there is a new **Run ID** row added of type **ETL job**.
7. Navigate to the **Jobs**, **History** tab. In this pane, job runs are listed. For more details about the run, choose **Logs**. Check that the run status is **Succeeded** when it finishes.

Step 6: Verify output data from Amazon S3

In this step, you check the output of the job run in the Amazon S3 bucket that you chose when you added the job. You can download the output file to your local machine and verify that matching records were identified.

1. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Download the target output file of the job `demo-etl-dblp-acm`. Open the file in a spreadsheet application (you might need to add a file extension `.csv` for the file to properly open).

   The following image shows an excerpt of the output in Microsoft Excel.

The data source and target file both have 4,911 records. However, the `Find matches` transform adds another column named `match_id` to identify matching records in the output. Rows with the same `match_id` are considered matching records. The `match_confidence_score` is a number between 0 and 1 that provides an estimate of the quality of matches found by `Find matches`.

3. Sort the output file by `match_id` to easily see which records are matches. Compare the values in the other columns to see if you agree with the results of the `Find matches` transform. If you don't, you can continue to teach the transform by adding more labels.

   You can also sort the file by another field, such as `title`, to see if records with similar titles have the same `match_id`.

Finding incremental matches

The Find matches feature allows you to identify duplicate or matching records in your dataset, even when the records don’t have a common unique identifier and no fields match exactly. The initial release of the Find matches transform identified matching records within a single dataset. When you add new data to the dataset, you had to merge it with the existing clean dataset and rerun matching against the complete merged dataset.

The incremental matching feature makes it simpler to match to incremental records against existing matched datasets. Suppose that you want to match prospects data with existing customer datasets. The incremental match capability provides you the flexibility to match hundreds of thousands of new prospects with an existing database of prospects and customers by merging the results into a single database or table. By matching only between the new and existing datasets, the find incremental matches optimization reduces computation time, which also reduces cost.

The usage of incremental matching is similar to Find matches as described in Tutorial: Creating a machine learning transform with AWS Glue. This topic identifies only the differences with incremental matching.

For more information, see the blog post on Incremental data matching.

Running an incremental matching job

For the following procedure, suppose the following:

- You have crawled the existing dataset into the table *first_records*. The *first_records* dataset must be a matched dataset, or the output of the matched job.
- You have created and trained a Find matches transform with AWS Glue version 2.0. This is the only version of AWS Glue that supports incremental matches.
- The ETL language is Scala. Note that Python is also supported.
- The model already generated is called `demo-xform`.

1. Crawl the incremental dataset to the table *second_records*.
2. On the AWS Glue console, in the navigation pane, choose **Jobs**.
3. Choose **Add job**, and follow the steps in the wizard to create an ETL Spark job with a generated script. Choose the following property values for your transform:
    a. For **Name**, choose **demo-etl**.
    b. For **IAM role**, choose an IAM role with permission to the Amazon S3 source data, labeling file, and AWS Glue API operations.
    c. For **ETL language**, choose **Scala**.
    d. For **Script file name**, choose **demo-etl**. This is the file name of the Scala script.
    e. For **Data source**, choose **first_records**. The data source you choose must match the machine learning transform data source schema.
    f. For **Transform type**, choose **Find matching records** to create a job using a machine learning transform.
    g. Select the incremental matching option, and for **Data Source** select the table named **second_records**.
    h. For **Transform**, choose **demo-xform**, the machine learning transform used by the job.
    i. Choose **Create tables in your data target** or **Use tables in the data catalog and update your data target**.

4. Choose **Save job and edit script** to display the script editor page.
5. Choose **Run job** to start the job run.

Using FindMatches in a visual job

To use the **FindMatches** transform in AWS Glue Studio, you can use the **Custom Transform** node that invokes the FindMatches API. For more information on how to use a custom transform, see Creating a custom transformation

> **Note**
>
> Currently, the FindMatches API only works with `Glue 2.0`. In order to run a job with the Custom transform that invokes the FindMatches API, ensure the AWS Glue version is `Glue 2.0` in the **Job details** tab. If the version of AWS Glue is not `Glue 2.0`, the job will fail at runtime with the following error message: “cannot import name 'FindMatches' from 'awsglueml.transforms'”.

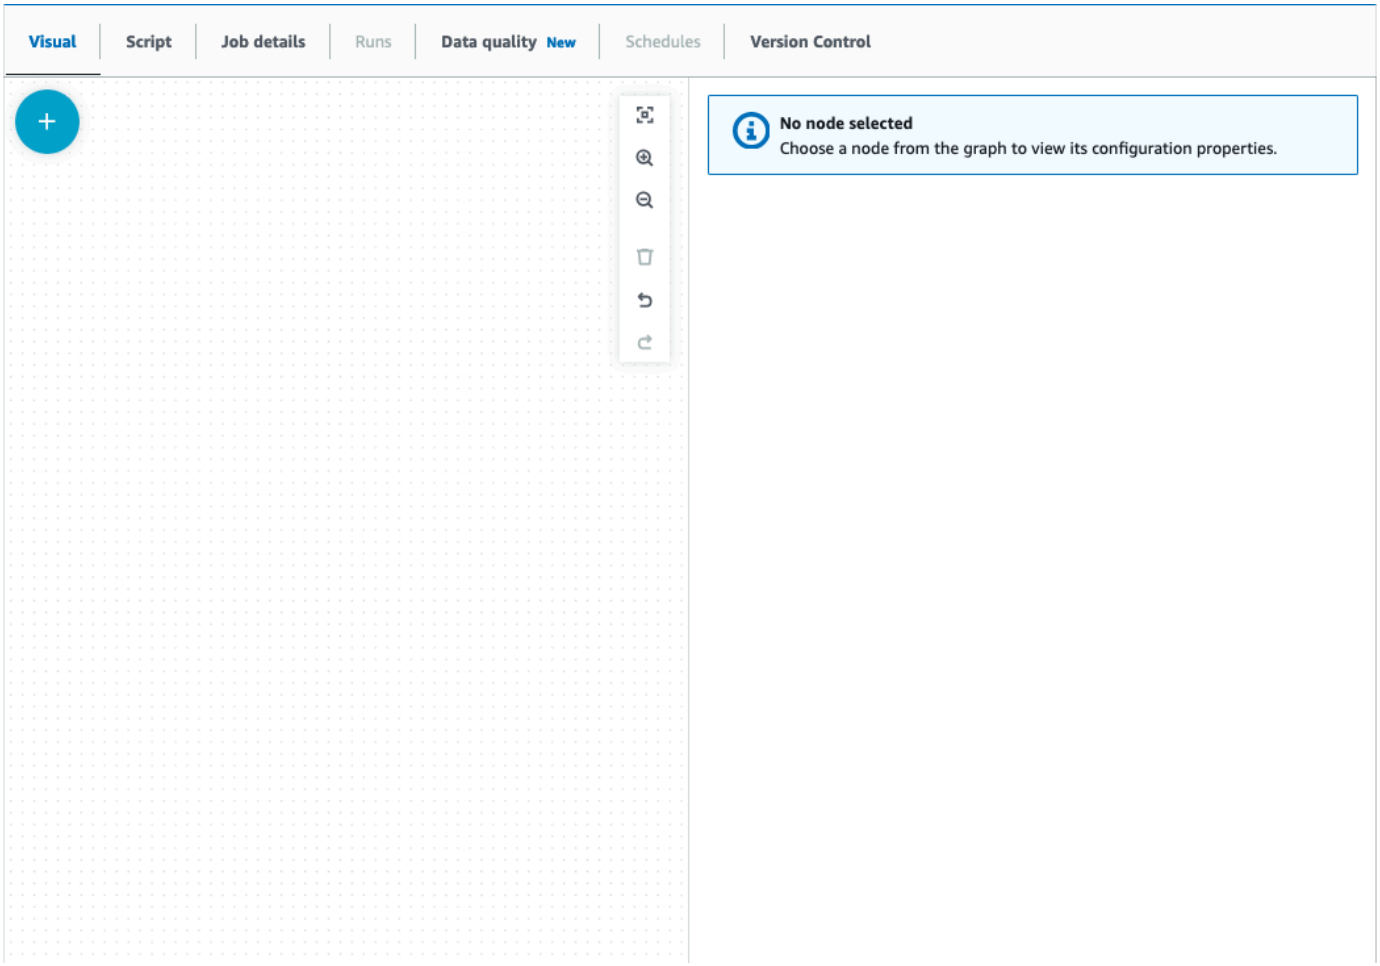
Prerequisites

- In order to use the **Find Matches** transform, open the AWS Glue Studio console at https://console.aws.amazon.com/gluestudio/.
- Create a machine learning transform. When created, a transformId is generated. You will need this ID for the steps below. For more information on how to create a machine learning transform, see Adding and editing machine learning transforms.

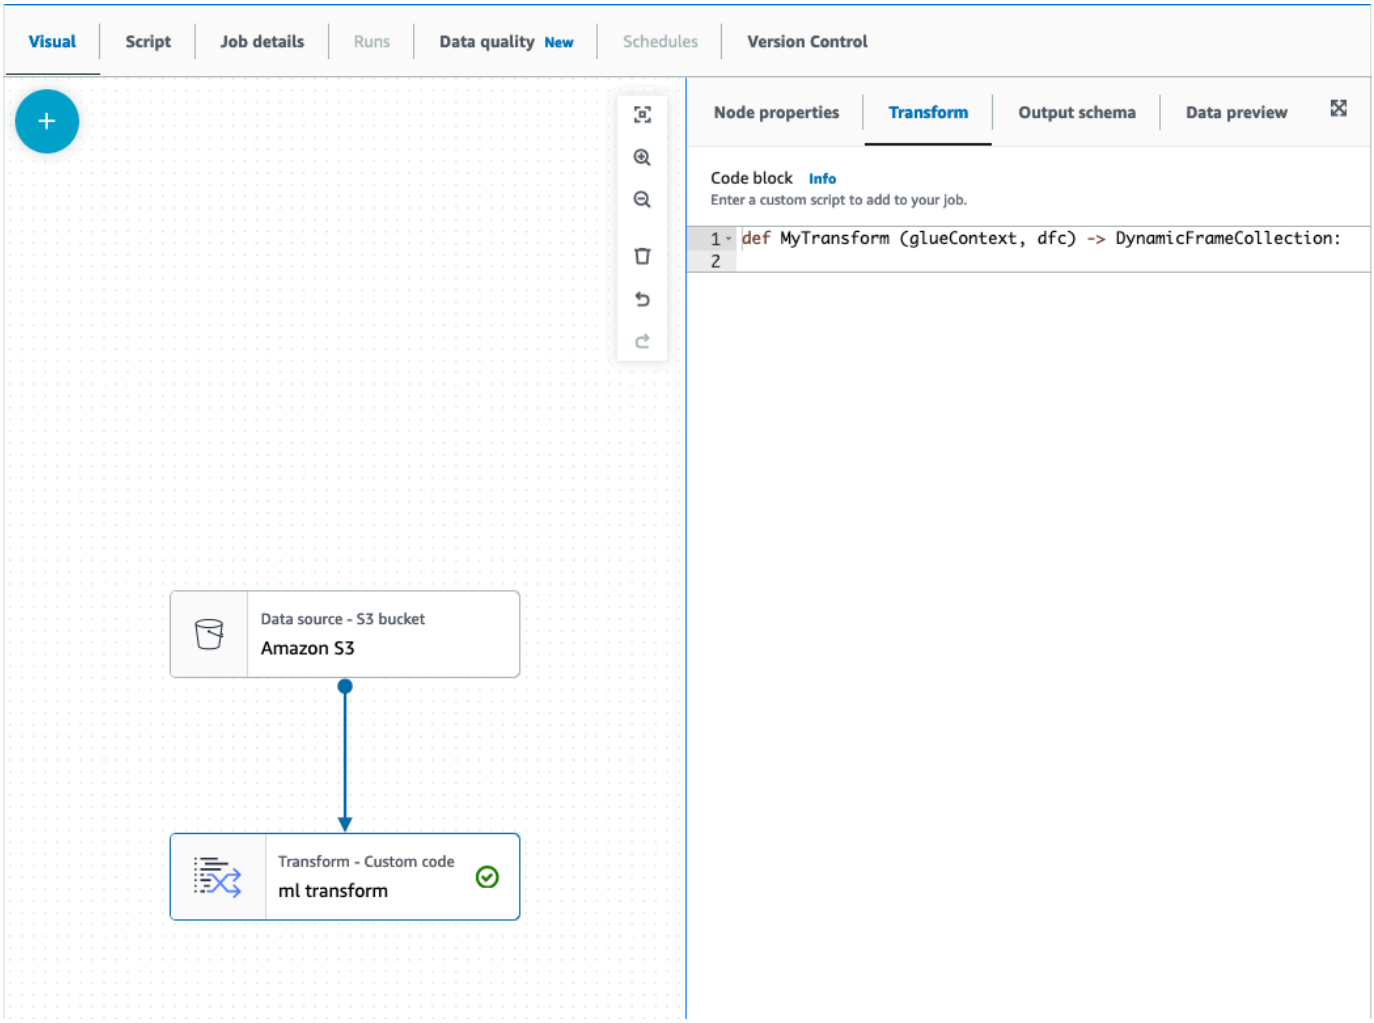
Adding a FindMatches transform

To add a FindMatches transform:

1. In the AWS Glue Studio job editor, open the Resource panel by clicking on the cross symbol in the upper left-hand corner of the visual job graph and choose a Data source by choosing the **Data tab**. This is the data source you want to check for matches.



2. Choose the data source node, then open the Resource panel by clicking on the cross symbol in the upper left-hand corner of the visual job graph and search for 'custom transform'. Choose the **Custom Transform** node to add it to the graph. The **Custom Transform** is linked to the data source node. If it is not, you can click on the **Custom Transform** node and choose the **Node properties** tab, then under **Node parents**, choose the data source.
3. Click the **Custom Transform** node in the visual graph, then choose the **Node properties** tab and name the custom transform. It is recommended that you rename the transform so that the transform name is easily identifiable in the visual graph.
4. Choose the **Transform** tab, where you can edit the code block. This is where the code to invoke the FindMatches API can be added.



The code block contains pre-populated code to get you started. Overwrite the pre-populated code with the template below. The template has a placeholder for the **transformId**, which you can provide.

```
def MyTransform (glueContext, dfc) -> DynamicFrameCollection:
    dynf = dfc.select(list(dfc.keys())[0])
    from awsglueml.transforms import FindMatches
    findmatches = FindMatches.apply(frame = dynf, transformId = "<your id>")
    return(DynamicFrameCollection({"FindMatches": findmatches}, glueContext))
```

5. Click the **Custom Transform** node in the visual graph, then open the Resource panel by clicking on the cross symbol in the upper left-hand corner of the visual job graph and search for 'Select From Collection'. There is no need to change the default selection since there is only one DynamicFrame in the collection.

6. You can continue adding transformations or store the result, which is now enriched with the find matches additional columns. If you want to reference those new columns in downstream transforms, you need to add them to the transform output schema. the easiest way to do that is to choose the **Data preview** tab and then in the schema tab choose “Use datapreview schema”.
7. To customize FindMatches, you can add additional parameters to pass to the 'apply' method. See FindMatches class.

Adding a FindMatches incrementally transformation

In the case of incremental matches, the process is the same as **Adding a FindMatches transformation** with the following differences:

- Instead of a parent node for the custom transform, you need two parent nodes.
- The first parent node should be the dataset.
- The second parent node should be the incremental dataset.

  Replace the `transformId` with your `transformId` in the template code block:

```
def MyTransform (glueContext, dfc) -> DynamicFrameCollection:
    dfs = list(dfc.values())
    dynf = dfs[0]
    inc_dynf = dfs[1]
    from awsglueml.transforms import FindIncrementalMatches
    findmatches = FindIncrementalMatches.apply(existingFrame = dynf, incrementalFrame
 = inc_dynf,
                                    transformId = "<your id>")
    return(DynamicFrameCollection({"FindMatches": findmatches}, glueContext))
```

- For optional parameters, see FindIncrementalMatches class.

Migrate Apache Spark programs to AWS Glue

Apache Spark is an open-source platform for distributed computing workloads performed on large datasets. AWS Glue leverages Spark's capabilities to provide an optimized experience for ETL. You can migrate Spark programs to AWS Glue to take advantage of our features. AWS Glue provides the same performance enhancements you would expect from Apache Spark on Amazon EMR.

Run Spark code

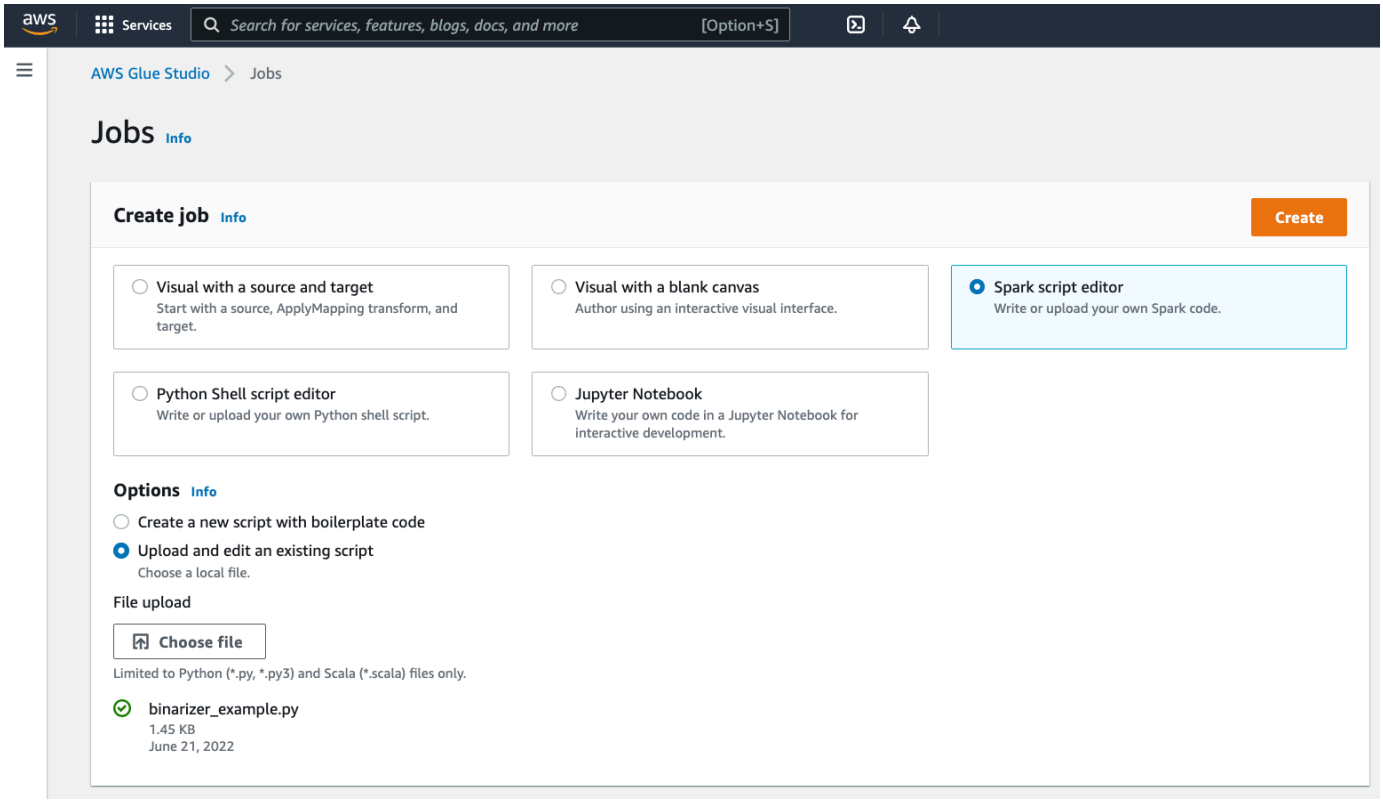
Native Spark code can be run in a AWS Glue environment out of the box. Scripts are often developed by iteratively changing a piece of code, a workflow suited for an Interactive Session. However, existing code is more suited to run in a AWS Glue job, which allows you to schedule and consistently get logs and metrics for each script run. You can upload and edit an existing script through the console.

1. Acquire the source to your script. For this example, you will use an example script from the Apache Spark repository. Binarizer Example
2. In the AWS Glue Console, expand the left-side navigation pane and select **ETL** > **Jobs**

   In the **Create job** panel, select **Spark script editor**. An **Options** section will appear. Under **Options**, select **Upload and edit an existing script**.

   A **File upload** section will appear. Under **File upload**, click **Choose file**. Your system file chooser will appear. Navigate to the location where you saved `binarizer_example.py`, select it and confirm your selection.

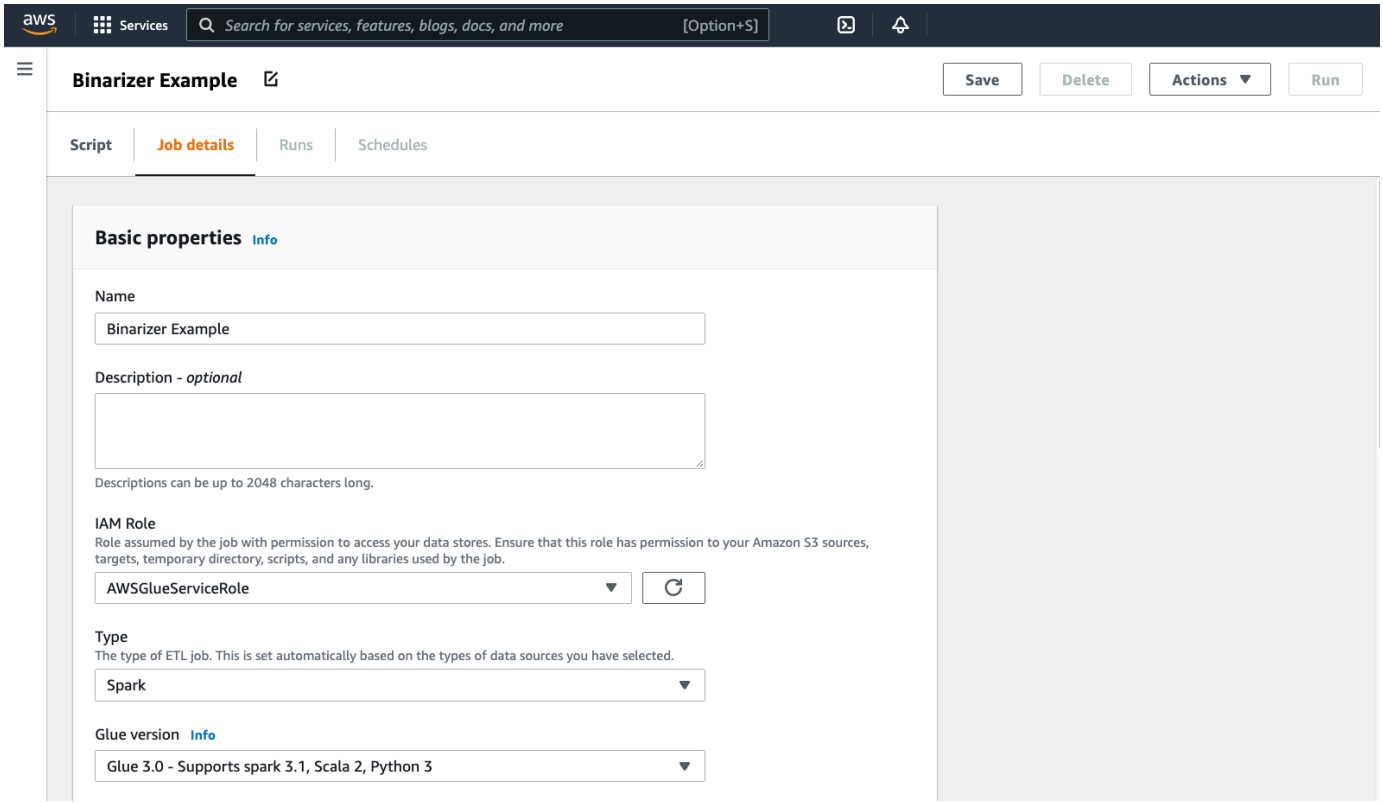
   A **Create** button will appear on the header for the **Create job** panel. Click it.



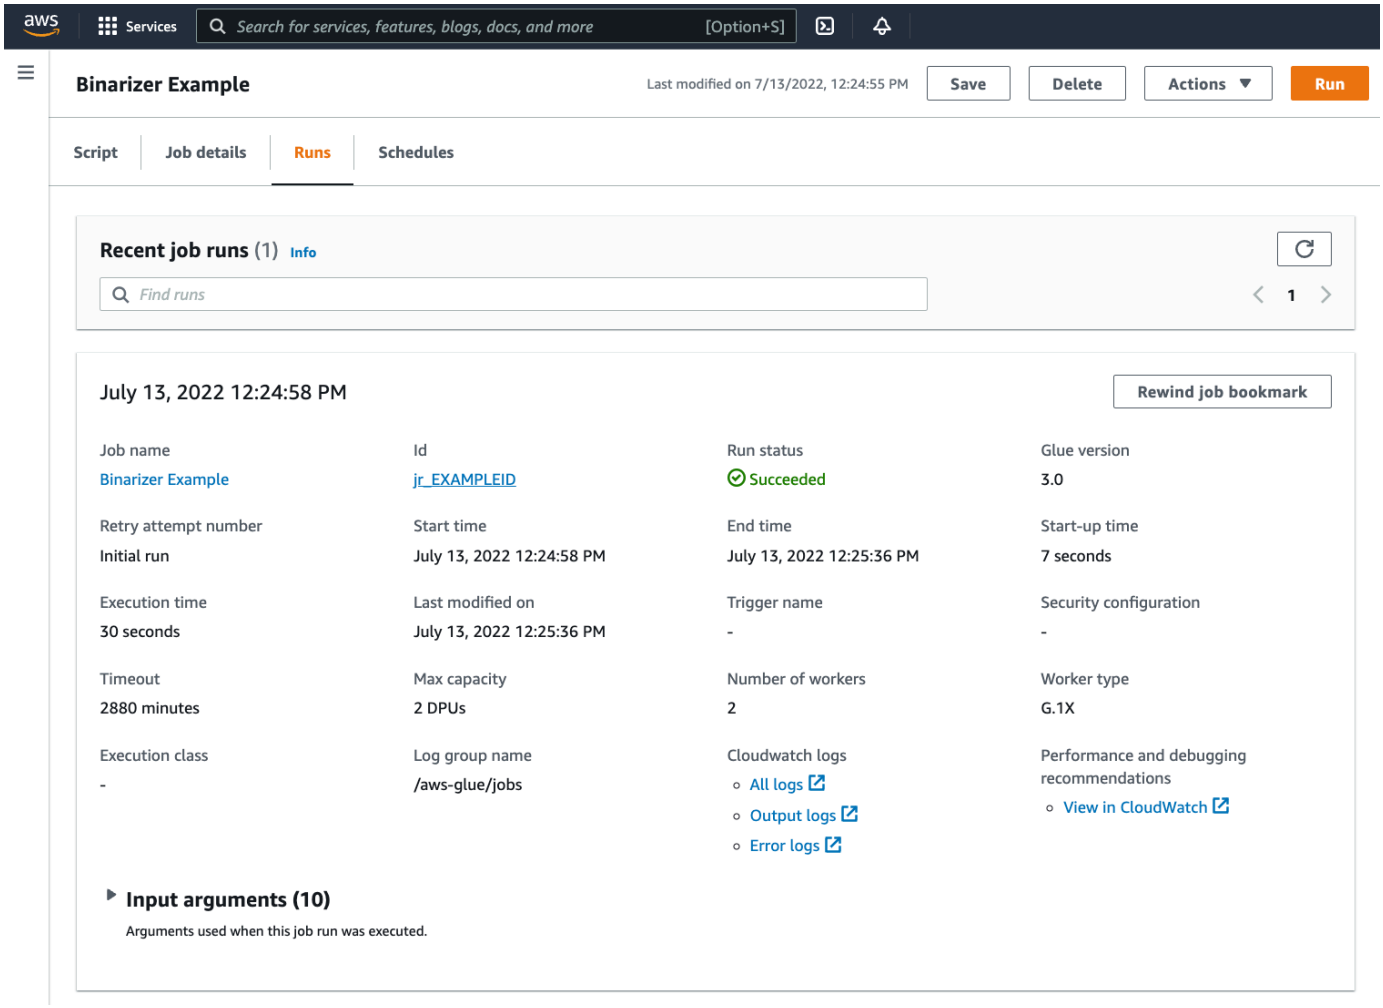
3. Your browser will navigate to the script editor. On the header, click the **Job details** tab. Set the **Name** and **IAM Role**. For guidance around AWS Glue IAM roles, consult the section called "Setting up IAM permissions".

   Optionally - set **Requested number of workers** to 2 and **Number of retries** to 1. These options are valuable when running production jobs, but turning them down will streamline your experience while testing out a feature.

   In the title bar, click **Save**, then **Run**

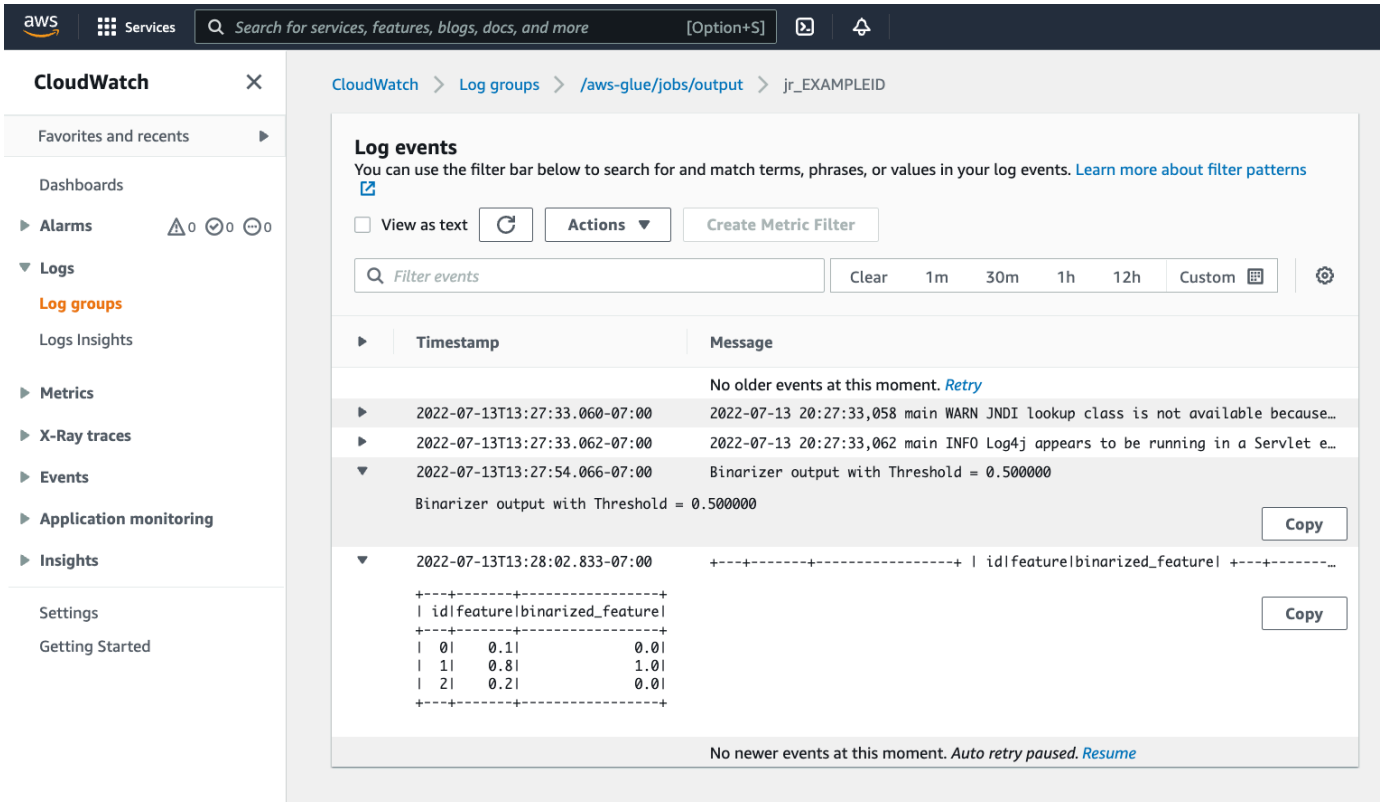


4. Navigate to the **Runs** tab. You will see a panel corresponding to your job run. Wait a few minutes and the page should automatically refresh to show **Succeeded** under **Run status**.



5. You will want to examine your output to confirm that the Spark script ran as intended. This Apache Spark sample script should write a string to the output stream. You can find that by navigating to **Output logs** under **Cloudwatch logs** in the panel for the successful job run. Note the job run id, a generated id under the **Id** label beginning with `jr_`.

   This will open the CloudWatch console, set to visualize the contents of the default AWS Glue log group `/aws-glue/jobs/output`, filtered to the contents of the log streams for the job run id. Each worker will have generated a log stream, shown as rows under the **Log streams** . One worker should have run the requested code. You will need to open all the log streams to identify the correct worker. Once you find the right worker, you should see the output of the script, as seen in the following image:



Common procedures needed for migrating Spark programs

Assess Spark version support

AWS Glue release versions define the version of Apache Spark and Python available to the AWS Glue job. You can find our AWS Glue versions and what they support at the section called "AWS Glue versions". You may need to update your Spark program to be compatible with a newer version of Spark in order to access certain AWS Glue features.

Include third-party libraries

Many existing Spark programs will have dependencies, both on private and public artifacts. AWS Glue supports JAR style dependencies for Scala Jobs as well as Wheel and source pure-Python dependencies for Python jobs.

Python - For information about Python dependencies, see the section called "Python libraries"

Common Python dependencies are provided in the AWS Glue environment, including the commonly requested Pandas library. Dependencies are included in AWS Glue Version 2.0+. For more information about provided modules, see the section called "Python modules already provided in AWS Glue". If you need to supply a Job with a different version of a dependency

included by default, you can use `--additional-python-modules`. For information about job arguments, see the section called "Job parameters".

You can supply additional Python dependencies with the `--extra-py-files` job argument. If you are migrating a job from a Spark program, this parameter is a good option because it is functionally equivalent to the `--py-files` flag in PySpark, and is subject to the same limitations. For more information about the `--extra-py-files` parameter, see the section called "Including Python files with PySpark native features"

For new jobs, you can manage Python dependencies with the `--additional-python-modules` job argument. Using this argument allows for a more thorough dependency management experience. This parameter supports Wheel style dependencies, including those with native code bindings compatible with Amazon Linux 2.

Scala

You can supply additional Scala dependencies with the `--extra-jars` Job Argument. Dependencies must be hosted in Amazon S3 and the argument value should be a comma delimited list of Amazon S3 paths with no spaces. You may find it easier to manage your configuration by rebundling your dependencies before hosting and configuring them. AWS Glue JAR dependencies contain Java bytecode, which can be generated from any JVM language. You can use other JVM languages, such as Java, to write custom dependencies.

Manage data source credentials

Existing Spark programs may come with complex or custom configuration to pull data from their datasources. Common datasource auth flows are supported by AWS Glue connections. For more information about AWS Glue connections, see Connecting to data.

AWS Glue connections facilitate connecting your Job to a variety of types of data stores in two primary ways: through method calls to our libraries and setting the **Additional network connection** in the AWS console. You may also call the AWS SDK from within your job to retrieve information from a connection.

Method calls – AWS Glue Connections are tightly integrated with the AWS Glue Data Catalog, a service that allows you to curate information about your datasets, and the methods available to interact with AWS Glue connections reflect that. If you have an existing auth configuration you would like to reuse, for JDBC connections, you can access your AWS Glue connection configuration through the `extract_jdbc_conf` method on the `GlueContext`. For more information, see the section called "extract_jdbc_conf"

Console configuration – AWS Glue Jobs use associated AWS Glue connections to configure connections to Amazon VPC subnets. If you directly manage your security materials, you may need to provide a `NETWORK` type **Additional network connection** in the AWS console to configure routing. For more information about the AWS Glue connection API, see the section called "Connections"

If your Spark programs has a custom or uncommon auth flow, you may need to manage your security materials in a hands-on fashion. If AWS Glue connections do not seem like a good fit, you can securely host security materials in Secrets Manager and access them through the boto3 or AWS SDK, which are provided in the job.

Configure Apache Spark

Complex migrations often alter Spark configuration to acommodate their workloads. Modern versions of Apache Spark allow runtime configuration to be set with the `SparkSession`. AWS Glue 3.0+ Jobs are provided a `SparkSession`, which can be modified to set runtime configuration. Apache Spark Configuration. Tuning Spark is complex, and AWS Glue does not guarantee support for setting all Spark configuration. if your migration requires substantial Spark-level configuration, contact support.

Set custom configuration

Migrated Spark programs may be designed to take custom configuration. AWS Glue allows configuration to be set on the job and job run level, through the job arguments. For information about job arguments, see the section called "Job parameters". You can access job arguments within the context of a job through our libraries. AWS Glue provides a utility function to provide a consistent view between arguments set on the job and arguments set on the job run. See the section called "getResolvedOptions" in Python and the section called "GlueArgParser" in Scala.

Migrate Java code

As explained in the section called "Third-party libraries", your dependencies can contain classes generated by JVM languages, such as Java or Scala. Your dependencies can include a `main` method. You can use a `main` method in a dependency as the entrypoint for a AWS Glue Scala job. This allows you to write your `main` method in Java, or reuse a `main` method packaged to your own library standards.

To use a `main` method from a dependency, perform the following: Clear the contents of the editing pane providing the default `GlueApp` object. Provide the fully qualified name of a class in a dependency as a job argument with the key `--class`. You should then be able to trigger a Job run.

You cannot configure the order or structure of the arguments AWS Glue passes to the `main` method. If your existing code needs to read configuration set in AWS Glue, this will likely cause incompatibility with prior code. If you use `getResolvedOptions`, you will also not have a good place to call this method. Consider invoking your dependency directly from a main method generated by AWS Glue. The following AWS Glue ETL script shows an example of this.

```
import com.amazonaws.services.glue.util.GlueArgParser

object GlueApp {
  def main(sysArgs: Array[String]) {
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)

    // Invoke static method from JAR. Pass some sample arguments as a String[], one
 defined inline and one taken from the job arguments, using getResolvedOptions
    com.mycompany.myproject.MyClass.myStaticPublicMethod(Array("string parameter1",
 args("JOB_NAME")))

    // Alternatively, invoke a non-static public method.
    (new com.mycompany.myproject.MyClass).someMethod()
  }
}
```

Working with Ray jobs in AWS Glue

> **Important**
>
> AWS Glue for Ray is no longer open to new customers. Existing customers can continue to use the service as normal. For more information, see AWS Glue for Ray end of support.

This section provides information about using AWS Glue for Ray jobs. For more information about writing AWS Glue for Ray scripts, consult the the section called “AWS Glue for Ray” section.

Topics

- Getting started with AWS Glue for Ray
- Supported Ray runtime environments
- Accounting for workers in Ray jobs
- Using job parameters in Ray jobs

- Monitoring Ray jobs with metrics

Getting started with AWS Glue for Ray

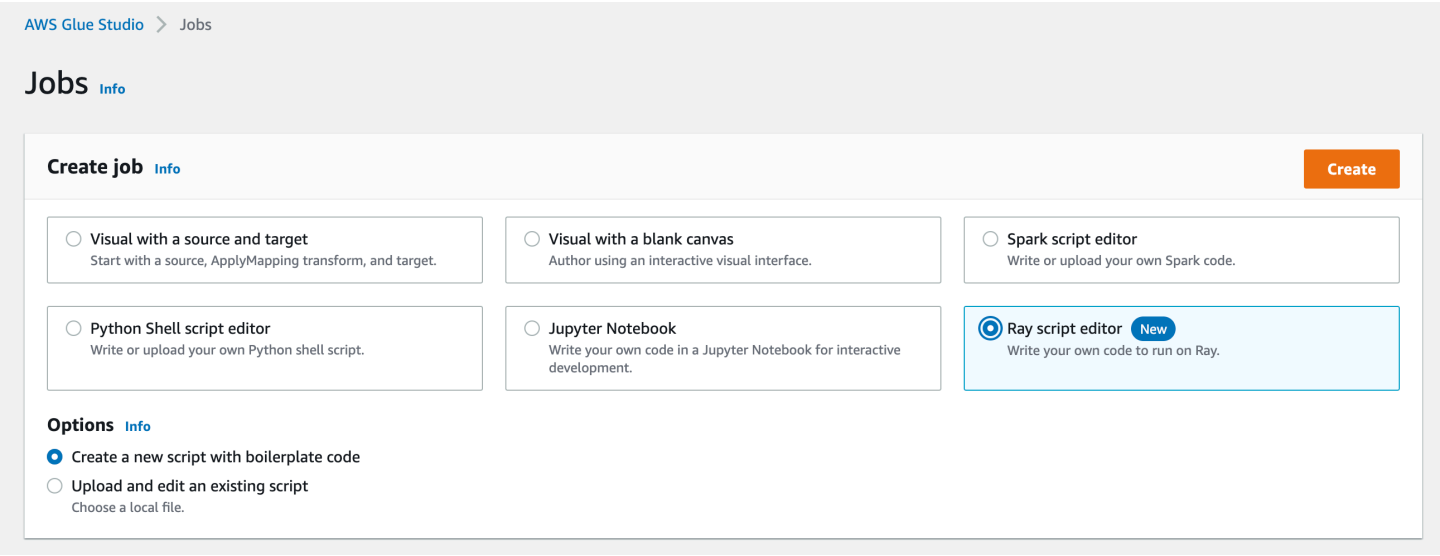
To work with AWS Glue for Ray, you use the same AWS Glue jobs and interactive sessions that you use with AWS Glue for Spark. AWS Glue jobs are designed for running the same script on a recurring cadence, while interactive sessions are designed to let you run snippets of code sequentially against the same provisioned resources.

AWS Glue ETL and Ray are different underneath, so in your script, you have access to different tools, features, and configuration. As a new computation framework managed by AWS Glue, Ray has a different architecture and uses different vocabulary to describe what it does. For more information, see Architecture Whitepapers in the Ray documentation.

> **Note**
>
> AWS Glue for Ray is available in US East (N. Virginia), US East (Ohio), US West (Oregon), Asia Pacific (Tokyo), and Europe (Ireland).

Ray jobs in the AWS Glue Studio console

On the **Jobs** page in the AWS Glue Studio console, you can select a new option when you're creating a job in AWS Glue Studio—**Ray script editor**. Choose this option to create a Ray job in the console. For more information about jobs and how they're used, see *Building visual ETL jobs*.



Ray jobs in the AWS CLI and SDK

Ray jobs in the AWS CLI use the same SDK actions and parameters as other jobs. AWS Glue for Ray introduces new values for certain parameters. For more information in the Jobs API, see the section called "Jobs".

Supported Ray runtime environments

In Spark jobs, `GlueVersion` determines the versions of Apache Spark and Python available in an AWS Glue for Spark job. The Python version indicates the version that is supported for jobs of type Spark. This is not how Ray runtime environments are configured.

For Ray jobs, you should set `GlueVersion` to `4.0` or greater. However, the versions of Ray, Python, and additional libraries that are available in your Ray job are determined by the `Runtime` field in the job definition.

The `Ray2.4` runtime environment will be available for a minimum of 6 months after release. As Ray rapidly evolves, you will be able to incorporate Ray updates and improvements through future runtime environment releases.

Valid values: `Ray2.4`

Runtime value	Ray and Python versions
`Ray2.4` (for AWS Glue 4.0+)	Ray 2.4.0 Python 3.9

Additional information

- For release notes that accompany AWS Glue on Ray releases, see the section called "AWS Glue versions".
- For Python libraries that are provided in a runtime environment, see the section called "Modules provided with Ray jobs".

Accounting for workers in Ray jobs

AWS Glue runs Ray jobs on new Graviton-based EC2 worker types, which are only available for Ray jobs. To appropriately provision these workers for the workloads Ray is designed for, we provide a different ratio of compute resources to memory resources from most workers. In order to account for these resources, we use the memory-optimized data processing unit (M-DPU) rather than the standard data processing unit (DPU).

- One M-DPU corresponds to 4 vCPUs and 32 GB of memory.
- One DPU corresponds to 4 vCPUs and 16 GB of memory. DPUs are used to account for resources in AWS Glue with Spark jobs and corresponding workers.

Ray jobs currently have access to one worker type, `Z.2X`. The `Z.2X` worker maps to 2 M-DPUs (8 vCPUs, 64 GB of memory) and has 128 GB of disk space. A `Z.2X` machine provides 8 Ray workers (one per vCPU).

The number of M-DPUs that you can use concurrently in an account is subject to a service quota. For more information about your AWS Glue account limits, see AWS Glue endpoints and quotas.

You specify the number of worker nodes that are available to a Ray job with `--number-of-workers (NumberOfWorkers)` in the job definition. For more information about Ray values in the Jobs API, see the section called "Jobs".

You can further specify a minimum number of workers that a Ray job must allocate with the `--min-workers` job parameter. For more information about job parameters, see the section called "Reference".

Using job parameters in Ray jobs

> **Important**
>
> AWS Glue for Ray is no longer open to new customers. Existing customers can continue to use the service as normal. For more information, see AWS Glue for Ray end of support.

You set arguments for AWS Glue Ray jobs the same way you set arguments for AWS Glue for Spark jobs. For more information about the AWS Glue API, see the section called "Jobs". You can

configure AWS Glue Ray jobs with different arguments, which are listed in this reference. You can also provide your own arguments.

You can configure a job through the console, on the **Job details** tab, under the **Job Parameters** heading. You can also configure a job through the AWS CLI by setting `DefaultArguments` on a job, or setting `Arguments` on a job run. Default arguments and job parameters stay with the job through multiple runs.

For example, the following is the syntax for running a job using `--arguments` to set a special parameter.

```
$ aws glue start-job-run --job-name "CSV to CSV" --arguments='--scriptLocation="s3://
my_glue/libraries/test_lib.py",--test-environment="true"'
```

After you set the arguments, you can access job parameters from within your Ray job through environment variables. This gives you a way to configure your job for each run. The name of the environment variable will be the job argument name without the `--` prefix.

For instance, in the previous example, the variable names would be `scriptLocation` and `test-environment`. You would then retrieve the argument through methods available in the standard library: `test_environment = os.environ.get('test-environment')`. For more information about accessing environment variables with Python, see os module in the Python documentation.

Configure how Ray jobs generate logs

By default, Ray jobs generate logs and metrics that are sent to CloudWatch and Amazon S3. You can use the `--logging_configuration` parameter to alter how logs are generated, currently you can use it to stop Ray jobs from generating various types of logs. This parameter takes a JSON object, whose keys correspond to the logs/behaviors you would like to alter. It supports the following keys:

- `CLOUDWATCH_METRICS` – Configures CloudWatch metrics series that can be used to visualize job health. For more information about metrics, see the section called “Ray job metrics”.
- `CLOUDWATCH_LOGS` – Configures CloudWatch logs that provide Ray application level details about the status the job run. For more information about logs, see the section called “Troubleshooting Ray errors”.
- `S3` – Configures what AWS Glue writes to Amazon S3, primarily similar information to CloudWatch logs but as files rather than log streams.

To disable a Ray logging behavior, provide the value `{\"IS_ENABLED\": \"False\"}`. For example, to disable CloudWatch metrics and CloudWatch logs, provide the following configuration:

```
"--logging_configuration": "{\"CLOUDWATCH_METRICS\": {\"IS_ENABLED\": \"False\"},
 \"CLOUDWATCH_LOGS\": {\"IS_ENABLED\": \"False\"}}"
```

Reference

Ray jobs recognize the following argument names that you can use to set up the script environment for your Ray jobs and job runs:

- `--logging_configuration` – Used to stop the generation of various logs created by Ray jobs. These logs are generated by default on all Ray jobs. Format: String-escaped JSON object. For more information, see the section called “Configure how Ray jobs generate logs”.
- `--min-workers` – The minimum number of worker nodes that are allocated to a Ray job. A worker node can run multiple replicas, one per virtual CPU. Format: integer. Minimum: 0. Maximum: value specified in `--number-of-workers (NumberOfWorkers)` on the job definition. For more information about accounting for worker nodes, see the section called “Accounting for workers in Ray jobs”.
- `--object_spilling_config` – AWS Glue for Ray supports using Amazon S3 as a way of extending the space available to Ray's object store. To enable this behavior, you can provide Ray an *object spilling*JSON config object with this parameter. For more information about Ray object spilling configuration, see Object Spilling in the Ray documentation. Format: JSON object.

  AWS Glue for Ray only supports spilling to disk or spilling to Amazon S3 at once. You can provide multiple locations for spilling, as long as they respect this limitation. When spilling to Amazon S3, you will also need to add IAM permissions to your job for this bucket.

  When providing a JSON object as configuration with the CLI, you must provide it as a string, with the JSON object string-escaped. For example, a string value for spilling to one Amazon S3 path would look like: `"{\"type\": \"smart_open\", \"params\": {\"uri\": \"s3path\"}}"`. In AWS Glue Studio, provide this parameter as a JSON object with no extra formatting.
- `--object_store_memory_head` – The memory allocated to the Plasma object store on the Ray head node. This instance runs cluster management services, as well as worker replicas. The value represents a percentage of free memory on the instance after a warm start. You use this parameter to tune memory intensive workloads—defaults are acceptable for most use cases. Format: positive integer. Minimum: 1. Maximum: 100.

For more information about Plasma, see The Plasma In-Memory Object Store in the Ray documentation.

- `--object_store_memory_worker` – The memory allocated to the Plasma object store on the Ray worker nodes. These instances only run worker replicas. The value represents a percentage of free memory on the instance after a warm start. This parameter is used to tune memory intensive workloads—defaults are acceptable for most use cases. Format: positive integer. Minimum: 1. Maximum: 100.

  For more information about Plasma, see The Plasma In-Memory Object Store in the Ray documentation.

- `--pip-install` – A set of Python packages to be installed. You can install packages from PyPI using this argument. Format: comma-delimited list.

  A PyPI package entry is in the format `package==version`, with the PyPI name and version of your target package. Entries use Python version matching to match the package and version, such as ==, not the single equals =. There are other version-matching operators. For more information, see PEP 440 on the Python website. You can also provide custom modules with `--s3-py-modules`.

- `--s3-py-modules` – A set of Amazon S3 paths that host Python module distributions. Format: comma-delimited list.

  You can use this to distribute your own modules to your Ray job. You can also provide modules from PyPI with `--pip-install`. Unlike with AWS Glue ETL, custom modules are not set up through pip, but are passed to Ray for distribution. For more information, see the section called "Additional Python modules for Ray jobs".

- `--working-dir` – A path to a .zip file hosted in Amazon S3 that contains files to be distributed to all nodes running your Ray job. Format: string. For more information, see the section called "Providing files to your Ray job".

Monitoring Ray jobs with metrics

> **Important**
>
> AWS Glue for Ray is no longer open to new customers. Existing customers can continue to use the service as normal. For more information, see AWS Glue for Ray end of support.

You can monitor Ray jobs using AWS Glue Studio and Amazon CloudWatch. CloudWatch collects and processes raw metrics from AWS Glue with Ray, which makes them available for analysis. These metrics are visualized in the AWS Glue Studio console, so you can monitor your job as it runs.

For a general overview of how to monitor AWS Glue, see the section called "Using CloudWatch metrics". For a general overview of how to use CloudWatch metrics that are published by AWS Glue, see the section called "Monitoring with CloudWatch".

Monitoring Ray jobs in the AWS Glue console

On the details page for a job run, below the **Run details** section, you can view pre-built aggregated graphs that visualize your available job metrics. AWS Glue Studio sends job metrics to CloudWatch for every job run. With these, you can build a profile of your cluster and tasks, as well as access detailed information about each node.

For more information about available metrics graphs, see the section called "Viewing Amazon CloudWatch metrics for a Ray job run".

Overview of Ray jobs metrics in CloudWatch

We publish Ray metrics when detailed monitoring is enabled in CloudWatch. Metrics are published to the `Glue/Ray` CloudWatch namespace.

- **Instance metrics**

  We publish metrics about the CPU, memory and disk utilization of instances assigned to a job. These metrics are identified by features such as `ExecutorId`, `ExecutorType` and `host`. These metrics are a subset of the standard Linux CloudWatch agent metrics. You can find information about metric names and features in the CloudWatch documentation. For more information, see Metrics collected by the CloudWatch agent.
- **Ray cluster metrics**

We forward metrics from the Ray processes that run your script to this namespace, then provide those most critical for you. The metrics that are available might differ by Ray version. For more information about which Ray version your job is running, see the section called "AWS Glue versions".

Ray collects metrics at the instance level. It also provides metrics for tasks and the cluster. For more information about Ray's underlying metric strategy, see Metrics in the Ray documentation.

> **Note**
>
> We don't publish Ray metrics to the `Glue/Job Metrics/` namespace, which is only used for AWS Glue ETL jobs.

Configuring job properties for Python shell jobs in AWS Glue

You can use a Python shell job to run Python scripts as a shell in AWS Glue. With a Python shell job, you can run scripts that are compatible with Python 3.6 or Python 3.9.

> **Note**
>
> Support for Pyshell v3.6 will end on March 1, 2026. To migrate your workloads, see Migrate from AWS Glue Python shell jobs. If you wish to continue with Python shell v3.9 see Migrating from Python shell 3.6 to Python shell 3.9.

Topics

- Limitations
- Execution environment
- Defining job properties for Python shell jobs
- Supported libraries for Python shell jobs
- Providing your own Python library
- Use AWS CloudFormation with Python shell jobs in AWS Glue
- Migrating from Python shell 3.6 to Python shell 3.9
- Migrate from AWS Glue Python shell jobs

Limitations

Note the following limitations of Python Shell jobs:

- You can't use job bookmarks with Python shell jobs.
- You can't package any Python libraries as `.egg` files in Python 3.9+. Instead, use `.whl`.
- The `--extra-files` option cannot be used, because of a limitation on temporary copies of S3 data.

Execution environment

Python shell jobs run in a managed execution environment that provides access to local storage for temporary data processing:

Local temporary storage

The `/tmp` directory is available for temporary storage during job execution. This directory provides approximately 14 GiB of free space that you can use for:

- Temporary file processing
- Intermediate data storage
- Caching small datasets

> **Note**
>
> The `/tmp` directory is ephemeral and is cleaned up after job completion. Do not use it for persistent storage of important data.

Defining job properties for Python shell jobs

These sections describe defining job properties in AWS Glue Studio, or using the AWS CLI.

AWS Glue Studio

When you define your Python shell job in AWS Glue Studio, you provide some of the following properties:

IAM role

Specify the AWS Identity and Access Management (IAM) role that is used for authorization to resources that are used to run the job and access data stores. For more information about permissions for running jobs in AWS Glue, see Identity and access management for AWS Glue.

Type

Choose **Python shell** to run a Python script with the job command named `pythonshell`.

Python version

Choose the Python version. The default is Python 3.9. Valid versions are Python 3.6 and Python 3.9.

Load common analytics libraries (Recommended)

Choose this option to include common libraries for Python 3.9 in the Python shell.

If your libraries are either custom or they conflict with the pre-installed ones, you can choose not to install common libraries. However, you can install additional libraries besides the common libraries.

When you select this option, the `library-set` option is set to `analytics`. When you de-select this option, the `library-set` option is set to none.

Script filename and Script path

The code in the script defines your job's procedural logic. You provide the script name and location in Amazon Simple Storage Service (Amazon S3). Confirm that there isn't a file with the same name as the script directory in the path. To learn more about using scripts, see AWS Glue programming guide.

Script

The code in the script defines your job's procedural logic. You can code the script in Python 3.6 or Python 3.9. You can edit a script in AWS Glue Studio.

Data processing units

The maximum number of AWS Glue data processing units (DPUs) that can be allocated when this job runs. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see AWS Glue pricing.

You can set the value to 0.0625 or 1. The default is 0.0625. In either case, the local disk for the instance will be 20GB.

CLI

You can also create a **Python shell** job using the AWS CLI, as in the following example.

```
aws glue create-job --name python-job-cli --role Glue_DefaultRole
    --command '{"Name" :  "pythonshell", "PythonVersion": "3.9", "ScriptLocation" :
"s3://amzn-s3-demo-bucket/scriptname.py"}'
    --max-capacity 0.0625
```

> **Note**
>
> You don't need to specify the version of AWS Glue since the parameter `--glue-version` doesn't apply for AWS Glue shell jobs. Any version specified will be ignored.

Jobs that you create with the AWS CLI default to Python 3. Valid Python versions are 3 (corresponding to 3.6), and 3.9. To specify Python 3.6, add this tuple to the `--command` parameter: `"PythonVersion":"3"`

To specify Python 3.9, add this tuple to the `--command` parameter: `"PythonVersion":"3.9"`

To set the maximum capacity used by a Python shell job, provide the `--max-capacity` parameter. For Python shell jobs, the `--allocated-capacity` parameter can't be used.

Supported libraries for Python shell jobs

In Python shell using Python 3.9, you can choose the library set to use pre-packaged library sets for your needs. You can use the `library-set` option to choose the library set. Valid values are `analytics`, and none.

The environment for running a Python shell job supports the following libraries:

Python version	**Python 3.6**	**Python 3.9**	
Library set	**N/A**	**analytics**	**none**
avro		1.11.0	
awscli	116.242	1.23.5	1.23.5

Python version	Python 3.6	Python 3.9	
awswrangler		2.15.1	
botocore	1.12.232	1.24.21	1.23.5
boto3	1.9.203	1.21.21	
elasticsearch		8.2.0	
numpy	1.16.2	1.22.3	
pandas	0.24.2	1.4.2	
psycopg2		2.9.3	
pyathena		2.5.3	
PyGreSQL	5.0.6		
PyMySQL		1.0.2	
pyodbc		4.0.32	
pyorc		0.6.0	
redshift-connector		2.0.907	
requests	2.22.0	2.27.1	
scikit-learn	0.20.3	1.0.2	
scipy	1.2.1	1.8.0	
SQLAlchemy		1.4.36	
s3fs		2022.3.0	

You can use the `NumPy` library in a Python shell job for scientific computing. For more information, see NumPy. The following example shows a NumPy script that can be used in a Python shell job. The script prints "Hello world" and the results of several mathematical calculations.

```
import numpy as np
print("Hello world")

a = np.array([20,30,40,50])
print(a)

b = np.arange( 4 )

print(b)

c = a-b

print(c)

d = b**2

print(d)
```

Providing your own Python library

Using PIP

Python shell using Python 3.9 lets you provide additional Python modules or different versions at the job level. You can use the `--additional-python-modules` option with a list of comma-separated Python modules to add a new module or change the version of an existing module. You cannot provide custom Python modules hosted on Amazon S3 with this parameter when using Python shell jobs.

For example to update or to add a new `scikit-learn` module use the following key and value: `"--additional-python-modules", "scikit-learn==0.21.3"`.

AWS Glue uses the Python Package Installer (pip3) to install the additional modules. You can pass additional pip3 options inside the `--additional-python-modules` value. For example, `"scikit-learn==0.21.3 -i https://pypi.python.org/simple/"`. Any incompatibilities or limitations from pip3 apply.

> **Note**
>
> To avoid incompatibilities in the future, we recommend that you use libraries built for Python 3.9.

Using an Egg or Whl file

You might already have one or more Python libraries packaged as an `.egg` or a `.whl` file. If so, you can specify them to your job using the AWS Command Line Interface (AWS CLI) under the "`--extra-py-files`" flag, as in the following example.

```
aws glue create-job --name python-redshift-test-cli --role role --command '{"Name" :
 "pythonshell", "ScriptLocation" : "s3://MyBucket/python/library/redshift_test.py"}'
    --connections Connections=connection-name --default-arguments '{"--extra-py-
files" : ["s3://amzn-s3-demo-bucket/EGG-FILE", "s3://amzn-s3-demo-bucket/WHEEL-FILE"]}'
```

If you aren't sure how to create an `.egg` or a `.whl` file from a Python library, use the following steps. This example is applicable on macOS, Linux, and Windows Subsystem for Linux (WSL).

To create a Python .egg or .whl file

1. Create an Amazon Redshift cluster in a virtual private cloud (VPC), and add some data to a table.
2. Create an AWS Glue connection for the VPC-SecurityGroup-Subnet combination that you used to create the cluster. Test that the connection is successful.
3. Create a directory named `redshift_example`, and create a file named `setup.py`. Paste the following code into `setup.py`.

   ```
   from setuptools import setup

   setup(
       name="redshift_module",
       version="0.1",
       packages=['redshift_module']
   )
   ```

4. In the `redshift_example` directory, create a `redshift_module` directory.
   In the `redshift_module` directory, create the files `__init__.py` and `pygresql_redshift_common.py`.
5. Leave the `__init__.py` file empty. In `pygresql_redshift_common.py`, paste the following code. Replace *`port`*, *`db_name`*, *`user`*, and *`password_for_user`* with details specific to your Amazon Redshift cluster. Replace *`table_name`* with the name of the table in Amazon Redshift.

```
import pg

def get_connection(host):
    rs_conn_string = "host=%s port=%s dbname=%s user=%s password=%s" % (
        host, port, db_name, user, password_for_user)

    rs_conn = pg.connect(dbname=rs_conn_string)
    rs_conn.query("set statement_timeout = 1200000")
    return rs_conn

def query(con):
    statement = "Select * from table_name;"
    res = con.query(statement)
    return res
```

6. If you're not already there, change to the `redshift_example` directory.
7. Do one of the following:

   - To create an `.egg` file, run the following command.

     ```
     python setup.py bdist_egg
     ```

   - To create a `.whl` file, run the following command.

     ```
     python setup.py bdist_wheel
     ```

8. Install the dependencies that are required for the preceding command.
9. The command creates a file in the `dist` directory:

   - If you created an egg file, it's named `redshift_module-0.1-py2.7.egg`.

- If you created a wheel file, it's named `redshift_module-0.1-py2.7-none-any.whl`.

Upload this file to Amazon S3.

In this example, the uploaded file path is either *s3://amzn-s3-demo-bucket/EGG-FILE* or *s3://amzn-s3-demo-bucket/WHEEL-FILE*.

10. Create a Python file to be used as a script for the AWS Glue job, and add the following code to the file.

```
from redshift_module import pygresql_redshift_common as rs_common

con1 = rs_common.get_connection(redshift_endpoint)
res = rs_common.query(con1)

print "Rows in the table cities are: "

print res
```

11. Upload the preceding file to Amazon S3. In this example, the uploaded file path is *s3://amzn-s3-demo-bucket/scriptname.py*.
12. Create a Python shell job using this script. On the AWS Glue console, on the **Job properties** page, specify the path to the `.egg/.whl` file in the **Python library path** box. If you have multiple `.egg/.whl` files and Python files, provide a comma-separated list in this box.

    When modifying or renaming `.egg` files, the file names must use the default names generated by the "python setup.py bdist_egg" command or must adhere to the Python module naming conventions. For more information, see the Style Guide for Python Code.

    Using the AWS CLI, create a job with a command, as in the following example.

```
aws glue create-job --name python-redshift-test-cli --role Role --command
 '{"Name" :  "pythonshell", "ScriptLocation" : "s3://amzn-s3-demo-bucket/
scriptname.py"}'
     --connections Connections="connection-name" --default-arguments '{"--extra-
py-files" : ["s3://amzn-s3-demo-bucket/EGG-FILE", "s3://amzn-s3-demo-bucket/WHEEL-
FILE"]}'
```

When the job runs, the script prints the rows created in the *table_name* table in the Amazon Redshift cluster.

Use AWS CloudFormation with Python shell jobs in AWS Glue

You can use AWS CloudFormation with Python shell jobs in AWS Glue. The following is an example:

```
AWSTemplateFormatVersion: 2010-09-09
Resources:
  Python39Job:
    Type: 'AWS::Glue::Job'
    Properties:
      Command:
        Name: pythonshell
        PythonVersion: '3.9'
        ScriptLocation: 's3://bucket/location'
      MaxRetries: 0
      Name: python-39-job
      Role: RoleName
```

The Amazon CloudWatch Logs group for Python shell jobs output is `/aws-glue/python-jobs/output`. For errors, see the log group `/aws-glue/python-jobs/error`.

Migrating from Python shell 3.6 to Python shell 3.9

To migrate your Python shell jobs to the latest AWS Glue version:

1. In the AWS Glue console (https://console.aws.amazon.com/glue/), choose your existing Python shell job.
2. In the **Job** details tab, set the Python version to `Python 3.9` and choose **Save**.
3. Ensure that your job script is compatible with Python 3.9 and that it runs successfully.

Migrate from AWS Glue Python shell jobs

AWS launched the AWS Glue Python shell jobs in 2018 in order to give customers an easy way to run Python scripts for small-to-medium sized ETL jobs, and to trigger SQL queries. However, there are now more modern and flexible options to address the workloads currently running on

PythonShell. This topic explains how to migrate your workloads from AWS Glue Python shell jobs to one of these alternative options in order to take advantage of the newer capabilities that are available.

Migrating workload to AWS Glue Spark jobs

AWS Glue Spark and PySpark jobs allow you to run your workloads in a distributed fashion. Since both AWS Glue Python Shell jobs and AWS Glue Spark jobs run on the same platform, it's easy to migrate, and you can continue using existing AWS Glue features that you're using with Python Shell jobs, such as AWS Glue Workflows, AWS Glue Triggers, AWS Glue's Amazon EventBridge integration, \ PIP-based package installation, and so on.

However, AWS Glue Spark jobs are designed to run Spark workloads, and the minimum number of workers is 2. If you migrate from Python Shell jobs without modifying your scripts, only one worker will be actually used, and the other workers will remain idle. This will increase your costs.

To make it efficient, rewrite your Python job script to utilize Spark's capabilities and distribute the workload across multiple workers. If your Python script is Pandas-based, it's easy to migrate using the New Pandas API on Spark. Learn more about this in the AWS Big Data Blog: Dive deep into AWS Glue 4.0 for Apache Spark.

Migrating workload to AWS Lambda

AWS Lambda is a serverless computing service that lets you run code without provisioning or managing servers. Because AWS Lambda has lower startup times and more flexible options for compute capacity, you can benefit from these advantages. For managing extra Python libraries, AWS Glue Python Shell jobs use PIP-based installation. However, for AWS Lambda, you need to choose one of the following options: a zip archive, a container image, or Lambda Layers.

On the other hand, AWS Lambda's maximum timeout is 900 seconds (15 minutes). If the job duration of your existing AWS Glue Python Shell job workload is more than that, or if your workload has a spiky pattern that may cause longer job durations, then we recommend exploring other options instead of AWS Lambda.

Migrating workload to Amazon ECS/Fargate

Amazon Elastic Container Service (Amazon ECS) is a fully managed service that simplifies the deployment, management, and scaling of containerized applications. AWS Fargate is a serverless compute engine for containerized workloads running on Amazon ECS and Amazon Elastic Kubernetes Service (Amazon EKS). There's no maximum timeout on Amazon ECS and Fargate,

so this is a good option for long-running jobs. Since you have full control over your container image, you can bring your Python script and extra Python libraries into the container and use them. However, you need to containerize your Python script to use this approach.

Migrating workload to Amazon Managed Workflows for Apache Airflow Python Operator

Amazon Managed Workflows for Apache Airflow (Managed Workflows for Apache Airflow) is a managed orchestration service for Apache Airflow that makes it easier to set up and operate end-to-end data pipelines in the cloud at scale. If you already have an MWAA environment, it will be straightforward to use the Python operator instead of AWS Glue Python Shell jobs. The Python operator is an operator that runs Python code inside an Airflow workflow. However, if you don't have an existing MWAA environment, we recommend exploring other options.

Migrating workload to Amazon SageMaker AI AI training jobs

Amazon SageMaker AI Training is a fully managed machine learning (ML) service offered by Amazon SageMaker AI that helps you efficiently train a wide range of ML models at scale. The core of Amazon SageMaker AI AI jobs is the containerization of ML workloads and the capability of managing AWS compute resources. If you prefer a serverless environment where there is no maximum timeout, Amazon SageMaker AI AI training jobs could be a good fit for you. However, the startup latency tends to be longer than AWS Glue Python Shell jobs. For jobs that are latency-sensitive, we recommend exploring other options.

Monitoring AWS Glue

Monitoring is an important part of maintaining the reliability, availability, and performance of AWS Glue and your other AWS solutions. AWS provides monitoring tools that you can use to watch AWS Glue, report when something is wrong, and take action automatically when appropriate:

You can use the following automated monitoring tools to watch AWS Glue and report when something is wrong:

- **Amazon CloudWatch Events** delivers a near real-time stream of system events that describe changes in AWS resources. CloudWatch Events enables automated event-driven computing. You can write rules that watch for certain events and trigger automated actions in other AWS services when these events occur. For more information, see the Amazon CloudWatch Events User Guide.
- **Amazon CloudWatch Logs** enables you to monitor, store, and access your log files from Amazon EC2 instances, AWS CloudTrail, and other sources. CloudWatch Logs can monitor information in

the log files and notify you when certain thresholds are met. You can also archive your log data in highly durable storage. For more information, see the Amazon CloudWatch Logs User Guide.

- **AWS CloudTrail** captures API calls and related events made by or on behalf of your AWS account and delivers the log files to an Amazon S3 bucket that you specify. You can identify which users and accounts call AWS, the source IP address from which the calls are made, and when the calls occur. For more information, see the AWS CloudTrail User Guide.

Additionally, you have access to the following insights in the AWS Glue console to help you debug and profile jobs:

- Spark jobs – you can see a visualization of selected CloudWatch metrics series, and newer jobs have access to the Spark UI. For more information, see the section called "Monitoring Spark jobs".
- Ray jobs – you can see a visualization of selected CloudWatch metrics series. For more information, see the section called "Ray job metrics".

Topics

- AWS tags in AWS Glue
- Automating AWS Glue with EventBridge
- Monitoring AWS Glue resources
- Logging AWS Glue API calls with AWS CloudTrail

AWS tags in AWS Glue

To help you manage your AWS Glue resources, you can optionally assign your own tags to some AWS Glue resource types. A tag is a label that you assign to an AWS resource. Each tag consists of a key and an optional value, both of which you define. You can use tags in AWS Glue to organize and identify your resources. Tags can be used to create cost accounting reports and restrict access to resources. If you're using AWS Identity and Access Management, you can control which users in your AWS account have permission to create, edit, or delete tags. In addition to the permissions to call the tag-related APIs, you also need the `glue:GetConnection` permission to call tagging APIs on connections, and the `glue:GetDatabase` permission to call tagging APIs on databases. For more information, see ABAC with AWS Glue.

In AWS Glue, you can tag the following resources:

- Connection
- Database
- Crawler
- Interactive session
- Development endpoint
- Job
- Trigger
- Workflow
- Blueprint
- Machine learning transform
- Data quality ruleset
- Stream schemas
- Stream schema registries

> **Note**
>
> As a best practice, to allow tagging of these AWS Glue resources, always include the `glue:TagResource` action in your policies.

Consider the following when using tags with AWS Glue.

- A maximum of 50 tags are supported per entity.
- In AWS Glue, you specify tags as a list of key-value pairs in the format `{"string": "string" ...}`
- When you create a tag on an object, the tag key is required, and the tag value is optional.
- The tag key and tag value are case sensitive.
- The tag key and the tag value must not contain the prefix *aws*. No operations are allowed on such tags.
- The maximum tag key length is 128 Unicode characters in UTF-8. The tag key must not be empty or null.
- The maximum tag value length is 256 Unicode characters in UTF-8. The tag value may be empty or null.

Tagging support for AWS Glue connections

You can restrict `CreateConnection`, `UpdateConnection`, `GetConnection` and, `DeleteConnection` action permission based on the resource tag. This enables you to implement the least privilege access control on AWS Glue jobs with JDBC data sources which need to fetch JDBC connection information from the Data Catalog.

Example usage

Create an AWS Glue connection with the tag ["connection-category", "dev-test"].

Specify the tag condition for the `GetConnection` action in the IAM policy.

```
{
   "Effect": "Allow",
   "Action": [
     "glue:GetConnection"
     ],
   "Resource": "*",
   "Condition": {
     "ForAnyValue:StringEquals": {
       "aws:ResourceTag/tagKey": "dev-test"
     }
   }
 }
```

Examples

The following examples create a job with assigned tags.

AWS CLI

```
aws glue create-job --name job-test-tags --role MyJobRole --command
 Name=glueetl,ScriptLocation=S3://aws-glue-scripts//prod-job1
--tags key1=value1,key2=value2
```

CloudFormation JSON

```

    ExecutionProperty:
      MaxConcurrentRuns: 2
    MaxRetries: 0
    Name: cf-job1
    Role:
      Ref: MyJobRole
      Tags:
         key1: value1
         key2: value2
```

For more information, see AWS Tagging Strategies.

For information about how to control access using tags, see ABAC with AWS Glue.

Automating AWS Glue with EventBridge

You can use Amazon EventBridge to automate your AWS services and respond automatically to system events such as application availability issues or resource changes. Events from AWS services are delivered to EventBridge in near real time. You can write simple rules to indicate which events are of interest to you, and what automated actions to take when an event matches a rule. The actions that can be automatically triggered include the following:

- Invoking an AWS Lambda function
- Invoking Amazon EC2 Run Command
- Relaying the event to Amazon Kinesis Data Streams
- Activating an AWS Step Functions state machine
- Notifying an Amazon SNS topic or an Amazon SQS queue

Some examples of using EventBridge with AWS Glue include the following:

- Activating a Lambda function when an ETL job succeeds
- Notifying an Amazon SNS topic when an ETL job fails

The following EventBridge are generated by AWS Glue.

- Events for `"detail-type":"Glue Job State Change"` are generated for `SUCCEEDED`, `FAILED`, `TIMEOUT`, and `STOPPED`.
- Events for `"detail-type":"Glue Job Run Status"` are generated for `RUNNING`, `STARTING`, and `STOPPING` job runs when they exceed the job delay notification threshold. You must set the job delay notification threshold property to receive these events.

  Only one event is generated per job run status when the job delay notification threshold is exceeded.
- Events for `"detail-type":"Glue Crawler State Change"` are generated for `Started`, `Succeeded`, and `Failed`.
- Events for `“detail_type”:“Glue Scheduled Crawler Invocation Failure”` are generated when the scheduled crawler fails to start. In the details of the notification:
  - `customerId` contains the account ID of the customer.
  - `crawlerName` contains the name of the crawler that failed to start.
  - `errorMessage` contains the exception message of the invocation failure.
- Events for `“detail_type”:“Glue Auto Statistics Invocation Failure“` are generated when the auto-managed column statistics task run fails to start. In the details of the notification:
  - `catalogId` contains the ID associated with a catalog.
  - `databaseName` contains the name of the affected database.
  - `tableName` contains the name of the affected table.
  - `errorMessage` contains the exception message of the invocation failure.
- Events for `“detail_type”:“Glue Scheduled Statistics Invocation Failure”` are generated when the (cron) scheduled column statistics task run fails to start. In the details of the notification:
  - `catalogId` contains the ID associated with a catalog.
  - `databaseName` contains the name of the affected database.
  - `tableName` contains the name of the affected table.
  - `errorMessage` contains the exception message of the invocation failure.
- Events for `“detail_type”:“Glue Statistics Task Started”` are generated when the column statistics task run starts.

- Events for “detail_type”:“Glue Statistics Task Succeeded” are generated when the column statistics task run succeeds.
- Events for “detail_type”:“Glue Statistics Task Failed” are generated when the column statistics task run fails.
- Events for "detail-type":"Glue Data Catalog Database State Change" are generated for CreateDatabase, DeleteDatabase, CreateTable, DeleteTable and BatchDeleteTable. For example, if a table is created or deleted, a notification is sent to EventBridge. Note that you cannot write a program that depends on the order or existence of notification events, as they might be out of sequence or missing. Events are emitted on a best effort basis. In the details of the notification:
  - The typeOfChange contains the name of the API operation.
  - The databaseName contains the name of the affected database.
  - The changedTables contains up to 100 names of affected tables per notification. When table names are long, multiple notifications might be created.
- Events for "detail-type":"Glue Data Catalog Table State Change" are generated for UpdateTable, CreatePartition, BatchCreatePartition, UpdatePartition, DeletePartition, BatchUpdatePartition and BatchDeletePartition. For example, if a table or partition is updated, a notification is sent to EventBridge. Note that you cannot write a program that depends on the order or existence of notification events, as they might be out of sequence or missing. Events are emitted on a best effort basis. In the details of the notification:
  - The typeOfChange contains the name of the API operation.
  - The databaseName contains the name of the database that contains the affected resources.
  - The tableName contains the name of the affected table.
  - The changedPartitions specifies up to 100 affected partitions in one notification. When partition names are long, multiple notifications might be created.

    For example if there are two partition keys, Year and Month, then "2018,01", "2018,02" modifies the partition where "Year=2018" and "Month=01" and the partition where "Year=2018" and "Month=02".

```
{
    "version":"0",
    "id":"abcdef00-1234-5678-9abc-def012345678",
    "detail-type":"Glue Data Catalog Table State Change",
    "source":"aws.glue",
    "account":"123456789012",
```

```
    "time":"2017-09-07T18:57:21Z",
    "region":"us-west-2",
    "resources":["arn:aws:glue:us-west-2:123456789012:database/default/foo"],

        "changedPartitions": [
            "2018,01",
            "2018,02"
        ],
        "databaseName": "default",
        "tableName": "foo",
        "typeOfChange": "BatchCreatePartition"
        }
}
```

For more information, see the Amazon CloudWatch Events User Guide. For events specific to AWS Glue, see AWS Glue Events.

Monitoring AWS Glue resources

AWS Glue has service limits to protect customers from unexpected excessive provisioning and from malicious actions intended to increase your bill. The limits also protect the service. Logging into the AWS Service Quota console, customers can view their current resource limits and request an increase (where appropriate).

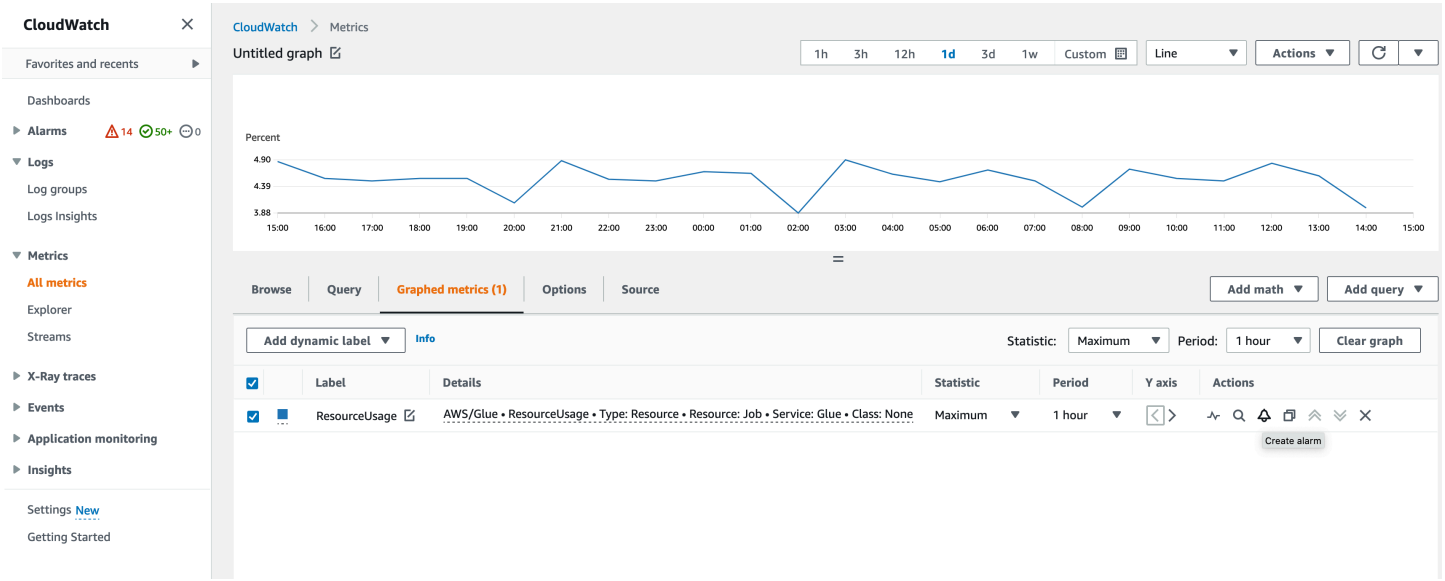
AWS Glue allows you to view the service's resource usage as a percentage in Amazon CloudWatch and to configure CloudWatch alarms on it to monitor usage. Amazon CloudWatch provides monitoring for AWS resources and the customer applications running on the Amazon infrastructure. The metrics are free of charge to you. The following metrics are supported:

- Number of workflows per account
- Number of triggers per account
- Number of jobs per account
- Number of concurrent job runs per account
- Number of blueprints per account
- Number of interactive sessions per account

Configuring and using resource metrics

To use this feature, you can go to the Amazon CloudWatch console to view the metrics and configure alarms. The metrics are under the AWS/Glue namespace and are a percentage of the actual resource usage count divided by the resource quota. The CloudWatch metrics are delivered to your accounts, which will be no cost for you. For example, if you have 10 workflows created, and your service quota allows you to have 200 workflows in maximum, then your usage is 10/200 = 5%, and in graph, you will see a datapoint of 5 as a percentage. To be more specific:

```
Namespace: AWS/Glue
Metric name: ResourceUsage
Type: Resource
Resource: Workflow (or Trigger, Job, JobRun, Blueprint, InteractiveSession)
Service: Glue
Class: None
```



To create an alarm on a metric in the CloudWatch console:

1. Once you locate the metric, go to **Graphed metrics**.
2. Click **Create alarm** under **Actions**.
3. Configure the alarm as needed.

We emit metrics whenever your resource usage has a change (such as an increase or decrease). But if your resource usage doesn't change, we emit metrics hourly, so that you have a continuous

CloudWatch graph. To avoid having missing data points, we do not recommend you to configure a period less than 1 hour.

You can also configure alarms using AWS CloudFormation as in the following example. In this example, once the workflow resource usage reaches 80%, it triggers an alarm to send a message to the existing SNS topic, where you can subscribe to it to get notifications.

```
{
 "Type": "AWS::CloudWatch::Alarm",
 "Properties": {
  "AlarmName": "WorkflowUsageAlarm",
  "ActionsEnabled": true,
  "OKActions": [],
  "AlarmActions": [
   "arn:aws:sns:af-south-1:085425700061:Default_CloudWatch_Alarms_Topic"
  ],
  "InsufficientDataActions": [],
  "MetricName": "ResourceUsage",
  "Namespace": "AWS/Glue",
  "Statistic": "Maximum",
  "Dimensions": [{
    "Name": "Type",
    "Value": "Resource"
   },
   {
    "Name": "Resource",
    "Value": "Workflow"
   },
   {
    "Name": "Service",
    "Value": "Glue"
   },
   {
    "Name": "Class",
    "Value": "None"
   }
  ],
  "Period": 3600,
  "EvaluationPeriods": 1,
  "DatapointsToAlarm": 1,
  "Threshold": 80,
  "ComparisonOperator": "GreaterThanThreshold",
  "TreatMissingData": "notBreaching"
```

```
  }
}
```

Logging AWS Glue API calls with AWS CloudTrail

AWS Glue is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in AWS Glue. CloudTrail captures all API calls for AWS Glue as events. The calls captured include calls from the AWS Glue console and code calls to the AWS Glue API operations. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for AWS Glue. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**. Using the information collected by CloudTrail, you can determine the request that was made to AWS Glue, the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the AWS CloudTrail User Guide.

AWS Glue information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in AWS Glue, that activity is recorded in a CloudTrail event along with other AWS service events in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History.

For an ongoing record of events in your AWS account, including events for AWS Glue, create a trail. A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- Creating a trail for your AWS account
- CloudTrail supported services and integrations
- Configuring Amazon SNS Notifications for CloudTrail
- Receiving CloudTrail Log Files from Multiple Regions and Receiving CloudTrail Log Files from Multiple Accounts

All AWS Glue actions are logged by CloudTrail and are documented in the AWS Glue API . For example, calls to the `CreateDatabase`, `CreateTable` and `CreateScript` actions generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentity Element.

However, CloudTrail doesn't log all information regarding calls. For example, it doesn't log certain sensitive information, such as the `ConnectionProperties` used in connection requests, and it logs a `null` instead of the responses returned by the following APIs:

```
BatchGetPartition       GetCrawlers          GetJobs          GetTable
CreateScript            GetCrawlerMetrics    GetJobRun        GetTables
GetCatalogImportStatus  GetDatabase           GetJobRuns       GetTableVersions
GetClassifier           GetDatabases         GetMapping       GetTrigger
GetClassifiers          GetDataflowGraph     GetObjects       GetTriggers
GetConnection           GetDevEndpoint       GetPartition     GetUserDefinedFunction
GetConnections          GetDevEndpoints      GetPartitions    GetUserDefinedFunctions
GetCrawler              GetJob               GetPlan
```

Understanding AWS Glue log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the `DeleteCrawler` action.

```
{
  "eventVersion": "1.05",
```

```
  "userIdentity": {
    "type": "IAMUser",
    "principalId": "AKIAIOSFODNN7EXAMPLE",
    "arn": "arn:aws:iam::123456789012:user/johndoe",
    "accountId": "123456789012",
    "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
    "userName": "johndoe"
  },
  "eventTime": "2017-10-11T22:29:49Z",
  "eventSource": "glue.amazonaws.com",
  "eventName": "DeleteCrawler",
  "awsRegion": "us-east-1",
  "sourceIPAddress": "72.21.198.64",
  "userAgent": "aws-cli/1.11.148 Python/3.6.1 Darwin/16.7.0 botocore/1.7.6",
  "requestParameters": {
    "name": "tes-alpha"
  },
  "responseElements": null,
  "requestID": "b16f4050-aed3-11e7-b0b3-75564a46954f",
  "eventID": "e73dd117-cfd1-47d1-9e2f-d1271cad838c",
  "eventType": "AwsApiCall",
  "recipientAccountId": "123456789012"
}
```

This example shows a CloudTrail log entry that demonstrates a `CreateConnection` action.

```
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "IAMUser",
    "principalId": "AKIAIOSFODNN7EXAMPLE",
    "arn": "arn:aws:iam::123456789012:user/johndoe",
    "accountId": "123456789012",
    "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
    "userName": "johndoe"
  },
  "eventTime": "2017-10-13T00:19:19Z",
  "eventSource": "glue.amazonaws.com",
  "eventName": "CreateConnection",
  "awsRegion": "us-east-1",
  "sourceIPAddress": "72.21.198.66",
  "userAgent": "aws-cli/1.11.148 Python/3.6.1 Darwin/16.7.0 botocore/1.7.6",
  "requestParameters": {
```

```
    "connectionInput": {
      "name": "test-connection-alpha",
      "connectionType": "JDBC",
      "physicalConnectionRequirements": {
        "subnetId": "subnet-323232",
        "availabilityZone": "us-east-1a",
        "securityGroupIdList": [
          "sg-12121212"
        ]
      }
    }
  },
  "responseElements": null,
  "requestID": "27136ebc-afac-11e7-a7d6-ab217e5c3f19",
  "eventID": "e8b3baeb-c511-4597-880f-c16210c60a4a",
  "eventType": "AwsApiCall",
  "recipientAccountId": "123456789012"
}
```

AWS Glue Streaming

AWS Glue Streaming, a component of AWS Glue, enables you to efficiently handle streaming data in near real-time, empowering you to carry out crucial tasks such as data ingestion, processing, and machine learning. Using the Apache Spark Streaming framework, AWS Glue Streaming provides a serverless service that can handle streaming data at scale. AWS Glue provides various optimizations on top of Apache Spark such as serverless infrastructure, auto-scaling, visual job development, instant-on notebooks for streaming jobs and other performance improvements.

Use cases for streaming

Some common use cases for AWS Glue Streaming include:

Near-real-time data processing: AWS Glue Streaming allows organizations to process streaming data in near real-time, enabling them to derive insights and make timely decisions based on the latest information.

Fraud detection: You can utilize AWS Glue Streaming for real-time analysis of streaming data, making it valuable for detecting fraudulent activities, such as credit card fraud, network intrusion, or online scams. By continuously processing and analyzing incoming data, you can swiftly identify suspicious patterns or anomalies.

Social media analytics: AWS Glue Streaming can process real-time social media data, such as tweets, posts, or comments, enabling organizations to monitor trends, sentiment analysis, and manage brand reputation in real-time.

Internet of Things (IoT) analytics: AWS Glue Streaming is suitable for handling and analyzing high-velocity streams of data generated by IoT devices, sensors, and connected machinery. It allows for real-time monitoring, anomaly detection, predictive maintenance, and other IoT analytics use cases.

Clickstream analysis: AWS Glue Streaming can process and analyze real-time clickstream data from websites or mobile applications. This enables businesses to gain insights into user behavior, personalize user experiences, and optimize marketing campaigns based on real-time clickstream data.

Log monitoring and analysis: AWS Glue Streaming can continuously process and analyze log data from servers, applications, or network devices in real-time. This helps in detecting anomalies, troubleshooting issues, and monitoring system health and performance.

Recommendation systems: AWS Glue Streaming can process user activity data in real-time and update recommendation models dynamically. This allows for personalized and real-time recommendations based on user behavior and preferences.

These are some examples of the diverse range of use cases where AWS Glue Streaming can be applied. Its integration with the AWS ecosystem and managed services make it a convenient choice for real-time stream processing and analytics in the cloud.

What are the benefits of using AWS Glue Streaming?

The benefits of using AWS Glue Streaming are as follows:

- **Serverless**: AWS Glue Streaming is serverless, eliminating the need to manage infrastructure. This reduces the operational overhead and allows users to focus on data processing and analytics tasks rather than infrastructure management.
- **Autoscaling**: AWS Glue Streaming provides autoscaling capabilities, dynamically adjusting the processing capacity based on the workload. It automatically scales out or in to handle fluctuations in data volume, ensuring optimal performance and resource utilization.
- **Visual development**: Streaming job development can be complex. AWS Glue Streaming addresses this challenge by offering AWS Glue Studio, a visual authoring tool. AWS Glue Studio simplifies the process of creating streaming workflows and enables developers to design and manage streaming applications visually, reducing the learning curve and increasing productivity.
- **Cost-effective**: As a serverless service, AWS Glue Streaming offers cost efficiency by eliminating the need for provisioning and maintaining infrastructure. Users are billed based on the resources consumed during the execution of streaming jobs, allowing for cost optimization and scaling based on actual usage.
- **Handles complex workloads**: AWS Glue Streaming is designed to handle complex streaming workloads. It can process and analyze large volumes of real-time data, support advanced transformations, and integrate with other AWS services, enabling sophisticated streaming data pipelines and analytics workflows.
- **No lock-in**: AWS Glue Streaming provides flexibility and avoids vendor lock-in. Users can leverage AWS Glue Streaming as part of the broader AWS ecosystem, integrating it with other AWS services seamlessly. This allows for easy integration with existing data sources, applications, and services without being tied to a specific technology or platform.

When to use AWS Glue Streaming?

There are many options when it comes to streaming use cases. We recommend AWS Glue streaming in the following scenarios.

1. **If you are already using AWS Glue or Spark for batch processing**, AWS Glue Streaming is the ideal choice for you. It provides a seamless transition to building streaming jobs without the need to learn a new language or framework. Leveraging your existing knowledge and infrastructure, AWS Glue Streaming simplifies the job development process and allows you to easily extend your data processing capabilities to real-time streaming scenarios.
2. **If you require a unified service or product to handle batch, streaming, and event-driven workloads**, AWS Glue Streaming is the solution for you. With AWS Glue Streaming, you can consolidate your data processing needs into a single framework, eliminating the complexity of managing multiple systems. This enables efficient development and maintenance of diverse data workflows while ensuring consistency and compatibility across different workload types.
3. **AWS Glue Streaming is well-suited for scenarios involving extremely large streaming data volumes and complex transformations**, such as joins between streams or relational databases. It can efficiently process and analyze massive streams of data, enabling you to tackle demanding workloads with ease. Whether it is high-velocity data ingestion or intricate data manipulations, AWS Glue Streaming's scalability and advanced processing capabilities ensure optimal performance and accurate results.
4. **If you prefer a visual approach to building streaming jobs**, AWS Glue offers AWS Glue Studio, with which you can visually design and manage your streaming applications, simplifying the development process. This intuitive interface enables developers to create, configure, and monitor streaming workflows using a visual interface, reducing the learning curve and increasing productivity.
5. **AWS Glue Streaming is an excellent choice for near-real-time use cases where there are stringent SLAs (Service Level Agreements)** greater than 10 seconds.
6. **If you are building a transactional data lake using Apache Iceberg, Apache Hudi, or Delta Lake**, AWS Glue Streaming provides native support for these open table formats. This seamless integration enables you to process streaming data directly from these transactional data lakes, ensuring data consistency, integrity, and compatibility.
7. **When needing to ingest streaming data for a variety of data targets**: AWS Glue Streaming provides native targets to a variety of data targets such as Amazon Redshift, Amazon RDS, Amazon Aurora, Oracle, SQL Server and other targets.

Supported data sources

AWS Glue Streaming supports the following data sources:

- Amazon Kinesis
- Amazon MSK (Managed Streaming for Apache Kafka)
- Self-managed Apache Kafka

Supported data targets

AWS Glue Streaming supports a variety of data targets such as:

- Data targets supported by AWS Glue Data Catalog
- Amazon S3
- Amazon Redshift
- MySQL
- PostgreSQL
- Oracle
- Microsoft SQL Server
- Snowflake
- Any database that can be connected using JDBC
- Apache Iceberg, Delta and Apache Hudi
- AWS Glue Marketplace connectors

Tutorial: Build your first streaming workload using AWS Glue Studio

In this tutorial, you are going to learn how to create a streaming job using AWS Glue Studio. AWS Glue Studio is a visual interface to create AWS Glue jobs.

You can create streaming extract, transform, and load (ETL) jobs that run continuously and consume data from streaming sources in Amazon Kinesis Data Streams, Apache Kafka, and Amazon Managed Streaming for Apache Kafka (Amazon MSK).

Prerequisites

To follow this tutorial you'll need a user with AWS console permissions to use AWS Glue, Amazon Kinesis, Amazon S3, Amazon Athena, AWS CloudFormation, AWS Lambda and Amazon Cognito.

Consume streaming data from Amazon Kinesis

Topics

- Generating mock data with Kinesis Data Generator
- Creating an AWS Glue streaming job with AWS Glue Studio
- Performing a transformation and storing the transformed result in Amazon S3

Generating mock data with Kinesis Data Generator

You can synthetically generate sample data in JSON format using the Kinesis Data Generator (KDG). You can find full instructions and details in the tool documentation.

1. To get started, click

   to run an AWS CloudFormation template on your AWS environment.

   > **Note**
   >
   > You may encounter a CloudFormation template failure because some resources, such as the Amazon Cognito user for Kinesis Data Generator already exist in your AWS account. This could be because you already set that up from another tutorial or blog. To address this, you can either try the template in a new AWS account for a fresh start, or explore a different AWS Region. These options let you run the tutorial without conflicting with existing resources.

   The template provisions a Kinesis data stream and a Kinesis Data Generator account for you. It also creates an Amazon S3 bucket to hold the data and a Glue Service Role with the required permission for this tutorial.
2. Enter a **Username** and **Password** that the KDG will use to authenticate. Note the username and password for further usage.

3. Select **Next** all the way to the last step. Acknowledge the creation of IAM resources. Check for any errors at the top of the screen, such as the password not meeting the minimum requirements, and deploy the template.
4. Navigate to the **Outputs** tab of the stack. Once the template is deployed, it will display the generated property **KinesisDataGeneratorUrl**. Click that URL.
5. Enter the **Username** and **Password** you noted down.
6. Select the Region you are using and select the Kinesis Stream `GlueStreamTest-{AWS::AccountId}`
7. Enter the following template:

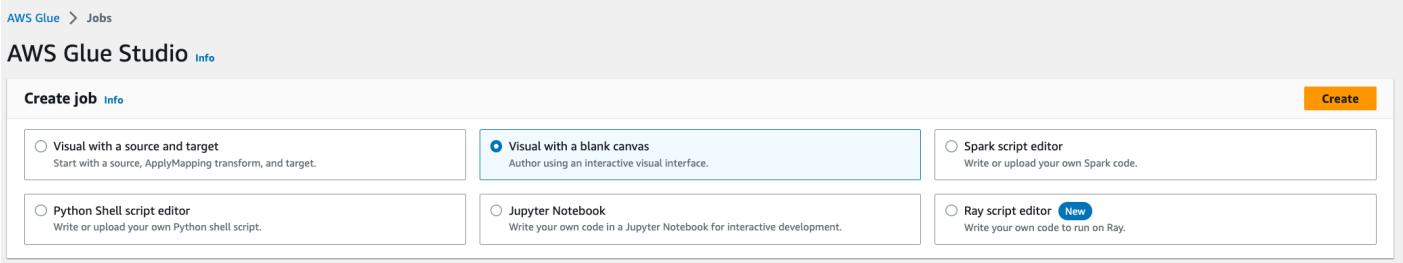
```
{
    "ventilatorid": {{random.number(100)}},
    "eventtime": "{{date.now("YYYY-MM-DD HH:mm:ss")}}",
    "serialnumber": "{{random.uuid}}",
    "pressurecontrol": {{random.number(
        {
            "min":5,
            "max":30
        }
    )}},
    "o2stats": {{random.number(
        {
            "min":92,
            "max":98
        }
    )}},
    "minutevolume": {{random.number(
        {
            "min":5,
            "max":8
        }
    )}},
    "manufacturer": "{{random.arrayElement(
        ["3M", "GE","Vyaire", "Getinge"]
    )}}"
}
```

   You can now view mock data with **Test template** and ingest the mock data to Kinesis with **Send data**.

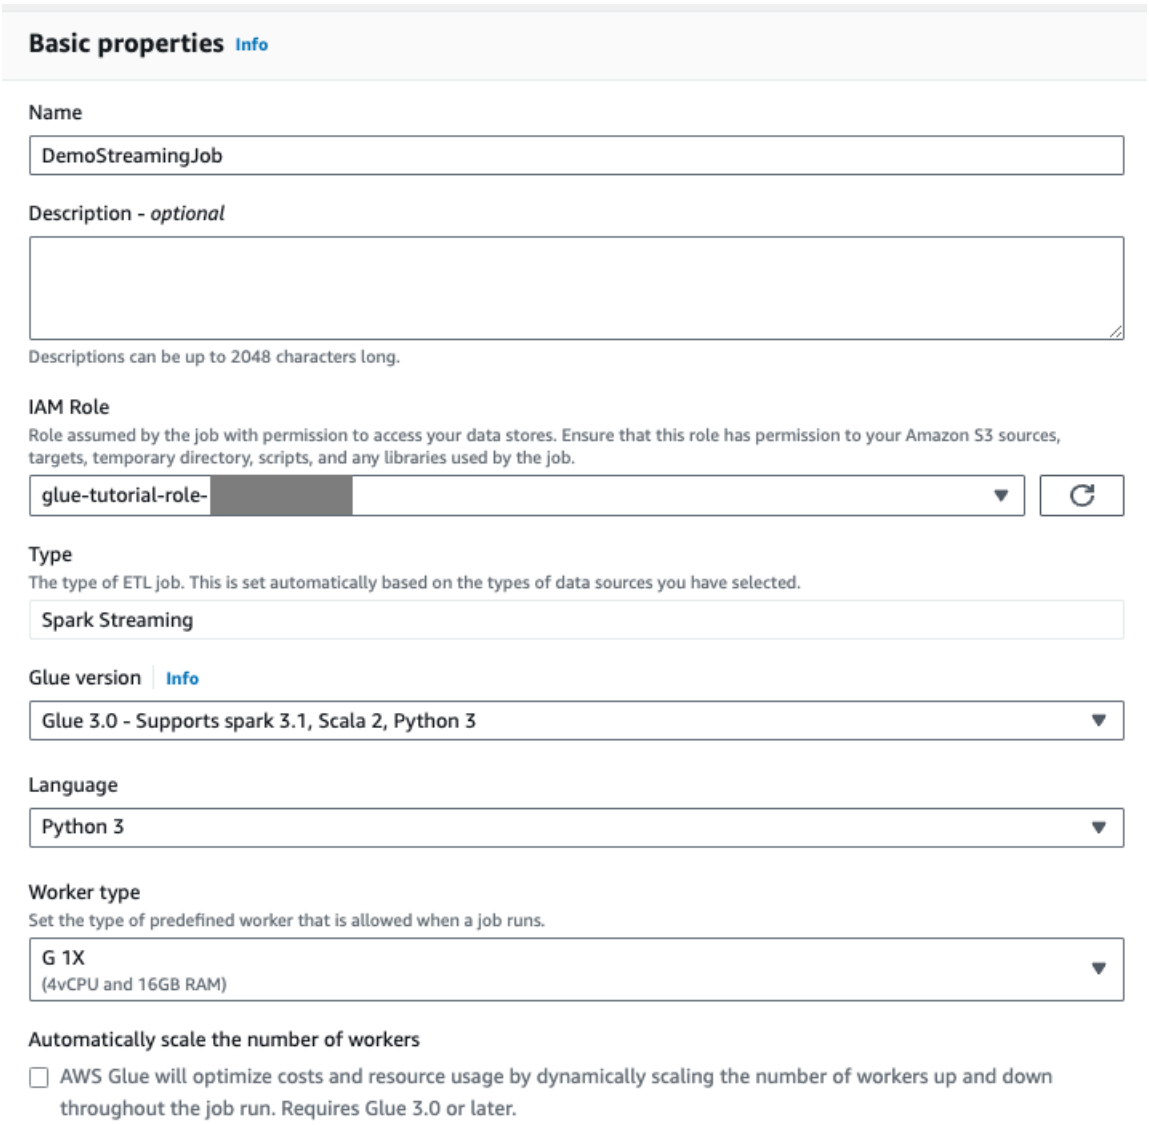
8. Click **Send data** and generate 5-10K records to Kinesis.

Creating an AWS Glue streaming job with AWS Glue Studio

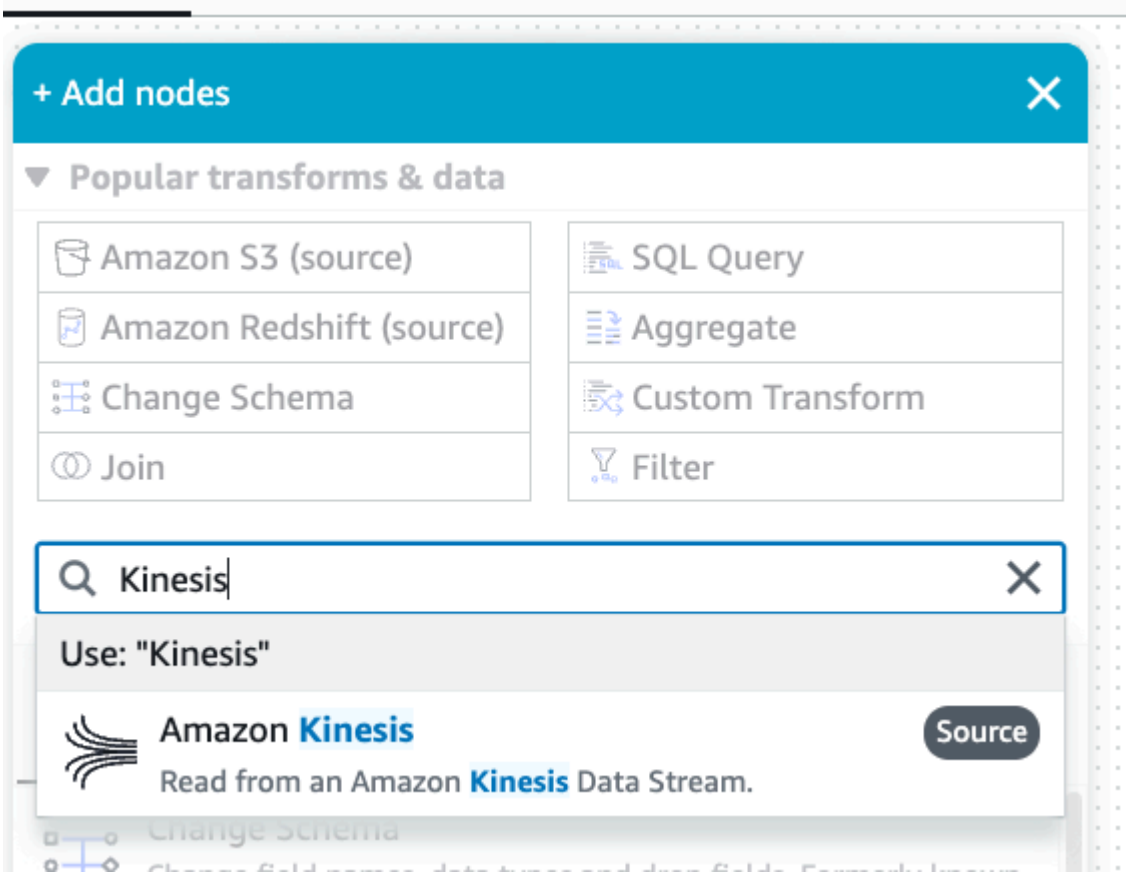
1. Navigate to AWS Glue in the console on the same Region.
2. Select **ETL jobs** under the left side navigation bar under **Data Integration and ETL**.
3. Create an AWS Glue Job via **Visual with a blank canvas**.



4. Navigate to the **Job Details** tab.
5. For the AWS Glue job name, enter `DemoStreamingJob`.
6. For **IAM Role**, select the role provisioned by the CloudFormation template, `glue-tutorial-role-${AWS::AccountId}`.
7. For **Glue version**, select **Glue 3.0**. Leave all other options as default.



8. Navigate to the **Visual tab**.
9. Click on the plus icon. Enter **Kinesis** in the search bar. Select the **Amazon Kinesis** data source.



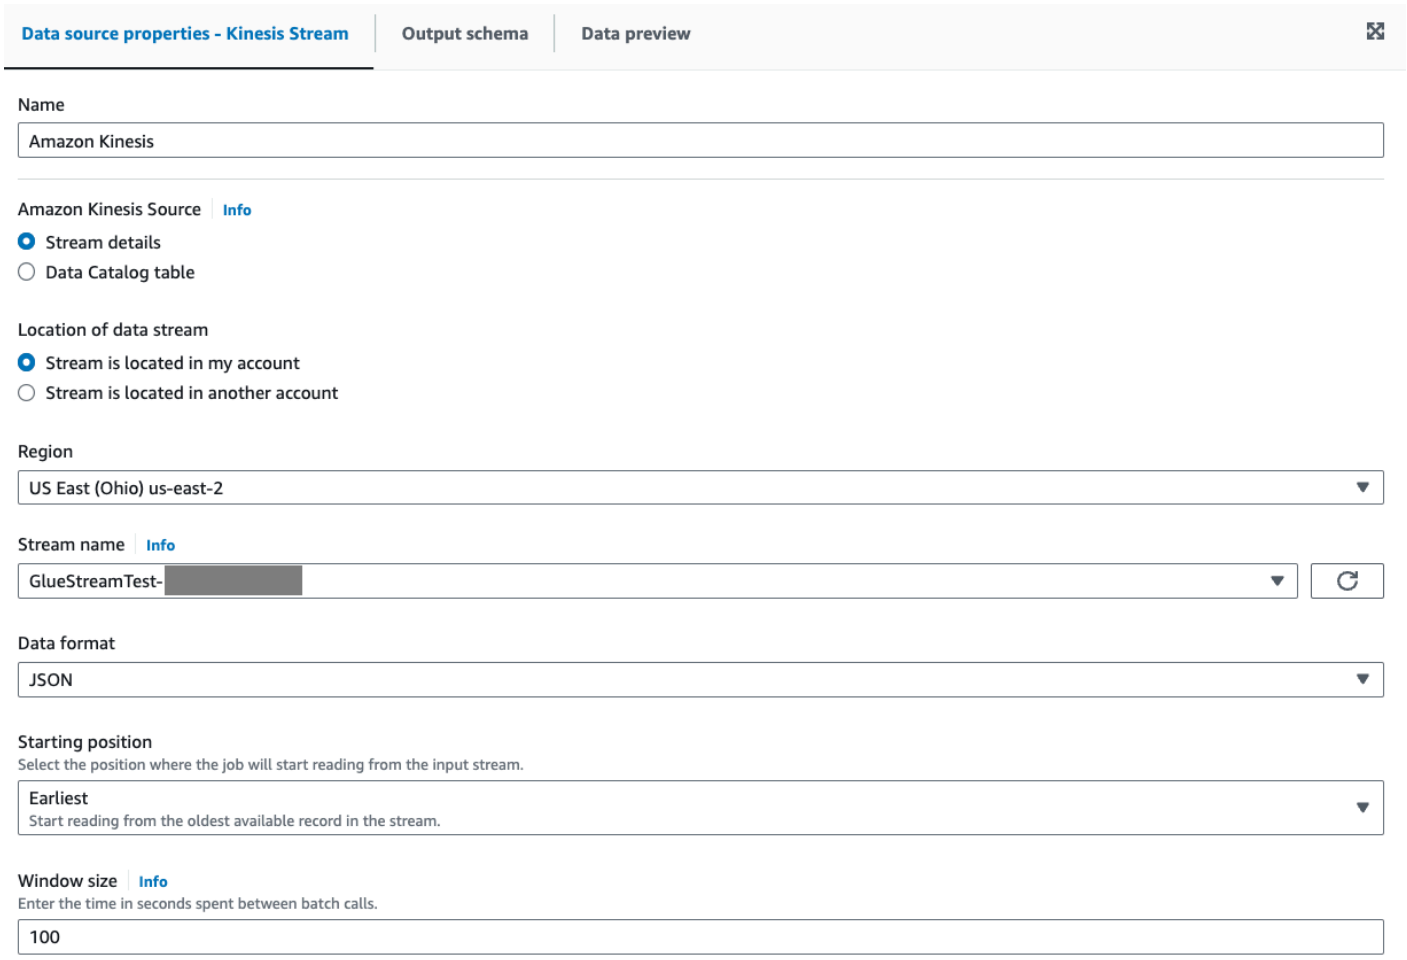
10 Select **Stream details** for **Amazon Kinesis Source** under the tab **Data source properties - Kinesis Stream**.

11 Select **Stream is located in my account** for **Location of data stream**.

12 Select the Region you are using.

13 Select the `GlueStreamTest-{AWS::AccountId}` stream.

14 Keep all other settings as default.

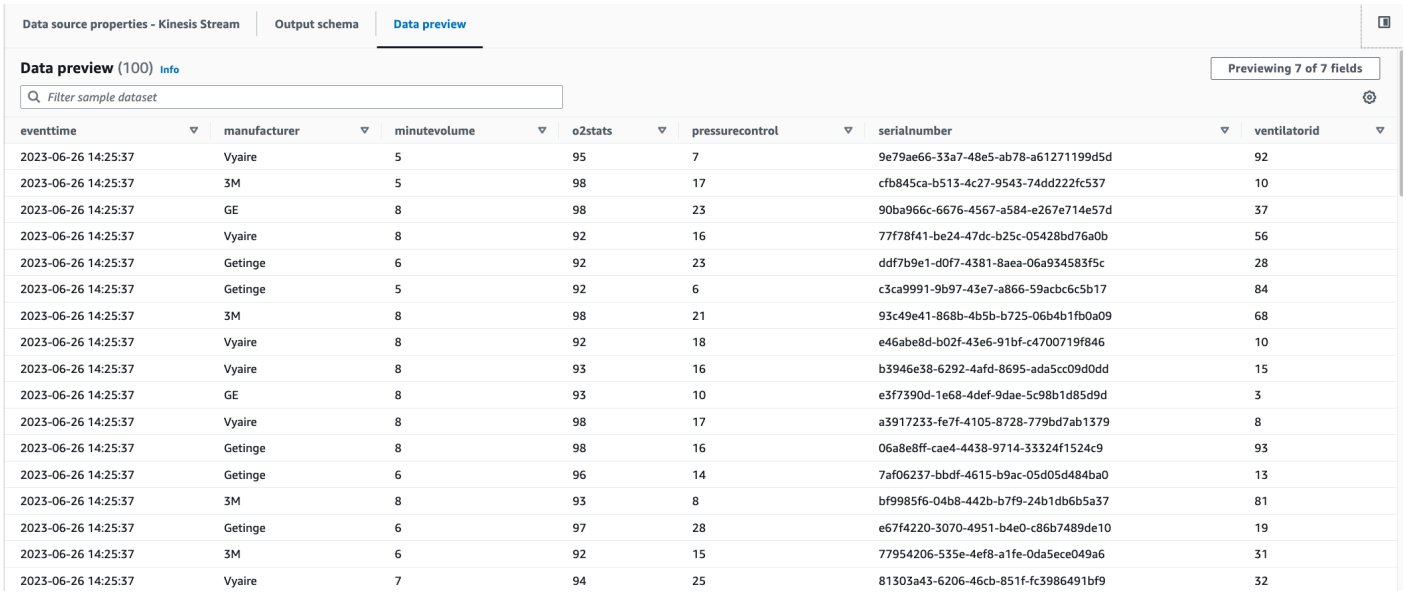


15. Navigate to the **Data preview** tab.

16. Click **Start data preview session**, which previews the mock data generated by KDG. Pick the Glue Service Role you previously created for the AWS Glue Streaming job.

    It takes 30-60 seconds for the preview data to show up. If it shows **No data to display**, click the gear icon and change the **Number of rows to sample** to `100`.

    You can see the sample data as below:



Data source properties - Kinesis Stream | Output schema | Data preview

Data preview (100) Info

Previewing 7 of 7 fields

Filter sample dataset

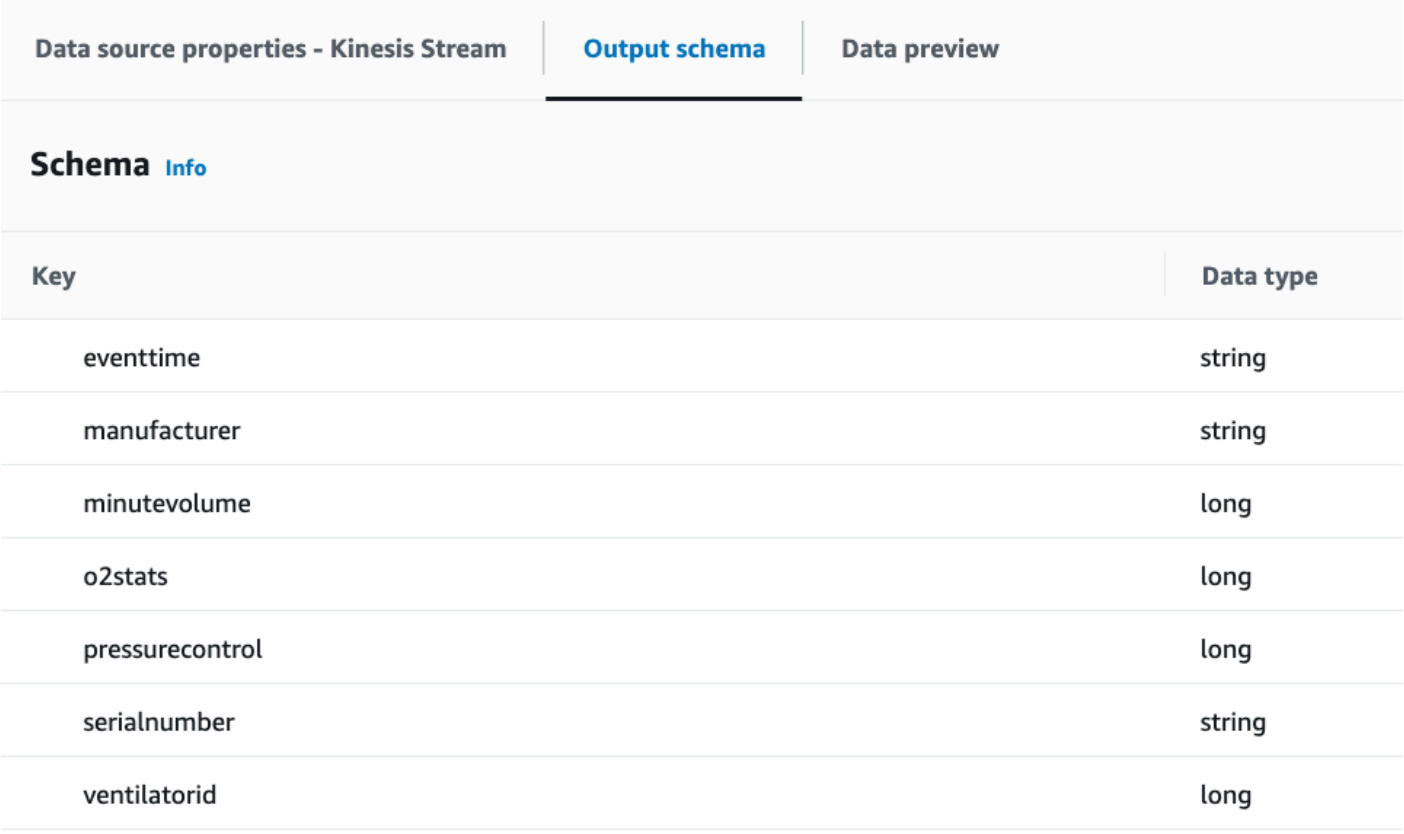
You can also see the inferred schema in the **Output schema** tab.



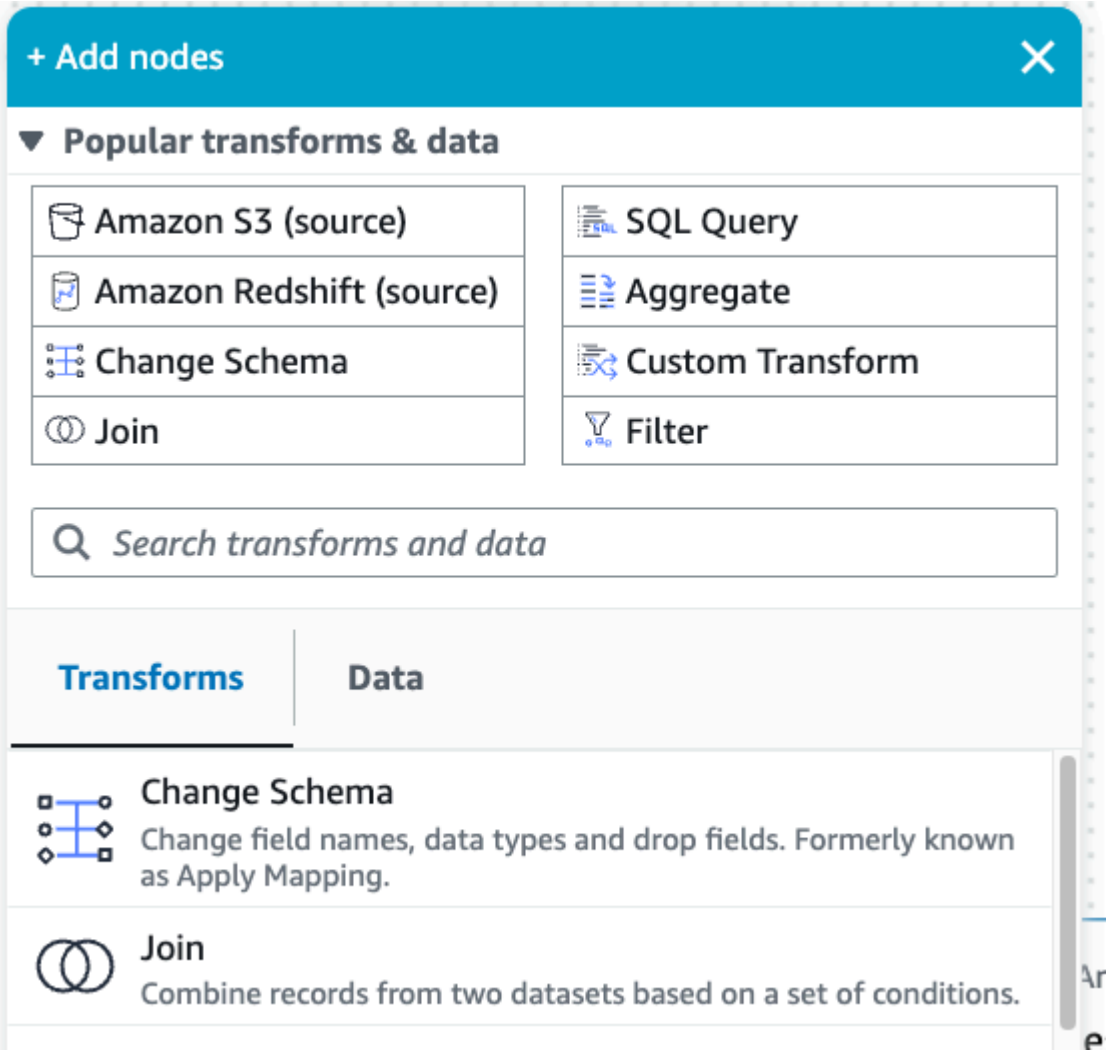
Data source properties - Kinesis Stream | Output schema | Data preview

Schema Info

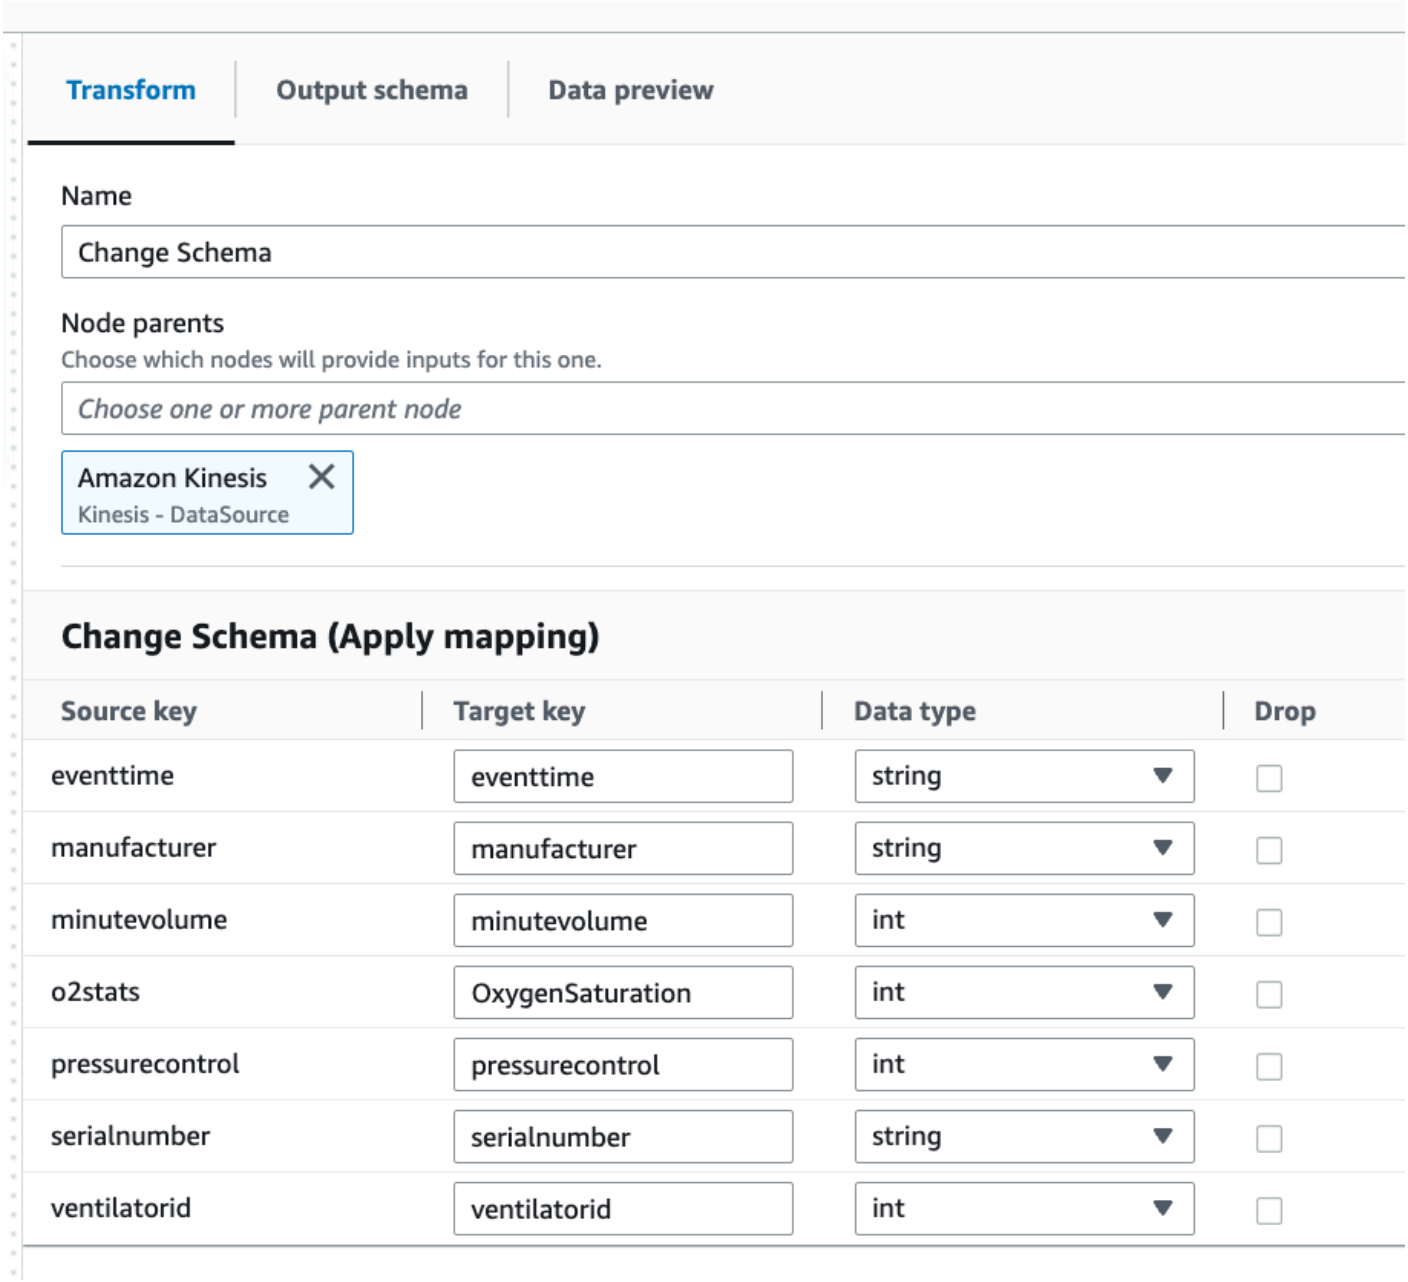
Key	Data type
eventtime	string
manufacturer	string
minutevolume	long
o2stats	long
pressurecontrol	long
serialnumber	string
ventilatorid	long

Performing a transformation and storing the transformed result in Amazon S3

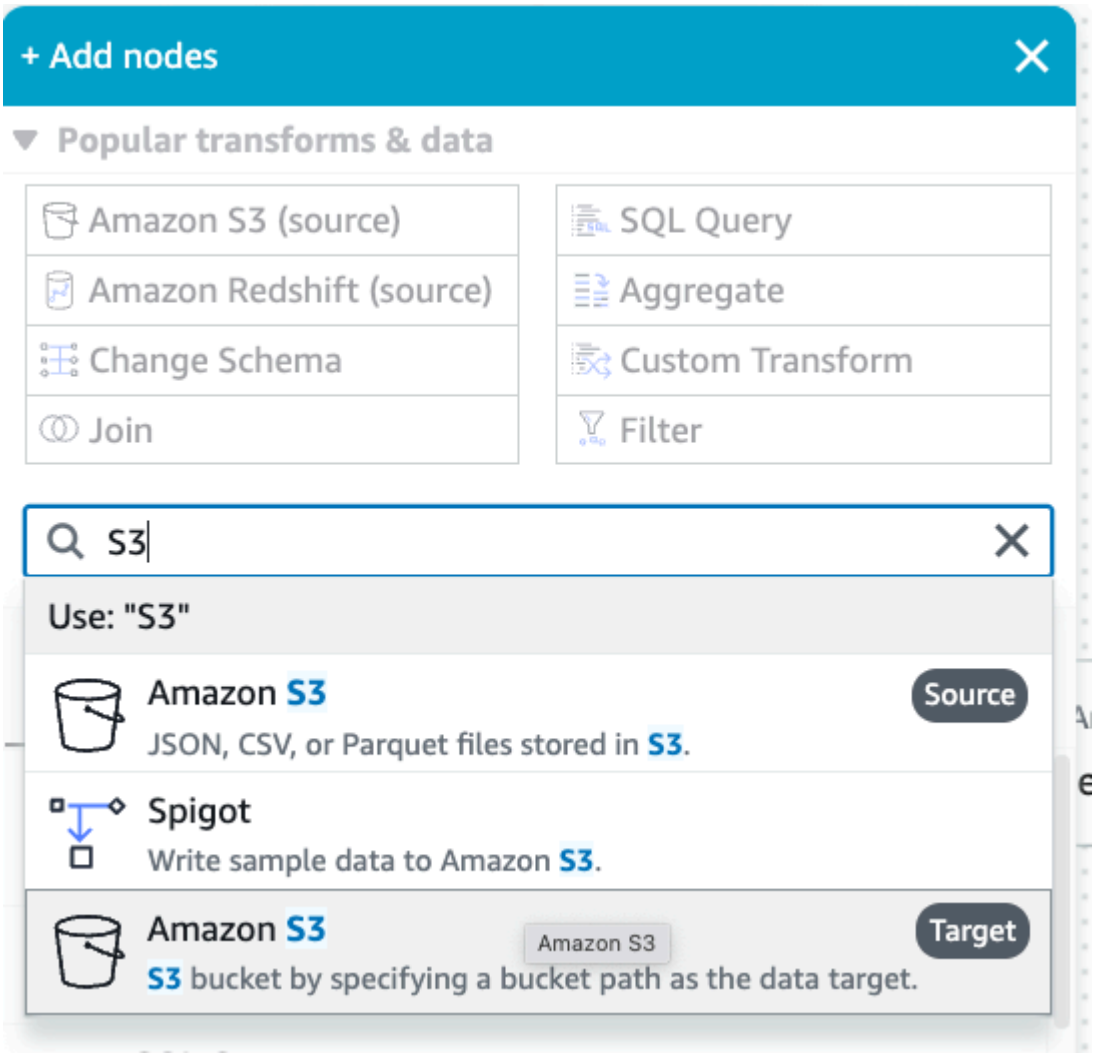
1. With the source node selected, click on the plus icon on the top left to add a **Transforms** step.
2. Select the **Change Schema** step.



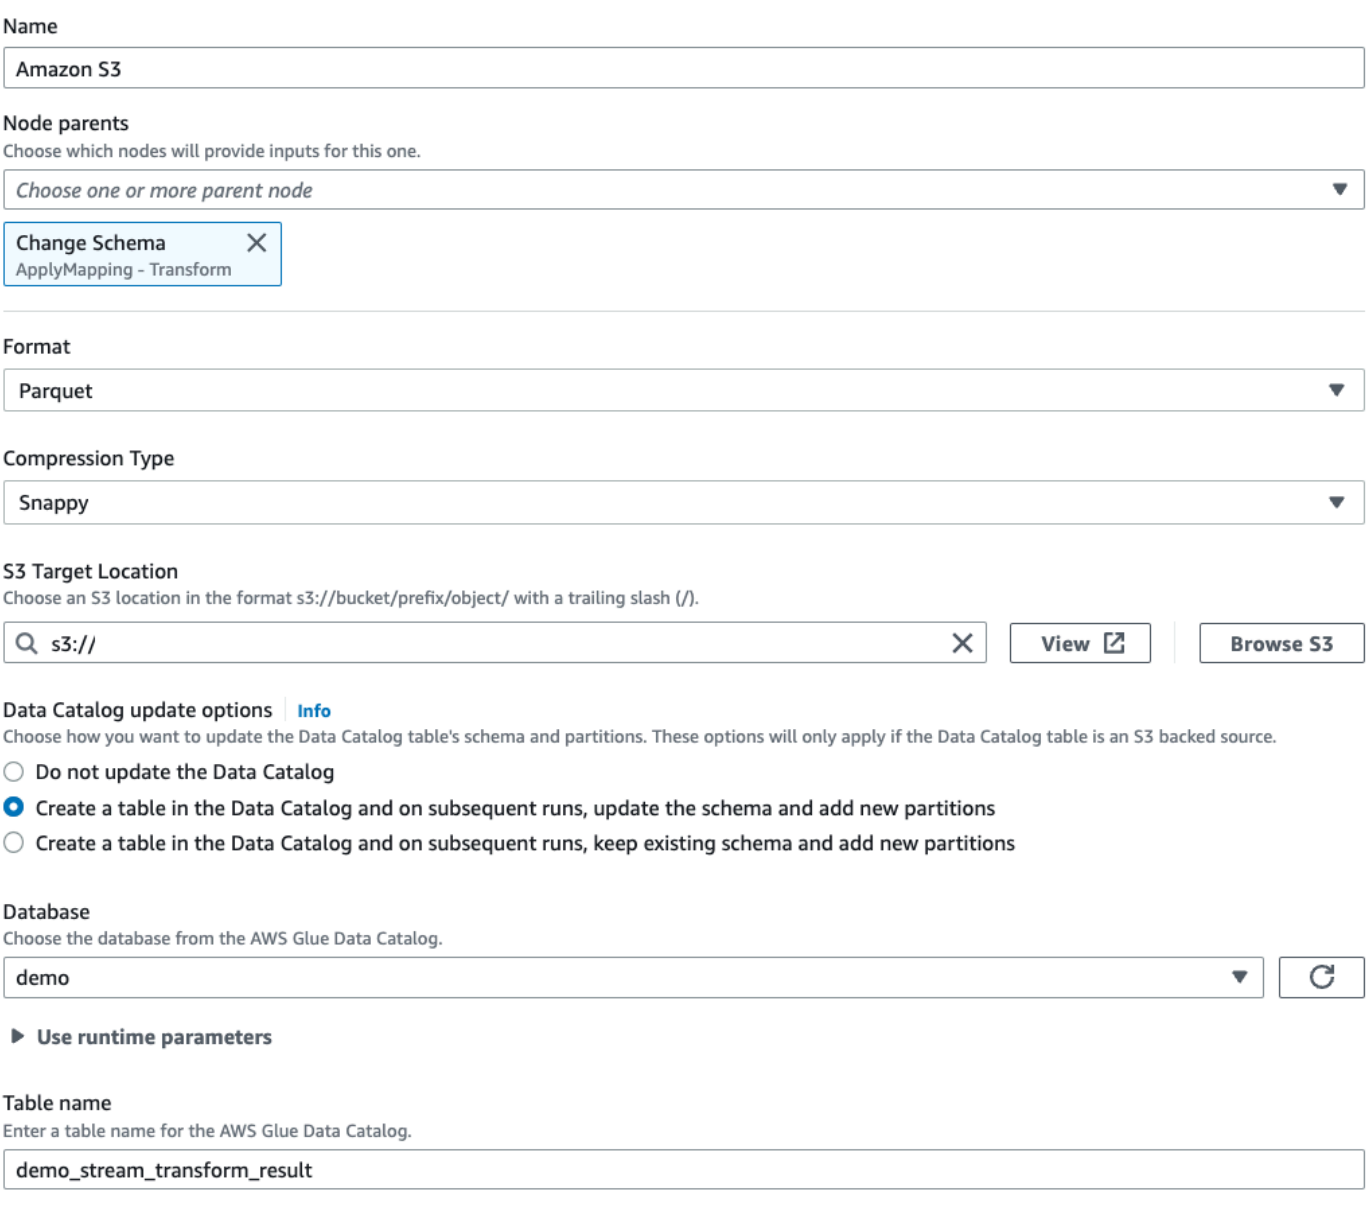
3. You can rename fields and convert the data type of fields in this step. Rename the `o2stats` column to `OxygenSaturation` and convert all `long` data type to `int`.



4. Click on the plus icon to add an **Amazon S3** target. Enter S3 in the search box and select the **Amazon S3 - Target** transform step.

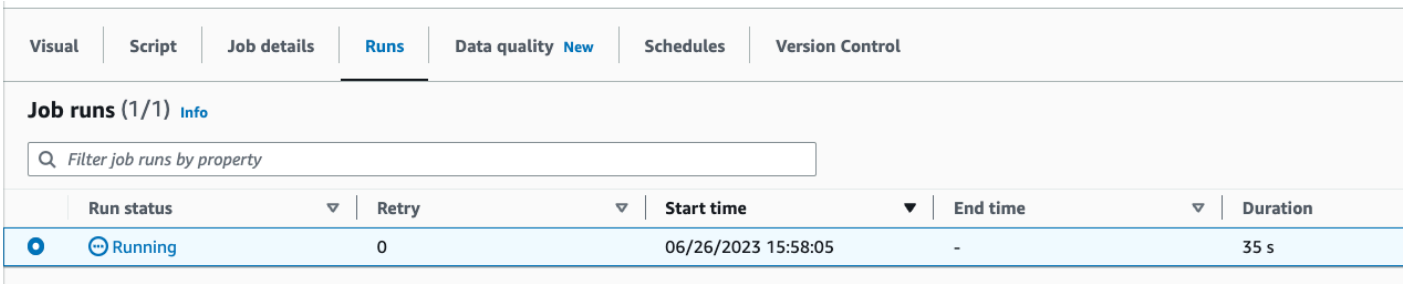


5. Select **Parquet** as the target file format.
6. Select **Snappy** as the compression type.
7. Enter an **S3 Target Location** created by the CloudFormation template, `streaming-tutorial-s3-target-{AWS::AccountId}`.
8. Select to **Create a table in the Data Catalog and on subsequent runs, update the schema and add new partitions**.
9. Enter the target **Database** and **Table** name to store the schema of the Amazon S3 target table.

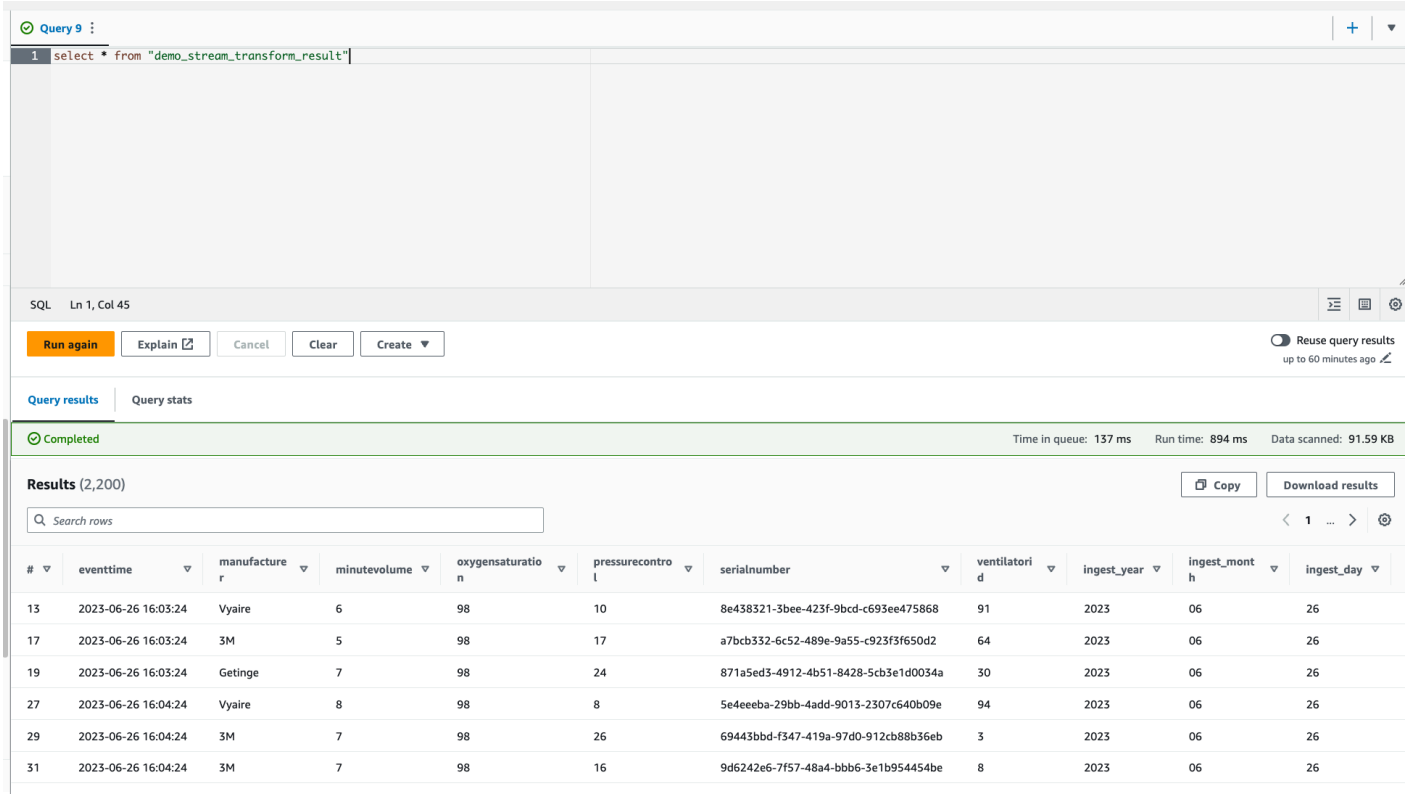


10. Click on the **Script** tab to view the generated code.
11. Click **Save** on the top right to save the ETL code and then click **Run** to kick-off the AWS Glue streaming job.

    You can find the **Run status** in the **Runs** tab. Let the job run for 3-5 minutes and then stop the job.



12. Verify the new table created in Amazon Athena.



Tutorial: Build your first streaming workload using AWS Glue Studio notebooks

In this tutorial, you will explore how to leverage AWS Glue Studio notebooks to interactively build and refine your ETL jobs for near real-time data processing. Whether you're new to AWS Glue or looking to enhance your skill set, this guide will walk you through the process, empowering you to harness the full potential of AWS Glue interactive session notebooks.

With AWS Glue Streaming, you can create streaming extract, transform, and load (ETL) jobs that run continuously and consume data from streaming sources such as Amazon Kinesis Data Streams, Apache Kafka, and Amazon Managed Streaming for Apache Kafka (Amazon MSK).

Prerequisites

To follow this tutorial you'll need a user with AWS console permissions to use AWS Glue, Amazon Kinesis, Amazon S3, Amazon Athena, AWS CloudFormation, AWS Lambda and Amazon Cognito.

Consume streaming data from Amazon Kinesis

Topics

- Generating mock data with Kinesis Data Generator
- Creating an AWS Glue streaming job with AWS Glue Studio
- Clean up
- Conclusion

Generating mock data with Kinesis Data Generator

> **Note**
>
> If you have already completed our previous Tutorial: Build your first streaming workload using AWS Glue Studio, you already have the Kinesis Data Generator installed on your account and you can skip steps 1-8 below and move on to the section Creating an AWS Glue streaming job with AWS Glue Studio.

You can synthetically generate sample data in JSON format using the Kinesis Data Generator (KDG). You can find full instructions and details in the tool documentation.

1. To get started, click

   to run an AWS CloudFormation template on your AWS environment.

> **Note**
>
> You may encounter a CloudFormation template failure because some resources, such as the Amazon Cognito user for Kinesis Data Generator already exist in your AWS account. This could be because you already set that up from another tutorial or blog. To address this, you can either try the template in a new AWS account for a fresh start, or explore a different AWS Region. These options let you run the tutorial without conflicting with existing resources.

The template provisions a Kinesis data stream and a Kinesis Data Generator account for you.

2. Enter a **Username** and **Password** that the KDG will use to authenticate. Note the username and password for further usage.
3. Select **Next** all the way to the last step. Acknowledge the creation of IAM resources. Check for any errors at the top of the screen, such as the password not meeting the minimum requirements, and deploy the template.
4. Navigate to the **Outputs** tab of the stack. Once the template is deployed, it will display the generated property **KinesisDataGeneratorUrl**. Click that URL.
5. Enter the **Username** and **Password** you noted down.
6. Select the Region you are using and select the Kinesis Stream `GlueStreamTest-{AWS::AccountId}`
7. Enter the following template:

```
{
    "ventilatorid": {{random.number(100)}},
    "eventtime": "{{date.now("YYYY-MM-DD HH:mm:ss")}}",
    "serialnumber": "{{random.uuid}}",
    "pressurecontrol": {{random.number(
        {
            "min":5,
            "max":30
        }
    )}},
    "o2stats": {{random.number(
        {
            "min":92,
            "max":98
```

```
        }
    )}},
    "minutevolume": {{random.number(
        {
            "min":5,
            "max":8
        }
    )}},
    "manufacturer": "{{random.arrayElement(
        ["3M", "GE","Vyaire", "Getinge"]
    )}}"
}
```

You can now view mock data with **Test template** and ingest the mock data to Kinesis with **Send data**.

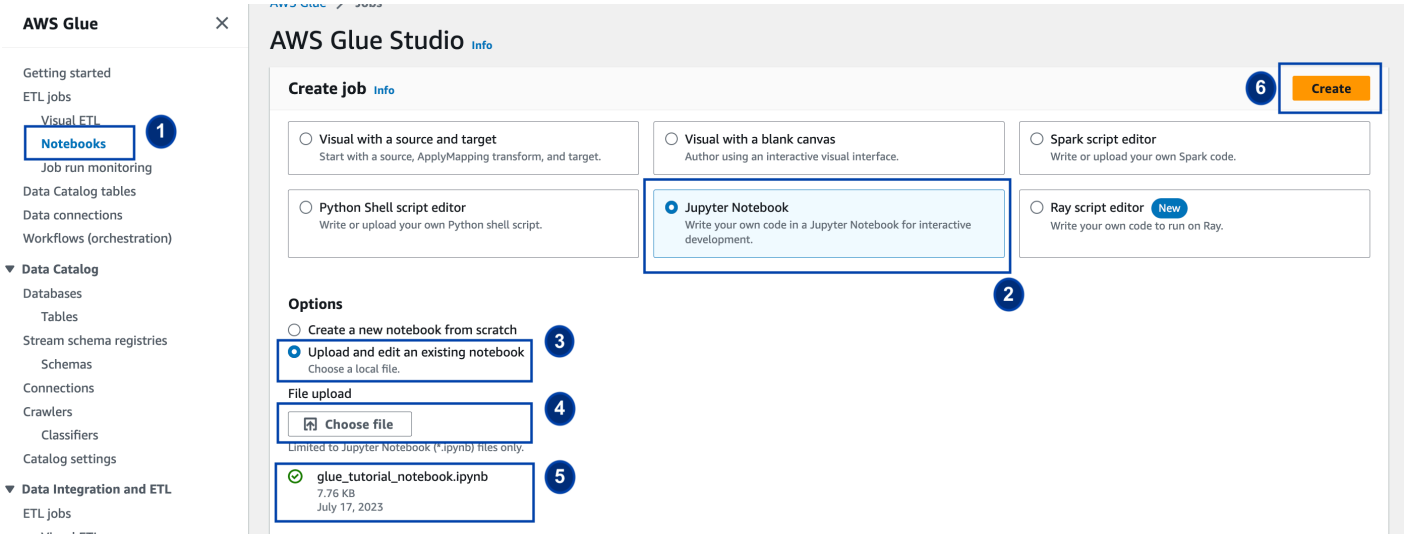
8. Click **Send data** and generate 5-10K records to Kinesis.

Creating an AWS Glue streaming job with AWS Glue Studio

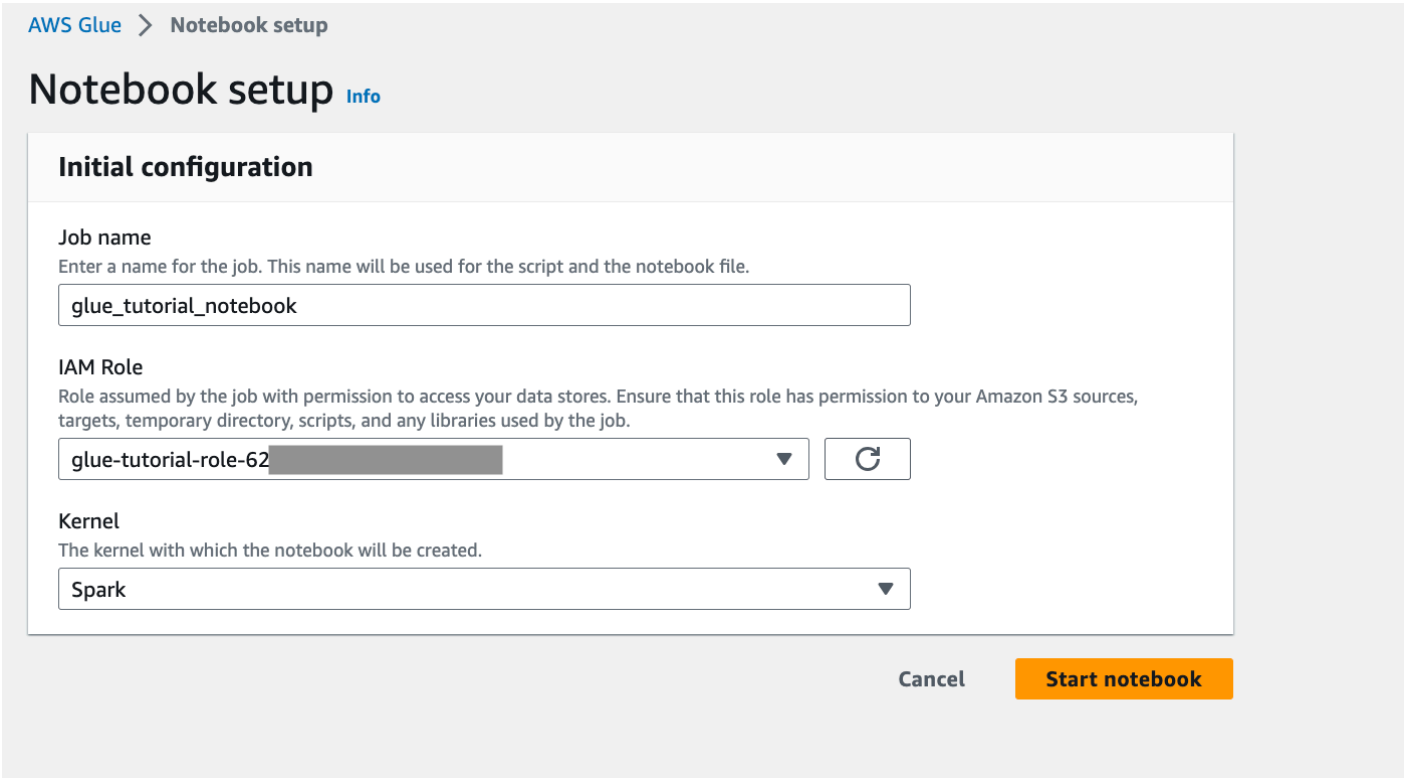
AWS Glue Studio is a visual interface that simplifies the process of designing, orchestrating, and monitoring data integration pipelines. It enables users to build data transformation pipelines without writing extensive code. Apart from the visual job authoring experience, AWS Glue Studio also includes a Jupyter notebook backed by AWS Glue Interactive sessions, which you will be using in the remainder of this tutorial.

Set up the AWS Glue Streaming interactive sessions job

1. Download the provided notebook file and save it to a local directory
2. Open the AWS Glue Console and on the left pane click **Notebooks** > **Jupyter Notebook** > **Upload and edit an existing notebook**. Upload the notebook from the previous step and click **Create**.



3. Provide the job a name, role and select the default Spark kernel. Next click **Start notebook**. For the **IAM Role**, select the role provisioned by the CloudFormation template. You can see this in the **Outputs** tab of CloudFormation.



The notebook has all necessary instructions to continue the tutorial. You can either run the instructions on the notebook or follow along with this tutorial to continue with the job development.

Run the notebook cells

1. (Optional) The first code cell, `%help` lists all available notebook magics. You can skip this cell for now, but feel free to explore it.
2. Start with the next code block `%streaming`. This magic sets the job type to streaming which lets you develop, debug and deploy an AWS Glue streaming ETL job.
3. Run the next cell to create an AWS Glue interactive session. The output cell has a message that confirms the session creation.

4. The next cell defines the variables. Replace the values with ones appropriate to your job and run the cell. For example:

```
output_database_name="default"
output_table_name="test_stream_001"

account_id = boto3.client("sts").get_caller_identity()["Account"]
region_name=boto3.client('s3').meta.region_name
stream_arn_name = "arn:aws:kinesis:{}:{}:stream/GlueStreamTest-{}".format(region_name,account_id,account_id)
s3_bucket_name = "streaming-tutorial-s3-target-{}".format(account_id)

output_location = "s3://{}/streaming_output/".format(s3_bucket_name)
checkpoint_location = "s3://{}/checkpoint_location/".format(s3_bucket_name)
```

5. Since the data is being streamed already to Kinesis Data Streams, your next cell will consume the results from the stream. Run the next cell. Since there are no print statements, there is no expected output from this cell.

6. In the following cell, you explore the incoming stream by taking a sample set and print its schema and the actual data. For example:

Sample and print the incoming records

the sampling is for debugging purpose. You may comment off the entire code cell below, before deploying the actual code

```
[4]: options = {
    "pollingTimeInMs": "20000",
    "windowSize": "5 seconds"
}
sampled_dynamic_frame = glueContext.getSampleStreamingDynamicFrame(data_frame, options, None)

count_of_sampled_records = sampled_dynamic_frame.count()

print(count_of_sampled_records)

sampled_dynamic_frame.printSchema()

sampled_dynamic_frame.toDF().show(10,False)
```

```

```

7. Next, define the actual data transformation logic. The cell consists of the `processBatch` method that is triggered during every micro-batch. Run the cell. At a high level, we do the following to the incoming stream:

   a. Select a subset of the input columns.

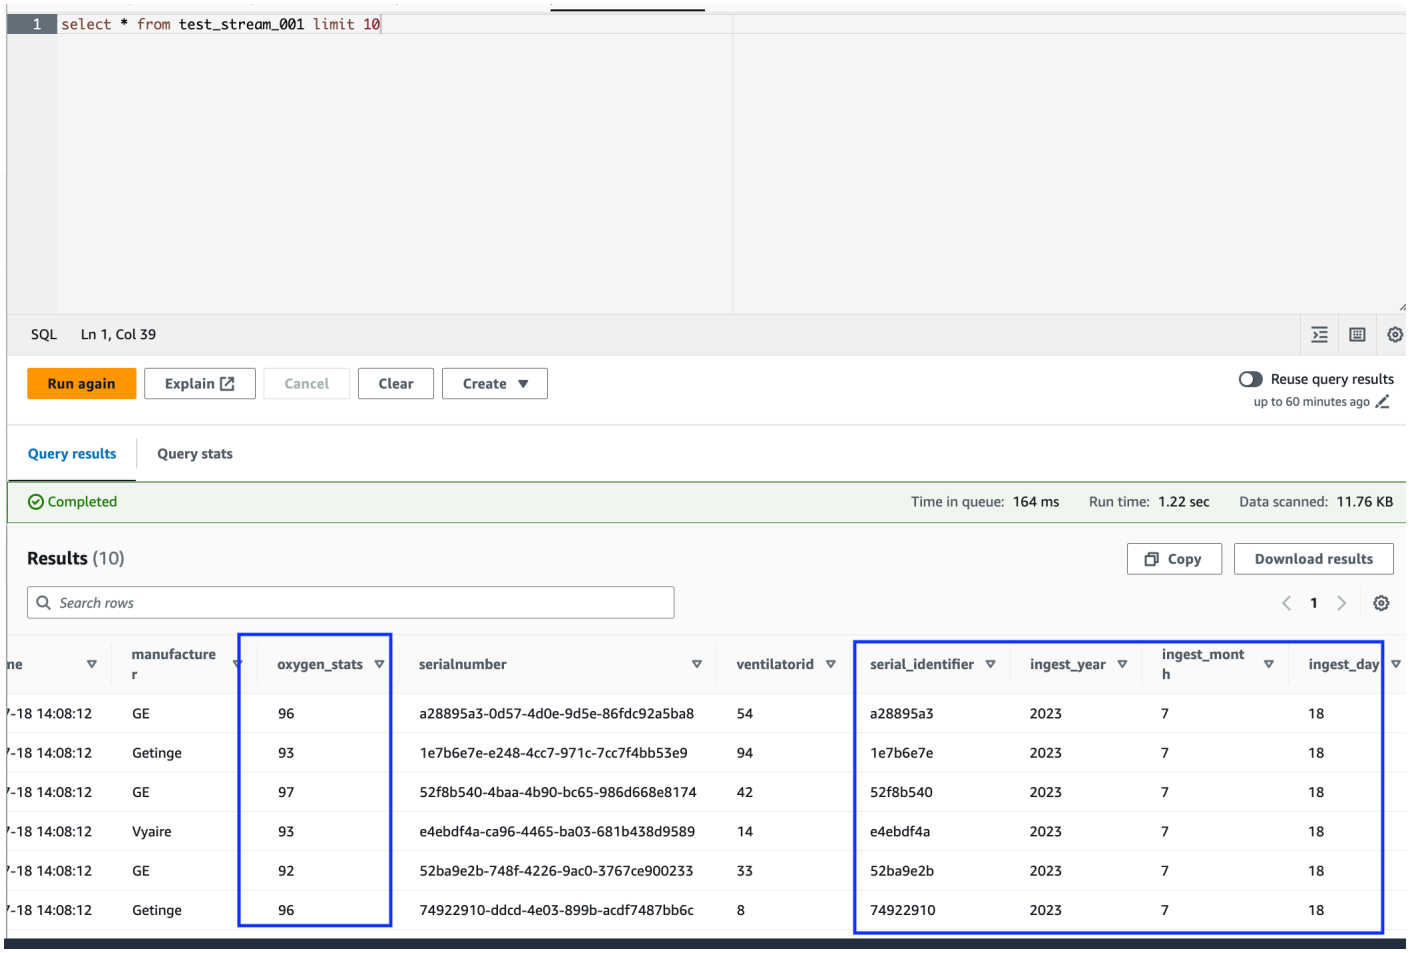
   b. Rename a column (o2stats to oxygen_stats).

   c. Derive new columns (serial_identifier, ingest_year, ingest_month and ingest_day).

   d. Store the results into an Amazon S3 bucket and also create a partitioned AWS Glue catalog table

8. In the last cell, you trigger the process batch every 10 seconds. Run the cell and wait for about 30 seconds for it to populate the Amazon S3 bucket and the AWS Glue catalog table.

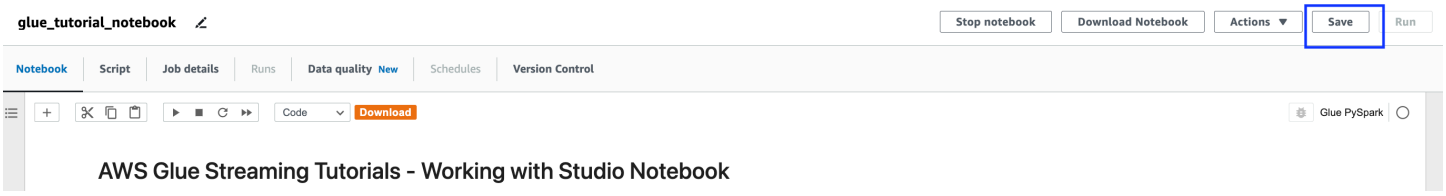
9. Finally, browse the stored data using the Amazon Athena query editor. You can see the renamed column and also the new partitions.



The notebook has all necessary instructions to continue the tutorial. You can either run the instructions on the notebook or follow along with this tutorial to continue with the job development.

Save and run the AWS Glue job

With the development and testing of your application complete using the interactive sessions notebook, click **Save** at the top of the notebook interface. Once saved you can also run the application as a job.



Clean up

To avoid incurring additional charges to your account, stop the streaming job that you started as part of the instructions. You can do this by stopping the notebook, which will end the session. Empty the Amazon S3 bucket and delete the AWS CloudFormation stack that you provisioned earlier.

Conclusion

In this tutorial, we demonstrated how to do the following using the AWS Glue Studio notebook

- Author a streaming ETL job using notebooks
- Preview incoming data streams
- Code and fix issues without having to publish AWS Glue jobs
- Review the end-to-end working code, remove any debugging, and print statements or cells from the notebook
- Publish the code as an AWS Glue job

The goal of this tutorial is to give you hands-on experience working with AWS Glue Streaming and interactive sessions. We encourage you to use this as a reference for your individual AWS Glue Streaming use cases. For more information, see Getting started with AWS Glue interactive sessions.

AWS Glue Streaming concepts

The following sections provide information on concepts of AWS Glue Streaming.

Topics

- Anatomy of a AWS Glue streaming job

Anatomy of a AWS Glue streaming job

AWS Glue streaming jobs operate on the Spark streaming paradigm and leverage structured streaming from the Spark framework. Streaming jobs constantly poll on the streaming data source, at a specific interval of time, to fetch records as micro batches. The following sections examine the different parts of a AWS Glue streaming job.

forEachBatch

The `forEachBatch` method is the entry point of a AWS Glue streaming job run. AWS Glue streaming jobs uses the `forEachBatch` method to poll data functioning like an iterator that remains active during the lifecycle of the streaming job and regularly polls the streaming source for new data and processes the latest data in micro batches.

```
glueContext.forEachBatch(
    frame=dataFrame_AmazonKinesis_node1696872487972,
    batch_function=processBatch,
    options={
        "windowSize": "100 seconds",
        "checkpointLocation": args["TempDir"] + "/" + args["JOB_NAME"] + "/
checkpoint/",
    },
)
```

Configure the `frame` property of `forEachBatch` to specify a streaming source. In this example, the source node that you created in the blank canvas during job creation is populated with the default DataFrame of the job. Set the `batch_function` property as the `function` that you decide to invoke for each micro batch operation. You must define a function to handle the batch transformation on the incoming data.

Source

In the first step of the `processBatch` function, the program verifies the record count of the DataFrame that you defined as frame property of `forEachBatch`. The program appends an ingestion time stamp to a non-empty DataFrame. The `data_frame.count()>0` clause determines whether the latest micro batch is not empty and is ready for further processing.

```
def processBatch(data_frame, batchId):
    if data_frame.count() >0:
        AmazonKinesis_node1696872487972 = DynamicFrame.fromDF(
            glueContext.add_ingestion_time_columns(data_frame, "hour"),
            glueContext,
            "from_data_frame",
        )
```

Mapping

The next section of the program is to apply mapping. The `Mapping.apply` method on a spark DataFrame allows you to define transformation rule around data elements. Typically you can rename, change the data type, or apply a custom function on the source data column and map those to the target columns.

```
    #Script generated for node ChangeSchema
    ChangeSchema_node16986872679326 = ApplyMapping.apply(
        frame =  AmazonKinesis_node1696872487972,
        mappings = [
            ("eventtime", "string", "eventtime", "string"),
            ("manufacturer", "string", "manufacturer", "string"),
            ("minutevolume", "long", "minutevolume", "int"),
            ("o2stats", "long", "OxygenSaturation", "int"),
            ("pressurecontrol", "long", "pressurecontrol", "int"),
            ("serialnumber", "string", "serialnumber", "string"),
```

```
            ("ventilatorid", "long", "ventilatorid", "long"),
            ("ingest_year", "string", "ingest_year", "string"),
            ("ingest_month", "string", "ingest_month", "string"),
            ("ingest_day", "string", "ingest_day", "string"),
            ("ingest_hour", "string", "ingest_hour", "string"),
        ],
        transformation_ctx="ChangeSchema_node16986872679326",
    )
        )
```

Sink

In this section, the incoming data set from the streaming source are stored at a target location. In this example we will write the data to an Amazon S3 location. The `AmazonS3_node_path` property details is pre-populated as determined by the settings you used during job creation from the canvas. You can set the `updateBehavior` based on your use case and decide to either Not update the data catalog table, or Create data catalog and update data catalog schema on subsequent runs, or create a catalog table and not update the schema definition on subsequent runs.

The `partitionKeys` property defines the storage partition option. The default behavior is to partition the data per the `ingestion_time_columns` that was made available in the source section. The `compression` property allows you to set the compression algorithm to be applied during target write. You have options to set Snappy, LZO, or GZIP as the compression technique. The `enableUpdateCatalog` property controls whether the AWS Glue catalog table needs to be updated. Available options for this property are `True` or `False`.

```
    #Script generated for node Amazon S3
    AmazonS3_node1696872743449 = glueContext.getSink(
        path =  AmazonS3_node1696872743449_path,
        connection_type = "s3",
        updateBehavior = "UPDATE_IN_DATABASE",
        partitionKeys = ["ingest_year", "ingest_month", "ingest_day", "ingest_hour"],
        compression = "snappy",
        enableUpdateCatalog = True,
        transformation_ctx = "AmazonS3_node1696872743449",
    )
```

AWS Glue Catalog sink

This section of the job controls the AWS Glue catalog table update behavior. Set `catalogDatabase` and `catalogTableName` property per your AWS Glue Catalog database name and the table name associated with the AWS Glue job that you are designing. You can define the file format of the target data via the `setFormat` property. For this example we will store the data in parquet format.

Once you set up and run the AWS Glue streaming job referring this tutorial, the streaming data produced at Amazon Kinesis Data Streams will be stored at the Amazon S3 location in a parquet format with snappy compression. On successful runs of the streaming job you will able to query the data through Amazon Athena.

```
AmazonS3_node1696872743449 = setCatalogInfo(
    catalogDatabase =  "demo", catalogTableName = "demo_stream_transform_result"
)
AmazonS3_node1696872743449.setFormat("glueparquet")
AmazonS3_node1696872743449.writeFormat("ChangeSchema_node16986872679326")
)
```

AWS Glue Streaming connections

The following sections provide information on how to use connections in AWS Glue Streaming.

Topics

- Working with Kafka connections
- Working with Kinesis connections

Working with Kafka connections

You can use a Kafka connection to read and write to Kafka data streams using information stored in a Data Catalog table, or by providing information to directly access the data stream. The connection supports a Kafka cluster or an Amazon Managed Streaming for Apache Kafka cluster. You can read information from Kafka into a Spark DataFrame, then convert it to a AWS Glue

DynamicFrame. You can write DynamicFrames to Kafka in a JSON format. If you directly access the data stream, use these options to provide the information about how to access the data stream.

If you use `getCatalogSource` or `create_data_frame_from_catalog` to consume records from a Kafka streaming source, or `getCatalogSink` or `write_dynamic_frame_from_catalog` to write records to Kafka, and the job has the Data Catalog database and table name information, and can use that to obtain some basic parameters for reading from the Kafka streaming source. If you use `getSource`, `getCatalogSink`, `getSourceWithFormat`, `getSinkWithFormat`, `createDataFrameFromOptions` or `create_data_frame_from_options`, or `write_dynamic_frame_from_catalog`, you must specify these basic parameters using the connection options described here.

You can specify the connection options for Kafka using the following arguments for the specified methods in the `GlueContext` class.

- Scala
  - `connectionOptions`: Use with `getSource`, `createDataFrameFromOptions`, `getSink`
  - `additionalOptions`: Use with `getCatalogSource`, `getCatalogSink`
  - `options`: Use with `getSourceWithFormat`, `getSinkWithFormat`
- Python
  - `connection_options`: Use with `create_data_frame_from_options`, `write_dynamic_frame_from_options`
  - `additional_options`: Use with `create_data_frame_from_catalog`, `write_dynamic_frame_from_catalog`
  - `options`: Use with `getSource`, `getSink`

For notes and restrictions about streaming ETL jobs, consult the section called “Streaming ETL notes and restrictions”.

Topics

- Configure Kafka
- Example: Reading from Kafka streams
- Example: Writing to Kafka streams
- Kafka connection option reference

Configure Kafka

There are no AWS prerequisites to connecting to Kafka streams available through the internet.

You can create a AWS Glue Kafka connection to manage your connection credentials. For more information, see the section called "Creating a connection for a Kafka data stream". In your AWS Glue job configuration, provide *connectionName* as an **Additional network connection**, then, in your method call, provide *connectionName* to the connectionName parameter.

In certain cases, you will need to configure additional prerequisites:

- If using Amazon Managed Streaming for Apache Kafka with IAM authentication, you will need appropriate IAM configuration.
- If using Amazon Managed Streaming for Apache Kafka within an Amazon VPC, you will need appropriate Amazon VPC configuration. You will need to create a AWS Glue connection that provides Amazon VPC connection information. You will need your job configuration to include the AWS Glue connection as an **Additional network connection**.

For more information about Streaming ETL job prerequisites, consult the section called "Streaming ETL jobs".

Example: Reading from Kafka streams

Used in conjunction with the section called "forEachBatch".

Example for Kafka streaming source:

```
kafka_options =
    { "connectionName": "ConfluentKafka",
      "topicName": "kafka-auth-topic",
      "startingOffsets": "earliest",
      "inferSchema": "true",
      "classification": "json"
    }
data_frame_datasource0 =
 glueContext.create_data_frame.from_options(connection_type="kafka",
 connection_options=kafka_options)
```

Example: Writing to Kafka streams

Examples for writing to Kafka:

Example with the `getSink` method:

```
data_frame_datasource0 =
glueContext.getSink(
 connectionType="kafka",
 connectionOptions={
  JsonOptions("""{
   "connectionName": "ConfluentKafka",
   "classification": "json",
   "topic": "kafka-auth-topic",
   "typeOfData": "kafka"}
  """)},
 transformationContext="dataframe_ApacheKafka_node1711729173428")
 .getDataFrame()
```

Example with the `write_dynamic_frame.from_options` method:

```
kafka_options =
    { "connectionName": "ConfluentKafka",
      "topicName": "kafka-auth-topic",
      "classification": "json"
    }
data_frame_datasource0 =
 glueContext.write_dynamic_frame.from_options(connection_type="kafka",
 connection_options=kafka_options)
```

Kafka connection option reference

When reading, use the following connection options with `"connectionType": "kafka"`:

- `"bootstrap.servers"` (Required) A list of bootstrap server URLs, for example, as `b-1.vpc-test-2.o4q88o.c6.kafka.us-east-1.amazonaws.com:9094`. This option must be specified in the API call or defined in the table metadata in the Data Catalog.
- `"security.protocol"` (Required) The protocol used to communicate with brokers. The possible values are `"SSL"` or `"PLAINTEXT"`.
- `"topicName"` (Required) A comma-separated list of topics to subscribe to. You must specify one and only one of `"topicName"`, `"assign"` or `"subscribePattern"`.
- `"assign"`: (Required) A JSON string specifying the specific `TopicPartitions` to consume. You must specify one and only one of `"topicName"`, `"assign"` or `"subscribePattern"`.

Example: '{"topicA":[0,1],"topicB":[2,4]}'

- `"subscribePattern"`: (Required) A Java regex string that identifies the topic list to subscribe to. You must specify one and only one of `"topicName"`, `"assign"` or `"subscribePattern"`.

  Example: 'topic.*'

- `"classification"` (Required) The file format used by the data in the record. Required unless provided through the Data Catalog.
- `"delimiter"` (Optional) The value separator used when `classification` is CSV. Default is `","`
- `"startingOffsets"`: (Optional) The starting position in the Kafka topic to read data from. The possible values are `"earliest"` or `"latest"`. The default value is `"latest"`.
- `"startingTimestamp"`: (Optional, supported only for AWS Glue version 4.0 or later) The Timestamp of the record in the Kafka topic to read data from. The possible value is a Timestamp string in UTC format in the pattern `yyyy-mm-ddTHH:MM:SSZ` (where `Z` represents a UTC timezone offset with a +/-. For example: "2023-04-04T08:00:00-04:00").

  Note: Only one of 'startingOffsets' or 'startingTimestamp' can be present in the Connection Options list of the AWS Glue streaming script, including both these properties will result in job failure.

- `"endingOffsets"`: (Optional) The end point when a batch query is ended. Possible values are either `"latest"` or a JSON string that specifies an ending offset for each `TopicPartition`.

  For the JSON string, the format is `{"topicA":{"0":23,"1":-1},"topicB":{"0":-1}}`. The value `-1` as an offset represents `"latest"`.

- `"pollTimeoutMs"`: (Optional) The timeout in milliseconds to poll data from Kafka in Spark job executors. The default value is `600000`.
- `"numRetries"`: (Optional) The number of times to retry before failing to fetch Kafka offsets. The default value is `3`.
- `"retryIntervalMs"`: (Optional) The time in milliseconds to wait before retrying to fetch Kafka offsets. The default value is `10`.
- `"maxOffsetsPerTrigger"`: (Optional) The rate limit on the maximum number of offsets that are processed per trigger interval. The specified total number of offsets is proportionally split across `topicPartitions` of different volumes. The default value is null, which means that the consumer reads all offsets until the known latest offset.

- `"minPartitions"`: (Optional) The desired minimum number of partitions to read from Kafka. The default value is null, which means that the number of spark partitions is equal to the number of Kafka partitions.
- `"includeHeaders"`: (Optional) Whether to include the Kafka headers. When the option is set to "true", the data output will contain an additional column named "glue_streaming_kafka_headers" with type `Array[Struct(key: String, value: String)]`. The default value is "false". This option is available in AWS Glue version 3.0 or later.
- `"schema"`: (Required when inferSchema set to false) The schema to use to process the payload. If classification is `avro` the provided schema must be in the Avro schema format. If the classification is not `avro` the provided schema must be in the DDL schema format.

  The following are schema examples.

  Example in DDL schema format

  ```
  'column1' INT, 'column2' STRING , 'column3' FLOAT
  ```

  Example in Avro schema format

  ```
  {
  "type":"array",
  "items":
  {
  "type":"record",
  "name":"test",
  "fields":
  [
    {
      "name":"_id",
      "type":"string"
    },
    {
      "name":"index",
      "type":
      [
        "int",
        "string",
        "float"
      ]
    }
  ]
  ```

```
}
}
```

- `"inferSchema"`: (Optional) The default value is 'false'. If set to 'true', the schema will be detected at runtime from the payload within `foreachbatch`.
- `"avroSchema"`: (Deprecated) Parameter used to specify a schema of Avro data when Avro format is used. This parameter is now deprecated. Use the `schema` parameter.
- `"addRecordTimestamp"`: (Optional) When this option is set to 'true', the data output will contain an additional column named "__src_timestamp" that indicates the time when the corresponding record received by the topic. The default value is 'false'. This option is supported in AWS Glue version 4.0 or later.
- `"emitConsumerLagMetrics"`: (Optional) When the option is set to 'true', for each batch, it will emit the metrics for the duration between the oldest record received by the topic and the time it arrives in AWS Glue to CloudWatch. The metric's name is "glue.driver.streaming.maxConsumerLagInMs". The default value is 'false'. This option is supported in AWS Glue version 4.0 or later.

When writing, use the following connection options with `"connectionType": "kafka"`:

- `"connectionName"` (Required) Name of the AWS Glue connection used to connect to the Kafka cluster (similar to Kafka source).
- `"topic"` (Required) If a topic column exists then its value is used as the topic when writing the given row to Kafka, unless the topic configuration option is set. That is, the `topic` configuration option overrides the topic column.
- `"partition"` (Optional) If a valid partition number is specified, that `partition` will be used when sending the record.

  If no partition is specified but a `key` is present, a partition will be chosen using a hash of the key.

  If neither `key` nor `partition` is present, a partition will be chosen based on sticky partitioning those changes when at least batch.size bytes are produced to the partition.
- `"key"` (Optional) Used for partitioning if `partition` is null.
- `"classification"` (Optional) The file format used by the data in the record. We only support JSON, CSV and Avro.

With Avro format, we can provide a custom avroSchema to serialize with, but note that this needs to be provided on the source for deserializing as well. Else, by default it uses the Apache AvroSchema for serializing.

Additionally, you can fine-tune the Kafka sink as required by updating the Kafka producer configuration parameters. Note that there is no allow listing on connection options, all the key-value pairs are persisted on the sink as is.

However, there is a small deny list of options that will not take effect. For more information, see Kafka specific configurations.

Working with Kinesis connections

You can use a Kinesis connection to read and write to Amazon Kinesis data streams using information stored in a Data Catalog table, or by providing information to directly access the data stream. You can read information from Kinesis into a Spark DataFrame, then convert it to a AWS Glue DynamicFrame. You can write DynamicFrames to Kinesis in a JSON format. If you directly access the data stream, use these options to provide the information about how to access the data stream.

If you use `getCatalogSource` or `create_data_frame_from_catalog` to consume records from a Kinesis streaming source, the job has the Data Catalog database and table name information, and can use that to obtain some basic parameters for reading from the Kinesis streaming source. If you use `getSource`, `getSourceWithFormat`, `createDataFrameFromOptions` or `create_data_frame_from_options`, you must specify these basic parameters using the connection options described here.

You can specify the connection options for Kinesis using the following arguments for the specified methods in the `GlueContext` class.

- Scala
  - `connectionOptions`: Use with `getSource`, `createDataFrameFromOptions`, `getSink`
  - `additionalOptions`: Use with `getCatalogSource`, `getCatalogSink`
  - `options`: Use with `getSourceWithFormat`, `getSinkWithFormat`
- Python
  - `connection_options`: Use with `create_data_frame_from_options`, `write_dynamic_frame_from_options`

- `additional_options`: Use with `create_data_frame_from_catalog`, `write_dynamic_frame_from_catalog`
- `options`: Use with `getSource`, `getSink`

For notes and restrictions about Streaming ETL jobs, consult the section called "Streaming ETL notes and restrictions".

Configure Kinesis

To connect to a Kinesis data stream in an AWS Glue Spark job, you will need some prerequisites:

- If reading, the AWS Glue job must have Read access level IAM permissions to the Kinesis data stream.
- If writing, the AWS Glue job must have Write access level IAM permissions to the Kinesis data stream.

In certain cases, you will need to configure additional prerequisites:

- If your AWS Glue job is configured with **Additional network connections** (typically to connect to other datasets) and one of those connections provides Amazon VPC **Network options**, this will direct your job to communicate over Amazon VPC. In this case you will also need to configure your Kinesis data stream to communicate over Amazon VPC. You can do this by creating an interface VPC endpoint between your Amazon VPC and Kinesis data stream. For more information, see Using Kinesis Data Streams with Interface VPC Endpoints.
- When specifying Amazon Kinesis Data Streams in another account, you must setup the roles and policies to allow cross-account access. For more information, see Example: Read From a Kinesis Stream in a Different Account.

For more information about Streaming ETL job prerequisites, consult the section called "Streaming ETL jobs".

Read from Kinesis

Example: Reading from Kinesis streams

Used in conjunction with the section called "forEachBatch".

Example for Amazon Kinesis streaming source:

```
kinesis_options =
   { "streamARN": "arn:aws:kinesis:us-east-2:777788889999:stream/fromOptionsStream",
     "startingPosition": "TRIM_HORIZON",
     "inferSchema": "true",
     "classification": "json"
   }
data_frame_datasource0 =
 glueContext.create_data_frame.from_options(connection_type="kinesis",
 connection_options=kinesis_options)
```

Write to Kinesis

Example: Writing to Kinesis streams

Used in conjunction with the section called "forEachBatch". Your DynamicFrame will be written to the stream in a JSON format. If the job cannot write after several retries, it will fail. By default, each DynamicFrame record will be sent to the Kinesis stream individually. You can configure this behavior using `aggregationEnabled` and associated parameters.

Example writing to Amazon Kinesis from a streaming job:

Python

```
glueContext.write_dynamic_frame.from_options(
    frame=frameToWrite
    connection_type="kinesis",
    connection_options={
        "partitionKey": "part1",
        "streamARN": "arn:aws:kinesis:us-east-1:111122223333:stream/streamName",
    }
)
```

Scala

```
glueContext.getSinkWithFormat(
                connectionType="kinesis",
                options=JsonOptions("""{
                    "streamARN": "arn:aws:kinesis:us-
east-1:111122223333:stream/streamName",
                    "partitionKey": "part1"
                }"""),
```

```
        )
        .writeDynamicFrame(frameToWrite)
```

Kinesis connection parameters

Designates connection options for Amazon Kinesis Data Streams.

Use the following connection options for Kinesis streaming data sources:

- `"streamARN"` (Required) Used for Read/Write. The ARN of the Kinesis data stream.
- `"classification"` (Required for read) Used for Read. The file format used by the data in the record. Required unless provided through the Data Catalog.
- `"streamName"` – (Optional) Used for Read. The name of a Kinesis data stream to read from. Used with `endpointUrl`.
- `"endpointUrl"` – (Optional) Used for Read. Default: "https://kinesis.us-east-1.amazonaws.com". The AWS endpoint of the Kinesis stream. You do not need to change this unless you are connecting to a special region.
- `"partitionKey"` – (Optional) Used for Write. The Kinesis partition key used when producing records.
- `"delimiter"` (Optional) Used for Read. The value separator used when `classification` is CSV. Default is `","`
- `"startingPosition"`: (Optional) Used for Read. The starting position in the Kinesis data stream to read data from. The possible values are `"latest"`, `"trim_horizon"`, `"earliest"`, or a Timestamp string in UTC format in the pattern `yyyy-mm-ddTHH:MM:SSZ` (where `Z` represents a UTC timezone offset with a +/-. For example "2023-04-04T08:00:00-04:00"). The default value is `"latest"`. Note: the Timestamp string in UTC Format for `"startingPosition"` is supported only for AWS Glue version 4.0 or later.
- `"failOnDataLoss"`: (Optional) Fail the job if any active shard is missing or expired. The default value is `"false"`.
- `"awsSTSRoleARN"`: (Optional) Used for Read/Write. The Amazon Resource Name (ARN) of the role to assume using AWS Security Token Service (AWS STS). This role must have permissions for describe or read record operations for the Kinesis data stream. You must use this parameter when accessing a data stream in a different account. Used in conjunction with `"awsSTSSessionName"`.

- "awsSTSSessionName": (Optional) Used for Read/Write. An identifier for the session assuming the role using AWS STS. You must use this parameter when accessing a data stream in a different account. Used in conjunction with "awsSTSRoleARN".
- "awsSTSEndpoint": (Optional) The AWS STS endpoint to use when connecting to Kinesis with an assumed role. This allows using the regional AWS STS endpoint in a VPC, which is not possible with the default global endpoint.
- "maxFetchTimeInMs": (Optional) Used for Read. The maximum time spent for the job executor to read records for the current batch from the Kinesis data stream, specified in milliseconds (ms). Multiple GetRecords API calls may be made within this time. The default value is 1000.
- "maxFetchRecordsPerShard": (Optional) Used for Read. The maximum number of records to fetch per shard in the Kinesis data stream per microbatch. Note: The client can exceed this limit if the streaming job has already read extra records from Kinesis (in the same get-records call). If maxFetchRecordsPerShard needs to be strict then it needs to be a multiple of maxRecordPerRead. The default value is 100000.
- "maxRecordPerRead": (Optional) Used for Read. The maximum number of records to fetch from the Kinesis data stream in each getRecords operation. The default value is 10000.
- "addIdleTimeBetweenReads": (Optional) Used for Read. Adds a time delay between two consecutive getRecords operations. The default value is "False". This option is only configurable for Glue version 2.0 and above.
- "idleTimeBetweenReadsInMs": (Optional) Used for Read. The minimum time delay between two consecutive getRecords operations, specified in ms. The default value is 1000. This option is only configurable for Glue version 2.0 and above.
- "describeShardInterval": (Optional) Used for Read. The minimum time interval between two ListShards API calls for your script to consider resharding. For more information, see Strategies for Resharding in *Amazon Kinesis Data Streams Developer Guide*. The default value is 1s.
- "numRetries": (Optional) Used for Read. The maximum number of retries for Kinesis Data Streams API requests. The default value is 3.
- "retryIntervalMs": (Optional) Used for Read. The cool-off time period (specified in ms) before retrying the Kinesis Data Streams API call. The default value is 1000.
- "maxRetryIntervalMs": (Optional) Used for Read. The maximum cool-off time period (specified in ms) between two retries of a Kinesis Data Streams API call. The default value is 10000.

- `"avoidEmptyBatches"`: (Optional) Used for Read. Avoids creating an empty microbatch job by checking for unread data in the Kinesis data stream before the batch is started. The default value is `"False"`.
- `"schema"`: (Required when inferSchema set to false) Used for Read. The schema to use to process the payload. If classification is `avro` the provided schema must be in the Avro schema format. If the classification is not `avro` the provided schema must be in the DDL schema format.

  The following are schema examples.

  Example in DDL schema format

  ```
  `column1` INT, `column2` STRING , `column3` FLOAT
  ```

  Example in Avro schema format

  ```
  {
    "type":"array",
    "items":
    {
      "type":"record",
      "name":"test",
      "fields":
      [
        {
          "name":"_id",
          "type":"string"
        },
        {
          "name":"index",
          "type":
          [
            "int",
            "string",
            "float"
          ]
        }
      ]
    }
  }
  ```

- `"inferSchema"`: (Optional) Used for Read. The default value is 'false'. If set to 'true', the schema will be detected at runtime from the payload within `foreachbatch`.

- `"avroSchema"`: (Deprecated) Used for Read. Parameter used to specify a schema of Avro data when Avro format is used. This parameter is now deprecated. Use the `schema` parameter.
- `"addRecordTimestamp"`: (Optional) Used for Read. When this option is set to 'true', the data output will contain an additional column named "__src_timestamp" that indicates the time when the corresponding record received by the stream. The default value is 'false'. This option is supported in AWS Glue version 4.0 or later.
- `"emitConsumerLagMetrics"`: (Optional) Used for Read. When the option is set to 'true', for each batch, it will emit the metrics for the duration between the oldest record received by the stream and the time it arrives in AWS Glue to CloudWatch. The metric's name is "glue.driver.streaming.maxConsumerLagInMs". The default value is 'false'. This option is supported in AWS Glue version 4.0 or later.
- `"fanoutConsumerARN"`: (Optional) Used for Read. The ARN of a Kinesis stream consumer for the stream specified in `streamARN`. Used to enable enhanced fan-out mode for your Kinesis connection. For more information on consuming a Kinesis stream with enhanced fan-out, see the section called “Using enhanced fan-out in Kinesis streaming jobs”.
- `"recordMaxBufferedTime"` – (Optional) Used for Write. Default: 1000 (ms). Maximum time a record is buffered while waiting to be written.
- `"aggregationEnabled"` – (Optional) Used for Write. Default: true. Specifies if records should be aggregated before sending them to Kinesis.
- `"aggregationMaxSize"` – (Optional) Used for Write. Default: 51200 (bytes). If a record is larger than this limit, it will bypass the aggregator. Note Kinesis enforces a limit of 50KB on record size. If you set this beyond 50KB, oversize records will be rejected by Kinesis.
- `"aggregationMaxCount"` – (Optional) Used for Write. Default: 4294967295. Maximum number of items to pack into an aggregated record.
- `"producerRateLimit"` – (Optional) Used for Write. Default: 150 (%). Limits per-shard throughput sent from a single producer (such as your job), as a percentage of the backend limit.
- `"collectionMaxCount"` – (Optional) Used for Write. Default: 500. Maximum number of items to pack into an PutRecords request.
- `"collectionMaxSize"` – (Optional) Used for Write. Default: 5242880 (bytes). Maximum amount of data to send with a PutRecords request.

AWS Glue streaming autoscaling

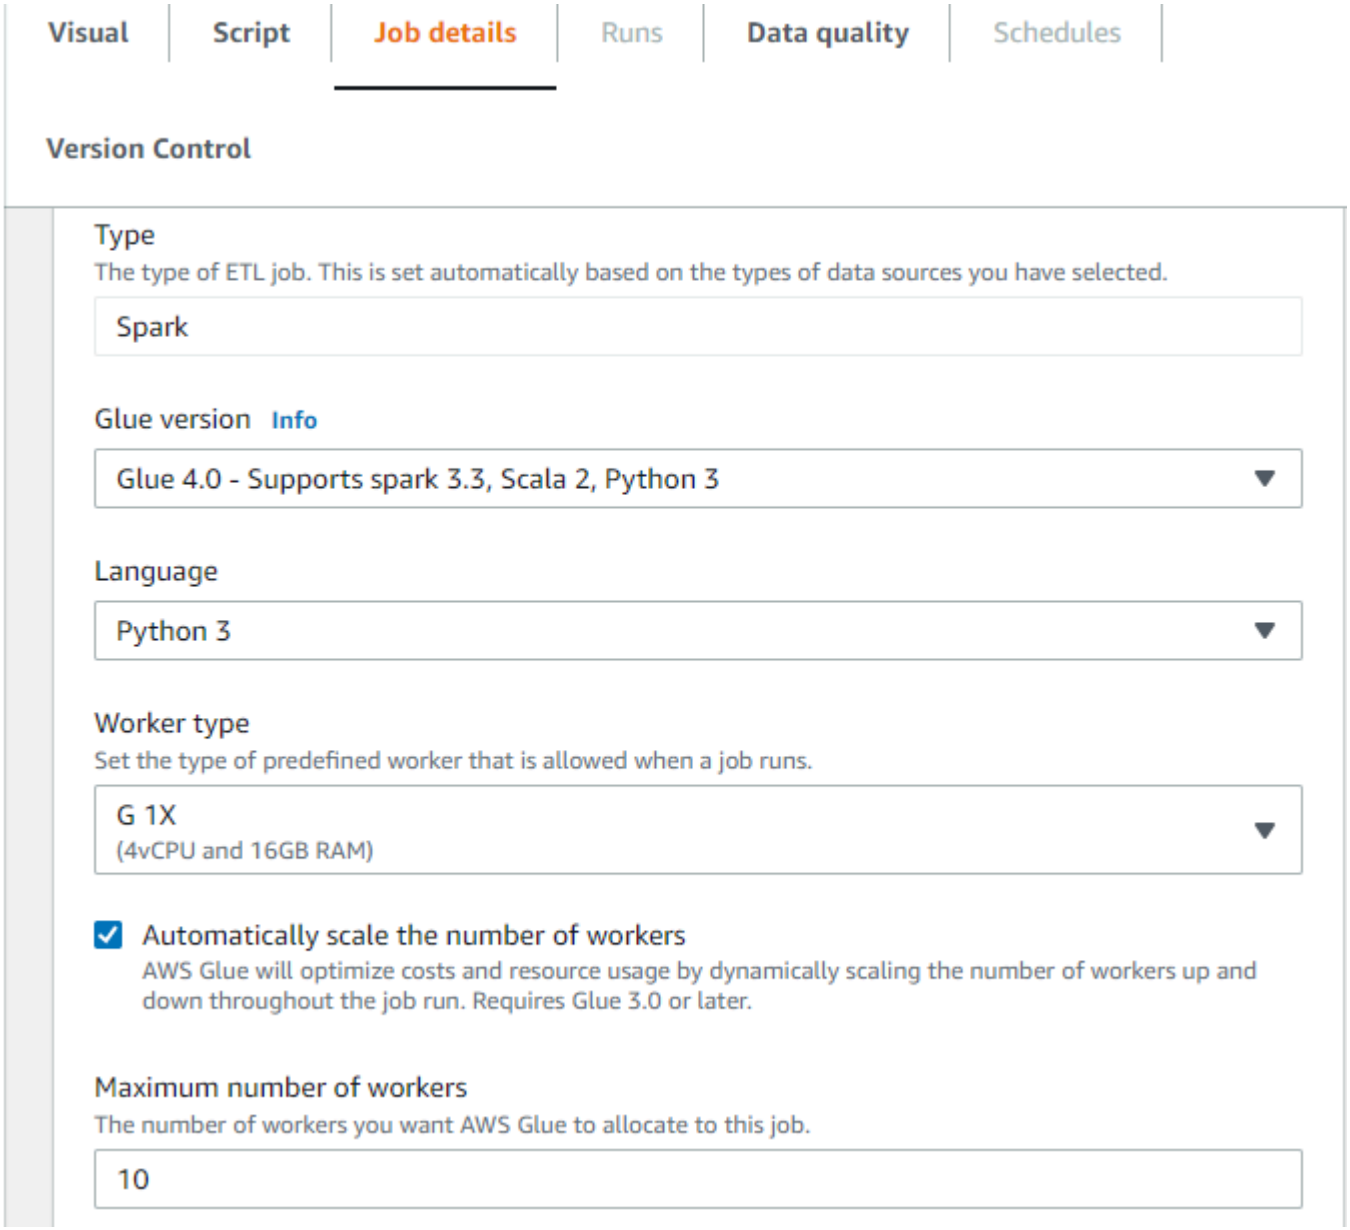
AWS Glue streaming ETL jobs continuously consume data from streaming sources, clean and transform the data in-flight, and make it available for analysis. By monitoring each stage of the job run, AWS Glue autoscaling can turn off workers when they are idle or add workers if additional parallel processing is possible.

The following sections provide information on AWS Glue streaming autoscaling

Enabling Auto Scaling in AWS Glue Studio

On the **Job details** tab in AWS Glue Studio, choose the type as **Spark** or **Spark Streaming**, and **Glue version** as **`Glue 3.0`** or **`Glue 4.0`**. Then a check box will show up below **Worker type**.

- Select the **Automatically scale the number of workers** option.
- Set the **Maximum number of workers** to define the maximum number of workers that can be vended to the job run.



Enabling Auto Scaling with the AWS CLI or SDK

To enable Auto Scaling From the AWS CLI for your job run, run `start-job-run` with the following configuration:

```
{
    "JobName": "<your job name>",
    "Arguments": {
        "--enable-auto-scaling": "true"
    },
```

```
    "WorkerType": "G.2X", // G.1X, G.2X, G.4X, G.8X, G.12X, G.16X, R.1X, R.2X, R.4X,
 and R.8X are supported for Auto Scaling Jobs
    "NumberOfWorkers": 20, // represents Maximum number of workers
    ...other job run configurations...
}
```

Once at ETL job run is finished, you can also call `get-job-run` to check the actual resource usage of the job run in DPU-seconds. Note: the new field **DPUSeconds** will only show up for your batch jobs on AWS Glue 3.0 or later enabled with Auto Scaling. This field is not supported for streaming jobs.

```
$ aws glue get-job-run --job-name your-job-name --run-id jr_xx --endpoint https://
glue.us-east-1.amazonaws.com --region us-east-1
{
    "JobRun": {
        ...
        "GlueVersion": "3.0",
        "DPUSeconds": 386.0
    }
}
```

You can also configure job runs with Auto Scaling using the AWS Glue SDK with the same configuration.

How it works

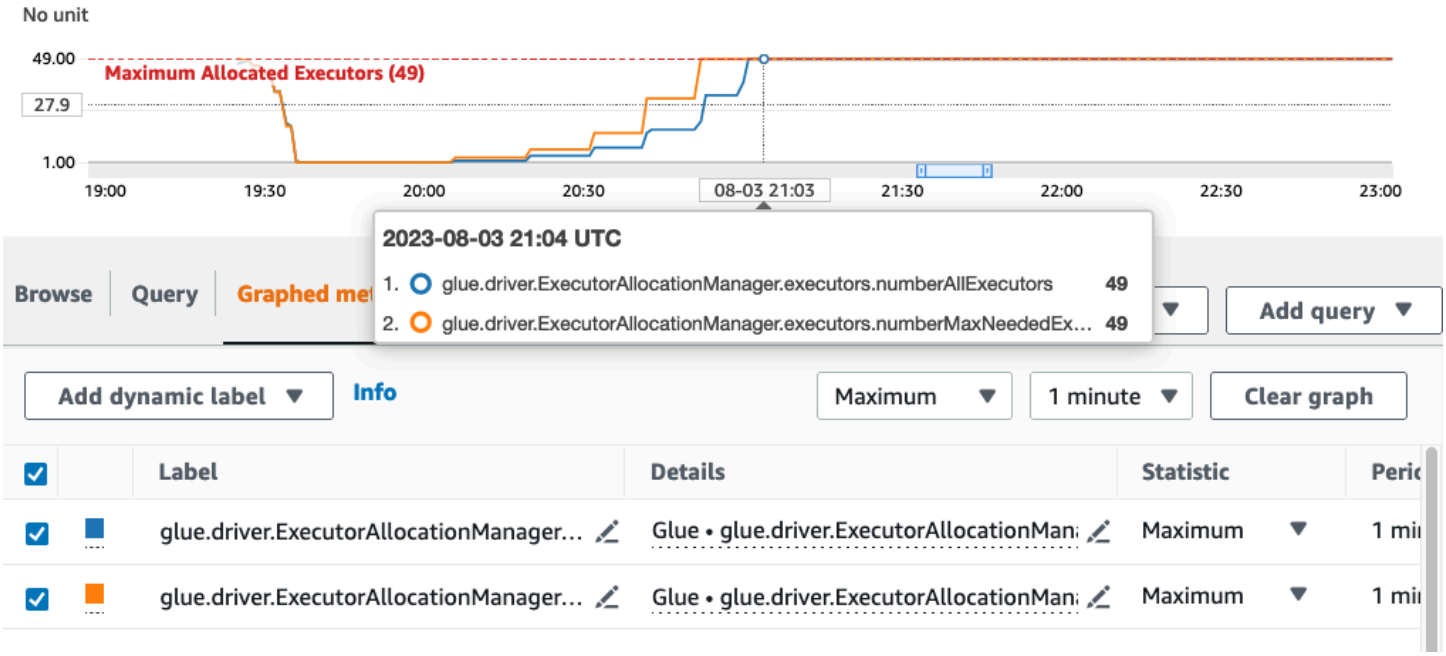
Scaling across microbatch

The following example is used to describe how autoscaling works.

- You have a AWS Glue job that starts with 50 DPUs.
- Autoscaling is enabled.

In this example, AWS Glue looks at the “batchProcessingTimeInMs“ metric for a few micro batches and determines if your jobs are completing within the window size that you have established. If your jobs are completing sooner and depending on how soon they complete, AWS Glue may scale down. This metric, plotted with ”numberAllExecutors“ can be monitored in Amazon CloudWatch to see how autoscaling works.

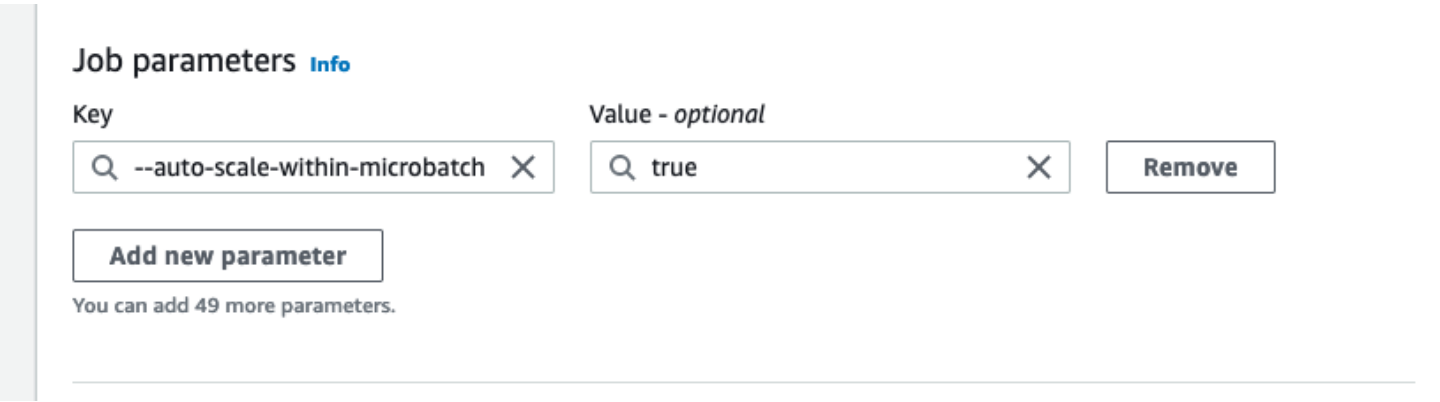
The number of executors exponentially scales up or down only after each micro batch completes. As you can see from the Amazon CloudWatch Monitoring log, AWS Glue looks at the number of needed executors (Orange Line) and scales the executors (blue line) to match that automatically.



Once AWS Glue scales down the number of executors and observes that data volumes increase, consequently increasing the micro batch processing time, AWS Glue will scale up to 50 DPUs, which is the specified upper limit.

Scaling within microbatch

In the above example, the system monitors a few completed micro-batches to make a decision on whether to scale up or down. Longer windows require autoscaling to respond more quickly within the microbatch, rather than waiting for a few micro batches. For these cases, you can use an additional configuration `--auto-scaIe-within-microbatch` to `true`. You can add this to the AWS Glue job properties in AWS Glue Studio as shown below.



Maintenance windows for AWS Glue Streaming

AWS Glue periodically performs maintenance activities. During these maintenance windows, AWS Glue will need to restart your streaming jobs. You can control when the jobs are restarted by specifying maintenance windows. In this section, we outline where you can setup the maintenance window and specific behaviors you should consider.

Topics

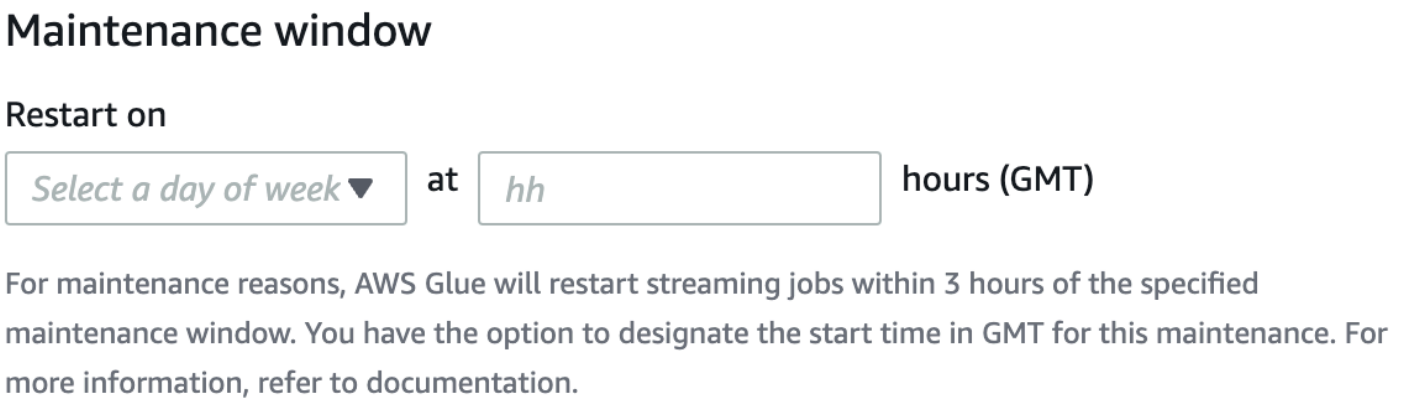
- Setting up a maintenance window
- Maintenance window behavior
- Job monitoring
- Data loss handling

Setting up a maintenance window

You can set up a maintenance window using AWS Glue Studio or APIs.

Setting up a maintenance windows in AWS Glue Studio

You can specify a maintenance window in the **Job Details** page of your AWS Glue Streaming job. You can specify the day and time in GMT. AWS Glue will restart your job within the specified time window.



Setting up a maintenance windows in the API

You can alternatively set up the maintenance window in the Create Job API. Here is an example of configuring a maintenance windows via the API.

```
aws glue create-job –name jobName –role roleArnForTheJob –command
 Name=gluestreaming,ScriptLocation=s3-path-to-the-script --maintenance-window="Sun:10"
```

An example command is as follows:

```
aws glue create-job –name testMaintenance –role arn:aws:iam::012345678901:role/
Glue_DefaultRole –command Name=gluestreaming,ScriptLocation=s3://glue-example-test/
example.py –maintenance-window="Sun:10
```

Maintenance window behavior

AWS Glue goes through a series of steps to decide when to restart a job:

1. When a new streaming job is initiated, AWS Glue first checks if there is a timeout associated with the job run. A timeout allows you to configure the end time of the job. If the timeout is less than 7 days, then the job will not be restarted.
2. If the timeout is greater than 7 days, then AWS Glue checks if the maintenance window is configured for the job. If it is then that window is picked up and the window gets assigned to the job run. AWS Glue will restart the job within 3 hours of the specified maintenance window. For instance, if you set up the maintenance window for Monday at 10:00AM GMT, your jobs will be restarted between 10:00AM GMT to 1:00PM GMT.
3. If the maintenance window is not configured, AWS Glue automatically sets the restart time to 7 days past job run initiation time. For instance, if you initiated your job on 7/1/2024 12:00AM GMT and you did not specify maintenance windows, your job will be set to restart on 7/8/2024 at 12:00 AM GMT.

   > **Note**
   >
   > If you are already running streaming jobs, this change will impact you starting July 1, 2024. You will have time until June 30th to configure your maintenance windows. After July 1st, any streaming jobs that you start will be restarted per this documentation. If you require any additional support, you can reach out to AWS Support.

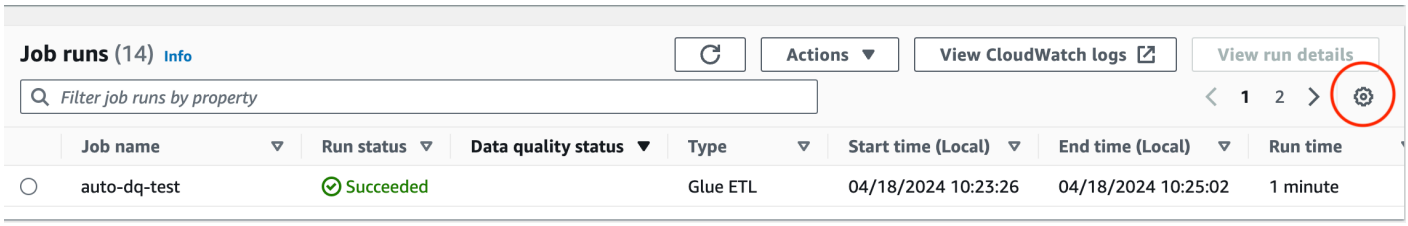
4. Sometimes, AWS Glue may not be able to restart the job, especially when the ongoing micro-batch is not processed. In these instances, the job will not be interrupted. In these instances, AWS Glue will restart the job after 14 days, and in this case, the maintenance window is not honored.

Job monitoring

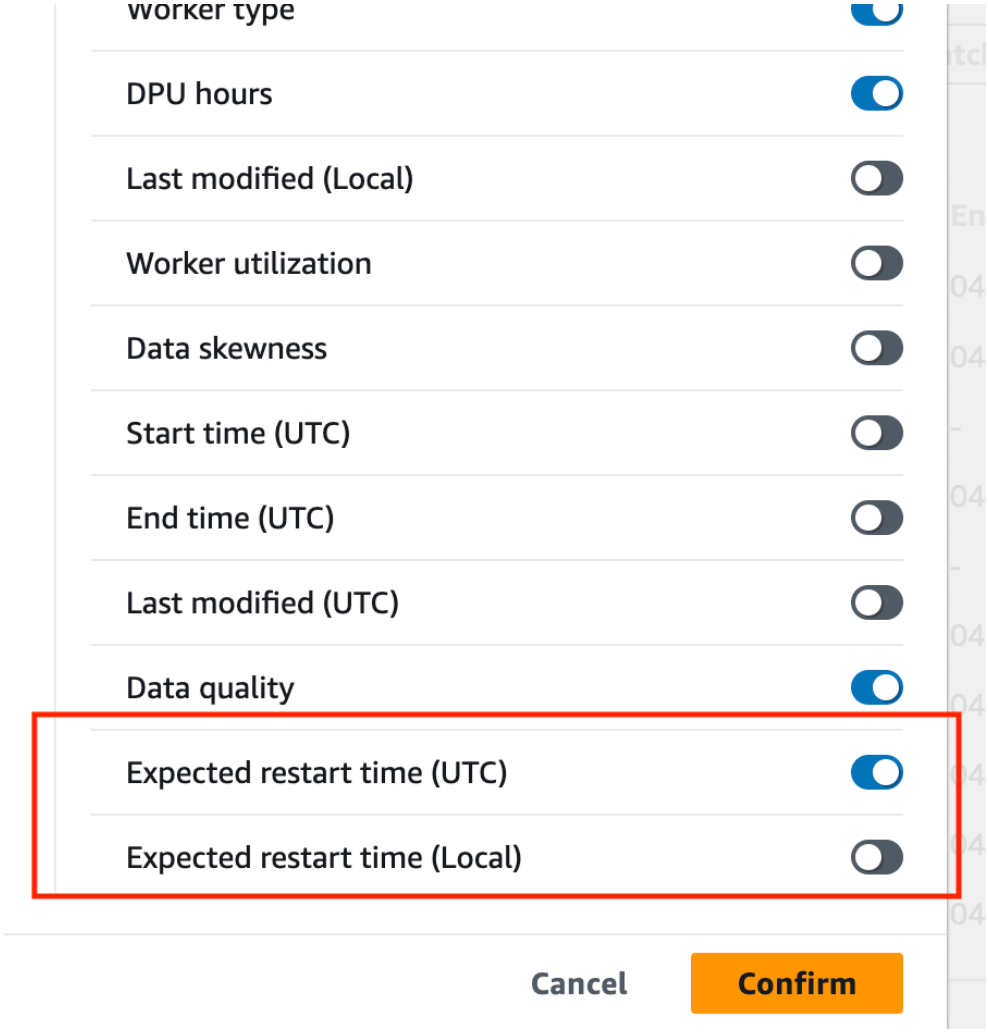
You can monitor the jobs in the AWS Glue Studio **Monitoring** page.

To see the expected next restart time of streaming jobs, show the column on the Job runs table on the **Monitoring** page.

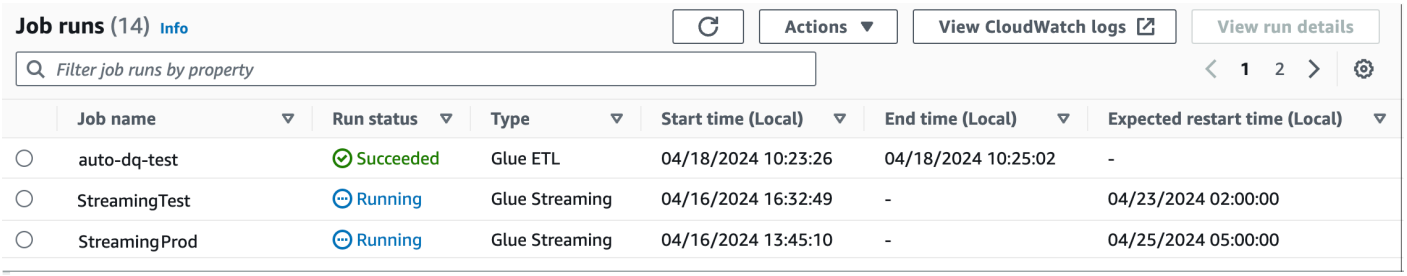
1. Click the Gear icon in the top right of the table.



2. Scroll down, and turn on the **Expected restart time** column. Both UTC and Local time options are available.



3. You can then view the columns in the table.



The original job will have an "EXPIRED" status and the new job instance will have a "RUNNING" status. The new job run that was restarted will have a job run ID as a concatenation of initial job run ID plus the prefix "restart_" representing the restart count. For example, if the initial job run ID is `jr_1234`, then the restarted job run will have the ID `jr1234_restart_1` for the first restart. The second restart will be `jr1234_restart_2` for the second restart and so on.

Your retry attempt will not be impacted because of the restarts. If a run fails and a new run is started due to an automatic retry, the counter of restart will start from 1 again . For example, if a run fails at `jr_1234_attempt_3_restart_5`, then an automatic retry will start new run with ID: `jr_id1_attempt_4` and when this attempt is restarted after 7 days, the new run ID will be `jr_id1_attempt_4_restart_1`.

Data loss handling

During maintenance restarts, AWS Glue Streaming follows a process that ensures data integrity and consistency between the previous job run and the restarted job run. Note that AWS Glue does not guarantee data integrity and consistency between job restarts and we recommend architecture considerations to handle duplicated data within streaming jobs.

1. Detecting maintenance restart conditions: AWS Glue Streaming monitors conditions that indicate when a maintenance restart should be triggered, such as when a maintenance window is reached after 7 days or a hard restart is necessary after 14 days.
2. Invoking a graceful termination: When the maintenance restart conditions are met, AWS Glue Streaming initiates a graceful termination process for the currently running job. This process involves the following steps:
   a. Stopping the ingestion of new data: The streaming job stops consuming new data from the input sources (for example, Kafka topics, Kinesis streams, or files).
   b. Processing pending data: The job continues to process any data that is already present in its internal buffers or queues.

c. Committing offsets and checkpoints: The job commits the latest offsets or checkpoints to external systems (for example, Kafka, Kinesis, or Amazon S3) to ensure that the restarted job can pick up from where the previous job left off.

3. Restarting the job: After the graceful termination process is complete, AWS Glue Streaming restarts the job using the preserved state and checkpoints. The restarted job picks up processing from the last committed offset or checkpoint, ensuring that no data is lost or duplicated.
4. Resuming data processing: The restarted job resumes data processing from the point where the previous job left off. It continues ingesting new data from the input sources, starting from the last committed offset or checkpoint, and processes the data according to the defined ETL logic.

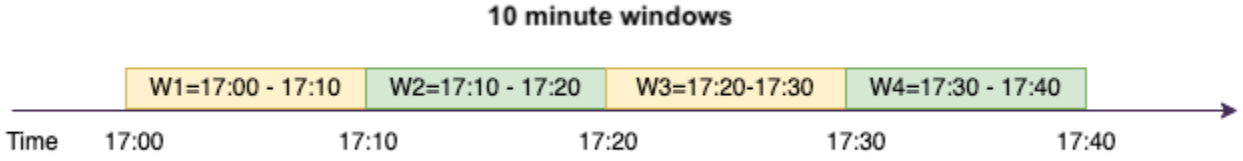
Advanced AWS Glue streaming concepts

In contemporary data-driven applications, the significance of data diminishes over time and its value transitions from being predictive to reactive. As a result, customers want to process data in real-time for making faster decisions. When dealing with real-time data feeds, such as from IoT sensors, the data may arrive unordered or experience delays in processing due to network latency and other source-related failures during ingestion. As part of the AWS Glue platform, AWS Glue Streaming builds on these capabilities to provide scalable, serverless streaming ETL, powered by Apache Spark structured streaming, empowering users with real-time data processing.

In this topic, we will explore advanced streaming concepts and capabilities of AWS Glue Streaming.

Time considerations when processing streams

There are four notions of time when processing streams:



- **Event-time** – The time at which the event occurred. In most cases, this field is embedded into the event-data itself, at the source.
- **Event-time-window** – The time frame between two event-times. As shown in the above diagram, **W1** is an event-time-window from 17:00 to 17:10. Each event-time-window is a grouping of multiple events.

- **Trigger-time** – The trigger time controls how often the processing of data and updating of results occurs. This is the time when the micro-batch processing started.
- **Ingestion-time** – The time when the stream-data was ingested into the streaming service. If event-time is not embedded into the event itself, this time can be used for windowing in some cases.

Windowing

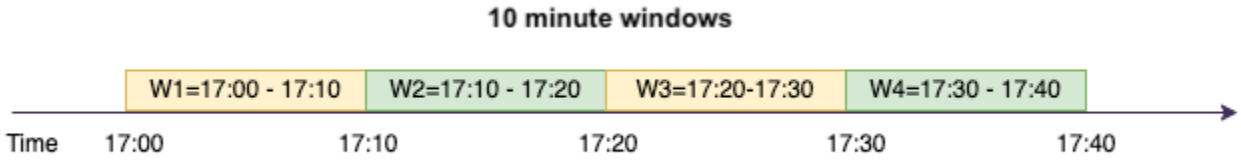
Windowing is a technique where you group and aggregate multiple events by event-time-window. We will explore the benefits of windowing and when you would use it in the following examples.

Depending on the business use case, there are three types of time windows supported by spark.

- Tumbling window – a series of non-overlapping fixed size event-time-windows over which you aggregate.
- Sliding window – similar to the tumbling windows from the point of being “fixed-sized”, but windows can overlap or slide as long as the duration of slide is smaller than the duration of window itself.
- Session window – starts with an input data event and continues to expands itself as long as it receives input within a gap or duration of inactivity. A session window can have a static or dynamic size of the window length, depending on the inputs.

Tumbling window

Tumbling window is a series of non-overlapping fixed size event-time-windows over which you aggregate. Lets understand this with a real world example.



Company ABC Auto wants to do a marketing campaign for a new brand of sports car. They want to pick a city where they have biggest sports car fans. To achieve this goal, they showcase a short 15 second advertisement introducing the car on their website. All the “clicks“ and the corresponding ”city“ are recorded and streamed to Amazon Kinesis Data Streams. We want to count the number

of clicks in a 10 minute window and group it by city to see which city has the highest demand. The following is the output of the aggregation.

window_start_time	window_end_time	city	total_clicks
2023-07-10 17:00:00	2023-07-10 17:10:00	Dallas	75
2023-07-10 17:00:00	2023-07-10 17:10:00	Chicago	10
2023-07-10 17:20:00	2023-07-10 17:30:00	Dallas	20
2023-07-10 17:20:00	2023-07-10 17:30:00	Chicago	50

As explained above, these event-time-windows are different from trigger-time intervals. For example, even if your trigger time is every minute, the output results will only show 10 minute non-overlapping aggregation windows. For optimization, its better to have the trigger interval aligned with the event-time-window.

In the table above, Dallas saw 75 clicks in the 17:00-17:10 window, while Chicago had 10 clicks. Also, there is no data for the 17:10 - 17:20 window for any city, so this window is omitted.

Now you can run further analysis on this data in the downstream analytics application to determine the most exclusive city to run the marketing campaign.

Using tumbling windows in AWS Glue

1. Create a Amazon Kinesis Data Streams DataFrame and read from it. Example:

```
parsed_df = kinesis_raw_df \
                .selectExpr('CAST(data AS STRING)') \
                .select(from_json("data", ticker_schema).alias("data")) \
                .select('data.event_time','data.ticker','data.trade','data.volume',
 'data.price')
```

2. Process data in a tumbling window. In the example below, data is grouped based on the input field “event_time” in 10 minute tumbling windows and writing the output to an Amazon S3 data lake.

```
grouped_df = parsed_df \
```

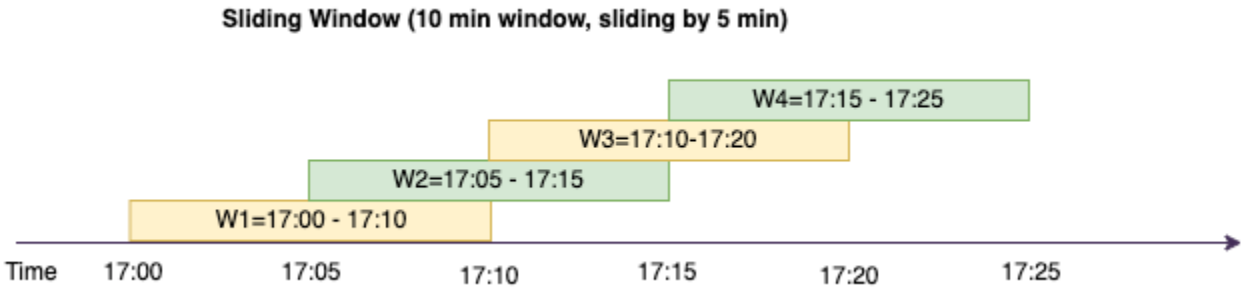
```
                .groupBy(window("event_time", "10 minutes"), "city") \
                .agg(sum("clicks").alias("total_clicks"))

summary_df = grouped_df \
                .withColumn("window_start_time", col("window.start")) \
                .withColumn("window_end_time", col("window.end")) \
                .withColumn("year", year("window_start_time")) \
                .withColumn("month", month("window_start_time")) \
                .withColumn("day", dayofmonth("window_start_time")) \
                .withColumn("hour", hour("window_start_time")) \
                .withColumn("minute", minute("window_start_time")) \
                .drop("window")

write_result = summary_df \
                .writeStream \
                .format("parquet") \
                .trigger(processingTime="10 seconds") \
                .option("checkpointLocation", "s3a://bucket-stock-stream/stock-
stream-catalog-job/checkpoint/") \
                .option("path", "s3a://bucket-stock-stream/stock-stream-catalog-
job/summary_output/") \
                .partitionBy("year", "month", "day") \
                .start()
```

Sliding window

Sliding windows are similar to the tumbling windows from the point of being “fixed-sized”, but windows can overlap or slide as long as the duration of slide is smaller than the duration of window itself. Due to the nature of sliding, an input can be bound to the multiple windows.



To better understand, lets consider the example of a bank that want to detect potential credit card fraud. A streaming application could monitor a continuous stream of credit card transactions.

These transactions could be aggregated into windows of 10 minutes duration and every 5 minutes, the window would slide forward, eliminating the oldest 5 minutes of data and adding the latest 5 minutes of new data. Within each window, the transactions could be grouped by country checking for suspicious patterns, such as a transaction in the US immediately followed by another in Australia. For simplicity, lets us categorize such transactions as fraud when the total transactions amount is greater than $100. If such a pattern is detected, it signals potential fraud and the card could be frozen.

The credit card processing system is sending a steam of transaction events to kinesis for each card-id along with the country. An AWS Glue job runs the analysis and produces the following aggregated output.

window_start_time	window_end_time	card_last_four	country	total_amount
2023-07-10 17:00:00	2023-07-10 17:10:00	6544	US	85
2023-07-10 17:00:00	2023-07-10 17:10:00	6544	Australia	10
2023-07-10 17:05:45	2023-07-10 17:15:45	6544	US	50
2023-07-10 17:10:45	2023-07-10 17:20:45	6544	US	50
2023-07-10 17:10:45	2023-07-10 17:20:45	6544	Australia	150

Based on the above aggregation, you can see the 10 minute window sliding every 5 minutes,summed by transaction amount. The anomaly is detected in the 17:10 - 17:20 window where there is an outlier, which is a transaction for $150 in Australia. AWS Glue can detect this anomaly and push an alarm-event with the offending key to an SNS topic using boto3. Further a Lambda function can subscribe to this topic and take action.

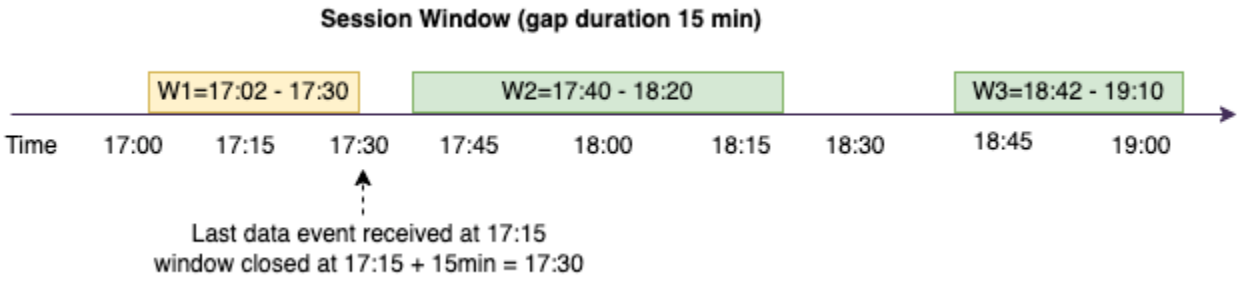
Process data in a sliding window

The `group-by` clause and the window function is used to implement the sliding window as shown below.

```
grouped_df = parsed_df \
            .groupBy(window(col("event_time"), "10 minute", "5 min"), "country",
 "card_last_four") \
            .agg(sum("tx_amount").alias("total_amount"))
```

Session window

Unlike the above two windows that have a fixed-size, session window can have a static or dynamic size of the window length, depending on the inputs. A session window starts with an input data event and continues to expands itself as long as it receives input within a gap or duration of inactivity.



Lets take an example. Company ABC hotel wants to find out when is the busiest time in a week and provide better deals for their guests. As soon as a guest checks-in, a session window is started and spark maintains a state with aggregation for that event-time-window. Every time a guests checks in, an event is generated and sent to Amazon Kinesis Data Streams. The hotel makes a decision that if there is no check-ins for a period of 15 minutes, the event-time-window can be closed. The next event-time-window will start again when there is a new check-in. The output looks as follows.

window_start_time	window_end_time	city	total_checkins
2023-07-10 17:02:00	2023-07-10 17:30:00	Dallas	50
2023-07-10 17:02:00	2023-07-10 17:30:00	Chicago	25
2023-07-10 17:40:00	2023-07-10 18:20:00	Dallas	75

window_start_time	window_end_time	city	total_checkins
2023-07-10 18:50:45	2023-07-10 19:15:45	Dallas	20

The first check-in occurred at event_time=17:02. The aggregation event-time-window will start at 17:02. This aggregation will continue as long as we receive events within 15 minute duration. In the above example, the last event we received was at 17:15 and then for the next 15 minutes there were no events. As a result, Spark closed that event-time-window at 17:15+15min = 17:30 and set it as 17:02 - 17:30. It started a new event-time-window at 17:47 when it received a new check-in data event.

Process data in a session window

The `group-by` clause and the window function is used to implement the sliding window.

```
grouped_df = parsed_df \
            .groupBy(session_window(col("event_time"), "10 minute"), "city") \
            .agg(count("check_in").alias("total_checkins"))
```

Output modes

Output mode is the mode in which the results from the unbounded table are written to the external sink. There are three modes available. In the following example you are counting occurrences of a word as lines of data are being streamed and processed in each micro batch.

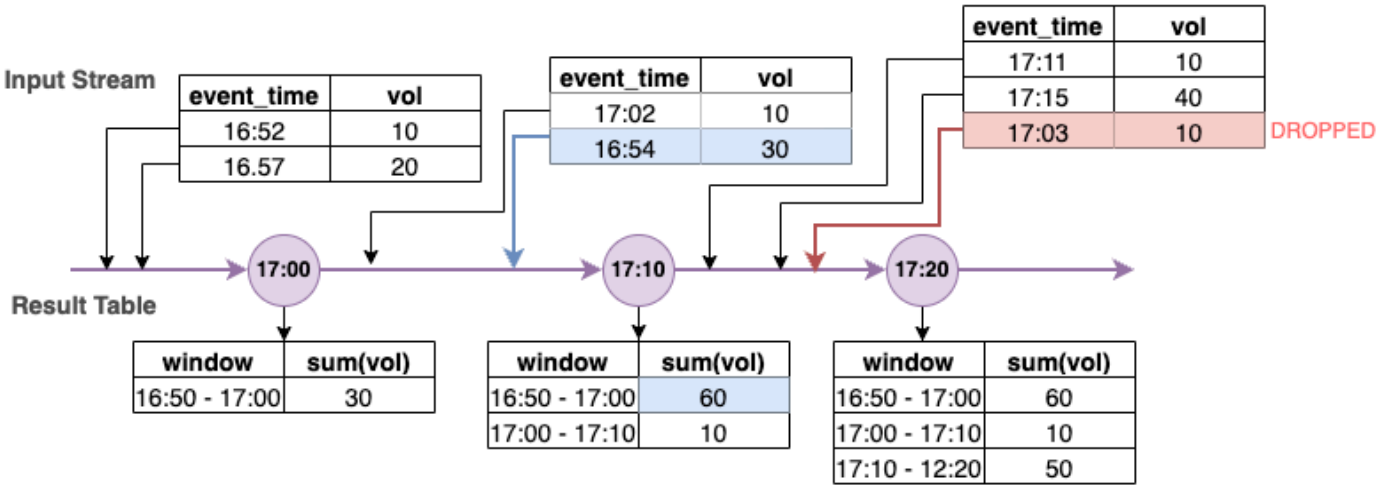
- **Complete mode** – The whole result table will be written to the sink after every micro batch processing even though the word count was not updated in the current event-time-window.
- **Append mode** – This is the default mode, where only the new words and or rows added to the result table since the last trigger will be written to the sink. This mode is good for stateless streaming for queries like map, flatMap, filter, etc.
- **Update mode** – Only the words and or rows in the Result Table that were updated or added since the last trigger will be written to the sink.

> **Note**
>
> Output mode = "update" is not supported for session windows.

Handling late data and watermarks

When working with real-time data there could be delays in the arrival of data due to network latency and upstream failures and we need a mechanism to perform the aggregation again on the missed event-time-window. However, to do this, state needs to be maintained. At the same time, the older data needs to be cleaned up to limit the size of the state. Spark version 2.1 added support for a feature called watermarking which maintains state and allows the user to specify the threshold for late data.

With reference to our stock ticker example above, lets consider the allowed threshold for the late data as no more than 10 minutes. To keep it simple we will assume tumbling window, ticker as AMZ, trade as BUY.



In the above diagram, we are calculating the total volume over a tumbling 10 minute window. We have the trigger at 17:00, 17:10 and 17:20. Above the timeline arrow, we have the input data stream and below is the unbounded results table.

In the first 10 minute tumbling window we aggregated based on event_time and the total_volume was calculated as 30. In the second event-time-window, spark got the first data event with event_time=17:02. Since this is the max event_time seen thus far by spark, the watermark threshold is set 10 minutes back (that is, watermark_event_time=16:52). Any data event with an event_time after 16:52 will be considered for time bound aggregation and any data event before that will be dropped. This allows spark to maintain an intermediate state for additional 10 minutes to accommodate late data. Around wall clock time 17:08 Spark received an event with an event_time=16:54 which was within threshold. Hence spark recalculated the “16:50 - 17:00“ event-time-window and the total volume was updated from 30 to 60.

However, at the trigger time 17:20, when spark received event with event_time=17:15 it set the watermark_event_time=17:05. Hence the late data event with event_time=17:03 was considered “too late” and ignored.

```
Watermark Boundary = Max(Event Time) - Watermark Threshold
```

Using watermarks in AWS Glue

Spark will not emit or write the data to the external sink until the watermark boundary is passed. To implement a watermark in AWS Glue, see the example below.

```
grouped_df = parsed_df \
                .withWatermark("event_time", "10 minutes") \
                .groupBy(window("event_time", "5 minutes"), "ticker") \
                .agg(sum("volume").alias("total_volume"))
```

About monitoring AWS Glue streaming jobs

Monitoring your streaming job is a critical part of building your ETL pipeline. Apart from using the Spark UI, you can also use Amazon CloudWatch to monitor the metrics. Below is a list of streaming metrics emitted by the AWS Glue framework. For a complete list of all the AWS Glue metrics, see Monitoring AWS Glue using Amazon CloudWatch metrics.

AWS Glue uses a structured streaming framework to process the input events. You can either use the Spark API directly in your code or leverage the `ForEachBatch` provided by `GlueContext`, which publishes these metrics. To understand these metrics, we need to first understand `windowSize`.

windowSize: `windowSize` is the micro-batch interval that you provide. If you specify a window size of 60 seconds, the AWS Glue streaming job will wait for 60 seconds (or more if the previous batch hasn’t completed by then) before it will read data in a batch from the streaming source and apply the transformations provided in `ForEachBatch`. This is also referred to as the trigger interval.

Lets review the metrics in greater detail to understand the health and performance characteristics.

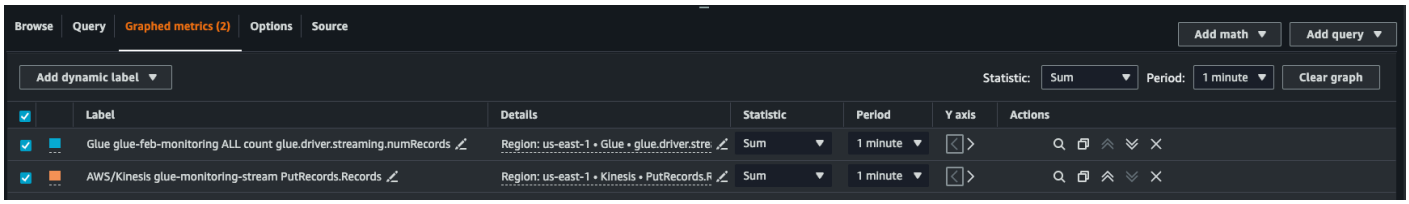
> **Note**
>
> The metrics are emitted every 30 seconds. If your `windowSize` is less than 30 seconds then the reported metrics are an aggregation. For example say your `windowSize` is 10 seconds and you are steadily processing 20 records per micro-batch. In this scenario, the emitted metric value for numRecords would be 60.
> A metric is not emitted if there is no data available for it. Also, in case of the consumer lag metric, you have to enable the feature to get metrics for it.

Visualizing AWS Glue streaming metrics

To plot visual metrics:

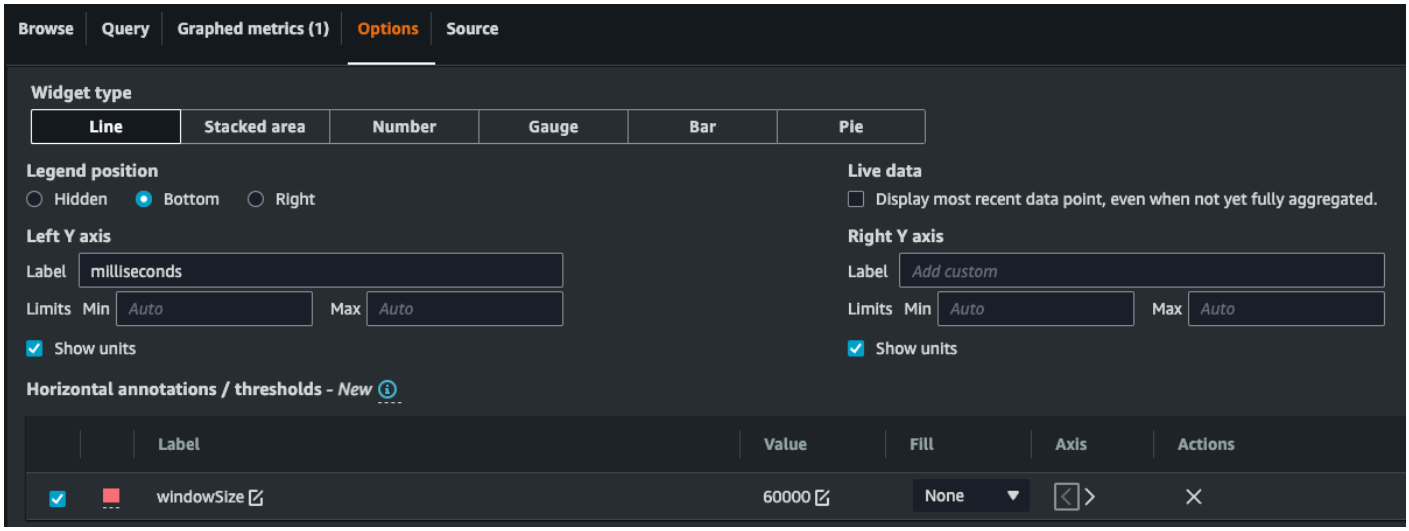
1. Go to **Metrics** in the Amazon CloudWatch console and then choose the **Browse** tab. Then choose **Glue** under "Custom namespaces".

2. Choose **Job Metrics** to show you the metrics for all your jobs.
3. Filter the metrics based on your JobName=glue-feb-monitoring and then JobRunId=ALL. You can click on the "+" sign as shown in the figure below to add it to the search filter.
4. Select the checkbox for the metrics that you are interested in. In the below figure we have selected `numberAllExecutors` and `numberMaxNeededExecutors`.

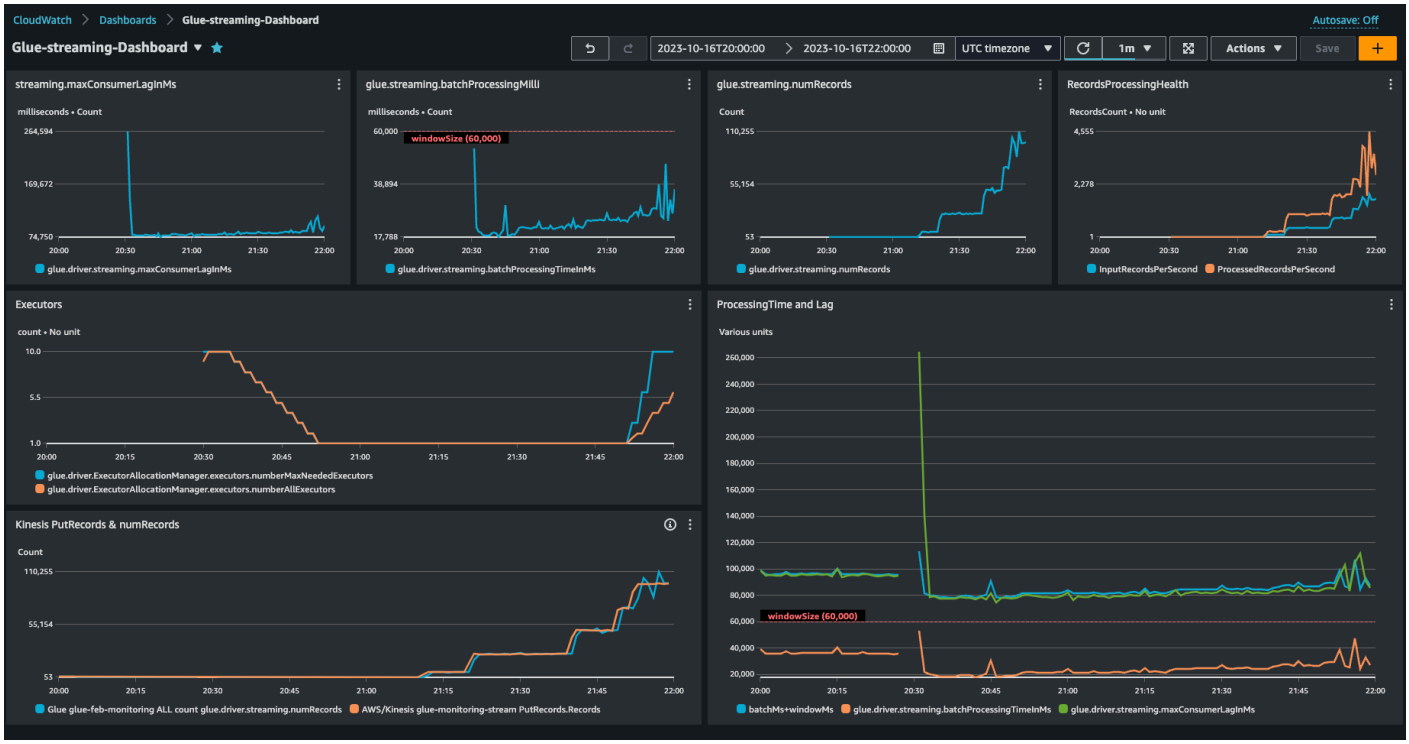


5. Once you have selected these metrics, you can go to the **Graphed metrics** tab and apply your statistics.

6. Since the metrics are emitted every min, you can apply the "average" over a minute for `batchProcessingTimeInMs` and `maxConsumerLagInMs`. For the `numRecords` you can apply the "sum" over every minute.
7. You can add a horizontal `windowSize` annotation to your graph using the **Options** tab.



8. Once you have your metrics selected, create a dashboard and add it. Here is a sample dashboard.

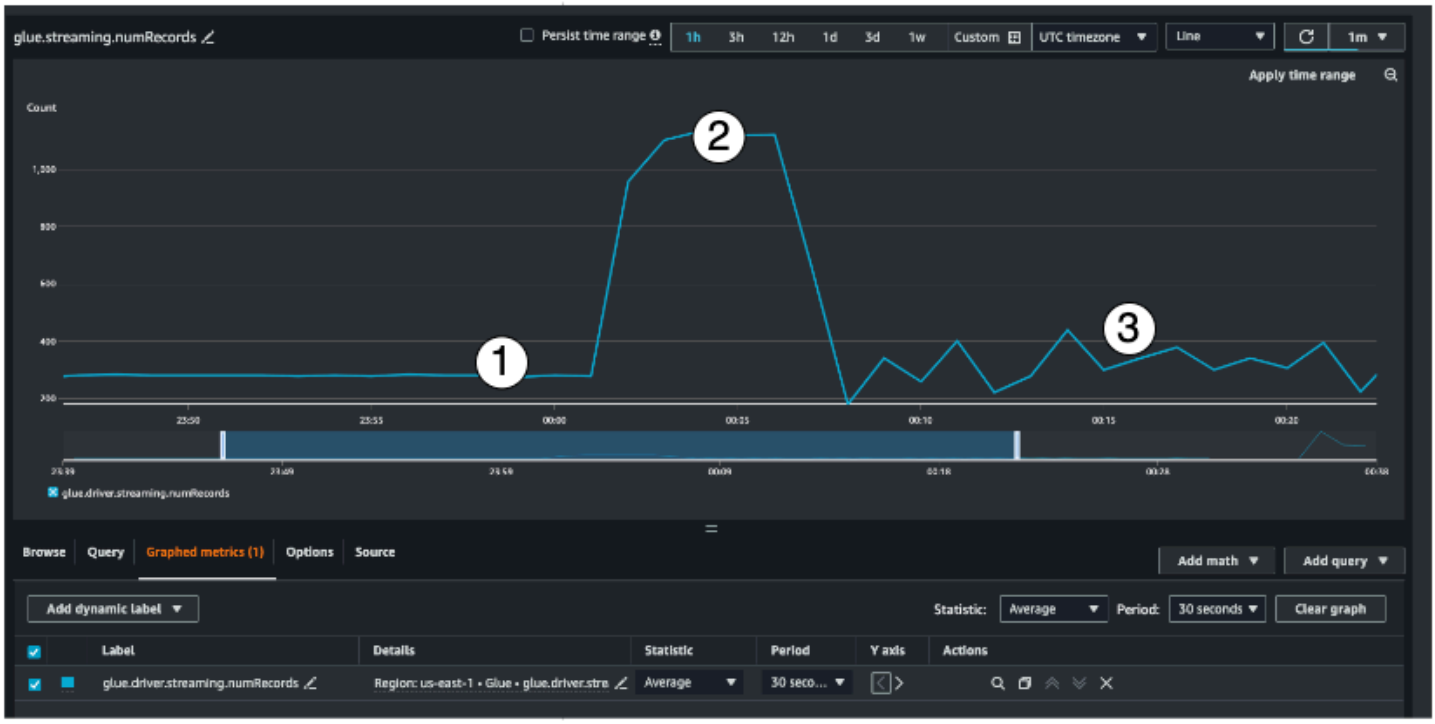


Using AWS Glue streaming metrics

This section describes each of the metrics and how they co-relate with each other.

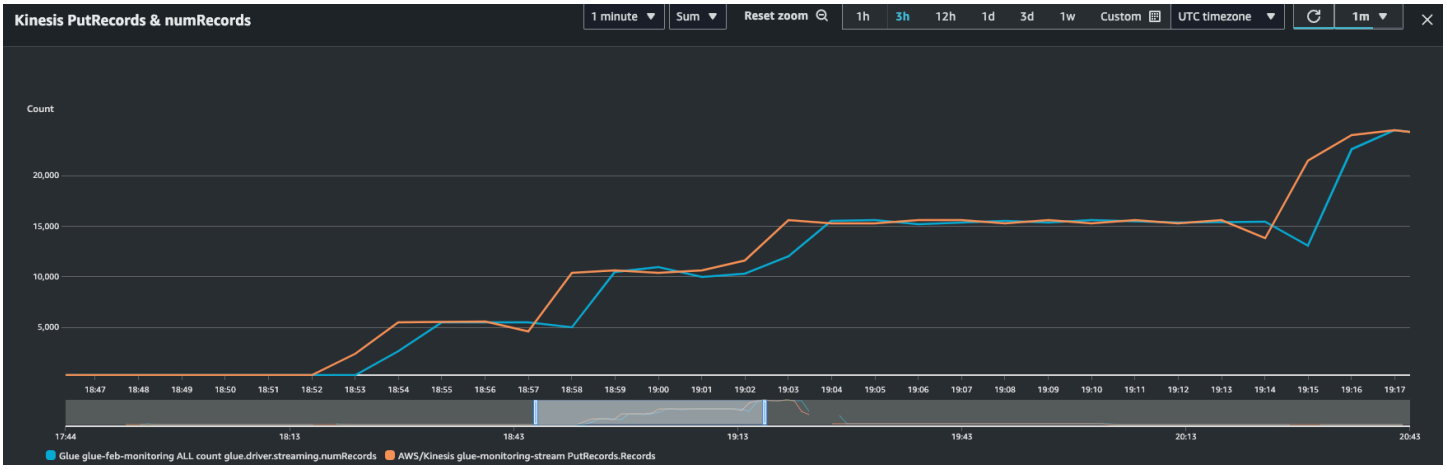
Number of records (metric: streaming.numRecords)

This metric indicates how many records are being processed.



This streaming metric provides visibility into the number of records you are processing in a window. Along with the number of records being processed, it will also help you understand the behavior of the input traffic.

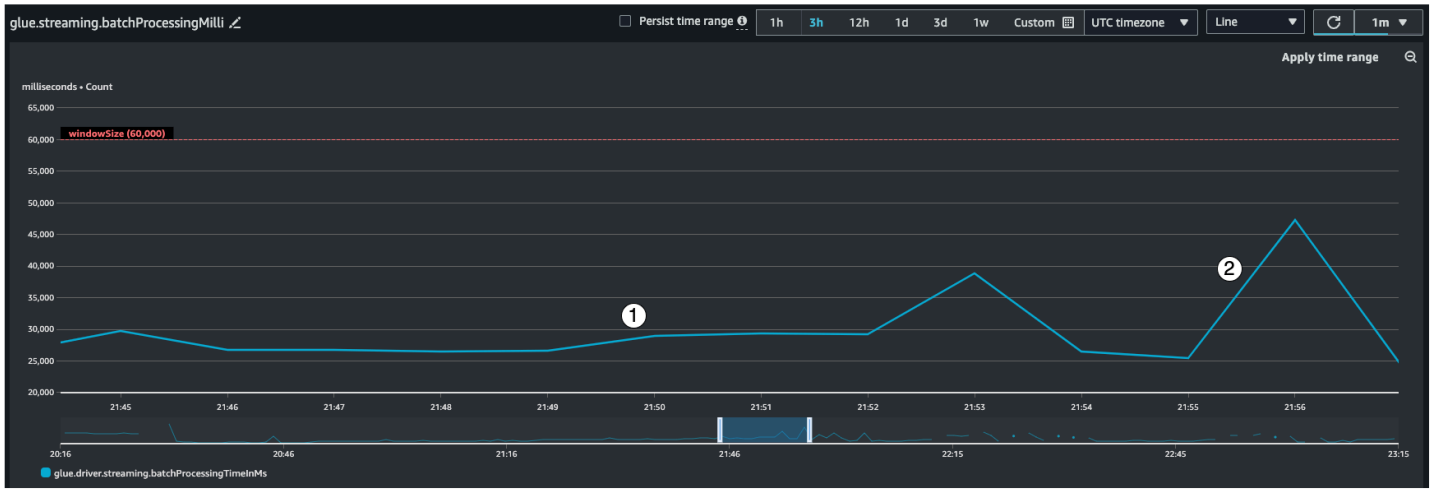
- Indicator #1 shows an example of stable traffic without any bursts. Typically this will be applications like IoT sensors that are collecting data at regular intervals and sending it to the streaming source.
- Indicator #2 shows an example of a sudden burst in traffic on an otherwise stable load. This could happen in a clickstream application when there is a marketing event like Black Friday and there is a burst in the number of clicks
- Indicator #3 shows an example of unpredictable traffic. Unpredictable traffic doesn't mean there is a problem. It is just the nature of the input data. Going back to the IoT sensor example, you can think of hundreds of sensors that are sending weather change events to the streaming source. As the weather change is not predictable, neither is the data. Understanding the traffic pattern is key to sizing your executors. If the input is very spiky, you may consider using autoscaling (more on that later).



You can combine this metric with the Kinesis PutRecords metric to make sure the number of events being ingested and the number of records being read are nearly the same. This is especially useful when you are trying to understand lag. As the ingestion rate increases, so do the `numRecords` read by AWS Glue.

Batch processing time (metric: streaming.batchProcessingTimeInMs)

The batch processing time metric helps you determine if the cluster is underprovisioned or overprovisioned.

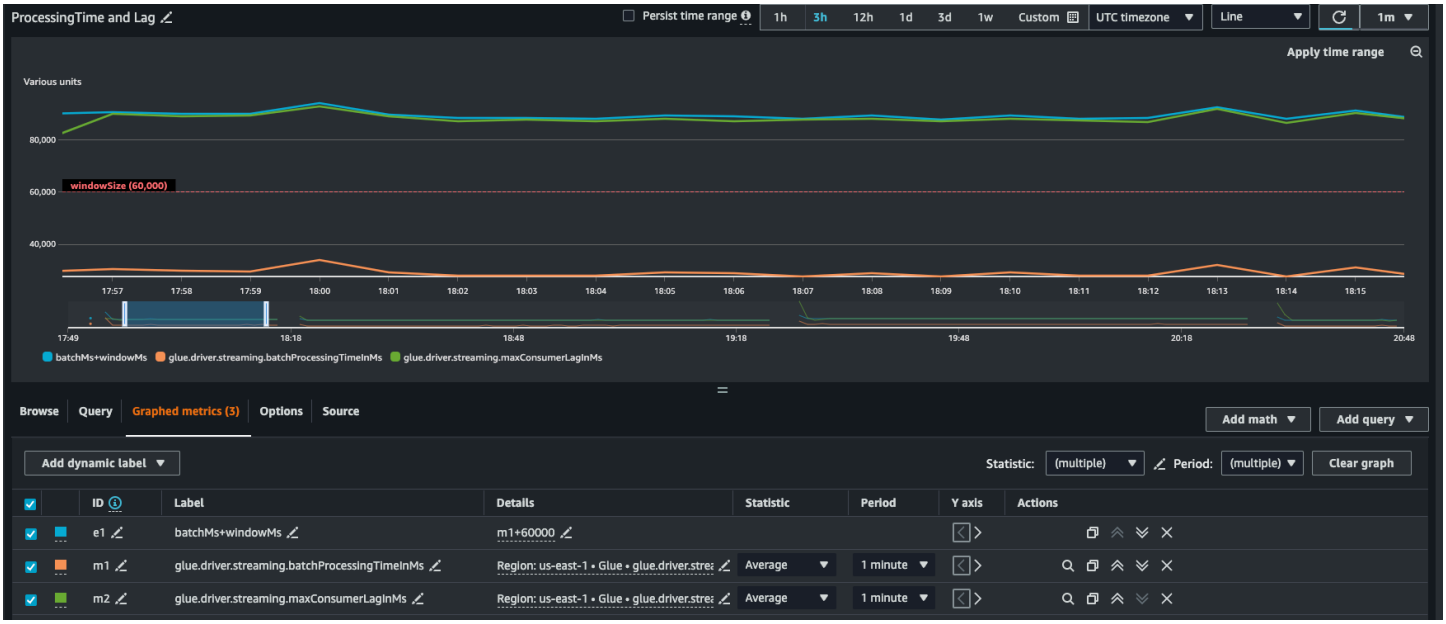


This metric indicates the number of milliseconds that it took to process each micro-batch of records. The main goal here is to monitor this time to make sure it less than the `windowSize` interval. It is okay if the `batchProcessingTimeInMs` goes over temporarily as long as it recovers in the following window interval. Indicator #1 shows a more or less stable time taken to process the job. However if the number of input records are increasing, the time it takes to process the job will increase as well as shown by indicator #2. If the `numRecords` is not going

up, but the processing time is going up, then you would need to take a deeper look into the job processing on the executors. It is a good practice to set a threshold and alarm to make sure the `batchProcessingTimeInMs` doesn't stay over 120% for more than 10 minutes. For more information on setting alarms, see Using Amazon CloudWatch alarms.

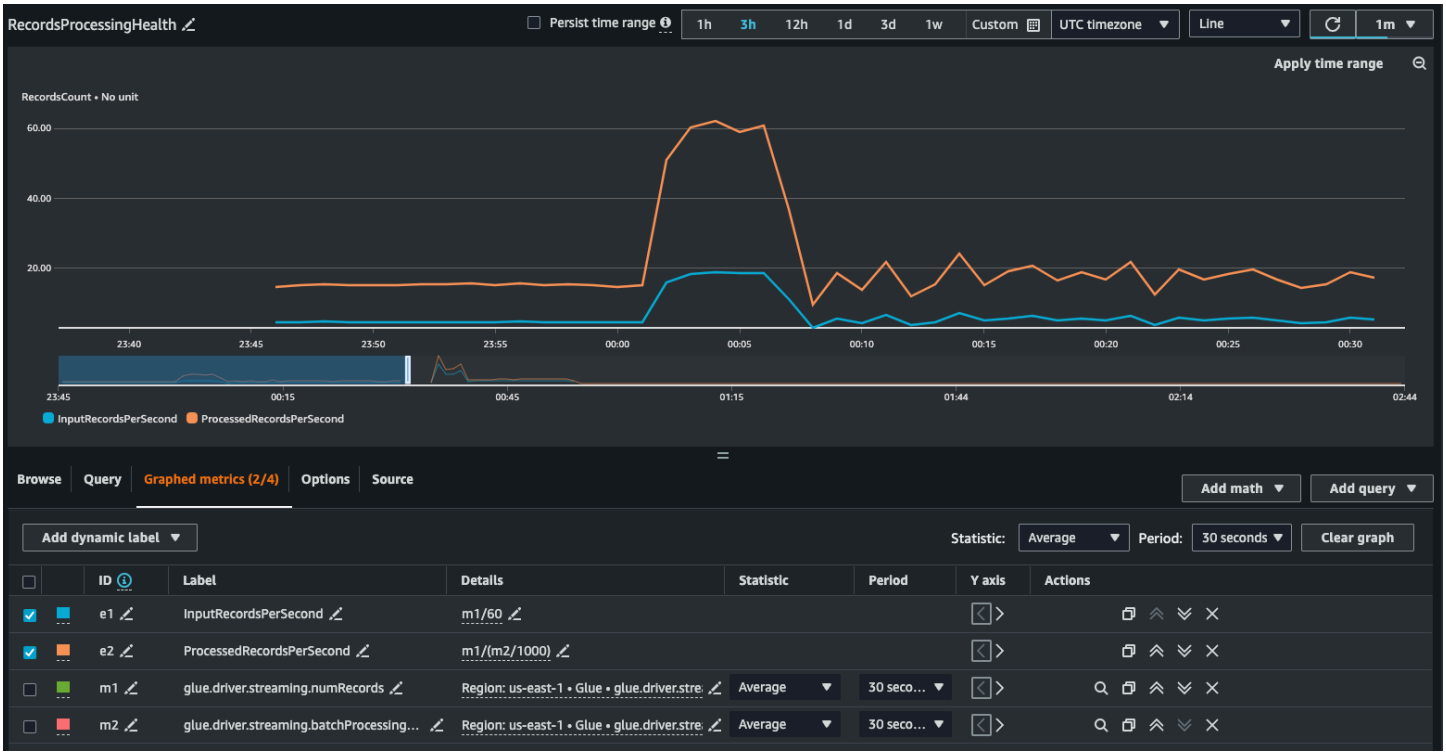
Consumer lag (metric: streaming.maxConsumerLagInMs)

The consumer lag metric helps you understand if there is a lag in processing events. If your lag is too high, then you could miss the processing SLA that your business depends on, even though you have a correct windowSize. You have to explicitly enable this metrics using the `emitConsumerLagMetrics` connection option. For more information, see KinesisStreamingSourceOptions.



Derived metrics

To gain deeper insights, you can create derived metrics to understand more about your streaming jobs in Amazon CloudWatch.



You can build a graph with derived metrics to decide if you need to use more DPUs. While autoscaling helps you do this automatically, you can use derived metrics to determine if autoscaling is working effectively.

- **InputRecordsPerSecond** indicates the rate at which you are getting input records. It is derived as follows: number of input records (glue.driver.streaming.numRecords)/ WindowSize.
- **ProcessingRecordsPerSecond** indicates the rate at which your records are being processed. It is derived as follows: number of input records (glue.driver.streaming.numRecords)/ batchProcessingTimeInMs.

If the input rate is higher than the processing rate, then you may need to add more capacity to process your job or increase the parallelism.

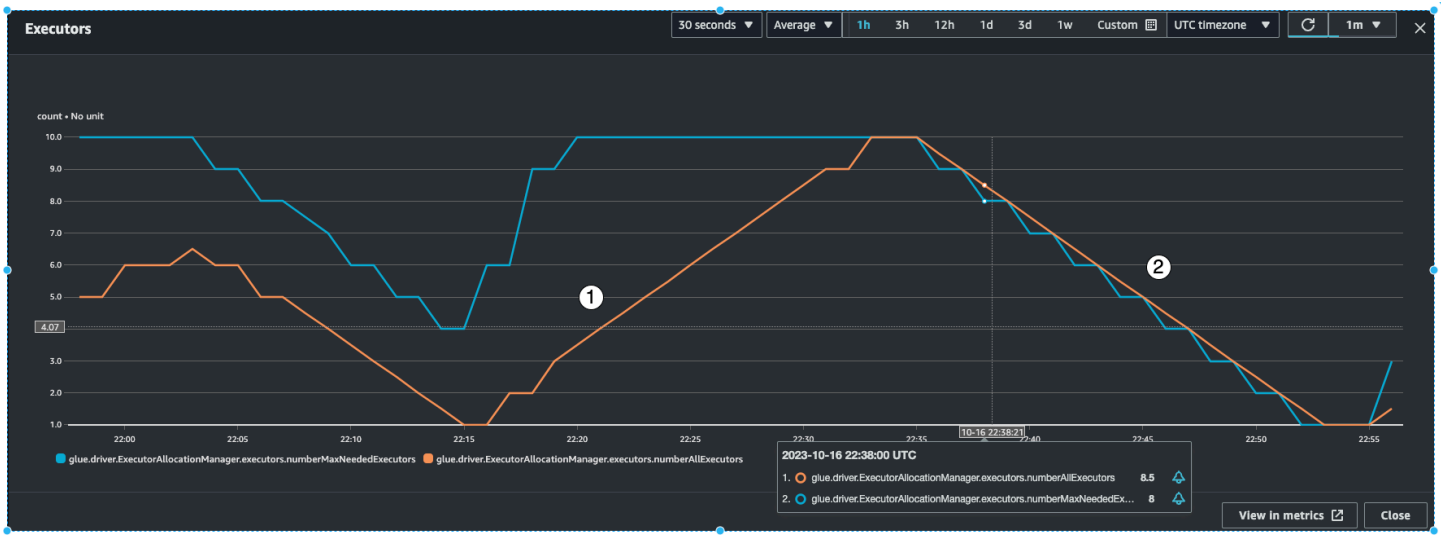
Autoscaling metrics

When your input traffic is spiky, then you should consider enabling autoscaling and specify the max workers. With that you get two additional metrics, `numberAllExecutors` and `numberMaxNeededExecutors`.

- **numberAllExecutors** is the number of actively running job executors

- **numberMaxNeededExecutors** is the number of maximum (actively running and pending) job executors needed to satisfy the current load.

These two metrics will help you understand if your autoscaling is working correctly.



AWS Glue will monitor the `batchProcessingTimeInMs` metric over a few micro-batches and do one of two things. It will scale-out the executors, if `batchProcessingTimeInMs` is closer to the `windowSize`, or scale-in the executors, if `batchProcessingTimeInMs` is comparatively lower than `windowSize`. Also, it will use an algorithm for step-scaling the executors.

- indicator #1 shows you how the active executors scaled up to catch up with the max needed executors so as to process the load.
- indicator #2 shows you how the active executers scaled in since the `batchProcessingTimeInMs` was low.

You can use these metrics to monitor current executor-level parallelism and adjust the number of max workers in your auto-scaling configuration accordingly.

How to get the best performance

Spark will try to create one task per shard, to read from, in the Amazon Kinesis stream. The data in each shard becomes a partition. It will then distribute these tasks across the executors/workers, depending of the number of cores on each worker (the number of cores per worker depends on the worker type you select `G.025X`, `G.1X`, etc). However it is non-deterministic how the tasks are

distributed. All tasks are executed in parallel on their respective cores. If there are more shards than the number of available executor cores, the tasks are queued up.

You can use a combination of the above metrics and the number of shards, to provision your executors for a stable load with some room for bursts. It is recommend that you run a few iterations of your job in order to determine the approximate number of workers. For an unstable/spiky workload you can do the same by setting up autoscaling and max workers.

Set the `windowSize` as per the SLA requirement of your business. For example, if your business requires that the processed data cannot be more than 120 seconds stale, then set your `windowSize` to at least 60 seconds such that your average consumer lag is less than 120 seconds (refer to the section on consumer lag above). From there depending on the `numRecords` and number of shards, plan for the capacity in DPUs making sure your `batchProcessingTimeInMs` is less than 70% of your `windowSize` most of the time.

> **Note**
>
> Hot shards can cause data skew which means that some shards/partitions are much bigger than the others. This may cause some tasks that are running in parallel to take longer time causing straggler tasks. As a result, the next batch can't start until all tasks from the previous one complete, this will impact the `batchProcessingTimeInMillis` and the max lag.

Zero-ETL integrations

Zero-ETL is a set of fully managed integrations by AWS that minimizes the need to build ETL data pipelines for common ingestion and replication use cases. It makes data available in Lakehouse architecture of Amazon SageMaker and Amazon Redshift from multiple operational, transactional, and application sources. Currently AWS Glue Zero-ETL supports DynamoDB, Oracle Database@AWS and SaaS sources like Salesforce, SAP, Zendesk as sources. With zero-ETL integration, you have fresher data for analytics, AI/ML, and reporting. You get more accurate and timely insights for use cases like business dashboards, optimized gaming experience, data quality monitoring, and customer behavior analysis. You can make data-driven predictions with more confidence, improve customer experiences, and promote data-driven insights across the business.

Amazon Redshift is a fast, fully managed, petabyte-scale data warehouse service that makes it simple and cost-effective to efficiently analyze all your data using your existing business intelligence tools.

Lakehouse architecture of Amazon SageMaker unifies all your data across Amazon Simple Storage Service (Amazon S3) data lakes and Amazon Redshift data warehouses, helping you build powerful analytics and AI/ML applications on a single copy of data. Lakehouse architecture of Amazon SageMaker gives you the flexibility to access and query your data in-place with all Apache Iceberg compatible tools and engines. With SageMaker Lakehouse, you also have the flexibility to access and query your data in-place with Apache Iceberg compatible tools and engines. Additionally, you can secure your data with integrated, fine-grained access controls, that are enforced across all your data in all analytic tools and engines. Define permissions once and confidently share data across your organization.

Zero-ETL capabilities in AWS Glue

Zero-ETL integrations in AWS Glue simplify data ingestion and replication from AWS data services and third-party applications to AWS destinations.

AWS services supported as zero-ETL sources in AWS Glue include:

- Amazon DynamoDB
- Oracle at AWS, ODB

Third-party applications supported as zero-ETL sources in AWS Glue include:

- Facebook Ads
- Instagram Ads
- Salesforce
- Salesforce Marketing Cloud Account Engagement
- SAP OData
- ServiceNow
- Zendesk
- Zoho CRM

Self-managed databases supported as zero-ETL sources in AWS Glue include:

- Oracle
- SQL Server
- MySQL
- PostgreSQL

For more information about zero-ETL integrations from self-managed sources, see AWS zero-ETL integration for self-managed database sources.

AWS services supported by Zero-ETL targets in AWS Glue include:

- General purpose Amazon S3 bucket via Lakehouse architecture of Amazon SageMaker
- Amazon S3 Tables via Lakehouse architecture of Amazon SageMaker
- Redshift Managed Storage via Lakehouse architecture of Amazon SageMaker
- Amazon Redshift Datawarehouse

> **Note**
>
> For self-managed database sources, you can replicate data only to an Amazon Redshift data warehouse. Other targets are not supported.

Configuring a source for a zero-ETL integration

Setting up an integration requires some prerequisites on the source such as configuring IAM roles or policies which AWS Glue uses to access data from the source (in order to write to the target), the use of KMS keys to encrypt the data in intermediate location, etc.

Topics

- Configuring Amazon DynamoDB source
- Configuring connection (SaaS) source
- Setting up Oracle Database at AWS as source

Configuring Amazon DynamoDB source

To access data from your source Amazon DynamoDB table, AWS Glue requires access to describe the table and export data from it. Amazon DynamoDB recently introduced a feature which allows configuring a Resource Based Access (RBAC) policy.

The following example Resource Based Access (RBAC) Policy uses a wild card (*) for integration:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "1111",
      "Effect": "Allow",
      "Principal": {
        "Service": "glue.amazonaws.com"
      },
      "Resource": "*",
      "Action": [
        "dynamodb:ExportTableToPointInTime",
        "dynamodb:DescribeTable",
        "dynamodb:DescribeExport"
      ],
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": "111122223333"
        },
        "ArnLike": {
          "aws:SourceArn": "arn:aws:glue:us-east-1:111122223333:integration:*"
```

```
        }
      }
    }
  ]
}
```

- For the Amazon DynamoDB table that you want to replicate, paste the above RBAC policy template into **Resource-based policy for table** and fill in the fields.
- If you want to make the policy restrictive, you must update the policy after creating the integration and specify the full `integrationArn` and use the `StringEquals` condition instead of `StringLike`.
- Make sure that Point-in-time recovery (PITR) is enabled for the Amazon DynamoDB table.
- Make sure that you add `Describe Export` to the Resource Based Access (RBAC) policy.

You can also add the RBAC policy to the table using the following command:

```
aws dynamodb put-resource-policy \
--resource-arn arn:aws:dynamodb:region:account-id:table/ddb-table-name \
--policy file://resource-policy-with-condition.json \
--region region
```

To verify that policy is applied correctly, use the following command to get the resource policy for a table:

```
aws dynamodb get-resource-policy \
--resource-arn arn:aws:dynamodb:region:account-id:table/ddb-table-name \
--region region
```

Configuring connection (SaaS) source

Prerequisites for setting up an integration

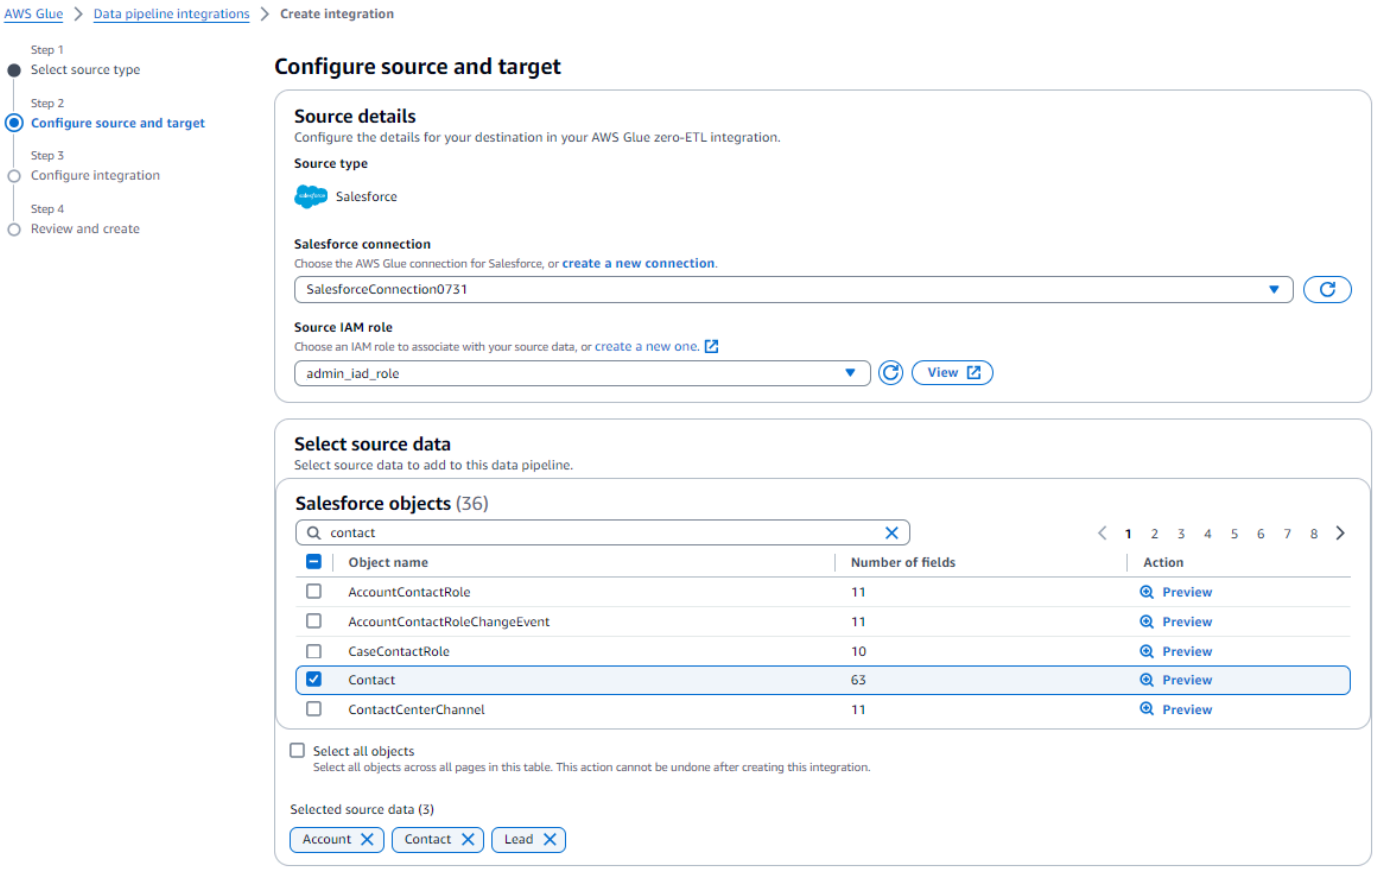
Before creating a zero-ETL integration from SaaS sources, you need to complete the following setup tasks:

- Create a AWS Glue connection with SaaS source.
- Create the source role to provide access to connection.
- Associate the role with the connection.

Configuring Salesforce source

To create a connection for a Salesforce source, see Connecting to Salesforce.

Once you've created the connection, you can specify the source data to replicate.



Using your zero-ETL integration you can perform DDL operations for supported entities. For a list of entities which are not supported, see Unsupported entities and fields for Salesforce.

Additional Salesforce Configuration

Salesforce Zero-ETL needs Lake Formation permission on AWS Glue database, otherwise it will get `IngestionFailed` from the Log with the following error:

```
"errorMessage": "Insufficient lake formation permissions on Target Glue database."
```

Unsupported entities and fields for Salesforce

The following Salesforce entities or fields are unsupported for use in a zero-ETL integration with a Salesforce source.

```
AccountChangeEvent, AccountContactRoleChangeEvent, AccountHistory, AccountShare,
 ActiveFeatureLicenseMetric, ActivePermSetLicenseMetric, ActiveProfileMetric,

Configuring a Salesforce Marketing Cloud Account Engagement source

To create a connection for a Salesforce Marketing Cloud Account Engagement source, see Connecting to Salesforce Marketing Cloud Account Engagement.

Using your zero-ETL integration you can perform DDL operations for the following supported entities:

Entity label	Entity name
Campaign	campaign
List	list
Dynamic Content	dynamic-content
List Membership	list-membership
Prospect	prospect
User	user
EmailTemplate	email-template
EngagementStudioProgram	engagement-studio-program
Landing Page	landing-page
List Email	list-email

Configuring an SAP OData source

To create a connection for an SAP OData source, see Connecting to SAP OData.

Zero-ETL integrations with an SAP OData source now supports entities starting with `EntityOf`. The ability to override the primary key is currently supported only for SAPOData `EntityOf` objects. Once this property has been set, it cannot be modified.

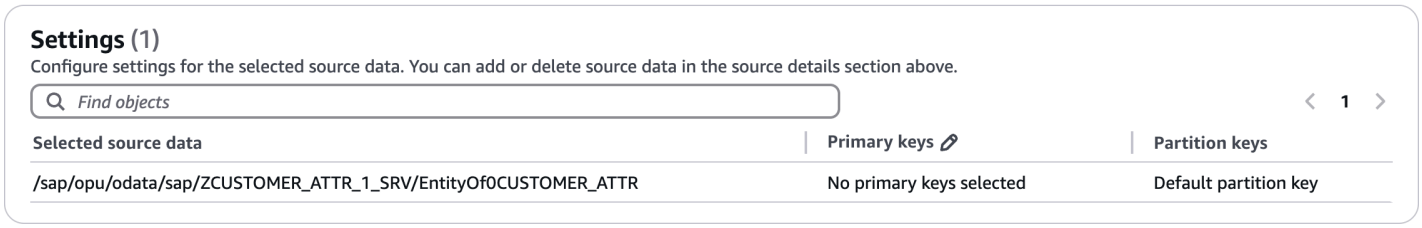
Support for special SAP entities

AWS Glue zero-ETL supports SAP OData entities that use SAP's Operational Data Provisioning (ODP) framework as well as those that do not use the ODP framework (non-ODP entities). The list of supported entities includes: ODP_SAP (Business Warehouse or BW extractors), ODP_CDS (Core Data Services or CDS Views) and non-ODP based OData services for SAP APIs. AWS Glue zero-ETL supports full snapshot and incremental change data capture for ODP and non-ODP SAP entities.

For ODP entities, incremental changes are captured using delta links. For non-ODP entities, if a queryable field that can be used for timestamp based ingestion is selected, then zero-ETL will use that field for incremental ingestion.

While ingesting data from SAP entities using AWS Glue zero-ETL, the following things should be noted:

- Zero-ETL can only ingest SAP entities which have been configured for GET_ENTITYSET method in SAP.
- For non-ODP SAP entities, if a timestamp field is not selected for incremental updates, AWS Glue zero-ETL supports a full data extraction and replication with upserts only (no deletions).
- For ODP extractor entities, we determine the valid primary key sets during data processing. Other SAP entities require an extra step of providing the valid primary key set as input, specifically SAP entities that start with `EntityOf`. When an `EntityOf` entity is selected, you will be directed to provide the set of primary keys.



Configuring a ServiceNow source

To create a connection for a ServiceNow source, see Connecting to ServiceNow.

Unsupported entities and fields for ServiceNow

The following ServiceNow entities or fields are unsupported for use in a zero-ETL integration with a ServiceNow source.

```

Price Books	price-book	Y	Y	Y	Y	Y	Y

Configuring a Facebook Ads source

To create a connection for a Facebook Ads source, see Connecting to Facebook Ads.

Using your zero-ETL integration you can perform the following DDL operations for supported entities:

Entity label	Entity name	Create supported	Update supported	Delete supported
Adset	*/adsets	Y	Y	Y
Campaign	*/campaigns	Y	Y	Y
Ads	*/ads	Y	Y	Y

Configuring an Instagram Ads source

To create a connection for an Instagram Ads source, see Connecting to Instagram Ads.

Using your zero-ETL integration you can perform the following DDL operations for supported entities:

Entity name	Create supported	Update supported	Delete supported
*/adsets	Y	Y	Y
*/campaigns	Y	Y	Y
*/ads	Y	Y	Y

Setting up the source role for integration

Create a source role to allow the zero-ETL integration to access your connection. This is applicable only for SaaS sources. This is a prerequisite for creating integrations with SaaS sources.

> **Note**
>
> To restrict access to only a few connections, you can first create the connection to obtain the connection ARN. See Configuring a source for a zero-ETL integration.

Create a role which has permissions for the integration to access the connection:

```

                "glue:RefreshOAuth2Tokens"
            ],
            "Resource": [
                "*"
            ]
        },
        {
            "Sid": "CloudWatchLogging",
            "Effect": "Allow",
            "Action": [
                "logs:CreateLogGroup",
                "logs:CreateLogStream",
                "logs:PutLogEvents"
            ],
            "Resource": [
                "*"
            ]
        }
    ]
}
```

Trust policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "glue.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

Associate the role with the connection using the AWS Glue CLI or API:

```
aws glue create-integration-resource-property \
--resource-arn arn:aws:glue:us-east-1:123456789012:connection/connectionName \
--source-processing-properties "{\"RoleArn\" :
 \"arn:aws:iam::123456789012:role/rolename\"}" \
--region us-east-1
```

Setting up Oracle Database at AWS as source

Currently AWS Glue supports Oracle Databases at AWS as source and Redshift as target. The details of the setup can be found at Setting up zero-ETL for Oracle Database at AWS.

Configuring a target for a zero-ETL integration

There are several options offered by AWS Glue when configuring a target for a zero-ETL integration. The target may be an encrypted Amazon Redshift data warehouse or a Lakehouse architecture of Amazon SageMaker.

Before selecting the target for the zero-ETL integration, you need to configure one of the following target resources. The configuration options for a target in a zero-ETL integration include:

- A general purpose Amazon S3 bucket using the lakehouse architecture of Amazon SageMaker. See Configuring a general purpose S3 bucket target.

- An Amazon S3 Tables bucket using the lakehouse architecture of Amazon SageMaker. See Configuring an Amazon S3 Tables bucket target.
- An Amazon Redshift Managed Storage using the lakehouse architecture of Amazon SageMaker. See Configuring an Amazon Redshift Managed Storage target.
- An Amazon Redshift data warehouse identified by a Redshift namespace. See Configuring an Amazon Redshift data warehouse target.

> **Note**
>
> You cannot modify the target of a zero-ETL integration after creation.

Configuring a general purpose S3 bucket target

This section describes the prerequisites and setup steps for configuring a general purpose S3 bucket as storage for your target in a zero-ETL integration, using the Lakehouse architecture of Amazon SageMaker.

Before creating a zero-ETL integration with the Lakehouse architecture of Amazon SageMaker using general purpose S3 storage, you need to complete the following setup tasks:

- Set up an AWS Glue database
- Provide Catalog RBAC policy
- Create target IAM role
- Associate target role, KMS (optional) and Connection (optional) with target resource
- (Optional) Configure target table properties

Setting up an AWS Glue database

To set up a target database in the Data Catalog with an Amazon S3 general purpose bucket location:

1. In the AWS Glue console home page, select **Database** under Data Catalog.
2. Choose **Add database** in the top right corner. If you have already created a database, make sure that the location with Amazon S3 URI is set for the database.

3. Enter a name and **Location** (Amazon S3 URI). Note that the location is required for the zero-ETL integration. Click **Create database** when done.

> **Note**
>
> The general purpose Amazon S3 bucket must be in the same region as the AWS Glue database.

For information on creating a new database in AWS Glue, see Getting started with the Data Catalog.

You can also use the `create-database` CLI to create the database in AWS Glue. Note that the `LocationUri` in `--database-input` is required.

Optimizing Iceberg tables

Once a table is created by AWS Glue in the target database, you can enable the compaction to speed up queries in Amazon Athena. For information on setting up the resources (IAM Role) for compaction, see Table optimization prerequisites.

For more information on setting up compaction on the AWS Glue table created by the integration, see Optimizing Iceberg tables.

Providing a catalog Resource Based Access (RBAC) policy

For integrations that use an AWS Glue database, add the following permissions to the catalog RBAC Policy to allow for integrations between source and target.

> **Note**
>
> For cross-account integrations, both the user creating the integration role policy and catalog resource policy need to allow `glue:CreateInboundIntegration` on the resource. For same-account, either a resource policy or role policy allowing `glue:CreateInboundIntegration` on the resource is sufficient. Both scenarios do still need to allow `glue.amazonaws.com` to `glue:AuthorizeInboundIntegration`.

You can access the **Catalog settings** under **Data Catalog**. Then provide the following permissions and fill in the missing information.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Principal": {
        "AWS": [
            "arn:aws:iam::123456789012:user/Alice"
        ]
      },
      "Effect": "Allow",
      "Action": [
        "glue:CreateInboundIntegration"
      ],
      "Resource": [
          "arn:aws:glue:us-east-1:111122223333:catalog",
          "arn:aws:glue:us-east-1:111122223333:database/database-name"
      ],
      "Condition": {
        "StringLike": {
        "aws:SourceArn": "arn:aws:dynamodb:us-east-1:444455556666:table/table-name"
        }
      }
    },
    {
      "Principal": {
        "Service": [
          "glue.amazonaws.com"
        ]
      },
      "Effect": "Allow",
      "Action": [
        "glue:AuthorizeInboundIntegration"
      ],
      "Resource": [
          "arn:aws:glue:us-east-1:111122223333:catalog",
          "arn:aws:glue:us-east-1:111122223333:database/database-name"
      ],
      "Condition": {
        "StringEquals": {
        "aws:SourceArn": "arn:aws:dynamodb:us-east-1:444455556666:table/table-name"
```

```
        }
      }
    }
  ]
}
```

Creating a target IAM role

Create a target IAM role with the following permissions and trust relationships:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": "s3:ListBucket",
            "Resource": "arn:aws:s3:::amzn-s3-bucket",
            "Effect": "Allow"
        },
        {
            "Action": [
                "s3:GetObject",
                "s3:PutObject",
                "s3:DeleteObject"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/prefix/*",
            "Effect": "Allow"
        },
        {
            "Action": [
                "glue:GetDatabase"
            ],
            "Resource": [
                "arn:aws:glue:us-east-1:111122223333:catalog",
                "arn:aws:glue:us-east-1:111122223333:database/database-name"
            ],
            "Effect": "Allow"
        },
        {
            "Action": [
                "glue:CreateTable",
                "glue:GetTable",
                "glue:GetTables",
                "glue:DeleteTable",
```

```
                "glue:UpdateTable",
                "glue:GetTableVersion",
                "glue:GetTableVersions",
                "glue:GetResourcePolicy"
            ],
            "Resource": [
                "arn:aws:glue:us-east-1:111122223333:catalog",
                "arn:aws:glue:us-east-1:111122223333:database/database-name",
                "arn:aws:glue:us-east-1:111122223333:table/database-name/*"
            ],
            "Effect": "Allow"
        },
        {
            "Action": [
                "cloudwatch:PutMetricData"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "cloudwatch:namespace": "AWS/Glue/ZeroETL"
                }
            },
            "Effect": "Allow"
        },
        {
            "Action": [
                "logs:CreateLogGroup",
                "logs:CreateLogStream",
                "logs:PutLogEvents"
            ],
            "Resource": "*",
            "Effect": "Allow"
        }
    ]
}
```

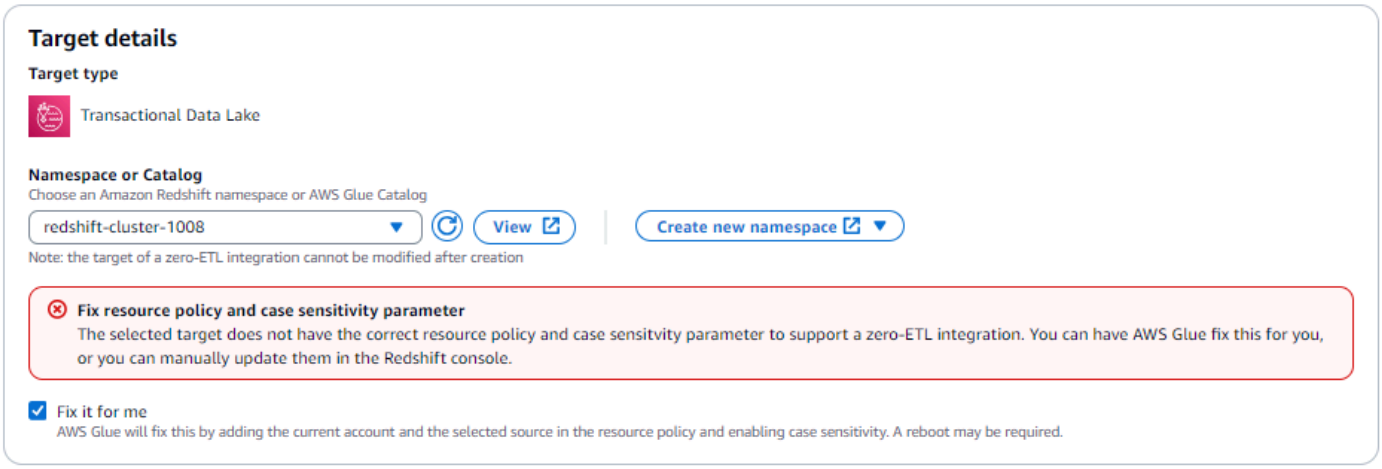
Add the following trust policy to allow the AWS Glue service to assume the role:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
```

```
      "Principal": {
        "Service": "glue.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

Associate target role, KMS (optional) and Connection (optional) with target resource

Associate the above target role with the target resource i.e. AWS Glue Database. Optionally, KMS for encrypting the data before storing in target iceberg table and Connection ARN for accessing the S3 bucket can be configured for the target AWS Glue database. This will allow AWS Glue to access data on the target S3 location using the provided role and optionally encrypt using the provided KMS key. If the target S3 bucket is configured to be accessible using a certain VPC, the connection ARN can be associated to allow AWS Glue to run the processing inside that VPC. For more information on setting up a VPC, see Create a VPC.



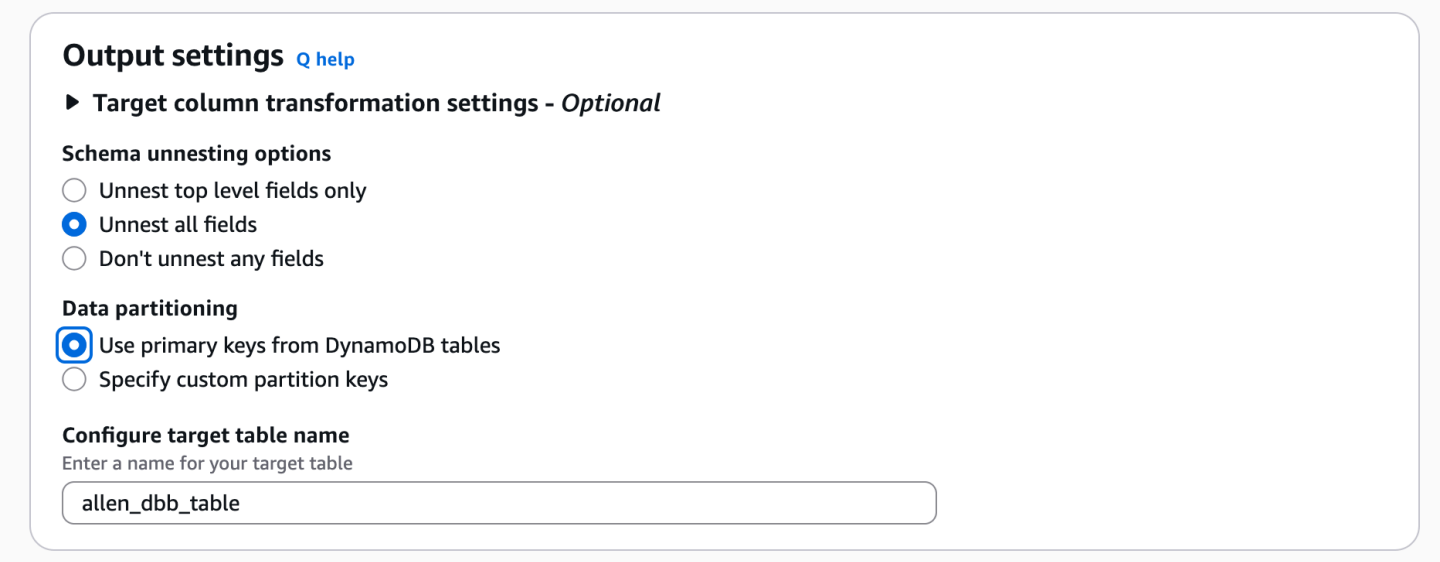
Or using the AWS Glue CLI / API:

```
aws glue create-integration-resource-property \
--resource-arn arn:aws:glue:us-east-1:123456789012:database/database-name \
--target-processing-properties '{"RoleArn":
 "arn:aws:iam::123456789012:role/gmi_target_role"}' \
--region us-east-1
```

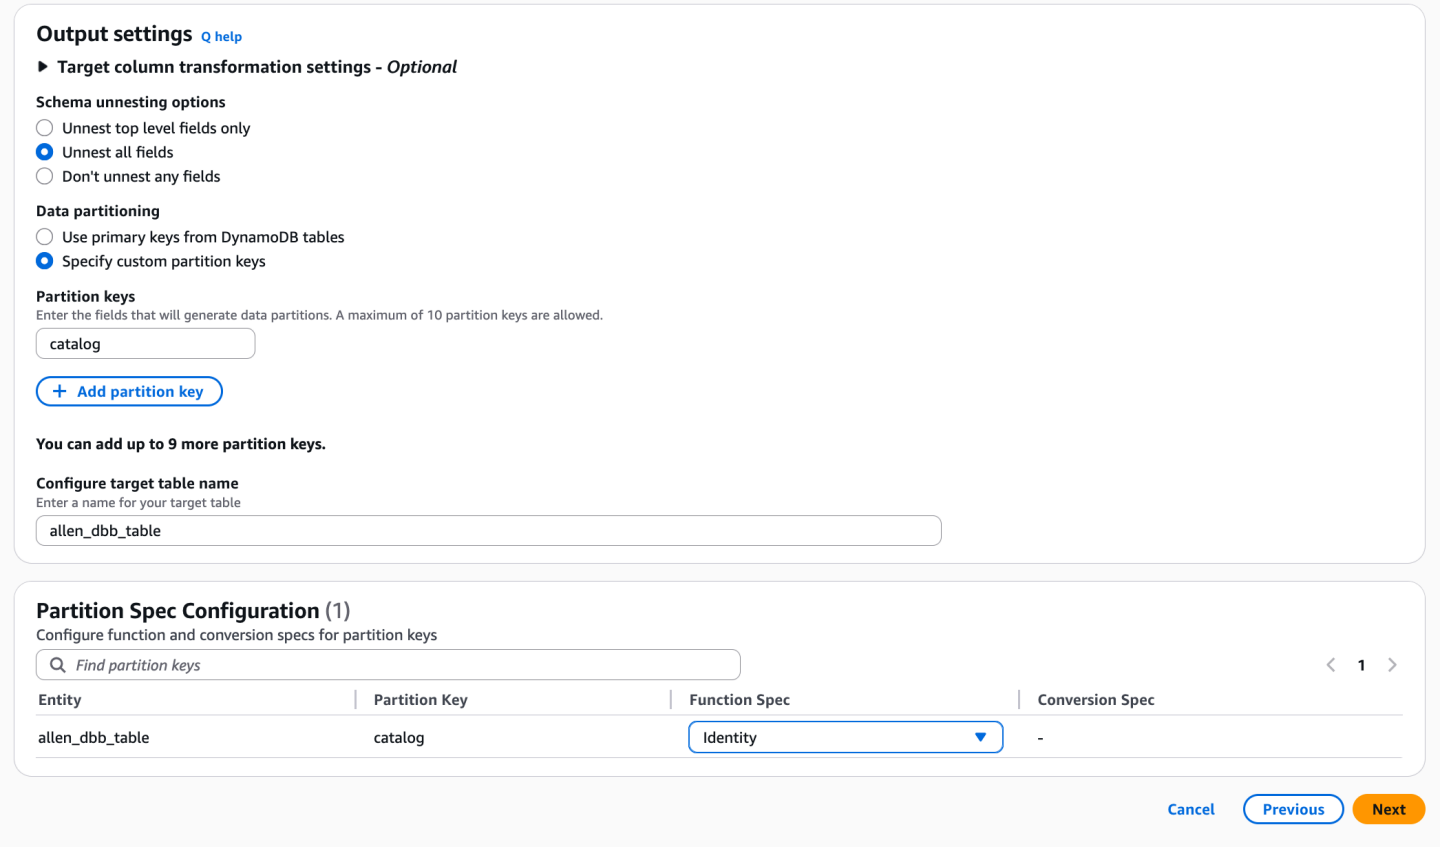
(Optional) Configure target table properties

Optionally, target table properties can be configured for the target tables that are going to be synced to the target.

You can configure these settings in the **Output settings** section of the integration creation workflow in the AWS Glue console:



When you select **Specify custom partition keys**, you can configure partition keys and their function and conversion specs:



If the source and target are in the same account, then this configuration can be done as part of integration creation workflow from the AWS Glue console UI. But if the target is in different account, then this configuration is required to be complete before creating the integration. When using the CLI or API, this should be done before invoking the Create-Integration API even when both source and target are in the same account. AWS Glue console UI just encapsulates this API call for the same account scenario.

If this is not configured, then default values will be used when syncing the table. This configuration can also be changed anytime after the integration creation as well.

> **Note**
>
> If this property is updated after the integration is created, then it could trigger a full table resync when the updated configuration conflicts with the existing configuration. For example, updating the table "un-nesting" from 'No-Unnest' to 'Full-Unnest', or changing the partition column.

Using CLI or API:

```
aws glue create-integration-table-properties \
--resource-arn arn:aws:glue:us-east-1:123456789012:database/database-name \
--table-name table-name \
--target-table-config '{
        "UnnestSpec":"TOPLEVEL"|"FULL"|"NOUNNEST",
        "PartitionSpec":
            [
                {
                    "FieldName":"string",
                    "FunctionSpec":"string",
                    "ConversionSpec":"string"}
                    ...
             ],
         "TargetTableName":"string"
     }' \
--region us-east-1
```

After configuring the Lakehouse architecture of Amazon SageMaker with general purpose Amazon S3 bucket storage, you can proceed to Configuring the integration with your target to complete the integration setup.

Configuring an Amazon S3 Tables bucket target

This section describes the prerequisites and setup steps for configuring Amazon S3 Tables as a target for your zero-ETL integration, using the lakehouse architecture of Amazon SageMaker.

Before creating a zero-ETL integration with Amazon S3 Tables as a target, you need to complete the following setup tasks:

- Setup Amazon S3 tables bucket (and analytics services integration)
- Provide Catalog RBAC policy
- Create target IAM role
- Associate target role, KMS (optional) and Connection (optional) with target resource
- (Optional) Configure target table properties

Setup Amazon S3 tables bucket (with analytics services integration)

1. Create an S3 table bucket in your account by following the instructions at Getting started with Amazon S3 Tables.

2. Enable Analytics integrations with your S3-Table bucket by following these instructions: Integrating AWS services with Amazon S3 Tables.
3. This will create a new S3-Table Catalog in AWS Lake Formation.

Provide Catalog RBAC Policy

The following permissions must be added to the Catalog RBAC Policy to allow for integrations between source and Amazon S3 tables catalog target.

Target AWS Glue Catalog resource policy needs to include AWS Glue Service permissions to `AuthorizeInboundIntegration`. Additionally, `CreateInboundIntegration` permission is required either on the source principal creating the integration or in the target AWS Glue resource policy.

> **Note**
>
> For cross-account scenario, both source principal as well as target AWS Glue Catalog resource policy need to include `glue:CreateInboundIntegration` permissions on the resource.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Principal": {
        "AWS": [
            "arn:aws:iam::123456789012:user/Alice"
        ]
      },
      "Effect": "Allow",
      "Action": [
        "glue:CreateInboundIntegration"
      ],
      "Resource": [
          "arn:aws:glue:us-east-1:111122223333:catalog/s3tablescatalog/*"
      ],
      "Condition": {
        "StringLike": {
        "aws:SourceArn": "arn:aws:dynamodb:us-east-1:444455556666:table/table-name"
```

```
        }
      }
    },
    {
      "Principal": {
        "Service": [
          "glue.amazonaws.com"
        ]
      },
      "Effect": "Allow",
      "Action": [
        "glue:AuthorizeInboundIntegration"
      ],
      "Resource": [
      "arn:aws:glue:us-east-1:111122223333:catalog/s3tablescatalog/*"
      ],
      "Condition": {
        "StringEquals": {
        "aws:SourceArn": "arn:aws:dynamodb:us-east-1:444455556666:table/table-name"
        }
      }
    }
  ]
}
```

Note

Replace *s3tablescatalog* with the parent catalog name of your S3 tables (if different). Default value (when hosting S3-Table Catalog in the same account) for this is `s3tablescatalog`.

Create target IAM Role

Create a target IAM role with the following permissions and trust relationships:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "s3tables:ListTableBuckets",
```

```
        "s3tables:GetTableBucket",
        "s3tables:GetTableBucketEncryption",
        "s3tables:GetNamespace",
        "s3tables:CreateNamespace",
        "s3tables:ListNamespaces",
        "s3tables:CreateTable",
        "s3tables:DeleteTable",
        "s3tables:GetTable",
        "s3tables:GetTableEncryption",
        "s3tables:ListTables",
        "s3tables:GetTableMetadataLocation",
        "s3tables:UpdateTableMetadataLocation",
        "s3tables:GetTableData",
        "s3tables:PutTableData"
      ],
      "Resource": "arn:aws:s3tables:us-east-1:111122223333:bucket/s3-table-bucket",
      "Effect": "Allow"
    },
    {
      "Action": [
        "cloudwatch:PutMetricData"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "cloudwatch:namespace": "AWS/Glue/ZeroETL"
        }
      },
      "Effect": "Allow"
    },
    {
      "Action": [
        "logs:CreateLogGroup",
        "logs:CreateLogStream",
        "logs:PutLogEvents"
      ],
      "Resource": "*",
      "Effect": "Allow"
    }
  ]
}
```

Add the following trust policy in the target IAM role to allow AWS Glue Service to assume it:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "glue.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

Note

Make sure there is no explicit DENY statement for this target IAM role in the S3-Tables bucket resource policy. An explicit DENY would override any ALLOW permissions and prevent the integration from working properly.

Associate target role, KMS (optional) and Connection (optional) with target resource

Associate the above target role with the target resource. Optionally, KMS for encrypting the data before storing in target iceberg table and Connection ARN for accessing target S3 bucket can be configured. If the target S3 bucket is configured to be accessible using a certain VPC, the connection ARN can be associated to allow AWS Glue to run the processing inside that VPC. For more information on setting up a VPC, see Create a VPC.

Using the AWS Glue CLI / API:

```
aws glue create-integration-resource-property \
--resource-arn arn:aws:glue:us-east-1:123456789012:catalog/s3tablescatalog/S3 table
 bucket name \
--target-processing-properties '{
                    "RoleArn": "arn:aws:iam::123456789012:role/target_role"
                }' \
--region us-east-1
```

(Optional) Configure target table properties

Optionally, target table properties can be configured for the target tables that are going to be synced to the target. The same rules apply as described in the general purpose S3 target section.

Using CLI or API:

```
aws glue create-integration-table-properties \
--resource-arn arn:aws:glue:us-east-1:123456789012:catalog/s3tablescatalog/S3 table
 bucket name \
--table-name table-name \
--target-table-config '' \
--region us-east-1
```

After configuring the Amazon S3-Tables storage using Lakehouse architecture of Amazon SageMaker, you can proceed to Configuring the integration with your target to complete the integration setup.

Configuring an Amazon Redshift Managed Storage target

This section describes the prerequisites and setup steps for configuring an Amazon Redshift managed storage (RMS) as a target for your zero-ETL integration, using the lakehouse architecture of Amazon SageMaker.

Before creating a zero-ETL integration with a Lakehouse architecture of Amazon SageMaker using Redshift managed storage, you need to complete the following setup tasks:

- Set up an Amazon Redshift cluster or Serverless workgroup
- Register the Amazon Redshift integration with Lake Formation
- Create a managed catalog in Lake Formation
- Configure IAM permissions

Setting up Amazon Redshift managed storage

To set up Amazon Redshift managed storage for your zero-ETL integration:

- Create or use an existing Amazon Redshift cluster or Serverless workgroup. Make sure the target Amazon Redshift workgroup or cluster has the `enable_case_sensitive_identifier` parameter turned on for the integration to be successful. For more information on enabling

case sensitivity, see Turn on case sensitivity for your data warehouse in the Amazon Redshift management guide.

- Register an integration from Redshift into the catalog in AWS Lake Formation. See Registering Amazon Redshift clusters and namespaces to the Data Catalog.
- Create a federated or managed catalog in AWS Lake Formation. For more information, see:
  - Bringing Amazon Redshift data into the Data Catalog
  - Creating an Amazon Redshift managed catalog in the Data Catalog
- Configure IAM permissions for the target role. The role needs permissions to access both Redshift and Lake Formation resources. At minimum, the role should have:
  - Permissions to access the Redshift cluster or workgroup
  - Permissions to access the Lake Formation catalog
  - Permissions to create and manage tables in the catalog
  - CloudWatch and CloudWatch Logs permissions for monitoring

After configuring the Amazon SageMaker Lakehouse catalog with Amazon Redshift managed storage, you can proceed to Configuring the integration with your target to complete the integration setup.

Configuring an Amazon Redshift data warehouse target

This section describes the prerequisites and setup steps for configuring an Amazon Redshift data warehouse as a target for your zero-ETL integration.

Before creating a zero-ETL integration with an Amazon Redshift data warehouse target, you need to complete the following setup tasks:

- Set up an Amazon Redshift cluster or Serverless workgroup
- Configure case sensitivity
- Configure IAM permissions

Setting up the Amazon Redshift data warehouse

To set up an Amazon Redshift data warehouse for your zero-ETL integration:

1. Navigate to the Amazon Redshift console and click **Create cluster** or use an existing cluster. To create an Amazon Redshift cluster, see Creating a cluster. For Amazon Redshift Serverless,

click **Create workgroup**. To create an Amazon Redshift Serverless workgroup, see Creating a workgroup with a namespace.

2. If creating a new cluster, choose an appropriate cluster size and ensure your cluster is encrypted. For Serverless, configure the workgroup settings according to your requirements.
3. Make sure the target Amazon Redshift workgroup or cluster has the `enable_case_sensitive_identifier` parameter turned on for the integration to be successful. For more information on enabling case sensitivity, see Turn on case sensitivity for your data warehouse in the Amazon Redshift management guide.
4. Configure IAM permissions to allow the zero-ETL integration to access your Amazon Redshift data warehouse. You'll need to create an IAM role with the following permissions:
   - Permissions to access the Amazon Redshift cluster or workgroup
   - Permissions to create and manage databases and tables in Amazon Redshift
   - CloudWatch and CloudWatch Logs permissions for monitoring
5. After the Amazon Redshift workgroup or cluster setup is complete, you need to configure your data warehouse for zero-ETL integrations. See Getting started with zero-ETL integrations in the Amazon Redshift Management Guide for more information.

> **Note**
>
> When using a Amazon Redshift data warehouse as a target, the integration creates a schema in the specified database to store the replicated data. The schema name is derived from the integration name.

> **Note**
>
> The target Amazon Redshift workgroup or cluster must have the `enable_case_sensitive_identifier` parameter turned on for the integration to be successful.

After configuring the Amazon Redshift data warehouse, you can proceed to Configuring the integration with your target to complete the integration setup.

Configuring the integration with your target

After configuring the source and target resources, follow these steps to complete the integration setup:

1. Navigate to "Zero-ETL integrations" page and start the integration creation workflow.
2. Select the source resource configured in the previous steps.
3. Select or specify the target resource (same account or cross account) configured in the previous steps.
4. Select the target IAM role configured previously.
5. Select the **Fix it for me** option (only available when the target is in same account).
   - For the regular Amazon S3 (AWS Glue Database) and S3-Table (Catalog) target, this will:
     - Apply an authorized service principal on the target Catalog resource policy.
     - Apply an authorized AWS Glue source Principal ARN to the target Catalog resource policy.
   - For the Amazon Redshift target, this will:
     - Apply an authorized service principal on the Amazon Redshift cluster or Serverless workgroup.
     - Apply an authorized AWS Glue source ARN to the Amazon Redshift cluster or Serverless workgroup.
     - Associate a new parameter group with `enable_case_sensitive_identifier = true`.

Use the following to create the integration via API or CLI: CreateIntegration API.

Configuring an integration

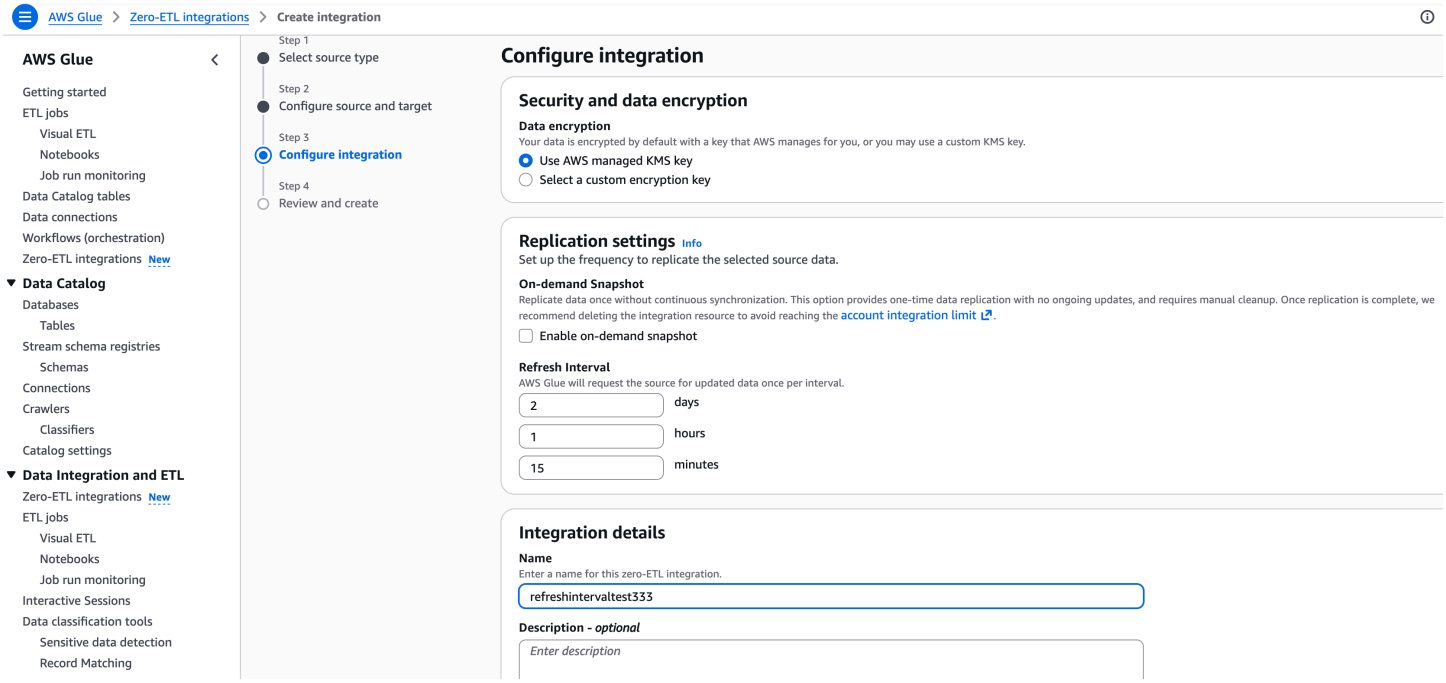
When setting up a zero-ETL integration, you can configure various parameters to control how data is synchronized between your source and target systems. The following settings are currently available for SaaS sources only.

Configuring Refresh Interval

You can configure the Refresh interval for integration for SaaS sources at the time of integration creation. The default value is 1 hour. You can configure the frequency at which CDC (Change Data Capture) pulls or incremental loads should occur. This provides flexibility to align the refresh rate

with your specific data update patterns, system load considerations, and performance optimization goals. Time increment can be set from 15 minutes to 8640 minutes (six days). The refresh interval cannot be modified after the integration is created when the target is Redshift. For other targets, the refresh interval can be modified after integration creation. For DynamoDB sources with refresh intervals of 24 hours or more, see Sequential daily batches for DynamoDB sources for details about sequential daily batch processing.

This can be done through console, by updating the refresh interval within Replication Settings.



The time increment can be set from 15 minutes to 8640 minutes (six days), allowing you to balance between data freshness and system resource utilization. Currently, the refresh interval is customizable for both DynamoDB and SaaS sources:

- **Minimum interval:** 15 minutes
- **Maximum interval:** 8640 minutes (6 days)
- **Default value:** 15 minutes for DynamoDB source and 60 minutes for SaaS source

Factors to consider when choosing a refresh interval:

- **Data volatility:** How frequently your source data changes
- **Business requirements:** How current your analytics data needs to be
- **Cost considerations:** More frequent updates may result in higher processing and storage costs

> **Note**
>
> RefreshInterval parameter defines frequency of trigger of CDC. The actual refresh frequency may be affected by the volume of changes in your source data and the processing capacity of the target system. Monitor your integration performance and adjust the refresh interval as needed to optimize for your specific use case.

Or through API by passing the `RefreshInterval` within IntegrationConfig as part of CreateIntegration Request. To modify the refresh interval programmatically, you can use the ModifyIntegration API with the IntegrationConfig parameter.

Sequential daily batches for DynamoDB sources

For zero-ETL integrations with an Amazon DynamoDB source, when you configure a refresh interval of 1440 minutes (24 hours) or greater, the integration uses sequential daily batch processing instead of a single export operation. This behavior is due to the DynamoDB export window limitation, which has a maximum export period of 24 hours.

When the refresh interval exceeds 24 hours, the integration operates as follows:

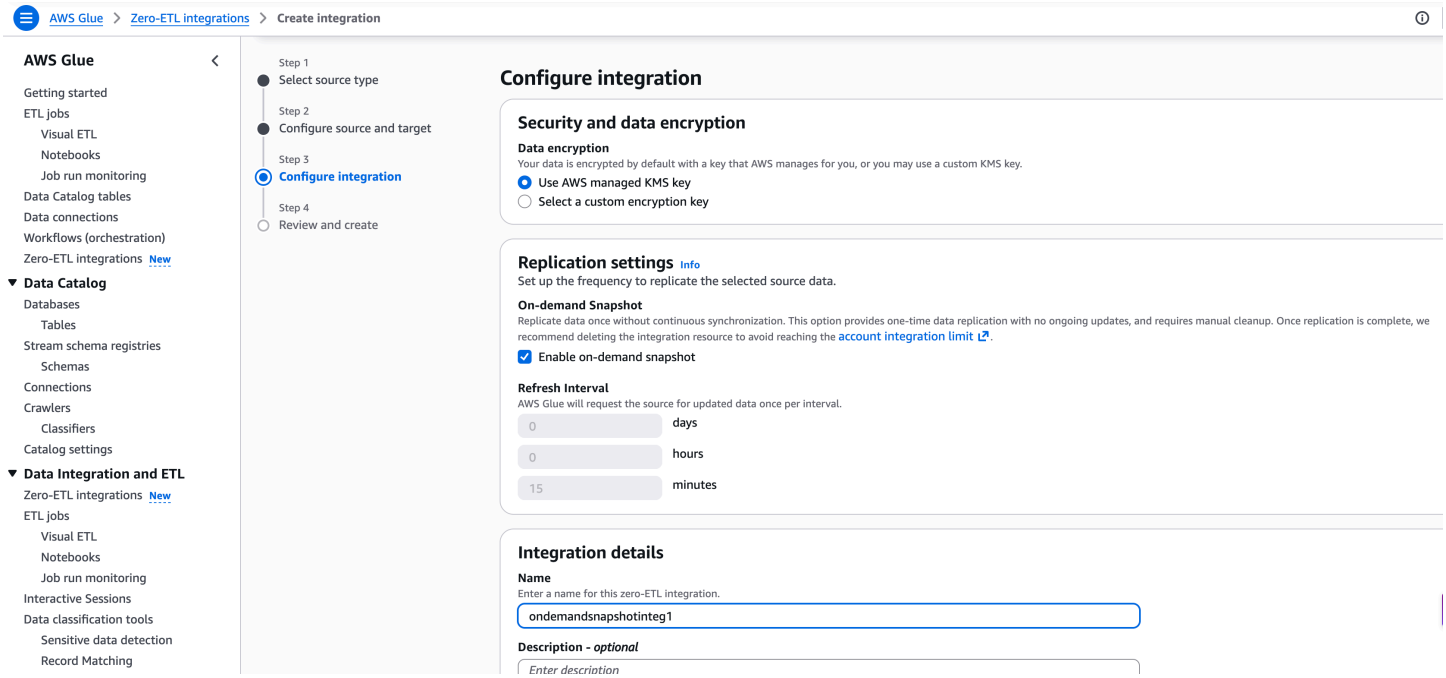
1. The CDC process waits for the full refresh interval duration (for example, 6 days for a 8640-minute interval).
2. After the refresh interval elapses, the integration performs multiple sequential DynamoDB exports, each covering up to a 24-hour window.
3. The CDC jobs process each batch sequentially to capture all changes that occurred during the refresh interval period.

For example, if you set a refresh interval of 8640 minutes (6 days), the integration will wait 6 days and then execute 6 or 7 sequential exports (1 tail export covering extra time spent on export operations) and CDC jobs to synchronize all changes from that period.

On-demand Snapshot

Zero-ETL by default includes continuous data capture (CDC) but if you have use cases to replicate full data once you can do so by using the On-demand Snapshot feature. The feature currently supported for only SaaS sources can be used to replicate data once without continuous synchronization. This option provides one-time data replication with no ongoing updates, and

requires manual cleanup. Once replication is complete, we recommend deleting the integration resource to avoid reaching the account integration limit.



Or through API by setting the `ContinuousSync` parameter to `false` within IntegrationConfig as part of CreateIntegration Request.

> **Note**
>
> The On-demand Snapshot setting cannot be modified after the integration is created. Choose this option carefully based on your data synchronization requirements.

Modifying Refresh interval

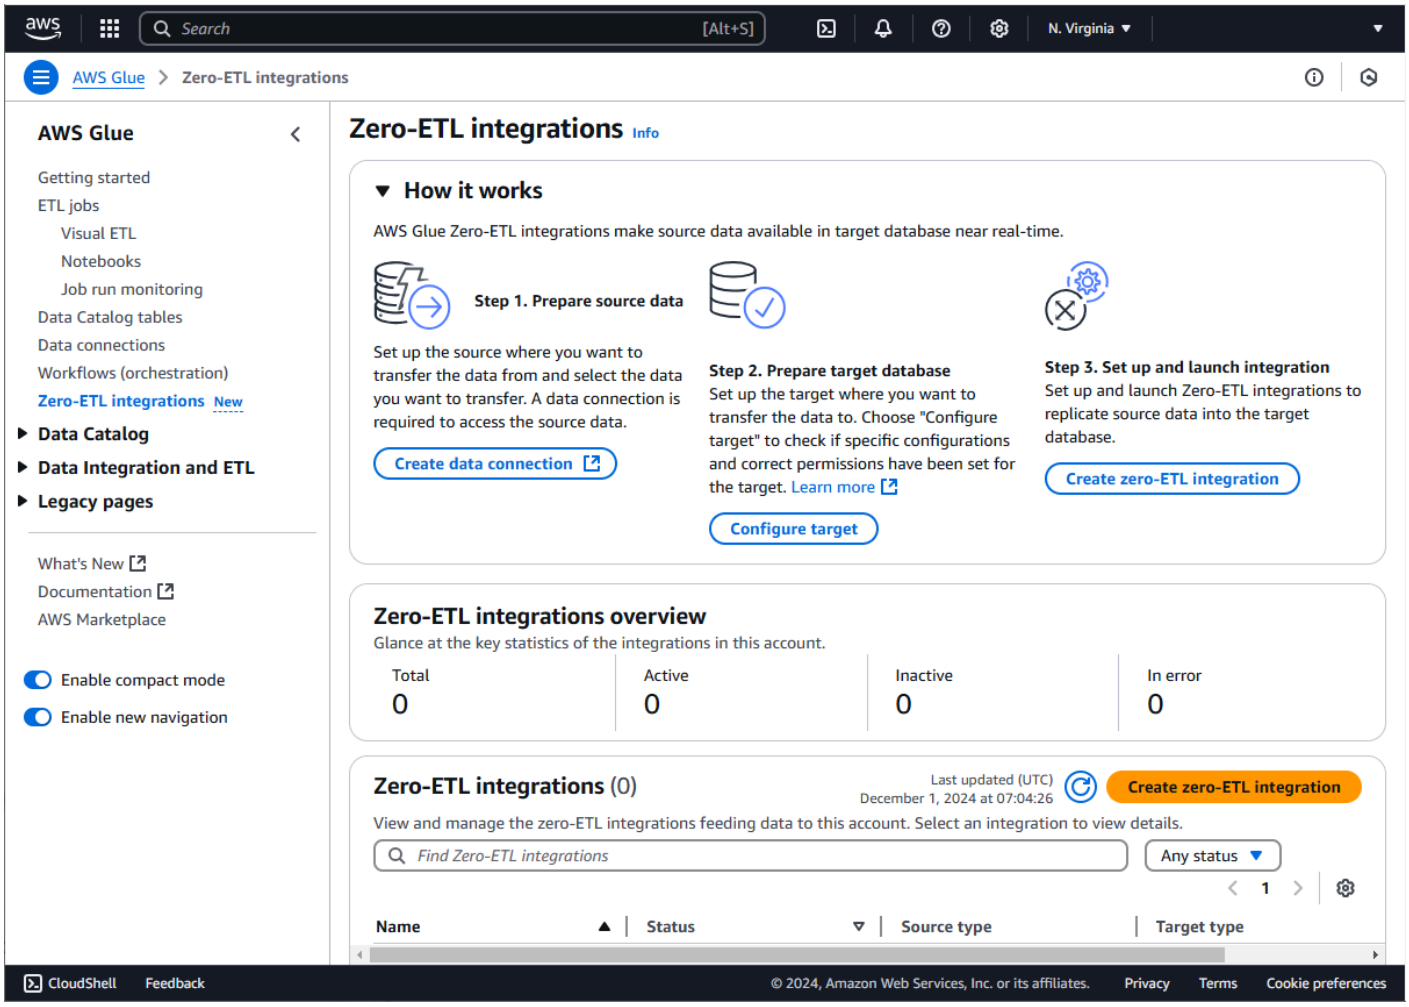
This feature is currently only available for AWS Glue targets and allows you to update the refresh interval for an existing integration.

Creating and managing integrations

Creating an integration

This section describes the general steps to create an integration. This example uses Amazon DynamoDB as a source.

1. On the AWS Glue console home page, select **Zero-ETL integrations**.
2. You can view all your integrations on the Zero ETL integration home page. To create a new integration, select **Create zero-ETL integration**.



3. You are prompted to select a **Source Type**. Select your source and click **Next**. Refer to the source configuration sections for SaaS integration sources.
4. In the **Configure source and target** page, select the tables or entities to replicate. For Amazon DynamoDB make sure the PITR and RBAC policy is configured.
5. Specify your integration target:
   - For an AWS Glue Data Catalog target, select the AWS Glue database you want to replicate the data to.
   - For an Amazon Redshift data warehouse target, select the Redshift cluster namespace or Redshift Serverless workgroup namespace.

   For more information, see Configuring the integration with your target.

6. Provide the **Target IAM Role** that you created in the prerequisites.
7. If you want to configure an optional **Target KMS Key** for your data being stored in the target, provide an enabled KMS Key. Likewise, if you want to configure a target network connection, select an AWS Glue connection.
8. The **Fix Target** button configures some of the steps in the Prerequisite section of this documentation. Namely it will 1) provide a Catalog RBAC Policy and 2) if no Amazon S3 URI is provided it will generate one for you, otherwise it will use the provided URI.
9. In the **Output setting** section of the **Configure source and target** page, select a schema unnesting option that you want for your data in the target. If you want to use customer partition keys for your data, select **Specify custom partition keys** and provide up to 10 keys. Otherwise, you can simply use the partition keys that are assigned to your DynamoDB table being replicated.
10. In the **Security and data encryption** section, you can provide a KMS key that will be used in the intermediary process of replicating your data to the target. Otherwise, an AWS managed KMS key will be used. Enter a name for the Zero ETL integration in **Integration details**.
11. Review and make sure that all the provided details are correct. Click **Create and launch integration** once everything has been confirmed.
12. In the Zero ETL home page, you can select the integration you created and the details for your integrations will appear. The "Status" indicates the state of your integration.

Modifying an integration

You can modify an existing integration.

1. Select **Edit** in the top right corner of your integration details page.
2. On the **Edit source and target** page you can change the Target IAM role and Target network connection. The other fields are not editable after integration creation. Click **Next**.
3. You can also edit the name and description of the integration in the **Edit integration and configuration** page. Click **Next**.
4. Review your edits and once confirmed, click **Update integration**.

Deleting an integration

Delete is a terminal state for an integration. Once deleted, the integration cannot be revived. Deleting an integration clears up all internal metadata and any intermediate stored data.

During this process any running tasks which are writing data to a target table are terminated. AWS Glue will not delete or cleanup the target AWS Glue database (in the Data Catalog) and the associated data in the Amazon S3 bucket in your account. You need to explicitly clean those up if required.

To delete an integration:

1. In the integration details page, click **Delete**.
2. Enter "Delete" and click **Delete**. Note: This is an irreversible action.
3. In the integration details page, the status shows "Deleting". Once the integration is actually deleted, it will no longer appear on the Zero ETL integration home page.

Integration states

Integration goes through various states from creation to deletion:

- `CREATING` - This is the first state when integration creation is initiated. In this state, AWS Glue does the initializations. This state should quickly move to CREATED state unless some configurations are missing.
- `ACTIVE` - Once the integration reaches this state, AWS Glue will start the data transfer (initial full load). Unless there are permission issues, after the initial full load completes, periodic change data capture will follow.
- `MODIFYING` - Once you make modification to the integration, the integration goes into Modifying state. Once the modification is applied, the integration goes to `ACTIVE` if integration was successful after the modification or will go into `NEEDS_ATTENTION` or `FAILED` if there were any issues.
- `NEEDS_ATTENTION` - Integration will move into this state if there are either user error or system error. User error includes missing permissions, missing source or target resource(s), unsupported data errors. System error includes internal system errors. For both the error types, AWS Glue Zero ETL will keep retrying for data sync for 7 days before marking the integration as FAILED. If you fix the issue before that, the integration will become ACTIVE again and start transferring data.
- `SYNCING` - Integration will move into this state if AWS Glue Zero ETL detects any data type changes in regards to incoming schema for columns within table/tables. In such cases AWS Glue Zero ETL will request fresh set of snapshots for all such tables. During this time the integration will be in SYNCING state and will eventually transition to ACTIVE state once newly requested snapshots are available for ingestion.

- `FAILED` - This is a non-recoverable state. Once the integration moves into this state, it cannot be recovered. The only way to start the data transfer from source to target again is to delete and re-create the integration. If AWS Glue Zero ETL identifies that user error or system error has not been fixed for a period of 7 days and all retries are exhausted, AWS Glue Zero ETL will mark the integration as FAILED.
- `DELETING` - When you invoke delete-integration API, AWS Glue first moves the integration into DELETING state. After all the metadata is cleared and internal processings are terminated, AWS Glue will move the integration into DELETED state.
- `DELETED` - This is the terminal state for integration. Integration cannot be moved from this state into any other state. If the data transfer is required from same source to target, you should create the integration again.

Monitoring an integration

Viewing Amazon CloudWatch logs for an integration

AWS Glue zero-ETL integrations generate CloudWatch logs for visibility into your data movement. Log events relating to each successful ingestion or any failures experienced due to problematic data records at source, or data write errors due to schema changes or insufficient permissions are emitted to a default log group created in a customer account.

For each integration created, the log events for that integration will be collected under `/aws-glue/zeroETL-integrations/logs/` in CloudWatch. Inside the log group, log messages will be split into log streams. Each integration created has a dedicated log stream to where all logs for that integration are written.

> **Note**
>
> For a cross-account scenario, source processing logs are emitted in the source account where the integration exists and target processing logs are emitted in the target account where the target database exists.

IAM permissions required to enable logging

When creating your integration, the following IAM permissions are needed by the source and target roles to enable CloudWatch logging for an integration. AWS Glue zero-ETL integrations use these permissions provided in the source and target roles to emit CloudWatch logs to customer accounts.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "logs:CreateLogGroup",
        "logs:CreateLogStream",
        "logs:PutLogEvents"
      ],
      "Resource": [
        "*"
      ]
    }
  ]
}
```

Log messages

Log format: zero-ETL integrations emit four types of log messages:

```
// Ingestion started
{
"integrationArn": "arn:aws:glue:us-east-2:123456789012:integration/1a012bba-123a-1bba-
ab1c-173de3b12345",
...
    "messageType": "IngestionStarted",
    "details": {
        "tableName": "testDDBTable",
        "message": "Ingestion Job started"
    }
}
// Data processing stats on successful table ingestion
```

```
{
...
    "messageType": "IngestionProcessingStats",
    "details": {
        "tableName": "testDDBTable",
        "insert_count": 100,
        "update_count": 10,
        "delete_count": 10
    }
}
// Ingestion failure logs for failed table-processing
{
...
    "messageType": "IngestionFailed",
    "details": {
        "tableName": "testDDBTable",
        "errorMessage": "Failed to ingest data with error: Target Glue database not
 found.",
        "error_code" : "client_error"
    }
}
// Ingestion completed notification with lastSyncedTimestamp
{
...
    "messageType": "IngestionCompleted",
    "details": {
        "tableName": "testDDBTable",
        "message": "Ingestion Job completed"
        "lastSyncedTimestamp": "1132344255745"
    }
}
```

Viewing Amazon CloudWatch metrics for an integration

Once an integration completes, you can see these CloudWatch metrics generated in your account for each AWS Glue job run:

CloudWatch metrics namespace: "AWS/Glue/ZeroETL"

Metrics dimensions:

- `integrationArn`
- `loadType`

- `tableName`

Metric names:

- `InsertCount` - number of records inserted in the target Iceberg table.
- `UpdateCount` - number of records updated in the target Iceberg table.
- `DeleteCount` - number of records deleted from the target Iceberg table.
- `IngestionSucceeded` - count 1, if the ingestion succeeded for the integration.
- `IngestionFailed` - count 1, if the ingestion failed for the integration.
- `LastSyncTimestamp` - timestamp until which source has been synced to target.

Managing event notifications with Amazon EventBridge

Zero-ETL integrations use Amazon EventBridge to manage event notifications to keep you up-to-date regarding changes in your integrations. Amazon EventBridge is a serverless event bus service that you can use to connect your applications with data from a variety of sources. In this case, the event source is AWS Glue. Events, which are monitored changes in an environment, are sent to EventBridge from AWS Glue automatically. Events are delivered in near real time.

To capture all Zero-ETL notifications, create an EventBridge rule which matches the following:

```
{
  "source": [{
    "prefix": "aws.glue-zero-etl"
  }],
  "detail-type": [{
    "prefix": "Glue Zero ETL"
  }]
}
```

The following table includes zero-ETL integration events:

Detail type	Explanation
AWS Glue Zero ETL Ingestion Completed	Individual execution for an entity has completed successfully.

Detail type	Explanation
AWS Glue Zero ETL Ingestion Failed	Individual execution for an entity has completed unsuccessfully (either with a client or system error).
AWS Glue Zero ETL Integration Resynced	Integration has been RESYNCED.
AWS Glue Zero ETL Integration Failed	Integration status has changed to FAILED due to an error.
AWS Glue Zero ETL Integration Needs Attention	Integration status has changed to NEEDS_ATTENTION due to an error.
AWS Glue Zero ETL Ingestion In Progress	Individual execution for an entity has made partial progress towards completion.

Schema unnesting & data partitioning

When working with NoSQL data sources like DynamoDB and SaaS applications, data often presents unique challenges for analytics:

1. Records within the same table may have different schema
2. Nested records within the same table can be represented differently
3. Complex nested structures like maps and arrays require transformation for efficient querying
4. Optimal data organization is needed to ensure query performance at scale

AWS Glue Zero-ETL integrations address these challenges through two powerful capabilities:

- **Schema Unnesting:** Automatically flattens complex nested data structures into analytics-friendly formats, with configurable levels of unnesting to balance between preserving data structure and optimizing for query simplicity.
- **Data Partitioning:** Organizes data into logical partitions based on specified columns or time-based dimensions, improving query performance and reducing costs by enabling partition pruning during query execution.

In order to query such data sources effectively, AWS Glue Zero-ETL provides out-of-the-box schema handling and partitioning schemes for source data being replicated in the target AWS Glue Database. You can configure schema unnesting and partitioning settings for each table through the CreateIntegrationTableProperty API, allowing for fine-tuned control over how data is structured and organized for analytics workloads.

Default unnesting & partitioning behavior

1. AWS Glue Zero-ETL defaults to FULL Unnest when no Unnesting options are provided for target table
2. AWS Glue Zero-ETL defaults to Bucket partitioning when no PartitionSpec are provided for target table

Schema unnesting

When integrating with analytics services through Zero-ETL, you can choose how nested structures are represented in the target tables. AWS Glue Zero-ETL provides schema unnesting options to flatten complex data structures into more analytics-friendly formats.

Unnesting options

When creating a Zero-ETL integration with a source, you can choose from the following unnesting options. These options correspond to specific enumeration values that you'll use when calling the CreateIntegrationTableProperty API. For all unnest options, we would traverse to most inner layer and map DDB type to target spark/iceberg primitive type with best efforts. The type mapping between source DDB and target table is as below:

DDB source data type	Target table data type
`"S"`	StringType
`"B"`	BinaryType
`"N"`	DoubleType
`"BOOL"`	BooleanType
`"SS"`	ArrayType(StringType)

DDB source data type	Target table data type
"NS"	ArrayType(DoubleType)
"BS"	ArrayType(BinaryType)
"L"	ArrayType(StringType)
"NULL"	Ignore
"M"	StructType (TOP/NOUNNEST)

No unnesting - NO_UNNEST

API value: `NO_UNNEST`

Preserves the original nested structure of Amazon DynamoDB items. Maps and lists are stored as structured columns in the target.

Best for: Preserving the exact structure of your Amazon DynamoDB data when your analytics tools can work with nested data.

Top level - TOP_LEVEL

API value: `TOP_LEVEL`

Flattens the top level of nested maps into individual columns. List structures remain nested.

Preserves the exact structure of your Amazon DynamoDB data when your analytics tools can work with nested data with all DDB type information removed.

Best for: Balancing between data structure preservation and query simplicity when your Amazon DynamoDB table items have a consistent schema.

Unnest all levels - FULL (default)

API value: `FULL`

Recursively flattens all nested structures (maps and lists) into individual columns with dot notation for naming.

Best for: Maximizing query simplicity when working with deeply nested structures and analytics tools that prefer flat schemas.

> **Note**
>
> Full unnesting can lead to very wide tables with many columns if your DynamoDB data has variable or deeply nested structures.

Example Using unnesting options in the API

When configuring schema unnesting through the CreateIntegrationTableProperty API, specify the unnesting option in the UnnestSpec parameter:

```
aws glue create-integration-table-property
  --resource-arn "arn:aws:glue:us-east-1:123456789012:database/my_db"
  --table-name "my-table"
  --cli-input-json '{
      "TargetTableConfig": {
          "UnnestSpec": "FULL",
          "TargetTableName": "my-target-table",
      }
  }'
```

Unnesting examples

Consider a DynamoDB item with the following structure:

```
// Input DynamoDB Record
{
  "Item": {
    "col_1": {
      "S": "value_1"
    },
    "col_2": {
      "M": {
        "col_3": {
          "M": {
            "id": {
              "S": "value_3"
            }
          }
        },
        "col_4": {
```

```
          "BOOL": true
        }
      }
    }
  }
}
```

NO_UNNEST example

With NO_UNNEST, the entire row is stored within one column plus the primary key. DynamoDB type information is preserved. This maintains compatibility with Redshift querying patterns.

Resulting Iceberg table (assuming col_1 is primary key):

col_1 (string)	value (struct)

value_1	<pre>{
	  "col_2": {
	    "M": {
	      "col_3": {
	        "M": {
	          "id": {
	            "S": "value_3"
	          }
	        }
	      },
	      "col_4": {
	        "BOOL": true
	      }
	    }
	  }
	}</pre>

Queries would need to use struct and array access patterns:

```
SELECT
  value.col_1,
  value.col_2.M.col_3.M.id.S,
  value.col_2.M.col_4.BOOL
FROM product_table;
```

TOP_LEVEL example

With TOP_LEVEL, only the top-level fields are unnested while keeping nested fields intact as structs. DynamoDB type information is removed and typing is maintained. Converts to string type when schema conflicts occur.

Resulting Glue table after replication:

col_1 (string)	col_2 (struct)
value_1	`{ "col_3": { "id": "value_3" }, "col_4": true }`

Queries would be simplified for the first level:

```
SELECT
  col_1,
  col_2.col_3.id,
  col_2.col_4
FROM product_table;
```

FULL example

With FULL unnesting, both top-level fields and nested struct/map fields are flattened. Dot notation is used for nested fields (e.g., "col_2.col_3.id"). Array elements remain unnested. Each leaf node becomes a top-level column.

Resulting Glue table after replication:

col_1 (string)	col_2.col_3.id (string)	col_2.col_4 (boolean)
value_1	value_3	TRUE

Queries would be fully flattened:

```
SELECT
  col_1,
  "col_2.col_3.id",
  "col_2.col_4"
FROM product_table;
```

Data partitioning

What is data partitioning?

Data partitioning is a technique that divides large datasets into smaller, more manageable segments called partitions. In the context of AWS Glue Zero-ETL integrations, partitioning organizes your data in the target location based on specific column values or transformations of those values.

Benefits of data partitioning

Effective data partitioning provides several key benefits for analytics workloads:

- **Improved query performance:** Queries can skip irrelevant partitions (partition pruning), reducing the amount of data that needs to be scanned.
- **Reduced costs:** By scanning less data, you can lower compute and I/O costs for your analytics queries.
- **Better scalability:** Partitioning allows parallel processing of data segments, enabling more efficient scaling of analytics workloads.
- **Simplified data lifecycle management:** You can manage retention policies at the partition level, making it easier to archive or delete older data.

Key partitioning concepts

Partition columns

> Columns in your data that are used to determine how records are organized into partitions. Effective partition columns should align with common query patterns and have appropriate cardinality.

Partition functions

Transformations applied to partition column values to create the actual partition boundaries. Examples include identity (using the raw value) and time-based functions (year, month, day, hour).

Partition pruning

The process where the query engine identifies and skips partitions that don't contain relevant data for a query, significantly improving performance.

Partition granularity

The level of detail at which data is partitioned. Finer granularity (more partitions) can improve query performance but may increase metadata overhead. Coarser granularity (fewer partitions) reduces metadata overhead but may result in scanning more data than necessary.

Partitioning in AWS Glue Zero-ETL integrations

AWS Glue Zero-ETL integrations use Apache Iceberg table format, which provides advanced partitioning capabilities. When you create a Zero-ETL integration, you can:

- Use default partitioning strategies optimized for your data source
- Define custom partitioning specifications tailored to your query patterns
- Apply transformations to partition columns (especially useful for timestamp-based partitioning)
- Combine multiple partition strategies for multi-level partitioning

Partitioning configurations are specified through the `CreateIntegrationTableProperty` API when setting up your Zero-ETL integration. Once configured, AWS Glue automatically applies these partitioning strategies to organize your data in the target location.

Partition specification API reference

Use the following parameters in the CreateIntegrationTableProperties API to configure partitioning:

PartitionSpec

An array of partition specifications that defines how data is partitioned in the target location.

```
{
  "partitionSpec": [
    {
      "fieldName": "timestamp_col",
      "functionSpec": "month",
      "conversionSpec": "epoch_milli"
    },
    {
      "fieldName": "category",
      "functionSpec": "identity"
    }
  ]
}
```

FieldName

A UTF-8 string (1-128 bytes) specifying the column name to use for partitioning.

FunctionSpec

Specifies the partitioning function. Valid values:

- `identity` - Uses source values directly without transformation
- `year` - Extracts the year from timestamp values (e.g., 2023)
- `month` - Extracts the month from timestamp values (e.g., 2023-01)
- `day` - Extracts the day from timestamp values (e.g., 2023-01-15)
- `hour` - Extracts the hour from timestamp values (e.g., 2023-01-15-14)

> **Note**
>
> Time-based functions (`year`, `month`, `day`, `hour`) require the `ConversionSpec` parameter to specify the source timestamp format.

ConversionSpec

A UTF-8 string that specifies the timestamp format of the source data. Valid values are:

- `epoch_sec` - Unix epoch timestamp in seconds
- `epoch_milli` - Unix epoch timestamp in milliseconds
- `iso` - ISO 8601 formatted timestamp

Partitioning strategies

Default partitioning

When no partition columns are specified, AWS Glue Zero-ETL applies default partitioning strategies optimized for your data source:

- **Primary key-based partitioning:** For sources with primary keys (like DynamoDB tables), AWS Glue Zero-ETL automatically partitions data using the primary key with bucketing to prevent partition explosion.

Default partitioning is designed to work well for common query patterns without requiring manual configuration. However, for specific query patterns or performance requirements, you may want to define custom partitioning strategies.

User-defined partitioning strategies

AWS Glue Zero-ETL allows you to define custom partitioning strategies using the `PartitionSpec` parameter. You can specify one or more partition columns and apply different partitioning functions to each column.

Identity partitioning uses the raw values from a column to create partitions. This strategy is useful for columns with low to medium cardinality, such as category, region, or status fields.

Example Identity partitioning example

```
{
  "partitionSpec": [
    {
      "fieldName": "category",
      "functionSpec": "identity"
    }
  ]
}
```

This creates separate partitions for each unique value in the "category" column.

> **Warning**
>
> Avoid using identity partitioning with high-cardinality columns (like primary keys or timestamps) as it can lead to partition explosion, which degrades performance and increases metadata overhead.

Time-based partitioning organizes data based on timestamp values at different granularities (year, month, day, or hour). This strategy is ideal for time-series data and enables efficient time-range queries.

When using time-based partitioning, AWS Glue Zero-ETL can automatically convert various timestamp formats to a standardized format before applying the partition function. This conversion is specified using the `ConversionSpec` parameter.

Example Time-based partitioning example

```
{
  "partitionSpec": [
    {
      "fieldName": "created_at",
      "functionSpec": "month",
      "conversionSpec": "epoch_milli"
    }
  ]
}
```

This partitions data by month based on the "created_at" column, which contains Unix epoch timestamps in milliseconds.

AWS Glue Zero-ETL supports the following time-based partition functions:

- **year:** Partitions data by year (e.g., 2023, 2024)
- **month:** Partitions data by month (e.g., 2023-01, 2023-02)
- **day:** Partitions data by day (e.g., 2023-01-01, 2023-01-02)
- **hour:** Partitions data by hour (e.g., 2023-01-01-01, 2023-01-01-02)

AWS Glue Zero-ETL supports the following timestamp formats through the `ConversionSpec` parameter:

- **epoch_sec:** Unix epoch timestamps in seconds
- **epoch_milli:** Unix epoch timestamps in milliseconds
- **iso:** ISO 8601 formatted timestamps

> **Note**
>
> The original column values remain unchanged in your source data. AWS Glue only transforms partition column values to Timestamp Type in the target database table. The transformations only apply to the partitioning process.

Multi-level partitioning combines multiple partition strategies to create a hierarchical partitioning scheme. This is useful for optimizing different types of queries against the same dataset.

Example Multi-level partitioning example

```
{
  "partitionSpec": [
    {
      "fieldName": "created_at",
      "functionSpec": "month",
      "conversionSpec": "iso"
    },
    {
      "fieldName": "region",
      "functionSpec": "identity"
    }
  ]
}
```

This creates a two-level partitioning scheme: first by month (from the "created_at" column), then by region. This enables efficient queries that filter by date ranges, specific regions, or a combination of these dimensions.

When designing multi-level partitioning schemes, consider:

- Placing higher-selectivity columns first in the partition hierarchy
- Balancing partition granularity with the number of partitions
- Aligning the partitioning scheme with your most common query patterns

Best practices

Partition column selection

- Do not use high-cardinality columns with the `identity` partition function. Using high-cardinality columns with identity partitioning creates many small partitions, which can significantly degrade ingestion performance. High-cardinality columns may include:
  - Primary keys
  - Timestamp fields (such as `LastModifiedTimestamp`, `CreatedDate`)
  - System-generated timestamps
- Do not select multiple timestamp partitions on same column. For example:

```
"partitionSpec": [
     {"fieldName": "col1", "functionSpec": "year", "conversionSpec" :
 "epoch_milli"},
     {"fieldName": "col1", "functionSpec": "month", "conversionSpec" :
 "epoch_milli"},
     {"fieldName": "col1", "functionSpec": "day", "conversionSpec" : "epoch_milli"},
     {"fieldName": "col1", "functionSpec": "hour", "conversionSpec" : "epoch_milli"}
]
```

Partition FunctionSpec/ConversionSpec selection

- Specify the correct ConversionSpec (epoch_sec | epoch_milli | iso) that represents format of column values chosen for timestamp based partitioning when using timestamp-based partition functions. AWS Glue Zero-ETL uses this parameter to correctly transform source data into timestamp format before partitioning.
- Use appropriate granularity (year/month/day/hour) based on data volume.
- Consider timezone implications when using ISO timestamps. AWS Glue Zero-ETL populates all the record values of chosen timestamp column with UTC timezone.

Error handling

NEEDS_ATTENTION State

An integration enters the NEEDS_ATTENTION state when:

- Specified partition columns do not exist in the source

- Timestamp conversion fails for partition columns

Limitations

Partitioning limitations

- Partition specifications cannot be changed after an integration is created. To use a different partitioning strategy, you must create a new integration.
- The maximum number of partition columns is limited to 10.

Cross-account integration limitations

- When creating cross-account integrations, AWS Glue Console has a limitation where it doesn't invoke CreateIntegrationTableProperty API for configuring UnnestSpec and PartitionSpec for target AWS Glue tables that are hosted in the account where integration does not exist.

  Workaround: The CreateIntegrationTableProperty API must be invoked by CX from the account where the target database exists.

Multiple integrations limitations

- If you need to replicate the same source with different schema unnest/partition configurations, it is required to create a new AWS Glue database for each integration separately. Later invoke CreateIntegrationTableProperty for each table from individual AWS Glue Database with desired schema unnesting and partitioning configurations.

Creating integrations using the APIs

You can use the following APIs to create and manage Zero-ETL integrations in AWS Glue:

- CreateIntegration
- CreateIntegrationTableProperties
- CreateIntegrationResourceProperty
- UpdateIntegrationTableProperties
- UpdateIntegrationResourceProperty

- ModifyingIntegration
- DeleteIntegration
- DeleteIntegrationTableProperties
- DescribeIntegrations
- DescribeInboundIntegrations
- GetIntegrationTableProperties
- GetIntegrationResourceProperty

For more information, see Integration APIs in AWS Glue.

Limitations

The following are general limitations of or considerations about zero-ETL integrations:

- Resource properties have a one-to-one relationship with the corresponding resource. Consequently, all integrations created using that resource must adhere to the singular resource property. Modifying a resource property will therefore impact all integrations associated with that resource.
- Table properties have a one-to-one relationship with the corresponding table or object within a resource. As a result, all integrations that process the same table to or from the same resource must adhere to the singular table property.
- You cannot rename a column at the source. If a column is renamed then there is no guarantee that the schema detection will be accurately done by AWS Glue and the repercussions on the integration are undefined.
- The following consideration applies to how the integration works with AWS Lake Formation managed tables: By default, you use the IAM/AWS Glue policy to manage your table and databases.
- If you want to use AWS Lake Formation to manage the table creation in that database, you need to make sure that the role is given sufficient Lake Formation permissions to create, modify and delete the table and database.
- The zero-ETL summary page does not contain any metrics at this time.

The following are source-specific limitations of zero-ETL integrations:

- Zero-ETL integrations with an SAP OData source now supports entities starting with `Entity0f`. The ability to override the primary key is currently supported only for SAPOData `Entity0f` objects. Once this property has been set, it cannot be modified.
- Zero-ETL integrations from Amazon DynamoDB to Amazon SageMaker Lakehouse (via S3) support a maximum DynamoDB table size of 100TB.
- The source DynamoDB table must be encrypted with either an Amazon-owned or customer-managed AWS KMS key. Amazon managed encryption is not supported for the source DynamoDB table.
- SAP OData works using a delta token, where the combination of an OAuth client plus an entity, or basic authentication plus an entity, can have only a single delta token. Avoid using the same entity in two different integrations with the same client.
- The following Salesforce entities or fields are unsupported for use in a zero-ETL integration with a Salesforce source. See Unsupported entities and fields for Salesforce.
- The following ServiceNow entities or fields are unsupported for use in a zero-ETL integration with a ServiceNow source. See Unsupported entities and fields for ServiceNow.

The following are target-specific limitations of zero-ETL integrations:

- Due to limitation in Data Catalog, AWS Glue Zero ETL can only support replication of tables with table names smaller than 255 characters.
- Due to limitation in Athena, the source column/nested field name should not contain special characters ":", which will cause the target table schema metadata showing up incorrectly. In such cases, AWS Glue Zero ETL will move the integration to FAILED state.
- Due to limitation in Iceberg, AWS Glue Zero ETL target can only support replication of 1000 columns per table. If chosen table in any integration has more than 1000 columns, AWS Glue Zero ETL will move the integration to FAILED state.
- Due to limitation in Data Catalog, AWS Glue Zero ETL can only support replicating table of schema size 10 MB. If chosen table in any integration has schema size larger than 10 MB, AWS Glue Zero ETL will move the integration to FAILED state.

Service quotas

AWS Glue Zero-ETL has the following service quotas:

- Each account can create 25 integrations by default.

- Each source can be associated with up to 15 integrations.
- Each target can be associated with up to 50 integrations.

Supported Regions

The following Regions are available with AWS Glue Zero-ETL:

Region	AWS Glue Zero-ETL
Africa (Cape Town)	Not available
Asia Pacific (Hong Kong)	Available
Asia Pacific (Tokyo)	Available
Asia Pacific (Seoul)	Available
Asia Pacific (Osaka)	Not available
Asia Pacific (Mumbai)	Not available
Asia Pacific (Hyderabad)	Not available
Asia Pacific (Singapore)	Available
Asia Pacific (Sydney)	Available
Asia Pacific (Jakarta)	Not available
Asia Pacific (Melbourne)	Not available
Asia Pacific (Malaysia)	Not available
Canada (Central)	Available
Canada West (Calgary)	Not available
China (Beijing)	Not available
China (Ningxia)	Not available

Region	AWS Glue Zero-ETL
Europe (Frankfurt)	Available
Europe (Zurich)	Not available
Europe (Stockholm)	Available
Europe (Milan)	Not available
Europe (Spain)	Not available
Europe (Ireland)	Available
Europe (London)	Available
Europe (Paris)	Not available
Israel (Tel Aviv)	Not available
Middle East (UAE)	Not available
Middle East (Bahrain)	Not available
South America (São Paulo)	Available
US East (N. Virginia)	Available
US East (Ohio)	Available
US West (N. California)	Not available
US West (Oregon)	Available
AWS GovCloud (US-East)	Not available
AWS GovCloud (US-West)	Not available

Troubleshooting zero-ETL integrations

Use the following sections to help troubleshoot problems that you have with AWS Glue zero-ETL integrations.

Troubleshooting zero-ETL integrations with Amazon DynamoDB source

Missing RBAC policy or point-in-time recovery on source DynamoDB table

Before creating the integration, source must be configured properly. If the source DynamoDB table is missing the RBAC policy with appropriate permissions or if the point-in-time recovery is disabled, then integration will go into Needs_Attention state. To resolve this issue, fix the permissions and/or enable the point-in-time recovery. The integration should automatically recover after some time once you fix the missing configurations.

Troubleshooting zero-ETL integrations with SaaS sources (using AWS Glue connection)

Connection not configured properly

If the AWS Glue connection is not configured properly, the integration may fail to access the SaaS source. Verify that the connection credentials are valid and that the source role has the appropriate permissions to access the connection.

Troubleshooting zero-ETL integrations with general purpose Amazon S3 target

Target-role is missing permissions

If the target role is missing the appropriate permissions or setup incorrectly, it will cause the integration to go into NEEDS_ATTENTION state. Please refer to the section for target role configuration to fix the issue. Integration should be automatically recovered after some time once you fix the issue.

Target Catalog RBAC policy is incorrectly configured

If the target catalog resource policy is incorrectly configured, it will also cause the integration to go into NEEDS_ATTENTION state. Please refer to the section for target role configuration to fix the issue. Integration should be automatically recovered after some time once you fix the issue.

Troubleshooting zero-ETL integrations with Amazon S3-Table target

Target-role is missing permissions

If the target role is missing the appropriate permissions or setup incorrectly, it will cause the integration to go into NEEDS_ATTENTION state. Please refer to the section for target role configuration to fix the issue. Integration should be automatically recovered after some time once you fix the issue.

Target Catalog RBAC policy is incorrectly configured

If the target catalog resource policy is incorrectly configured, it will also cause the integration to go into NEEDS_ATTENTION state. Please refer to the section for target role configuration to fix the issue. Integration should be automatically recovered after some time once you fix the issue.

General troubleshooting guide for AWS Glue zero-ETL integration errors

All integrations emit CloudWatch logs after the completion of each process e.g. full data load or change data capture. You can refer to those logs to determine the exact root cause of the failure or error.

Additionally, AWS Glue also creates system table in the target AWS Glue database or S3-Table. During the time when integration remains operational (i.e. not in FAILED or DELETED state), AWS Glue will keep appending the statuses for each individual operations on the target i.e. completion of full data load or change data capture with statistics such as number of records, number of insertions, deletions etc.

AWS Glue Data Quality

AWS Glue Data Quality allows you to measure and monitor the quality of your data so that you can make good business decisions. Built on top of the open-source DeeQu framework, AWS Glue Data Quality provides a managed, serverless experience. AWS Glue Data Quality works with Data Quality Definition Language (DQDL), which is a domain specific language that you use to define data quality rules. To learn more about DQDL and supported rule types, see Data Quality Definition Language (DQDL) reference.

For additional product details and pricing, see the service page for AWS Glue Data Quality.

Benefits and key features

Benefits and key features of AWS Glue Data Quality include:

- **Serverless** – There is no installation, patching or maintenance.
- **Get started quickly** – AWS Glue Data Quality quickly analyzes your data and creates data quality rules for you. You can get started with two clicks: "Create Data Quality Rules → Recommend rules".
- **Detect data quality issues** – Use machine learning (ML) to detect anomalies and hard-to-detect data quality issues.
- **Improvise your rules** – with 25+ out-of-the-box DQ rules to start from, you can create rules that suit your specific needs.
- **Evaluate quality and make confident business decisions** – Once you evaluate the rules, you get a Data Quality score that provides an overview of the health of your data. Use Data Quality score to make confident business decisions.
- **Zero in on bad data** – AWS Glue Data Quality helps you identify the exact records that caused your quality scores to go down. Easily identify them, quarantine and fix them.
- **Pay as you go** – There are no annual licenses you need to use AWS Glue Data Quality.
- **No lock-in** – AWS Glue Data Quality is built on open source DeeQu, allowing you to keep the rules you are authoring in an open language.
- **Data quality checks** – You can enforce data quality checks on Data Catalog and AWS Glue ETL pipelines allowing you to manage data quality at rest and in transit.
- **ML-based data quality detection** – Use machine learning (ML) to detect anomalies and hard-to-detect data quality issues.

- **Open language to express rules** – ensures that data quality rules are authored consistently and simply. Business users can easily express data quality rules in a straightforward language that they can understand. For engineers, this language provides the flexibility to generate code, implement consistent version control, and automate deployments.

How it works

There are two entry points for AWS Glue Data Quality: the AWS Glue Data Catalog and AWS Glue ETL jobs. This section provides an overview of the use cases and AWS Glue features that each entry point supports.

Data quality for the AWS Glue Data Catalog

AWS Glue Data Quality evaluates objects that are stored in the AWS Glue Data Catalog. It offers non-coders an easy way to set up data quality rules. These personas include data stewards and business analysts.

You might choose this option for the following use cases:

- You want to perform data quality tasks on data sets that you've already cataloged in the AWS Glue Data Catalog.
- You work on data governance and need to identify or evaluate data quality issues in your data lake on an ongoing basis.

You can manage data quality for the Data Catalog using the following interfaces:

- The AWS Glue management console
- AWS Glue APIs

To get started with AWS Glue Data Quality for the AWS Glue Data Catalog see Getting started with AWS Glue Data Quality for the Data Catalog.

Data quality for AWS Glue ETL jobs

AWS Glue Data Quality for AWS Glue ETL jobs lets you perform *proactive* data quality tasks. Proactive tasks help you identify and filter out bad data *before* you load a data set into your data lake.

Video: Introducing AWS Glue Data Quality for ETL Pipelines

You might choose data quality for ETL jobs for the following use cases:

- You want to incorporate data quality tasks into your ETL jobs
- You want to write code that defines data quality tasks in ETL scripts
- You want to manage the quality of data that flows in your visual data pipelines

You can manage data quality for ETL jobs using the following interfaces:

- AWS Glue Studio, AWS Glue Studio notebooks, and AWS Glue interactive sessions
- AWS Glue libraries for ETL scripting
- AWS Glue APIs

To get started with data quality for ETL jobs, see Tutorial: Getting started with Data Quality in the *AWS Glue Studio User Guide*.

Comparing data quality for the Data Catalog to data quality for ETL jobs

This table provides an overview of features that each entry point for AWS Glue Data Quality supports.

Feature	Data quality for the Data Catalog	Data quality for ETL jobs
Data sources	Amazon S3, Amazon Redshift, JDBC sources compatibl e with the Data Catalog, and transactional data lake formats such as Apache	All data sources supported by AWS Glue, including custom connectors and third-party connectors.

Feature	Data quality for the Data Catalog	Data quality for ETL jobs
	Iceberg, Apache Hudi, and Delta Lake. AWS Lake Formation managed OTF formats are also supported with some limitations. Amazon Athena views that are cataloged in AWS Glue Data Catalog are not supported. Please see Supported source types.	
Data Quality rule recommend ations	Supported	Not supported
Author and run DQDL rules	Supported	Supported
Auto scaling	Not supported	Supported
AWS Glue Flex support	Not supported	Supported
Scheduling	Supported when evaluatin g Data Quality rules and via Step Functions.	Supported when using Step Functions and workflows.
Identifying records that failed data quality checks	Not supported	Supported
Integration with Amazon Eventbridge	Supported	Supported
Integration with AWS Cloudwatch	Supported	Supported
Writing data quality results to Amazon S3	Supported	Supported

Feature	Data quality for the Data Catalog	Data quality for ETL jobs
Incremental data quality	Supported via pushdown predicates	Supported via AWS Glue bookmarks
AWS CloudFormation support	Supported	Supported
ML-based anomaly detection	Not supported	Supported
Dynamic rules	Not supported	Supported

Considerations

Consider the following items before you use AWS Glue Data Quality:

- Data quality rules can't evaluate nested or list-type data sources. See Flatten nested structs.

Terminology

The following list defines terms that are related to AWS Glue Data Quality.

Data Quality Definition Language (DQDL)

A domain-specific language that you can use to write AWS Glue Data Quality rules.

To learn more about DQDL, see the Data Quality Definition Language (DQDL) reference guide.

data quality

Describes how well a dataset serves its specific purpose. AWS Glue Data Quality evaluates rules against a dataset to measure data quality. Each rule checks for particular characteristics like data freshness or integrity. To quantify data quality, you can use a *data quality score*.

data quality score

The percentage of data quality rules that pass (result in true) when you evaluate a ruleset with AWS Glue Data Quality.

rule

A DQDL expression that checks your data for a specific characteristic and returns a Boolean value. For more information, see Rule structure.

analyzer

A DQDL expression that gathers data statistics. An analyzer gathers data statistics that can be used by ML algorithms to detect anomalies and hard-to-detect data quality issues over time.

ruleset

An AWS Glue resource that comprises a set of data quality rules. A ruleset must be associated with a table in the AWS Glue Data Catalog. When you save a ruleset, AWS Glue assigns an Amazon Resource Name (ARN) to the ruleset.

data quality score

The percentage of data quality rules that pass (result in true) when you evaluate a ruleset with AWS Glue Data Quality.

observation

An unconfirmed insight generated by AWS Glue by analyzing data statistics gathered from rules and analyzers over time.

Limits

AWS Glue Data Quality service limits:

- You can have 2,000 rules in a ruleset. If your rulesets are larger, we recommend splitting into multiple rulesets.
- The size of the ruleset is 65KB. If your rulesets are larger, we recommend splitting into multiple rulesets.
- AWS Glue Data Quality collects statistics when you create a rule or analyzer. There is no cost associated with storing these statistics. However, there is a limit of 100,000 statistics per account, and these statistics will be retained for a maximum of two years.

Release notes for AWS Glue Data Quality

This topic describes features introduced in AWS Glue Data Quality.

General availability: new features

The following new features are available with the general availability of AWS Glue Data Quality:

- The ability to identify which records failed data quality checks is now supported in AWS Glue Studio
- New data quality ruletypes such as validating referential integrity of data between two data sets, comparing data between two datasets, and data type checks
- Improved user experience in the AWS Glue Data Catalog
- Support for Apache Iceberg, Apache Hudi and Delta Lake
- Support for Amazon Redshift
- Simplified notification with Amazon EventBridge
- AWS CloudFormation support for creating rulesets
- Performance improvements: caching option in ETL and AWS Glue Studio for faster performance when evaluating data quality

Nov 27, 2023 (Preview)

- ML-powered anomaly detection capabilities are now available in AWS Glue ETL and AWS Glue Studio. With this, you can now detect anomalies and hard-to-detect data quality issues
- Dynamic Rules allows you to provide dynamic thresholds (ex: `RowCount> avg(last(10))`)

Mar 12, 2024

- DQDL improvements
  - Support for Keywords like NULL, BLANKS, WHITESPACES_ONLY
  - Options to specify how AWS Glue Data Quality must handle Composite rules
  - ColumnValues rule type will not allow NULL values to pass during comparisons
  - Support for NOT operator in DQDL

June 26, 2024

- DQDL improvements

- DQDL now supports where clause so that you can filter data before applying DQ rules

August 7, 2024

- Anomaly Detection and Dynamic Rules are now generally available

Nov 22, 2024

- Complex composite rules allows you to author more complex business rules with nested support
- New rule types for managing data quality for your files
  - FileFreshness
  - FileSize
  - FileUniqueness
  - FileMatch
- Default data quality checks in Visual ETL jobs

Dec 6, 2024

- AWS Glue Data Quality now supports Amazon SageMaker AI LakeHouse tables and AWS Lake Formation managed Iceberg, Delta and HUDI tables in AWS Glue ETL 5.0.

Jul 7, 2025

- AWS Glue Data Quality; now supports Amazon S3 Tables, RMS, Lakehouse and AWS Lake Formation managed Iceberg tables in AWS Glue Data Catalog.

Nov 21, 2025

- AWS Glue Data Quality now supports rule labeling for enhanced reporting. You can organize and analyze data quality results more effectively by querying results by specific labels to identify failing rules within particular categories, count rule outcomes by team or domain, and create focused reports for different stakeholders. For more information, see Labels.

- AWS Glue Data Quality now supports Constants in DQDL, allowing you to define constant values and reference them throughout your script. This helps prevent issues related to query size limits when working with large SQL statements. For more information, see Constants.

Anomaly detection in AWS Glue Data Quality

Case for Machine Learning in Data Quality

Engineers manage hundreds of data pipelines simultaneously. Each pipeline can extract data from various sources and load it into the data lake or other data repositories. To ensure high-quality data is delivered for decision-making, they establish data quality rules. These rules assess the data based on fixed criteria reflecting the current business state. However, when the business environment changes, data properties shift, rendering these fixed criteria outdated and causing poor data quality.

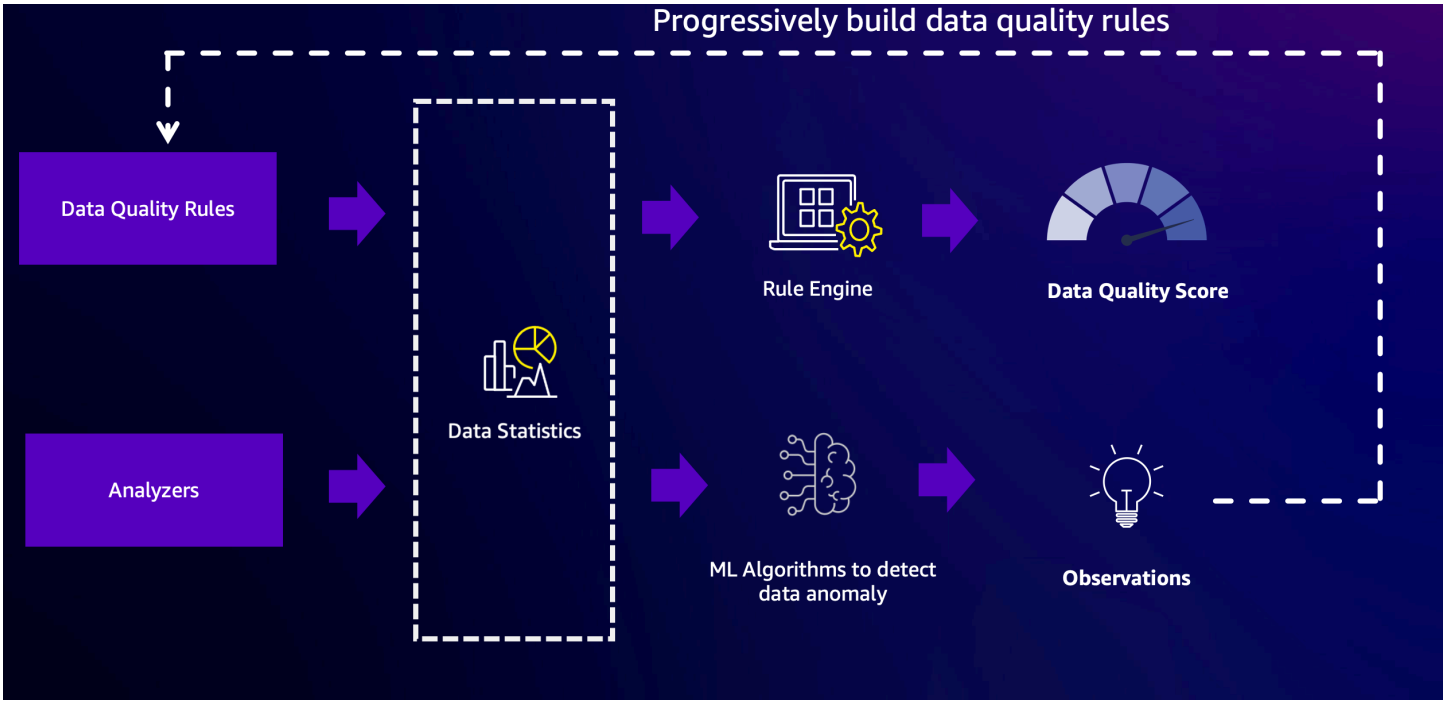
For example, a data engineer at a retail company established a rule that validates daily sales must exceed a one-million-dollar threshold. After a few months, daily sales surpassed two million dollars, rendering the threshold obsolete. The data engineer could not update the rules to reflect the latest thresholds due to a lack of notification and the effort required to manually analyze and update the rule. Later in the month, business users noticed a 25% drop in their sales. After hours of investigation, the data engineers discovered that an ETL pipeline responsible for extracting data from some stores had failed without generating errors. The rule with outdated thresholds continued to operate successfully without detecting this issue.

Alternatively, proactive alerts that can detect these anomalies could have enabled users to detect this issue. Moreover, tracking seasonality in business can highlight significant data quality problems. For instance, retail sales may be highest on weekends and during the holiday season while relatively low on weekdays. Divergence from this pattern may indicate data quality issues or shifts in business circumstances. Data quality rules cannot detect seasonal patterns as this requires advanced algorithms that can learn from past patterns capturing seasonality to detect deviations.

Finally, users find it challenging to create and maintain rules due to the technical nature of the rule creation process and the time involved to author them. As a result, they prefer exploring data insights first before defining rules. Customers need the ability to spot anomalies with ease, enabling them to proactively detect data quality issues and make confident business decisions.

How it works

> **Note**
>
> Anomaly detection is only supported in AWS Glue ETL. This is not supported in Data Catalog-based data quality.



AWS Glue Data Quality combines the power of rule-based data quality and anomaly detection capabilities to deliver high-quality data. To get started, you must first configure rules and analyzers, and then enable anomaly detection.

Rules

Rules – Rules express the expectations for your data in an open language called the Data Quality Definition Language (DQDL). An example of a rule is shown below. This rule will be successful when there are no empty or NULL values in the `passenger_count` column:

```
Rules = [
    IsComplete "passenger_count"
]
```

Analyzers

In situations where you know the critical columns but may not know enough about the data to write specific rules, you can monitor those columns using Analyzers. Analyzers are a way to gather data statistics without defining explicit rules. An example of configuring Analyzers is shown below:

```
Analyzers = [
AllStatistics "fare_amount",
DistinctValuesCount "pulocationid",
RowCount
]
```

In this example, three Analyzers are configured:

1. The first Analyzer, `AllStatistics "fare_amount"`, will capture all available statistics for the `fare_amount` field.
2. The second Analyzer, `DistinctValuesCount "pulocationid"`, will capture the count of distinct values in the `pulocationid` column.
3. The third Analyzer, `RowCount`, will capture the total number of records in the dataset.

Analyzers serve as a simple way to gather relevant data statistics without specifying complex rules. By monitoring these statistics, you can gain insights into the data quality and identify potential issues or anomalies that may require further investigation or the creation of specific rules.

Data statistics

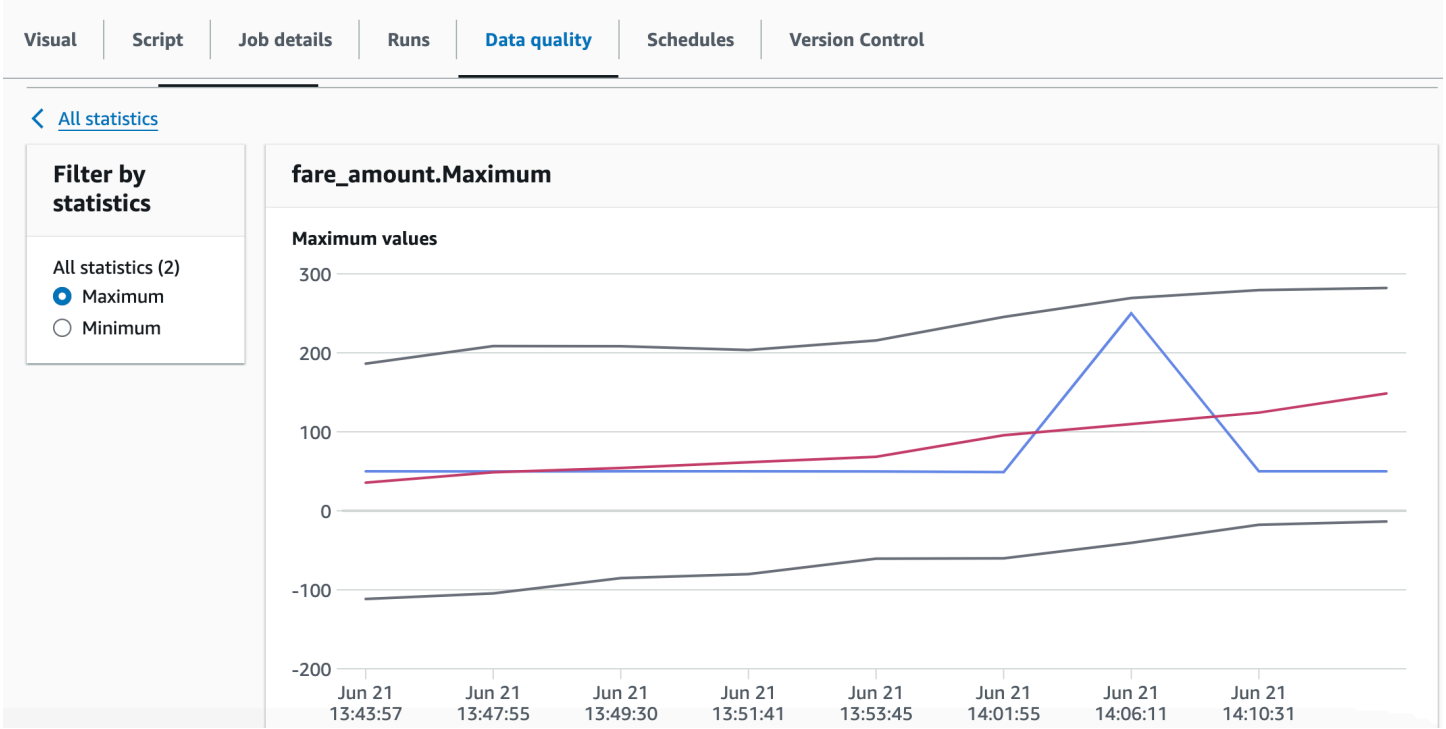
Both Analyzers and Rules in AWS Glue Data Quality gather data statistics, also known as data profiles. These statistics provide insights into the characteristics and quality of your data. The collected statistics are stored over time within the AWS Glue service, allowing you to track and analyze changes in your data profiles.

You can easily retrieve these statistics and write them to Amazon S3 for further analysis or long-term storage by invoking the appropriate APIs. This functionality enables you to integrate data profiling into your data processing workflows and leverage the collected statistics for various purposes, such as data quality monitoring, anomaly detection.

By storing the data profiles in Amazon S3, you can take advantage of the scalability, durability, and cost-effectiveness of Amazon's object storage service. Additionally, you can leverage other

AWS services or third-party tools to analyze and visualize the data profiles, enabling you to gain deeper insights into your data quality and make informed decisions about data management and governance.

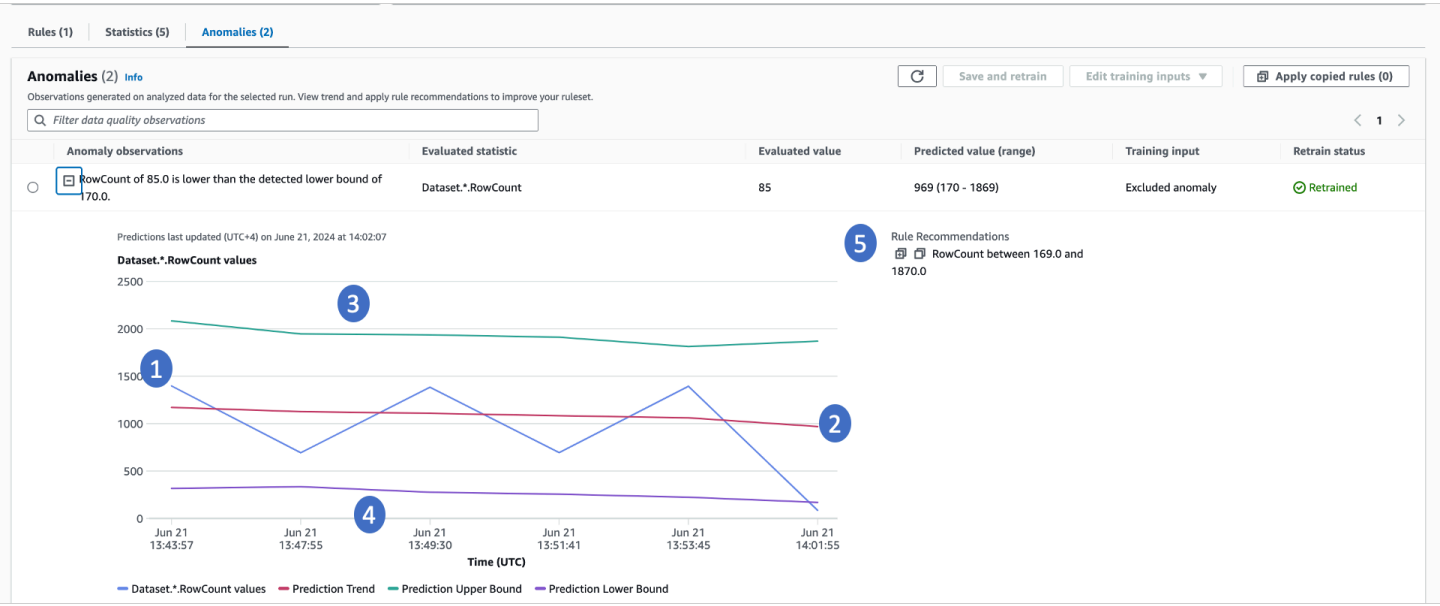
Here is an example of data statistics stored over time.



> **Note**
>
> AWS Glue Data Quality will gather statistics only once, even if you have both **Rule** and **Analyzer** for the same columns, making the statistics generation process efficient.

Anomaly Detection

AWS Glue Data Quality requires a minimum of three data points to detect anomalies. It utilizes a machine learning algorithm to learn from past trends and then predict future values. When the actual value does not fall within the predicted range, AWS Glue Data Quality creates an Anomaly Observation. It provides a visual representation of the actual value and the trends. Four values are displayed on the graph below.



1. The actual statistic and its trend over time.
2. A derived trend by learning from the actual trend. This is useful for understanding the trend direction.
3. The possible upper bound for the statistic.
4. The possible lower bound for the statistic.
5. Recommended data quality rules that can detect these issues in the future.

There are a few important things to note regarding Anomalies:

- When anomalies are generated, data quality scores are not impacted.
- When an anomaly is detected, it is considered normal for subsequent runs. The machine learning algorithm will consider this anomalous value as input unless it is explicitly excluded.

Retraining

Retraining the anomaly detection model is critical to detect the right anomalies. When anomalies are detected, AWS Glue Data Quality includes the anomaly in the model as a normal value.
To ensure the anomaly detection works accurately, it is important to provide feedback by acknowledging or rejecting the anomaly. AWS Glue Data Quality provides mechanisms both in AWS Glue Studio and APIs to provide feedback to the model. To know more, refer to the documentation on setting up Anomaly Detection in AWS Glue ETL pipelines.

Details of the Anomaly Detection algorithm

- The Anomaly Detection algorithm examines data statistics over time. The algorithm considers all available data points and ignores any statistics that are explicitly excluded.
- These data statistics are stored in the AWS Glue service, and you can provide AWS KMS keys to encrypt them. Refer to the Security Guide on how to provide AWS KMS keys to encrypt the AWS Glue Data Quality statistics.
- The time component is crucial for the Anomaly Detection algorithm. Based on past values, AWS Glue Data Quality determines the upper and lower bounds. During this determination, it considers the time component. The limits will differ for the same values over a one-minute interval, an hourly interval, or a daily interval.

Capturing seasonality

AWS Glue Data Quality's anomaly detection algorithm can capture seasonal patterns. For example, it can understand that weekday patterns differ from weekend patterns. This can be seen in the example below, where AWS Glue Data Quality detects a seasonal trend in the data values. You don't need to do anything specific to enable this capability. Over time, AWS Glue Data Quality learns seasonal trends and detects anomalies when these patterns break.

Cost

You will be charged based on the time it takes to detect anomalies. Every statistic is charged 1 DPU for the time it takes to detect anomalies. Refer to AWS Glue Pricing for detailed examples.

Key considerations

There is no cost to store the statistics. However, there is a limit of 100,000 statistics per account. These statistics will be stored for maximum of two years.

Configure IAM permissions for AWS Glue Data Quality

This topic provides information to help you understand the actions and resources that you an IAM administrator can use in an AWS Identity and Access Management (IAM) policy for AWS Glue Data Quality. It also includes sample IAM policies with the minimum permissions you need to use AWS Glue Data Quality with the AWS Glue Data Catalog.

For additional information about security in AWS Glue, see Security in AWS Glue.

IAM permissions for AWS Glue Data Quality

The following table lists the permissions that a user needs in order to perform specific AWS Glue Data Quality operations. To set fine-grained authorization for AWS Glue Data Quality, you can specify these actions in the `Action` element of an IAM policy statement.

AWS Glue Data Quality actions

Action	Description	Resource types
`glue:CreateDataQualityRuleset`	Grants permission to create a data quality ruleset.	`::dataQualityRuleset/<name>`
`glue:DeleteDataQualityRuleset`	Grants permission to delete a data quality ruleset.	`::dataQualityRuleset/<name>`
`glue:GetDataQualityRuleset`	Grants permission to retrieve a data quality ruleset.	`::dataQualityRuleset/<name>`
`glue:ListDataQualityRulesets`	Grants permission to retrieve all data quality rulesets.	`::dataQualityRuleset/*`

Action	Description	Resource types
glue:UpdateDataQualityRuleset	Grants permission to update a data quality ruleset.	::dataQualityRuleset/<name>
glue:GetDataQualityResult	Grants permission to retrieve a data quality task run result. This IAM action also provides permissions to the following APIS: • BatchGetDataQualityQualityResult • ListDataQualityStatistics • ListDataQualityStatisticAnnotations	::dataQualityRuleset/<name>
glue:ListDataQualityResults	Grants permission to retrieve all data quality task run results.	::dataQualityRuleset/*
glue:CancelDataQualityRuleRecommendationRun	Grants permission to stop an in-progress data quality recommendation task run.	::dataQualityRuleset/*
glue:GetDataQualityRuleRecommendationRun	Grants permission to retrieve a data quality recommendation task run.	::dataQualityRuleset/*
glue:ListDataQualityRuleRecommendationRuns	Grants permission to retrieve all data quality recommendation task runs.	::dataQualityRuleset/*
glue:StartDataQualityRuleRecommendationRun	Grants permission to start a data quality recommendation task run.	::dataQualityRuleset/*

Action	Description	Resource types
glue:CancelDataQualityRulesetEvaluationRun	Grants permission to stop an in-progress data quality task run.	::dataQualityRuleset/*
glue:GetDataQualityRulesetEvaluationRun	Grants permission to retrieve a data quality task run.	::dataQualityRuleset/*
glue:ListDataQualityRulesetEvaluationRuns	Grants permission to retrieve all data quality task runs.	::dataQualityRuleset/*
glue:StartDataQualityRulesetEvaluationRun	Grants permission to start a data quality task run.	::dataQualityRuleset/<name>
glue:PublishDataQuality	Grants permission to publish data quality results.	::dataQualityRuleset/<name>
glue:GetDataQualityModel	Grants permission to retrieve Data Quality Model.	::dataQualityRuleset/<name>, ::job/<name>
glue:GetDataQualityModelResult	Grants permission to retrieve Data Quality Model Results.	::dataQualityRuleset/<name>, ::job/<name>
glue:PutDataQualityStatisticAnnotation	Grants permission to add annotations to Statistics. This IAM action also provides permissions to the following APIS: • BatchPutDataQualityStatisticAnnotation	::dataQualityRuleset/<name>, ::job/<name>

Action	Description	Resource types
glue:PutDataQualityProfileAnnotation	Grants permission to put annotations to all Statistics in a Profile.	::dataQualityRuleset/<name>, ::job/<name>

IAM setup required for scheduling evaluation runs

IAM permissions

To run scheduled Data Quality evaluation runs, you must add the IAM:PassRole action to the permissions policy.

AWS EventBridge Scheduler required permissions

Action	Description	Resource types
iam:PassRole	Grants permission for IAM to allow the user to pass the approved roles.	ARN of the role used to call StartDataQualityRulesetEvaluationRun

Without these permissions the following error occurs:

```
"errorCode": "AccessDenied"
"errorMessage": "User: arn:aws:sts::account_id:assumed-role/AWSGlueServiceRole is not
authorized to perform: iam:PassRole on resource: arn:aws:iam::account_id:role/service-
role/AWSGlueServiceRole
because no identity-based policy allows the iam:PassRole action"
```

IAM trusted entities

The AWS Glue and AWS EventBridge Scheduler services need to be listed in the trusted entities in order to create and run a scheduled StartDataQualityEvaluationRun.

JSON

```
{
```

```
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "glue.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    },
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "scheduler.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

Example IAM policies

An IAM role for AWS Glue Data Quality needs the following types of permissions:

- Permissions for AWS Glue Data Quality operations so that you can get recommended data quality rules and run a data quality task against a table in the AWS Glue Data Catalog. The example IAM policies in this section include the minimum permissions required for AWS Glue Data Quality operations.
- Permissions that grant access to your Data Catalog table and the underlying data. These permissions vary depending on your use case. For example, for data that you catalog in Amazon S3, the permissions should include access to Amazon S3.

> **Note**
>
> You must configure Amazon S3 permissions in addition to the permissions described in this section.

Minimum permissions to get recommended data quality rules

This example policy includes the permissions you need in order to generate recommended data quality rules.

JSON

```
{

```

Minimum permissions to run a data quality task

This example policy includes the permissions you need in order to run a data quality evaluation task.

The following policy statements are optional, depending on your use case:

- `AllowCloudWatchPutMetricDataToPublishTaskMetrics` - Required if you want to publish data quality run metrics to Amazon CloudWatch.
- `AllowS3PutObjectToWriteTaskResults` - Required if you want to write data quality run results to Amazon S3.

Getting started with AWS Glue Data Quality for the Data Catalog

This getting started section provides instructions to help you get started with AWS Glue Data Quality on the AWS Glue console. You'll learn how to complete essential tasks such as generating data quality rule recommendations and evaluating a ruleset against your data.

Topics

- Prerequisites
- Step-by-step example
- Generating rule recommendations
- Monitoring rule recommendations
- Editing recommended rulesets
- Creating a new ruleset
- Running a ruleset to evaluate data quality
- Viewing the data quality score and results
- Using preprocessing queries
- Supported source types
- Related topics

Prerequisites

Before you use AWS Glue Data Quality, you should be familiar with using the Data Catalog and crawlers in AWS Glue. With AWS Glue Data Quality, you can evaluate quality for tables in a Data Catalog database. You also need the following:

- A table in the Data Catalog to evaluate your data quality ruleset against.
- An IAM role for AWS Glue that you supply when you generate rule recommendations or run a data quality task. This role must have permission to access resources that various AWS Glue Data Quality processes require to run on your behalf. These resources include AWS Glue, Amazon S3, and CloudWatch. To view example policies that include the minimum permissions for AWS Glue Data Quality, see Example IAM policies.

  To learn more about IAM roles for AWS Glue, see Create an IAM policy for the AWS Glue service and Create an IAM role for the AWS Glue service. You can also view a list of all AWS Glue permissions that are specific to data quality in Authorization for AWS Glue Data Quality actions.
- A database with at least one table that contains a variety of data. The table used in this tutorial is named `yyz-tickets`, with the table `tickets`. This data is a collection of publicly available information from the City of Toronto for parking citations. If you create your own table, make sure that it's populated with a variety of valid data to get the best set of recommended rules.

Step-by-step example

For a step-by-step example with sample datasets, see the AWS Glue Data Quality blog post.

Generating rule recommendations

Rule recommendations make it easy to get started with data quality without writing code. With AWS Glue Data Quality, you can analyze your data, identify rules, and create a ruleset that you can evaluate in a data quality task. Recommendation runs are automatically deleted after 90 days.

To generate data quality rule recommendations

1. Open the AWS Glue console at https://console.aws.amazon.com/glue/.
2. Choose **Tables** in the navigation pane. Then choose the table that you want to generate data quality rule recommendations for.
3. On the table details page, select the **Data quality** tab to access AWS Glue Data Quality rules and settings for your table.

4. On the **Data quality** tab, choose **Add rules and monitor data quality**.
5. On the **Ruleset builder** page, an alert at the top of the page will prompt you to start a recommendation task if there are no rule recommendation runs.
6. Choose **Recommend rules** to open the modal and input your parameters for the recommendation task.
7. Choose an IAM role with access to AWS Glue. This role must have permission to access resources that various AWS Glue Data Quality processes require to run on your behalf.
8. After the fields are completed according to your preferences, choose **Recommend rules** to start the recommendation task run. If recommendation runs are in progress or completed, you can manage your runs in this alert. You might need to refresh the alert to view the status change. Completed and in-progress recommendation task runs appear in the **Run history** page that lists all recommendation runs for the past 90 days.

What the recommended rules mean

AWS Glue Data Quality generates rules based on the data from each column of the input table. It uses the rules to identify potential boundaries where data can be filtered to maintain quality requirements. The following list of generated rules includes examples that are useful for understanding what the rules mean and what they might do when applied to your data.

For a full list of the generated Data Quality Definition Language (DQDL) rule types, see DQDL rule type reference.

- `IsComplete "SET_FINE_AMOUNT"` –The `IsComplete` rule verifies that the column is filled in for any given row. Use this rule to tag columns as non-optional in data.
- `Uniqueness "TICKET_NUMBER" > 0.95` – The `Uniqueness` rule verifies that the data within the column meets some threshold of uniqueness. In this example, the data that populates any given row for `"TICKET_NUMBER"` was determined to be at most 95% identical in content to all other rows, which suggests this rule.
- `ColumnValues "PROVINCE" in ["ON", "QC", "AB", "NY",...]` – The `ColumnValues` rule defines valid values for the column, based on existing column contents. In this example, the data for each row is a 2-letter license code plate for a state or province.
- `ColumnLength "INFRACTION_DESCRIPTION" between 15 and 31` – The `ColumnLength` rule enforces a length restriction on a column's data. This rule is generated from the sample data based on the minimum and maximum recorded lengths for a column of strings.

Monitoring rule recommendations

When data quality rule recommendations are running, the **Add rules and monitor data quality** page displays information and additional actions that you can take in the top bar.

When rule recommendations are in progress, you can choose **Stop run** before the recommendation task is complete. While the task is in progress, you will see the status, **in progress**, and the date and time when the run started.

When the rule recommendations are complete, the rule recommendation bar displays the number of rules recommended, the status of the last recommendation run, and the date and timestamp when it finished.

You can add the recommended rules by choosing **Insert Rule Recommendation**. To view previously recommended rules, select a specific date. To run a new recommendation, choose **More actions**, and then choose **Recommended rules**.

Set default settings by choosing **Manage user settings**. You can set the default path for Amazon S3 to store rulesets or to set up a default role to run the Data Catalog.

Editing recommended rulesets

Because AWS Glue Data Quality generates rules based on existing data that you have available, you might see some unexpected or undesirable rules in the automated suggestions. In order to get the most out of the recommended rulesets, you need to evaluate and modify them. For this step of the tutorial, you take the rules generated in the previous step and adjust them to enforce more restrictive qualities on some data. You also relax other rules to ensure that correct, unique data can be added later.

Edit a suggested ruleset

1. In the AWS Glue console, choose **Data Catalog**, and then choose **Databases tables** in the navigation pane. Choose the table `tickets`.
2. On the table details page, choose the **Data quality** tab to access AWS Glue Data Quality rules and settings for the table.
3. In the **Rulesets** section, select the ruleset generated in Generating rule recommendations.
4. Choose **Actions**, and then choose **Edit** in the console window. The ruleset editor loads in the console. It includes an editing pane for your rules and a quick reference for DQDL.

5. Remove line 2 of the script. This relaxes the requirement that the database size is constrained within a certain number of rows. After the edit, your file should contain the following on lines 1–3:

```
Rules = [
    IsComplete "TAG_NUMBER_MASKED",
    ColumnLength "TAG_NUMBER_MASKED" between 6 and 9,
```

6. Remove line 25 of the script. This relaxes the requirement that 96% of recorded provinces are ON. After the edit, your file should contain the following from line 24 to the end of the ruleset:

```
ColumnValues "PROVINCE" in ["ON", "QC", "AB", "NY", "AZ", "NS", "BC", "MI", "PQ",
 "MB", "PA", "FL", "SK", "NJ", "OH", "NB", "IL", "MA", "CA",
    "VA", "TX", "NF", "MD", "PE", "CT", "NC", "GA", "IN", "OR", "MN", "TN", "WI",
 "KY", "MO", "WA", "NH", "SC", "CO", "OK", "VT", "RI", "ME", "AL",
    "YT", "IA", "DE", "AR", "LA", "XX", "WV", "MT", "KS", "NT", "DC", "NV", "NE",
 "UT", "MS", "NM", "ID", "SD", "ND", "AK", "NU", "GO", "WY", "HI"],
ColumnLength "PROVINCE" = 2
]
```

7. Change line 14 to the following:

```
IsComplete "TIME_OF_INFRACTION",
```

   This *strengthens* the requirement on the column by limiting the database to only tickets that contain a recorded time of infraction. You should always consider tickets without a recorded time of infraction to be invalid data in this dataset. This is different than situations where partitioning or transformation might be more appropriate for further data use or inspection to determine a quality rule.

8. Choose **Update Ruleset**at the bottom of the console page.

Creating a new ruleset

A ruleset is a group of data quality rules that you evaluate against your data. In the AWS Glue console, you can author custom rulesets using Data Quality Definition Language (DQDL).

To create a data quality ruleset

1. In the AWS Glue console, choose **Data Catalog**, choose **Databases**, and then choose **Tables** in the navigation pane. Select the table `tickets`.
2. Open the **Data quality** tab.
3. In the **Rulesets** section, choose **Create ruleset**. The DQDL editor launches in the console. It has a text area for direct editing, and a quick reference for DQDL rules and the table schema.
4. Start adding rules to the text area of the DQDL editor. You can either write rules directly from this tutorial, or use the **DQDL rule builder** feature of the data quality rules editor.

   > **Note**
   >
   > **How to use the DQDL rule builder**
   >
   > 1. Select a rule type from the list, and select the plus sign to insert example syntax into the editor pane.
   > 2. Exchange the placeholder column names with your own column names. Column names from the table are available in the **Schema** tab.
   > 3. Update the expression parameter as you see fit. For a full list of expressions that DQDL supports, see Expressions.

   As an example, the following rules are constraints for data validation of the `ticket_number` column in the `tickets` table. To add the following rules, use the DQDL rule builder or directly edit your ruleset:

   ```
   IsComplete "ticket_number",
   IsUnique "ticket_number",
   ColumnValues "ticket_number" > 9000000000
   ```

5. Provide a name for your new ruleset in the **Ruleset name** field.
6. Choose **Save ruleset**.

Evaluating data quality across multiple datasets

You can set up data quality rules across multiple datasets using ReferentialIntegrity and DatasetMatch rulesets. ReferentialIntegrity checks to see if data in the primary dataset is present in other datasets.

To add a reference dataset, choose the **Schema** tab and then choose **Update reference tables**. You will be prompted to select a database and a table. You can add the table and then set up data quality rules. Rule types like AggregateMatch, RowCountMatch, ReferentialIntegrity, SchemaMatch, and DatasetMatch support the ability to perform data quality checks across multiple datasets.

Running a ruleset to evaluate data quality

When you run a data quality task, AWS Glue Data Quality evaluates a ruleset against your data and calculates a data quality score. This score represents the percentage of data quality rules that passed for the input.

To run a data quality task

1. In the AWS Glue console, choose **Data Catalog**, choose **Databases**, and then choose **Tables** in the navigation pane. Select the table `tickets`.
2. Choose the **Data quality** tab.
3. In the **Rulesets** list, select the ruleset that you want to evaluate against the table. For this step, we recommend using a ruleset that you've written or modified already rather than generated rules. Choose **Run**.
4. In the modal, choose your IAM role. This role must have permission to access resources that various AWS Glue Data Quality processes require to run on your behalf. You can save the IAM role as the default or modify it by going to the **Default Setting** page.
5. Under **Data quality actions**, choose whether you want to **Publish metrics to Amazon CloudWatch**. When this option is selected, AWS Glue Data Quality publishes metrics that indicate the number of rules that passed and the number of rules that failed. To take action on metrics stored this way, you can use CloudWatch alarms. Key metrics are also published to Amazon EventBridge for you to set up alerts. For more information, see Setting up alerts, deployments, and scheduling.
6. In **Run Frequency**, choose run on demand or schedule the ruleset. When you schedule a ruleset, you're prompted for a task name. The schedule will be created in Amazon EventBridge. You can edit your schedule in Amazon EventBridge.

7. To save the data quality results in Amazon S3, select a **Data quality results location**. The IAM role that you previously selected for this task must have write access to this location.
8. Under **Additional Configurations**, enter the **Requested number of workers** that you want AWS Glue to allocate for your data quality task.
9. You can optionally set up a filter at the data source. This helps you reduce the data that you're reading. You can also use a filter to run incremental validations by selecting partition information and passing them as parameters via API calls. To improve performance, you can provide a partition predicate.
10. Choose **Run**. You should see your new task in the **Data quality task runs** list. When the **Run status** column for the task shows as **Completed**, you can view the quality score results. You might need to refresh your console window for the status to update correctly.
11. To view the column for the data quality result details, choose the “+” icon to expand the ruleset. The results show you the rules that passed and failed in the evaluation, and what triggered the rule failure.

Viewing the data quality score and results

To see the latest run on all created rulesets

1. In the AWS Glue console, choose **Tables** in the navigation pane. Then choose the table that you want to run a data quality task for.
2. Choose the **Data quality** tab.
3. The **Data quality snapshot** shows a general trend of runs over time. The last 10 runs over all rulesets are displayed by default. To filter by ruleset, select the desired one from the dropdown list. If there are less than 10 runs, all the completed runs that are available are displayed.
4. In the **Data quality** table, each ruleset with its latest run (if there is one) is shown, along with the score. Expanding the ruleset displays the rules that are in that ruleset, along with the rule results for that run.

To see the latest run on a particular ruleset

1. In the AWS Glue console, choose **Tables** in the navigation pane. Then choose the table that you want to run a data quality task for.
2. Choose the **Data quality** tab.

3. In the **Data quality** table, choose on a specific ruleset.
4. On the **Ruleset details** page, choose the **Run history** tab.

   All of the evaluation runs for this particular ruleset are listed in the table within this tab. You can see the history of the scores and the status of the runs.
5. To see more information about a particular run, choose the **Run ID** to go to the **Evaluation run details** page. On this page, you can see specifics about the run and more details about the status of individual rule results.

Using preprocessing queries

AWS Glue Data Quality supports preprocessing queries that allow you to transform your data before running data quality checks. This feature enables you to:

- Create derived columns for data quality validation.
- Filter data based on specific conditions.
- Perform calculations or transformations for quality checks.
- Validate relationships between columns.

> **Note**
>
> This feature is only supported in APIs and is not supported via the console.

Using preprocessing queries with the CLI and SDK

Recommendation runs

The following examples show how to use preprocessing queries with recommendation runs.

AWS CLI:

```
aws glue start-data-quality-rule-recommendation-run \
  --data-source '{"DataQualityGlueTable": { \
    "DatabaseName": "mydatabase", \
    "TableName": "mytable", \
    "PreProcessingQuery": "SELECT sepal_length, sepal_width, petal_length, petal_width,
 class, (sepal_length + sepal_width) as sepal_total FROM `mydatabase.mytable`" \
```

```
  }}' \
  --role "arn:aws:iam::123456789012:role/GlueDataQualityRole" \
  --created-ruleset-name "my-ruleset-with-preprocessing"
```

Java SDK:

```
StartDataQualityRuleRecommendationRunRequest request = new
 StartDataQualityRuleRecommendationRunRequest()
    .withDataSource(new DataSource()
        .withDataQualityGlueTable(new DataQualityGlueTable()
            .withDatabaseName("mydatabase")
            .withTableName("mytable")
            .withPreProcessingQuery("SELECT sepal_length, sepal_width, " +
                "(sepal_length + sepal_width) as sepal_total " +
                "FROM `mydatabase.mytable`")))
    .withRole("arn:aws:iam::123456789012:role/GlueDataQualityRole")
    .withCreatedRulesetName("my-ruleset-with-preprocessing");

glueClient.startDataQualityRuleRecommendationRun(request);
```

Ruleset evaluation runs

The following examples show how to use preprocessing queries with ruleset evaluation runs.

AWS CLI:

```
aws glue start-data-quality-ruleset-evaluation-run \
  --data-source '{"DataQualityGlueTable": { \
    "DatabaseName": "mydatabase", \
    "TableName": "mytable", \
    "PreProcessingQuery": "SELECT order_id, amount, (tax + shipping) as total_fees FROM
 `mydatabase.mytable`" \
  }}' \
  --role "arn:aws:iam::123456789012:role/GlueDataQualityRole" \
  --ruleset-names '["my-ruleset"]'
```

Java SDK:

```
StartDataQualityRulesetEvaluationRunRequest request = new
 StartDataQualityRulesetEvaluationRunRequest()
    .withDataSource(new DataSource()
```

```
        .withDataQualityGlueTable(new DataQualityGlueTable()
            .withDatabaseName("mydatabase")
            .withTableName("mytable")
            .withPreProcessingQuery("SELECT order_id, amount, " +
                "(tax + shipping) as total_fees " +
                "FROM `mydatabase.mytable`")))
    .withRole("arn:aws:iam::123456789012:role/GlueDataQualityRole")
    .withRulesetNames(Arrays.asList("my-ruleset"));

glueClient.startDataQualityRulesetEvaluationRun(request);
```

Considerations when authoring preprocessing queries

When writing a preprocessing query:

- The table reference must be formatted as `` `databaseName.tableName` `` using backticks.
- The query must be a valid SELECT statement.
- Column names in the query output will be used for data quality rules.

The following example shows a preprocessing query:

```
SELECT
    sepal_length,
    sepal_width,
    petal_length,
    petal_width,
    class,
    (sepal_length + sepal_width) as sepal_total
FROM `mydatabase.mytable`
```

Limitations

- The query must reference the table using backticks and the full `` `databaseName.tableName` `` format.
- Maximum query length is 51,200 characters.
- The query must return at least one row of data.
- All columns referenced in your ruleset must be present in the query output.

Supported source types

Table type support by AWS Lake Formation configuration

Table Type	AWS Lake Formation - All Table Access	AWS Lake Formation Enabled with Columns	AWS Lake Formation Enabled with Data Filters	Cross-Account AWS Lake Formation Support - All Table Access	AWS Lake Formation Disabled
Parquet	Supported	Not Supported	Not Supported	Supported	Supported
ORC	Supported	Not Supported	Not Supported	Supported	Supported
CSV, JSON, TSV	Supported	Not Supported	Not Supported	Supported	Supported
Avro	Supported	Not Supported	Not Supported	Supported	Supported
JSON	Supported	Not Supported	Not Supported	Supported	Supported
Iceberg	Supported	Not Supported	Not Supported	Supported	Supported
HUDI	Not Supported	Not Supported	Not Supported	Not Supported	Supported
Delta	Not Supported	Not Supported	Not Supported	Not Supported	Supported
RMS	Supported*	Supported*	Supported*	Not Supported	Not Supported
Amazon S3 Tables	Supported*	Not Supported	Not Supported	Not applicable	Supported

Table Type	AWS Lake Formation - All Table Access	AWS Lake Formation Enabled with Columns	AWS Lake Formation Enabled with Data Filters	Cross-Account AWS Lake Formation Support - All Table Access	AWS Lake Formation Disabled
Amazon RDS and Aurora	Not applicable	Not applicable	Not applicable	Not applicable	Not Supported
JDBC	Not applicable	Not applicable	Not applicable	Not applicable	Supported

* Amazon S3 tables and SageMaker Lakehouse support in AWS Glue Console is not supported. Currently, Amazon S3 table and SageMaker Lakehouse Data Catalog Recommendation Runs and Data Catalog Data Quality Evaluation runs are only supported via the CLI.

Other known limitations

- Delta Lake Symlink Tables: Not supported for AWS Glue Data Quality recommendation runs or Data Catalog Data Quality evaluation runs.
- Amazon S3 Table Asset publishing in SageMaker Unified Studio: Currently, publishing Amazon S3 Tables as Assets in SageMaker Unified Studio is unavailable; visualizing Amazon S3 Table Data Quality runs is unavailable from SageMaker Unified Studio as a result.

Evaluating data quality with AWS Glue Studio

AWS Glue Data Quality evaluates and monitors the quality of your data based on rules that you define. This makes it easy to identify the data that needs action. In AWS Glue Studio, you can add data quality nodes to your visual job to create data quality rules on tables in your Data Catalog.

You can then monitor and evaluate changes to your datasets as they evolve over time. For an overview of how to work with AWS Glue Data Quality in AWS Glue Studio, see the following video.

The following are the high-level steps for how you work with AWS Glue Data Quality:

1. **Create data quality rules** – Build a set of data quality rules using the DQDL builder by choosing built-in rulesets that you configure.
2. **Configure a data quality job** – Define actions based on the data quality results and output options.
3. **Save and run a data quality job** – Create and run a job. Saving the job will save the rulesets that you created for the job.
4. **Monitor and review the data quality results** – Review the data quality results after the job run is complete. Optionally, schedule the job for a future date.

Benefits

Data analysts, data engineers, and data scientists can use the Evaluate Data Quality node in AWS Glue Studio to analyze, configure, monitor, and improve the quality of data from the visual job editor. The benefits of using the data quality node include the following:

- **You can detect data quality issues** - You can check for issues by creating rules that check characteristics of your datasets.
- **It's easy to get started** - You can start with pre-built rules and actions.
- **Tight integration** - You can use data quality nodes in AWS Glue Studio because AWS Glue Data Quality runs on top of the AWS Glue Data Catalog.

Evaluating data quality for ETL jobs in AWS Glue Studio

In this tutorial, you get started with AWS Glue Data Quality in AWS Glue Studio. You will learn how to:

- Create rules using the Data Quality Definition Language (DQDL) rule builder.
- Specify data quality actions, data to output, and the output location of the data quality results.
- Review data quality results.

To practice with an example, review the blog post **Getting started with AWS Glue Data Quality for ETL pipelines**.

Step 1: Add the Evaluate Data Quality transform node to the visual job

In this step, you add the Evaluate Data Quality node to the visual job editor.

To add the data quality node

1. In the AWS Glue Studio console, choose **Visual with a source and target** from the **Create job** section, and then choose **Create**.
2. Choose a node that you want to apply the data quality transform to. Typically, this will be a transform node or a data source.
3. Open the resource panel on the left by choosing the "+" icon. Then search for **Evaluate Data Quality** in the search bar and choose **Evaluate Data Quality** from the search results.
4. The visual job editor showsthe **Evaluate Data Quality** transform node branching from the node you selected. On the right side of the console, the **Transform** tab is automatically opened. If you need to change the parent node, choose the **Node properties** tab, and then choose the node parent from the dropdown menu.

   When you choose a new node parent, a new connection is made between the parent node and the **Evaluate Data Quality** node. Remove any unwanted parent nodes. Only one parent node can be connected to one **Evaluate Data Quality** node.
5. The Evaluate Data Quality transform supports multiple parents so you can validate data quality rules across multiple datasets. Rules that support multiple datasets include ReferentialIntegrity, DatasetMatch, SchemaMatch, RowCountMatch, and AggregateMatch.

   When you add multiple inputs to the Evaluate Data Quality transform, you need to select your “primary” input. Your primary input is the dataset that you want to validate data quality for. All other nodes or inputs are treated as references.

   You can use the Evaluate Data Quality transform to identify specific records that failed data quality checks. We recommend that you choose your primary dataset because new columns that flag bad records are added to the primary dataset.
6. You can specify aliases for input data sources. Aliases provide another way to reference the input source when you're using the ReferentialIntegrity rule. Becauseonly one data source can be designated as the primary source, each additional data source that you add will require an alias.

In the following example, the ReferentialIntegrity rule specifies the input data source by the alias name and performs a one-to-one comparison to the primary data source.

```
Rules = [
 ReferentialIntegrity “Aliasname.name” = 1
]
```

Step 2: Create a rule using DQDL

In this step, you create a rule using DQDL. For this tutorial, you create a single rule using the **Completeness** rule type. This rule type checks the percentage of complete (non-null) values in a column against a given expression. For more information about using DQDL, see DQDL.

1. On the **Transform** tab, add a **Rule type** by choosing the **Insert** button. This adds the rule type to the rule editor, where you can enter the parameters for the rule.

   Note

   When you're editing rules, ensure that the rules are within the brackets and that the rules are separated by commas. For example, a complete rule expression will look like the following:

   ```
   Rules= [
       Completeness "year">0.8, Completeness "month">0.8
   ]
   ```

   This example specifies the parameter for completeness for the columns named 'year' and 'month'. For the rule to pass, these columns must be greater than 80% 'complete', or must have data in over 80% of instances for each respective column.

   In this example, search for and insert the **Completeness** rule type. This adds the rule type to the rule editor. This rule type has the following syntax: `Completeness <COL_NAME> <EXPRESSION>`.

Most rule types require that you provide an expression as a parameter in order to create a Boolean response. For more information on supported DQDL expressions, see DQDL expressions. Next, you'll add the column name.

2. In the DQDL rule builder, choose the **Schema** tab. Use the search bar to locate the column name in the input schema. The input schema displays the column name and data type.
3. In the rule editor, click to the right of the rule type to insert the cursor where the column will be inserted. Alternately, you can enter in the name of the column in the rule.

   For example, from the list of columns in the input schema list, choose the **Insert** button next to the column (in this example, **year**). This adds the column to the rule.
4. Then, in the rule editor, add an expression to evaluate the rule. Because the **Completeness** rule type checks the percentage of complete (non-null) values in a column against a given expression, enter an expression such as `> 0.8`. This rule checks the column if it's greater than 80% complete (non-null) values.

Step 3: Configure data quality outputs

After creating data quality rules, you can select additional options to specify data quality node output.

1. In **Data quality transform output**, choose from the following options:

   - **Original data** – Choose to output original input data. When you choose this option, a new child node “rowLevelOutcomes” is added to the job. The schema matches the schema of the primary dataset that was passed as input to the transform. This option is useful if you just want to pass the data through and fail the job when quality issues occur.

     Another use case is when you want to detect bad records that failed data quality checks. To detect bad records, choose the option **Add new columns to indicate data quality errors**. This action adds four new columns to the schema of the “rowLevelOutcomes” transform.
     - **DataQualityRulesPass** (string array) – Provides an array of rules that passed data quality checks.
     - **DataQualityRulesFail** (string array) – Provides an array of rules that failed data quality checks.
     - **DataQualityRulesSkip** (string array) – Provides an array of rules that were skipped. The following rules cannot identify error records because they're applied at the dataset level.

- AggregateMatch
- ColumnCount
- ColumnExists
- ColumnNamesMatchPattern
- CustomSql
- RowCount
- RowCountMatch
- StandardDeviation
- Mean
- ColumnCorrelation

- **DataQualityEvaluationResult** – Provides “Passed” or “Failed” status at the row level. Note that your overall results can be FAIL, but a certain record might pass. For example, the RowCount rule might have failed, but all other rules might have been successful. In such instances, this field status is 'Passed'.

2. **Data quality results** – Choose to output configured rules and their pass or fail status. This option is useful if you want to write your results to Amazon S3 or other databases.
3. **Data quality output settings** (Optional) – Choose **Data quality output settings** to reveal the **Data quality result location** field. Then, choose **Browse** to search for an Amazon S3 location to set as the data quality output target.

Step 4. Configure data quality actions

You can use actions to publish metrics to CloudWatch or to stop jobs based on specific criteria. Actions are only available after you create a rule. When you choose this option, the same metrics are also published to Amazon EventBridge. You can use these options to create alerts for notification.

- **On ruleset failure** – You can choose what to do if a ruleset fails while the job is running. If you want the job to fail if data quality fails, choose when the job should fail by selecting one of the following options. By default, this action is not selected, and the job completes its run even if data quality rules fail.
  - **None** – If you choose **None** (default), the job does not fail and continues to run despite ruleset failures.

- **Fail job after loading data to target** – The job fails and no data is saved. In order to save the results, choose an Amazon S3 location where the data quality results will be saved.
- **Fail job without loading to target data** – This option fails the job immediately when a data quality error occurs. It does not load any data targets, including the results from the data quality transform.

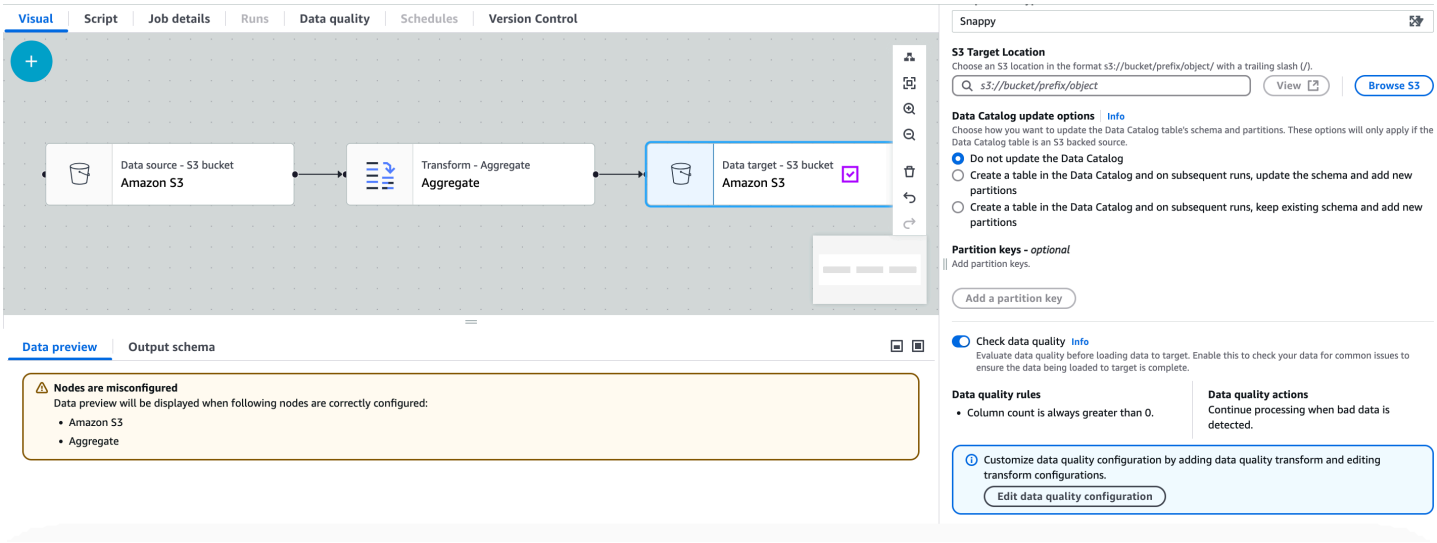
Step 5: View data quality results

After running the job, view the data quality results by choosing the **Data quality** tab.

1. For each job run, view the data quality results. Each node displays a data quality status and status detail. Choose a node to view all rules and the status of each rule.
2. Choose **Download results** to download a CSV file that contains information about the job run and data quality results.
3. If you have more than one job run with data quality results, you can filter the results by date and time range. Choose *Filter by a date and time range* to expand the filter window.
4. Choose a relative range or absolute range. For absolute ranges, use the calendar to select a date, and enter values for start time and end time. When you're done, choose **Apply**.

Automatic Data Quality

When you create a AWS Glue ETL job with Amazon S3 as the target, AWS Glue ETL automatically enables a Data Quality rule that checks if the data being loaded has at least one column. This rule is designed to ensure that the data being loaded is not empty or corrupted. However, if this rule fails, the job will not fail; instead, you will notice a reduction in your data quality score. Additionally, Anomaly Detection is enabled by default, which monitors the number of columns in the data. If there are any variations or abnormalities in the column count, AWS Glue ETL will inform you about these anomalies. This feature helps you identify potential issues with the data and take appropriate actions. To view the Data Quality rule and its configuration, you can click on the Amazon S3 target in your AWS Glue ETL job. The rule's configuration will be displayed, as shown in the provided screenshot.



You can add additional data quality rules by selecting **Edit data quality configuration**.

Aggregated Metrics

You may require aggregated metrics such as number of records that passed, failed, skipped at a rule level or at the ruleset level to build dashboards. In order to get the Aggregated Metrics and Rule Metrics for each rule, first, enable Aggregated Metrics by adding the `publishAggregatedMetrics` option to your `EvaluateDataQuality` function.

The possible options for `additional_options` `publishAggregatedMetrics` are `ENABLED` and `DISABLED`. As an example:

```
EvaluateDataQualityMultiframe = EvaluateDataQuality().process_rows(
    frame=medicare_dyf,
    ruleset=EvaluateDataQuality_ruleset,
    publishing_options={
        "dataQualityEvaluationContext": "EvaluateDataQualityMultiframe",
        "enableDataQualityCloudWatchMetrics": False,
        "enableDataQualityResultsPublishing": False,
    },
    additional_options={"publishAggregatedMetrics.status": "ENABLED"},
)
```

If not specified, the `publishAggregatedMetrics.status` is `DISABLED` by default and the ruleMetrics and aggregated metrics would now be computed. This feature is currently supported in AWS Glue Interactive Sessions and in Glue ETL jobs. This is not supported in Glue Catalog Data Quality APIs.

Retrieving aggregated metrics results

When `additionalOptions "publishAggregatedMetrics.status": "ENABLED"`, you can get the results in two places:

1. `AggregatedMetrics` and `RuleMetrics` are returned through the `GetDataQualityResult()` when providing the `resultId` where `AggregatedMetrics` and `RuleMetrics` include:

   Aggregated Metrics:

   - Total rows processed
   - Total rows passed
   - Total rows failed
   - Total Rules Processed
   - Total Rules Passed
   - Total Rules Failed

```
[redacted] % aws --region us-east-1 glue get-data-quality-result --result-id "dqresult-09655f0234b3e3d129381bd162d0347ed25d1c05"
{
    "ResultId": "dqresult-09655f0234b3e3d129381bd162d0347ed25d1c05",
    "ProfileId": "dqprofile-[redacted]",
    "Score": 0.6666666666666666,
    "RulesetName": "EvaluateDataQuality_node1741974822533",
    "EvaluationContext": "EvaluateDataQuality_node1741974822533",
    "StartedOn": 1750687515.374,
    "CompletedOn": 1750687537.485,
    "JobName": "[redacted]_aggregatedmetrics_test",
    "JobRunId": "jr_[redacted]",
    "RuleResults": [
        {
            "Name": "Rule_1",
            "Description": "IsUnique \"customer_identifier\"",
            "Result": "PASS",
            "EvaluatedMetrics": {
                "Column.customer_identifier.Uniqueness": 1.0
            },
            "EvaluatedRule": "IsUnique \"customer_identifier\"",
            "RuleMetrics": {
                "rows_passed": 10.0,
                "rows_failed": 0.0,
                "rows_skipped": 0.0,
                "total_rows": 10.0
            }
        },
        {
            "Name": "Rule_2",
            "Description": "RowCount > 10",
            "EvaluationMessage": "Value: 10 does not meet the constraint requirement!",
            "Result": "FAIL",
            "EvaluatedMetrics": {
                "Dataset.*.RowCount": 10.0
            },
            "EvaluatedRule": "RowCount > 10",
            "RuleMetrics": {
                "rows_passed": 0.0,
                "rows_failed": 0.0,
                "rows_skipped": 10.0,
                "total_rows": 10.0
            }
        },
        {
            "Name": "Rule_3",
            "Description": "Completeness \"customer_identifier\" > 0.5",
            "Result": "PASS",
            "EvaluatedMetrics": {
                "Column.customer_identifier.Completeness": 1.0
            },
            "EvaluatedRule": "Completeness \"customer_identifier\" > 0.5",
            "RuleMetrics": {
                "rows_passed": 10.0,
                "rows_failed": 0.0,
                "rows_skipped": 0.0,
                "total_rows": 10.0
            }
        }
    ],
    "AggregatedMetrics": {
        "TotalRowsProcessed": 10.0,
        "TotalRowsPassed": 10.0,
        "TotalRowsFailed": 0.0,
        "TotalRulesProcessed": 3.0,
        "TotalRulesPassed": 2.0,
        "TotalRulesFailed": 1.0
    }
}
```

Also, at a rule level, the following metrics are provided:

Rule Metrics:

- Rows Passed
- Rows Failed
- Row Skipped
- Total Rows Processed

2. `AggregatedMetrics` is returned as an additional data frame and `RuleOutcomes` data frame is augmented to include `RuleMetrics`.

Example implementation

The following example shows how to implement aggregated metrics in Scala:

```
// Script generated for node Evaluate Data Quality
val EvaluateDataQuality_node1741974822533_ruleset = """
  # Example rules: Completeness "colA" between 0.4 and 0.8, ColumnCount > 10
  Rules = [
      IsUnique "customer_identifier",
      RowCount > 10,
      Completeness "customer_identifier" > 0.5
  ]
"""

val EvaluateDataQuality_node1741974822533 =
 EvaluateDataQuality.processRows(frame=ChangeSchema_node1742850392012,
 ruleset=EvaluateDataQuality_node1741974822533_ruleset,
 publishingOptions=JsonOptions("""{"dataQualityEvaluationContext":
 "EvaluateDataQuality_node1741974822533", "enableDataQualityCloudWatchMetrics":
 "true", "enableDataQualityResultsPublishing": "true"}"""),
 additionalOptions=JsonOptions("""{"compositeRuleEvaluation.method":"ROW","observations.scope":
 "publishAggregatedMetrics.status": "ENABLED"}""" ))

println("---------------------------------ROW LEVEL
 OUTCOMES---------------------------------")
val rowLevelOutcomes_node = EvaluateDataQuality_node1741974822533("rowLevelOutcomes")

rowLevelOutcomes_node.show(10)

 println("---------------------------------RULE LEVEL
 OUTCOMES---------------------------------")

val ruleOutcomes_node = EvaluateDataQuality_node1741974822533("ruleOutcomes")

ruleOutcomes_node.show()

 println("---------------------------------AGGREGATED
 METRICS---------------------------------")

val aggregatedMetrics_node = EvaluateDataQuality_node1741974822533("aggregatedMetrics")
```

```
aggregatedMetrics_node.show()
```

Sample results

Results are returned as follows:

```
{
    "Rule": "IsUnique \"customer_identifier\"",
    "Outcome": "Passed",
    "FailureReason": null,
    "EvaluatedMetrics": {
        "Column.customer_identifier.Uniqueness": 1
    },
    "EvaluatedRule": "IsUnique \"customer_identifier\"",
    "PassedCount": 10,
    "FailedCount": 0,
    "SkippedCount": 0,
    "TotalCount": 10
}
{
    "Rule": "RowCount > 10",
    "Outcome": "Failed",
    "FailureReason": "Value: 10 does not meet the constraint requirement!",
    "EvaluatedMetrics": {
        "Dataset.*.RowCount": 10
    },
    "EvaluatedRule": "RowCount > 10",
    "PassedCount": 0,
    "FailedCount": 0,
    "SkippedCount": 10,
    "TotalCount": 10
}
{
    "Rule": "Completeness \"customer_identifier\" > 0.5",
    "Outcome": "Passed",
    "FailureReason": null,
    "EvaluatedMetrics": {
        "Column.customer_identifier.Completeness": 1
    },
    "EvaluatedRule": "Completeness \"customer_identifier\" > 0.5",
    "PassedCount": 10,
    "FailedCount": 0,
    "SkippedCount": 0,
```

```
    "TotalCount": 10
}
```

Aggregated Metrics are as follows:

```
{ "TotalRowsProcessed": 10, "PassedRows": 10, "FailedRows": 0, "TotalRulesProcessed":
 3, "RulesPassed": 2, "RulesFailed": 1 }
```

Data Quality rule builder

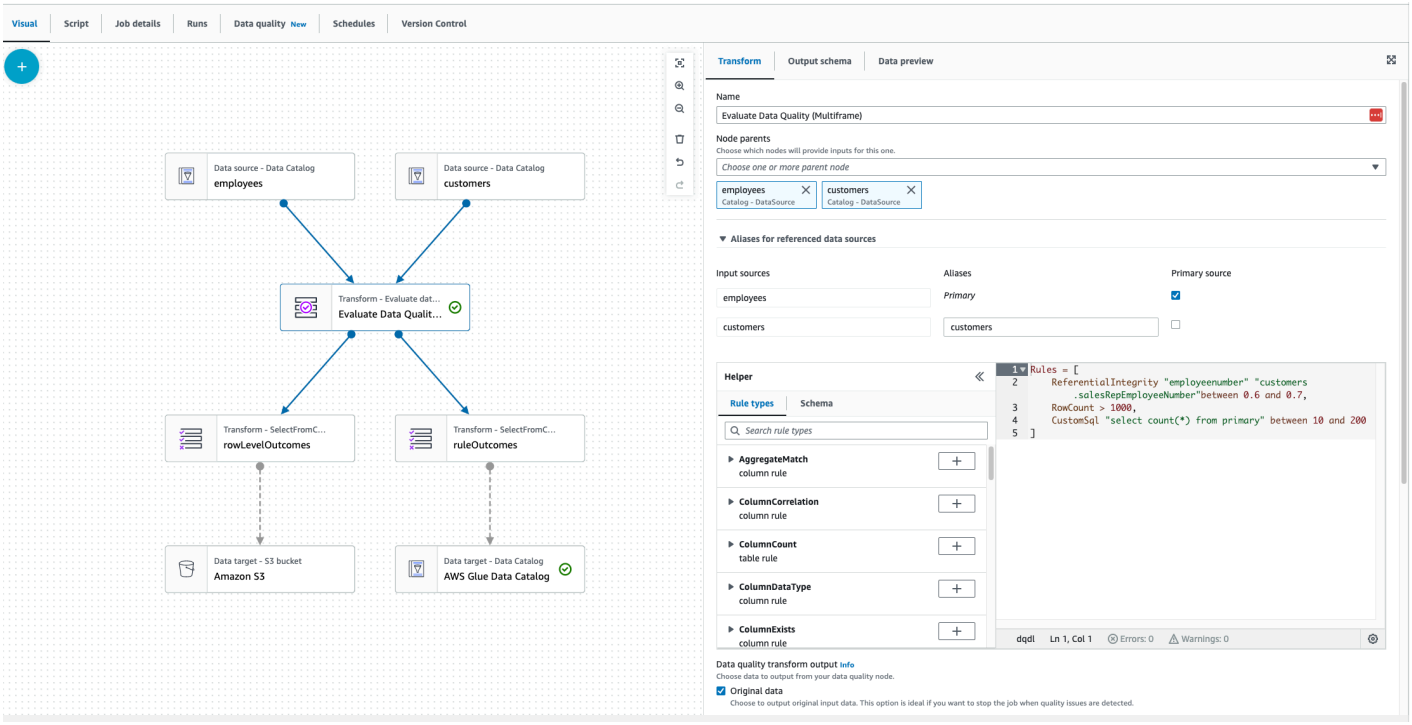
With the Data Quality Definition Language (DQDL) rule builder, you can create data quality rules to evaluate your data. Start by selecting a rule type, and then specify the parameters in the rule editor. The rule editor also shows you any errors and warnings as you create rules.

The DQDL guide provides comprehensive documentation on how to construct rules using the DQDL syntax, built-in rule types, and examples.

Evaluate Data Quality node

When you're working with the **Evaluate Data Quality** transform node and the DQDL rule builder, you can expand the working space.

- To expand the **Transform** tab to fill the entire screen, choose the expand icon in the upper-right hand corner of the node details panel.
- To expand the DQDL rule editor, choose the **<<** icon to expand the rule editor and collapse the **Rule types** and **Schema** tabs.



Components

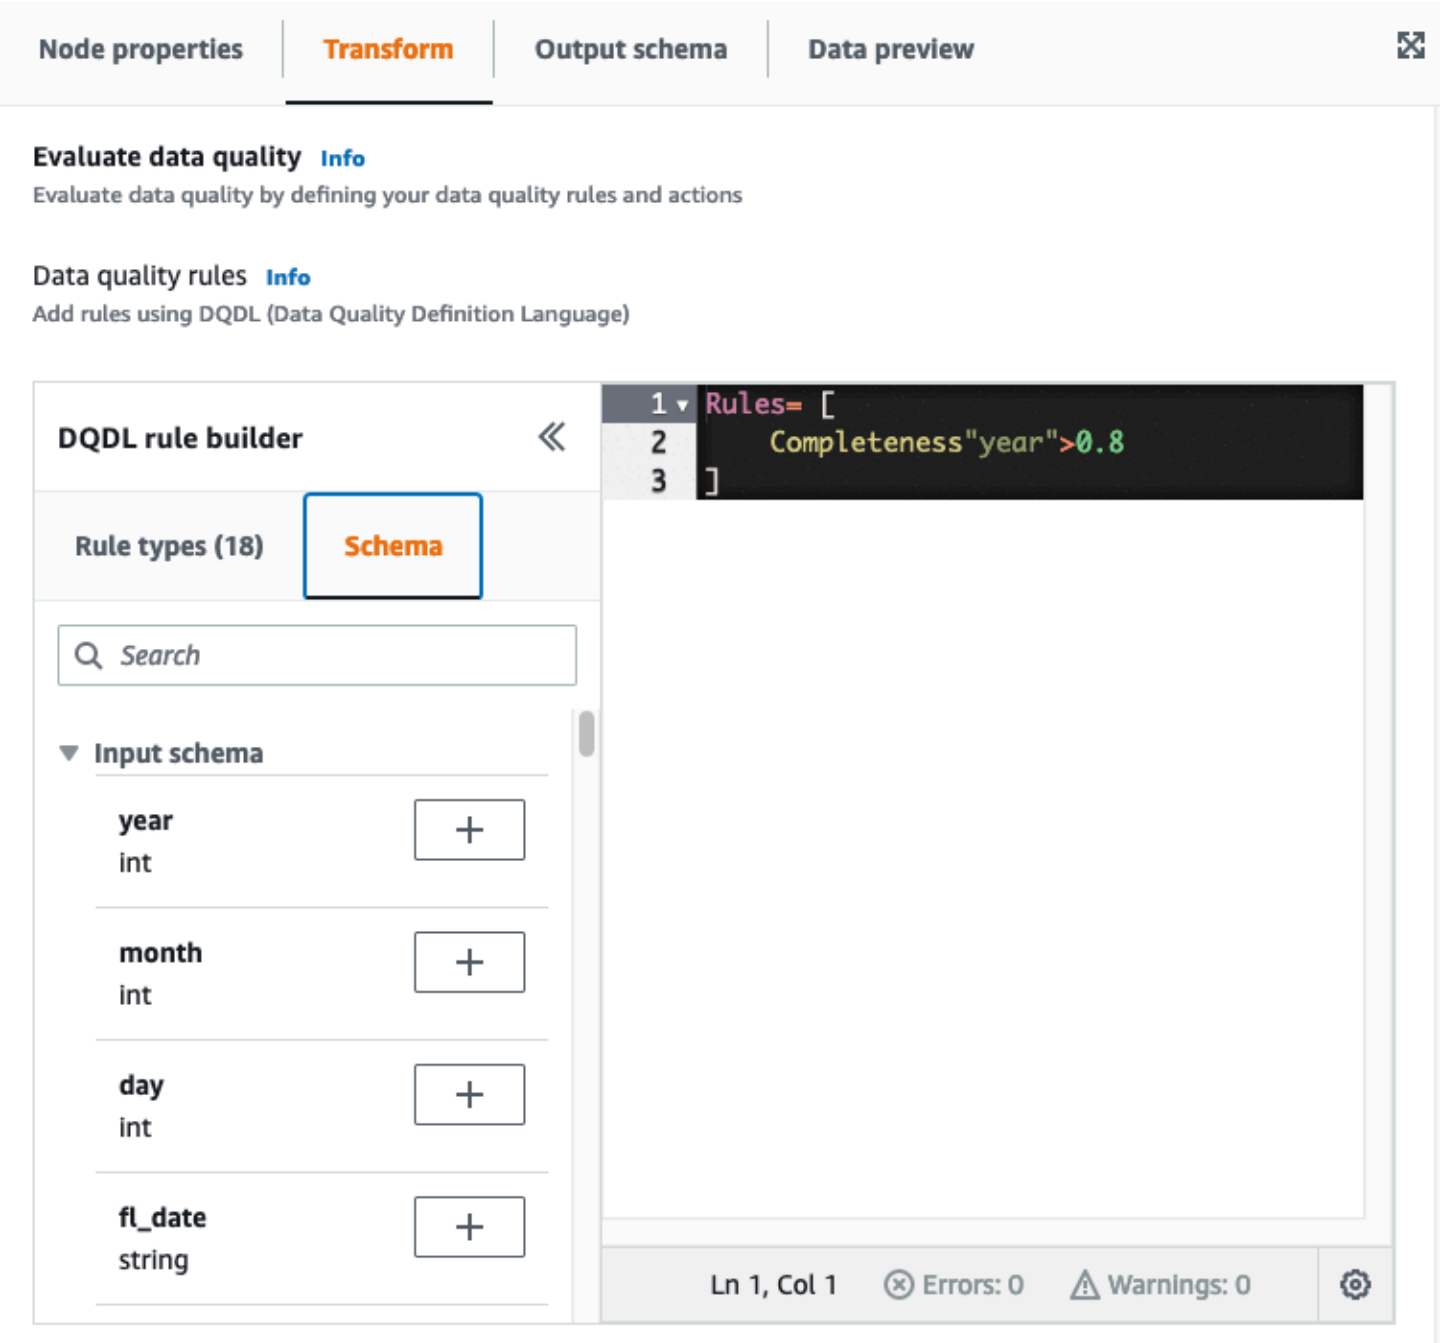
There are 26 rule types that are built into AWS Glue Studio. Each rule type has a description and examples of how they can be used.

Data quality rule types

AWS Glue Studio provides built-in rule types for ease in creating a rule. For more information on rule types, see DQDL rule type reference.

Schema

The **Schema** tab displays the column names and data type from the parent node. Schemas from multiple nodes are displayed. You can view the input schema, search by column name, and insert the column into the rule editor.



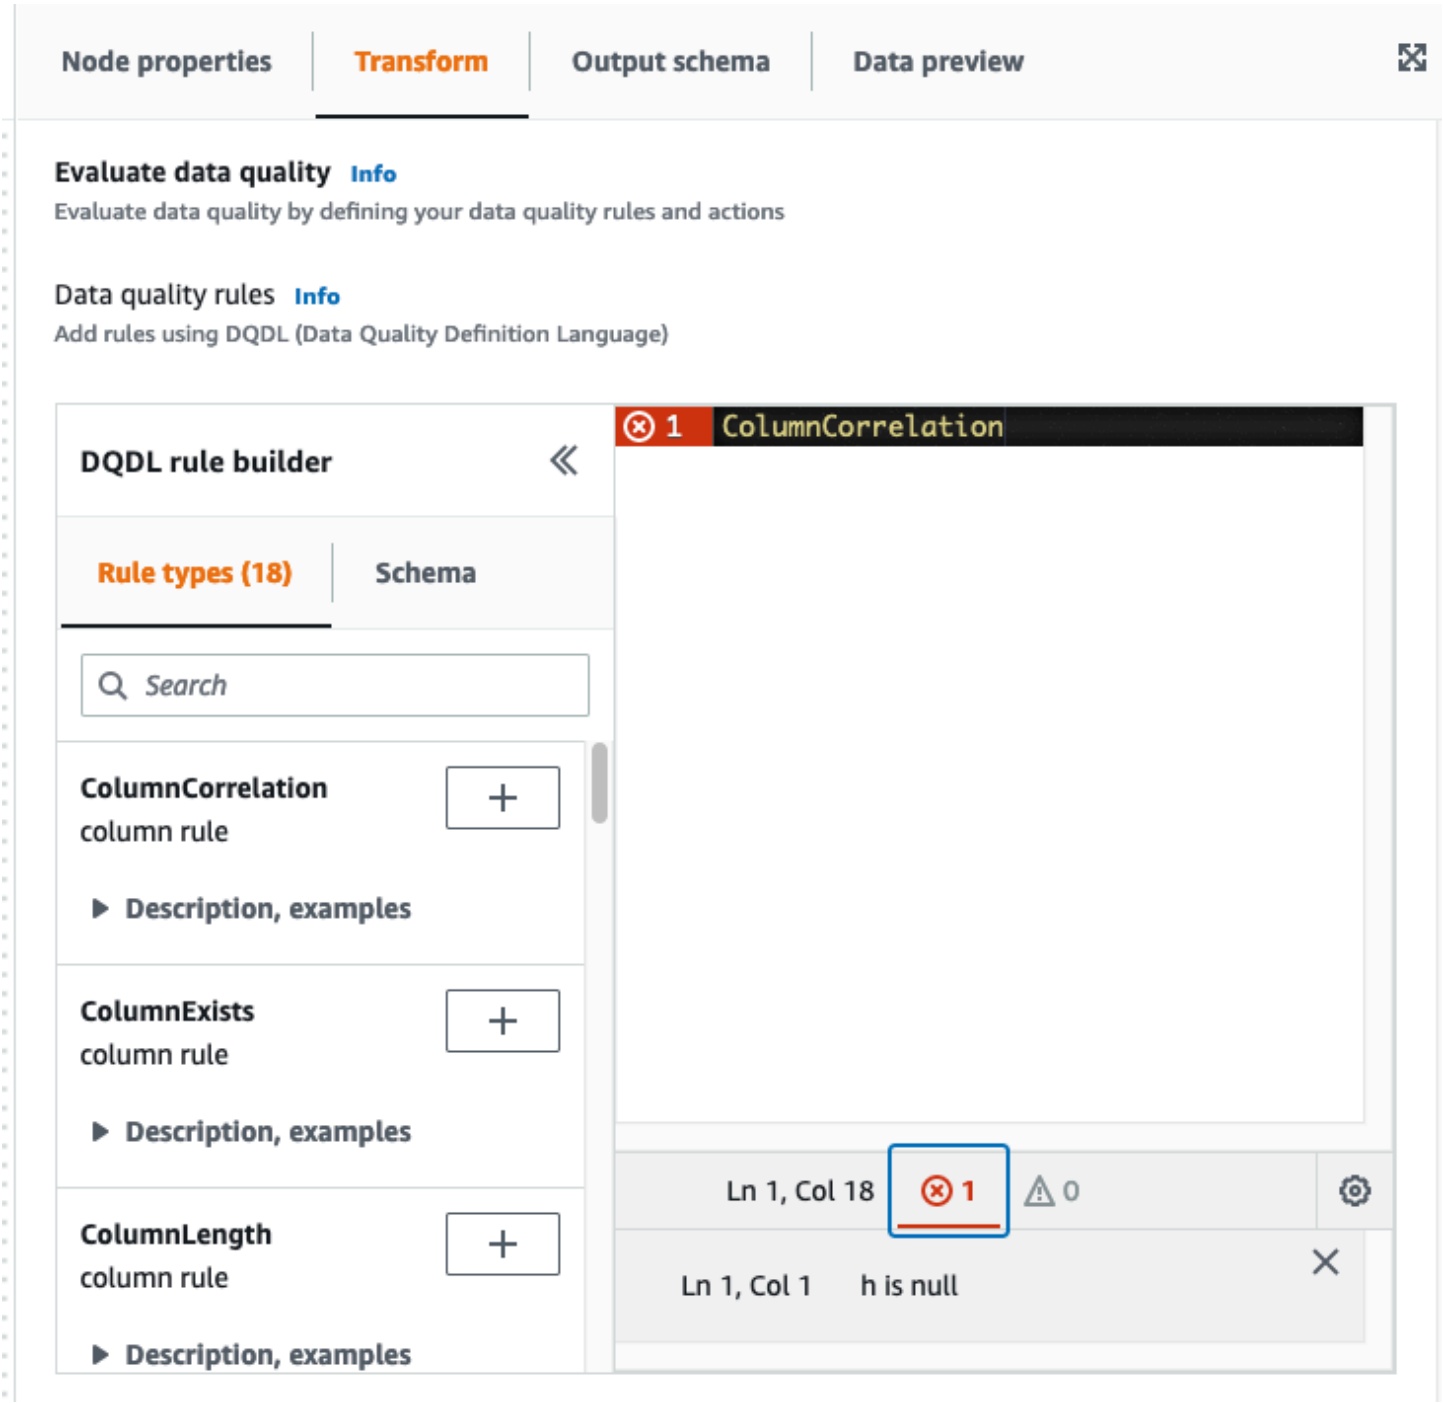
Rule editor

The rule editor is a text editor where you can write and edit rules. If you select a rule type from the DQDL rule builder, the rule type is added to the rule editor. You can then specify parameters, add rules, and edit rules as needed by modifying the text. AWS Glue Studio validates the rules in the rule editor and displays errors and warnings if there are any.

Errors and warnings

If a rule doesn't follow the DQDL rule syntax, the rule editor shows several visual indicators that there is an error:

- The rule editor displays an error icon and red color on the line with the error.
- The rule editor displays the number of errors next to the red error icon.
- When you choose the line with the error, descriptions of the error and location (line and column) are displayed at the bottom of the rule editor.



Data quality actions

By default, this action is not selected and the job will complete its run even if the data quality rules fail.

Choose between the following actions. You can use actions to publish results to CloudWatch or stop jobs based on specific criteria. Actions are only available after you create a rule.

- **Publish results to CloudWatch** – When you run a job, add the results to CloudWatch.
- **Fail job when data quality fails** – If data quality rules fail, the job will also fail as a result.

Data quality transform output

- **Original data** – Choose to output original input data. This option is ideal if you want to stop the job when quality issues are detected.
- **Data quality metrics** – Choose to output configured rules and their pass or fail status. This option is useful if you want to take a custom action.

Data quality output settings

Set the data quality result location by specifying the Amazon S3 location as the data quality output target.

Configuring anomaly detection in AWS Glue ETL jobs

To begin with anomaly detection in AWS Glue Studio, open a AWS Glue Studio job and click on the **Evaluate Data Quality Transform**.

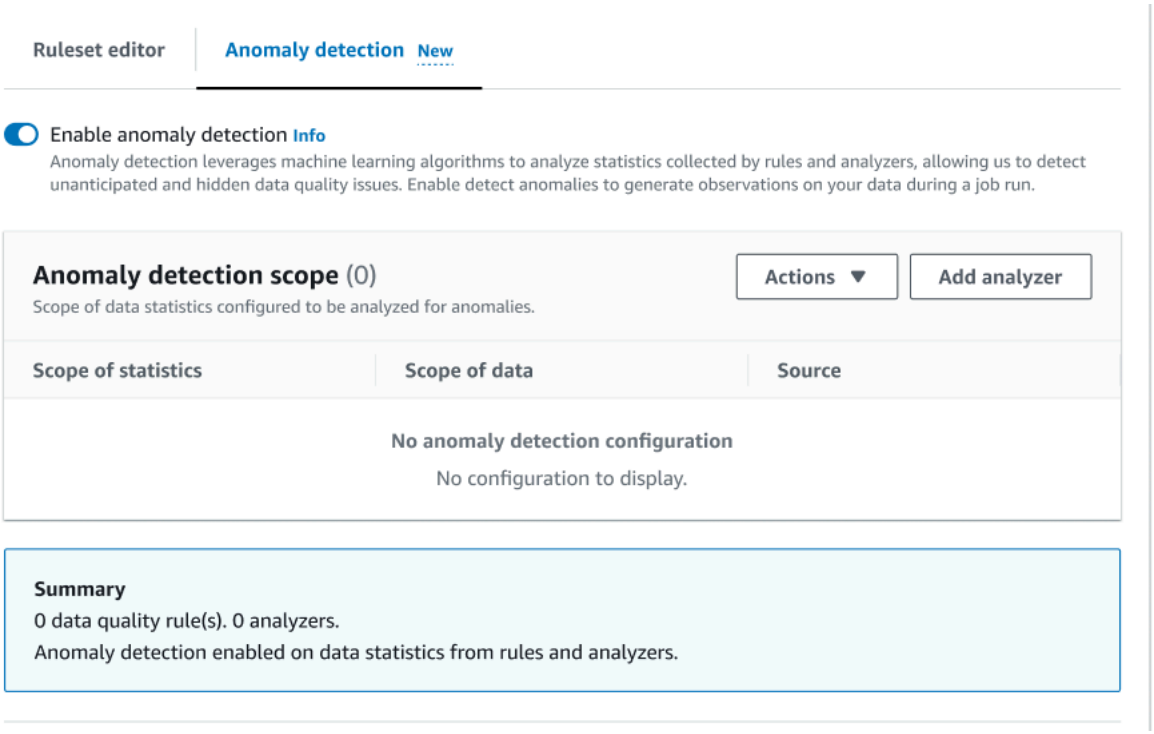
By enabling this feature, AWS Glue Data Quality will analyze your data over time to detect anomalies. It provides valuable data statistics and observations about your data, allowing you to take action on any identified anomalies.

Review the Anomaly Detection documentation to understand the inner workings of this feature.

Enabling anomaly detection

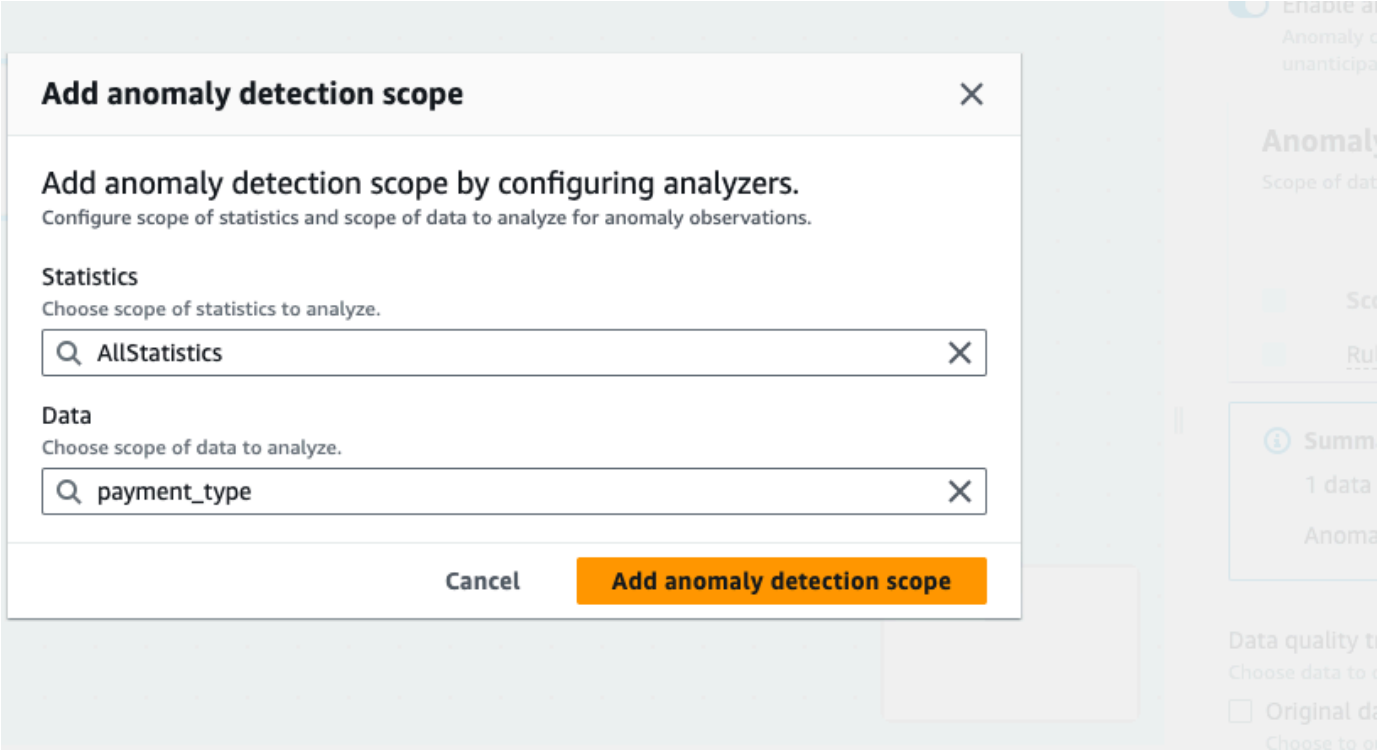
To enable anomaly detection in AWS Glue Studio:

1. Choose the **Data Quality** node in your job, then choose the **Anomaly detection** tab. Toggle to turn on **Enable Anomaly Detection**.



2. Define the data to monitor for anomalies by choosing **Add analyzer**. There are two fields that you can populate: Statistics and Data.

   - **Statistics** are information about your data's shape and other properties. You can choose one or more statistics at a time, or choose **All statistics**. Statistics include: Completeness, Uniqueness, Mean, Sum, StandardDeviation, Entropy, DistinctValuesCount, UniqueValueRatio and more. Refer to the Analyzers documentation for more details.
   - **Data** is the columns in your dataset. You can choose all columns or individual columns.



3. Choose **Add anomaly detection scope** to save your changes. After you've added analyzers, you can see them in the **Anomaly detection scope** section.

   You can also use the **Actions** menu to edit your analyzers, or choose the **Ruleset editor** tab and edit the analyzer directly in the ruleset editor notepad. You will see the analyzers that you saved under any rules that you've created.

```
Rules = [

]

Analyzers = [
    Completeness “id”
]
```

Once the updated ruleset and analyzers are configured, AWS Glue Data Quality continuously monitors incoming data streams. It can signal potential anomalies through alerts or job stops, depending on your settings. This proactive monitoring helps ensure data quality and integrity throughout your data pipelines.

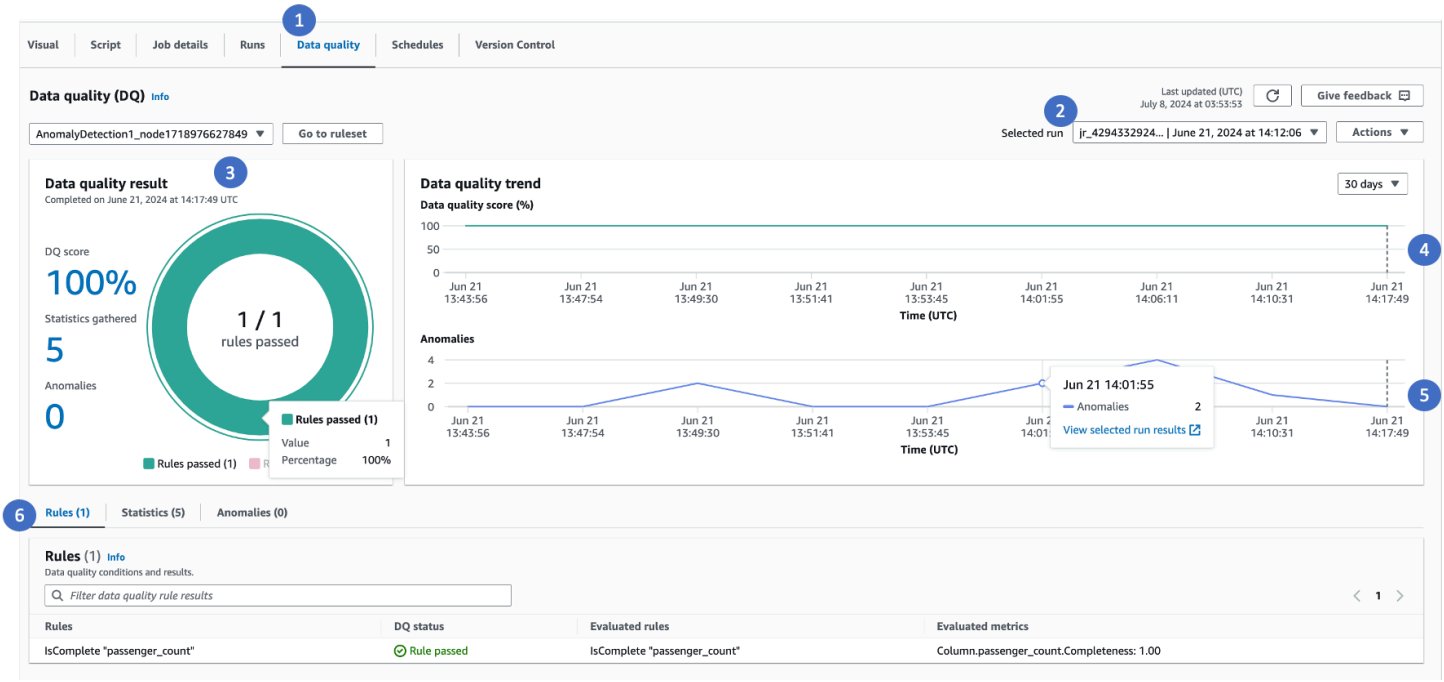
In the next section, you will learn how to effectively monitor anomalies identified by the system. You'll also learn how to view and analyze the data statistics gathered by AWS Glue Data Quality. Additionally, you'll understand how to provide feedback to the machine learning model that powers the Anomaly Detection feature. This feedback loop is crucial for improving the model's accuracy and ensuring it can effectively detect anomalies that align with your specific business requirements and data patterns.

Viewing data quality scores and anomalies

In this section, we will explore the data quality dashboard and different functionalities that it provides.

Visualize and understand high level data quality metrics and trends

Once your job is successful, choose the **Data Quality** tab to view data quality scores and anomalies.



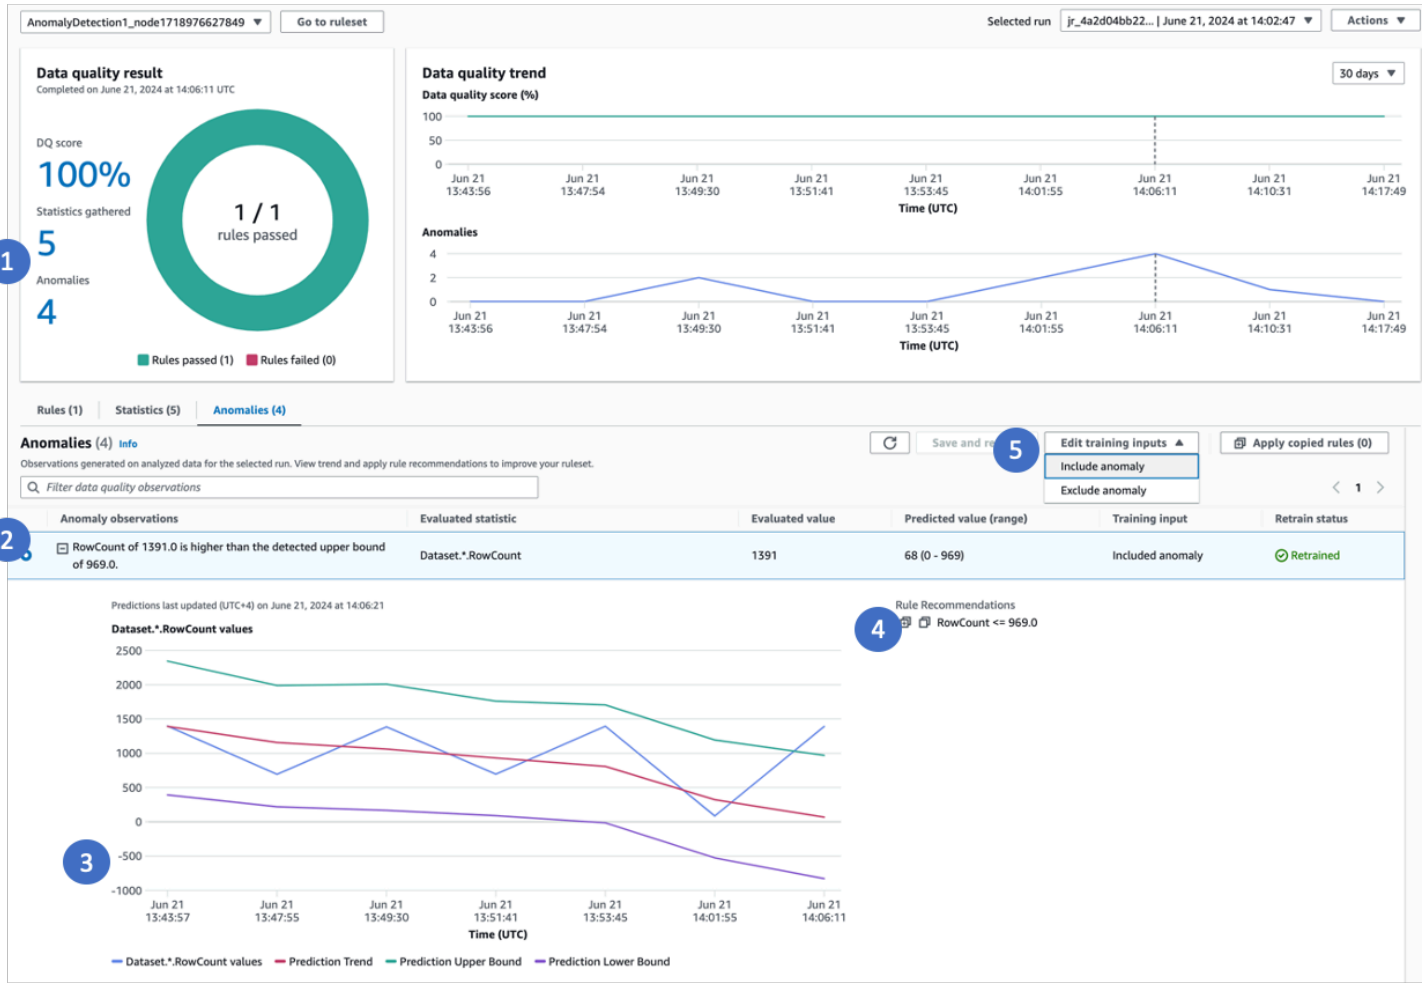
The following components in the Data quality tab provide useful information.

1. Choose the **Data Quality** tab to view data quality metrics.
2. Select a specific job run ID to view the Data Quality score.
3. This pane shows three important information. You can choose each to navigate to specific tables to view anomalies, data statistics or rules.

- Data Quality score when rules are configured.
- Number of statistics gathered by Rules and Analyzers.
- Total number of anomalies detected.

4. This trend chart shows how data quality is trending over time. You can hover over the trend and go to a specific time when data quality scores have deteriorated.
5. Anomaly trends over time will show you the number of anomalies detected over time.
6. Tabs:
   - Rules Tab is the default tab that shows list of all the rules and status. Evaluated Rules is useful in case of dynamic rules to view the actual value the rule was evaluated to.
   - Statistics Tab lists all the statistics, allowing you to view the metrics and the trends over time.
   - Anomalies tab shows the list of anomalies that were detected.

Viewing anomalies and training anomaly detection algorithm

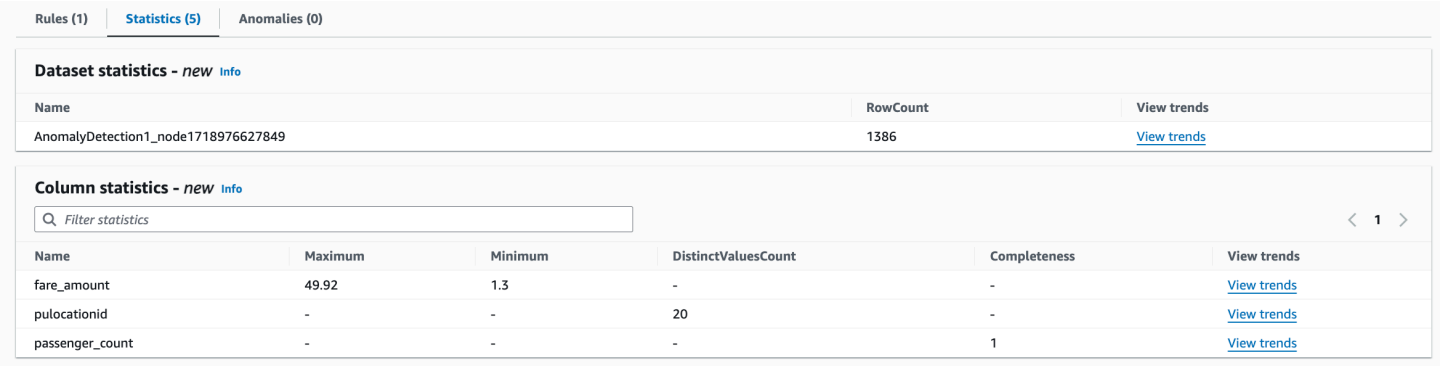


Call outs for the image above:

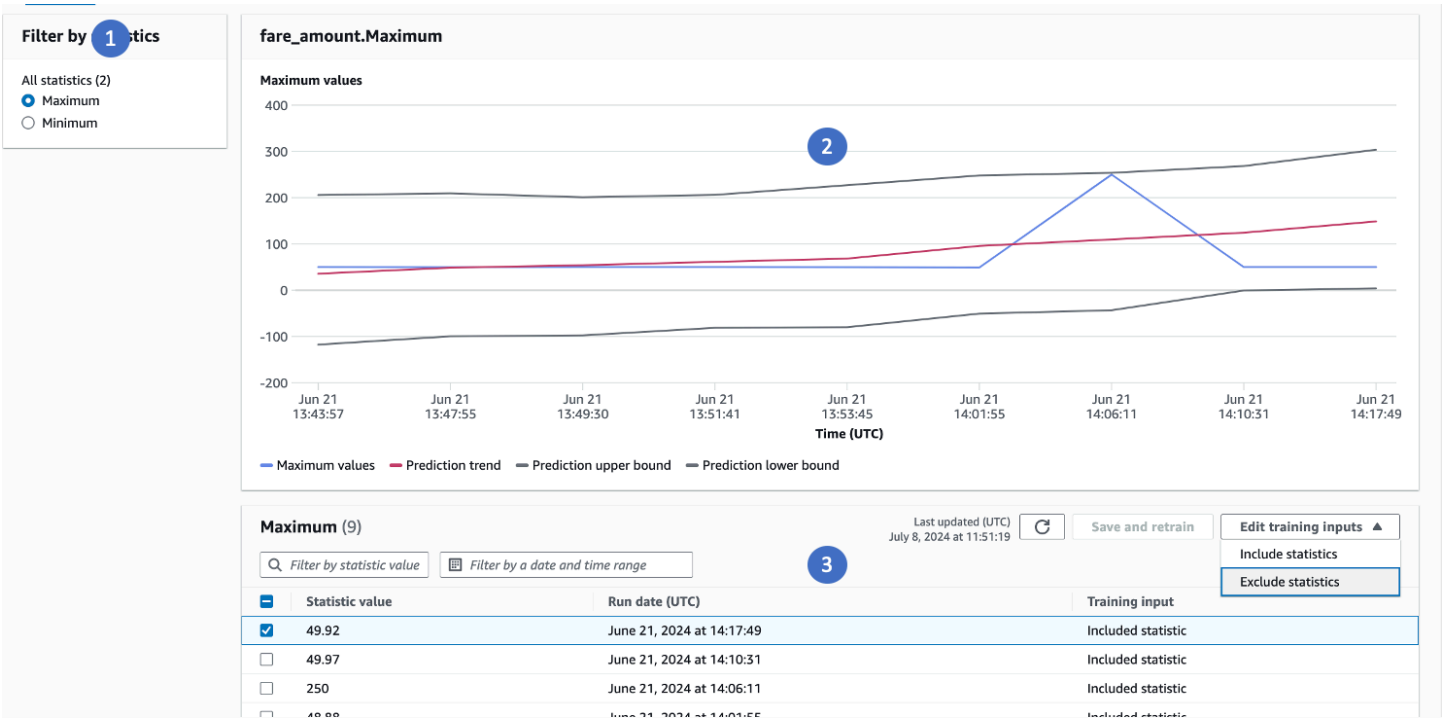
1. When anomalies are detected, click the anomaly or select the Anomalies tab
2. AWS Glue Data Quality provides a detailed explanation of the anomaly, the actual value, predicted range
3. AWS Glue Data Quality shows a trend line. It has the actual value, a derived trend based on the actual values (red line), the upper bound and the lower bound
4. AWS Glue Data Quality recommends data quality rules that can be used to capture the patterns for future. You can copy all the rules that are recommended to you and apply them to your data quality node to capture these patterns effectively.
5. You can provide inputs to the machine learning (ML) model to exclude anomalous values, ensuring that future runs detect anomalies accurately. If you don't explicitly exclude anomalies, AWS Glue Data Quality will automatically consider them as part of the model for future predictions. It's important to note that only the latest run will reflect the model inputs you provide. For example, if you went back and excluded anomalous points from a few previous runs, the model will not reflect those changes unless you view and update the model inputs in the latest run. The model will continue to use the previously provided inputs until you make necessary adjustments in the most recent run. By actively managing the exclusion of anomalous values, you can refine the ML model's understanding of what constitutes an anomaly for your specific data patterns and requirements, leading to more accurate anomaly detection over time.

Viewing Data Statistics over time and providing training inputs

Sometimes, you may want to view data statistics or data profiles and view how they are progressing over time. To do this, choose **Statistics** or open the **Statistics** tab. You can then view the latest data statistics gathered by AWS Glue Data Quality.



Clicking **View Trends** shows you how each of the statistics are progressing over time.



1. You can select the statistic for a specified column
2. You can view how the trends are progressing
3. You can select anomalous values and choose to exclude or include them. By providing this feedback, the algorithm will either exclude or include the identified anomalous data points and retrain the model. This retraining process ensures accurate anomaly detection moving forward, as the model learns from the feedback you've provided about which values should be considered anomalous or not.

   Through this feedback loop, you have the ability to refine the algorithm's understanding of what constitutes an anomaly for your specific data patterns and business requirements. By excluding values that should not be flagged as anomalies, or including values that were missed, the retrained model will become better at differentiating between expected and truly anomalous data points.

Data Quality for ETL jobs in AWS Glue Studio notebooks

In this tutorial, you learn how to use AWS Glue Data Quality for extract, transform, and load (ETL) jobs in AWS Glue Studio notebooks.

You can use notebooks in AWS Glue Studio to edit job scripts and view the output without having to run a full job. You can also add markdown and save notebooks as `.ipynb` files and job scripts. Note that you can start a notebook without installing software locally or managing servers. When you're satisfied with your code, you can use AWS Glue Studio to easily convert your notebook to an AWS Glue job.

The dataset that you use in this example consists of Medicare Provider payment data that was downloaded from two *Data.CMS.gov* datasets: "Inpatient Prospective Payment System Provider Summary for the Top 100 Diagnosis-Related Groups - FY2011" and "Inpatient Charge Data FY 2011".

After downloading the data, we modified the dataset to introduce a couple of erroneous records at the end of the file. This modified file is located in a public Amazon S3 bucket at `s3://awsglue-datasets/examples/medicare/Medicare_Hospital_Provider.csv`.

Prerequisites

- AWS Glue role with Amazon S3 permission to write to your destination Amazon S3 bucket
- A new notebook (see Getting started with notebooks in AWS Glue Studio)

Creating an ETL job in AWS Glue Studio

To create an ETL job

1. Change the session version to AWS Glue 3.0.

   To do this, remove all boilerplate code cells with the following magic and run the cell. Note that this boilerplate code is automatically provided in the first cell when a new notebook is created.

   ```
   %glue_version 3.0
   ```

2. Copy the following code and run it in the cell.

   ```
   import sys
   from awsglue.transforms import *
   from awsglue.utils import getResolvedOptions
   from pyspark.context import SparkContext
   from awsglue.context import GlueContext
   ```

```
from awsglue.job import Job

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
```

3. In the next cell, import the `EvaluateDataQuality` class that evaluatesAWS Glue Data Quality.

```
from awsgluedq.transforms import EvaluateDataQuality
```

4. In the next cell, read in the source data by using the .csv file that's stored in the public Amazon S3 bucket.

```
medicare = spark.read.format(
"csv").option(
"header", "true").option(
"inferSchema", "true").load(
's3://awsglue-datasets/examples/medicare/Medicare_Hospital_Provider.csv')
medicare.printSchema()
```

5. Convert the data to an AWS Glue DynamicFrame.

```
from awsglue.dynamicframe import DynamicFrame
medicare_dyf = DynamicFrame.fromDF(medicare,glueContext,"medicare_dyf")
```

6. Create the ruleset using Data Quality Definition Language (DQDL).

```
EvaluateDataQuality_ruleset = """
    Rules = [
        ColumnExists "Provider Id",
        IsComplete "Provider Id",
        ColumnValues  " Total Discharges " > 15
]
    ]
"""
```

7. Validate the dataset against the ruleset.

```
EvaluateDataQualityMultiframe = EvaluateDataQuality().process_rows(
    frame=medicare_dyf,
    ruleset=EvaluateDataQuality_ruleset,
    publishing_options={
        "dataQualityEvaluationContext": "EvaluateDataQualityMultiframe",
        "enableDataQualityCloudWatchMetrics": False,
        "enableDataQualityResultsPublishing": False,
    },
    additional_options={"performanceTuning.caching": "CACHE_NOTHING"},
)
```

8. Review the results.

```
ruleOutcomes = SelectFromCollection.apply(
    dfc=EvaluateDataQualityMultiframe,
    key="ruleOutcomes",
    transformation_ctx="ruleOutcomes",
)

ruleOutcomes.toDF().show(truncate=False)
```

Output:

```
---------------------------------------+-------
+-----------------------------------------------------
+-----------------------------------------+
|Rule                                    |Outcome|FailureReason
                  |EvaluatedMetrics                            |
+---------------------------------------+-------
+-----------------------------------------------------
+-----------------------------------------+
|ColumnExists "Provider Id"              |Passed |null
                  |{}                                          |
|IsComplete "Provider Id"                |Passed |null
                  |{Column.Provider Id.Completeness -> 1.0}    |
|ColumnValues " Total Discharges " > 15|Failed |Value: 11.0 does not meet the
 constraint requirement!|{Column. Total Discharges .Minimum -> 11.0}|
```

```
+-------------------------------------+-------
+-------------------------------------------------
+-----------------------------------------+
```

9. Filter passed rows and review the failed rows from the Data Quality row-level results.

```
owLevelOutcomes = SelectFromCollection.apply(
dfc=EvaluateDataQualityMultiframe,
key="rowLevelOutcomes",
transformation_ctx="rowLevelOutcomes",
)

rowLevelOutcomes_df = rowLevelOutcomes.toDF() # Convert Glue DynamicFrame to
 SparkSQL DataFrame
rowLevelOutcomes_df_passed =
 rowLevelOutcomes_df.filter(rowLevelOutcomes_df.DataQualityEvaluationResult ==
 "Passed") # Filter only the Passed records.
rowLevelOutcomes_df.filter(rowLevelOutcomes_df.DataQualityEvaluationResult ==
 "Failed").show(5, truncate=False) # Review the Failed records
```

Output:

```
+----------------------------------------+-----------
+-------------------------------------+--------------------------+-------------
+--------------+-----------------+-----------------------------------
+------------------+-------------------------+-----------------------
+-------------------------+-------------------------
+-----------------------------------------+---------------------------
+---------------------------+

only showing top 5 rows
```

Note that AWS Glue Data Quality added four new columns (DataQualityRulesPass, DataQualityRulesFail, DataQualityRulesSkip, and DataQualityEvaluationResult). This indicates the records that passed, the records that failed, rules skipped for row-level evaluation, and the overall row-level results.

10. Write the output to an Amazon S3 bucket to analyze the data and visualize the results.

```
#Write the Passed records to the destination.

glueContext.write_dynamic_frame.from_options(
       frame = rowLevelOutcomes_df_passed,
       connection_type = "s3",
       connection_options = {"path": "s3://glue-sample-target/output-dir/
medicare_parquet"},
       format = "parquet")
```

Data Quality Definition Language (DQDL) reference

Data Quality Definition Language (DQDL) is a domain specific language that you use to define rules for AWS Glue Data Quality.

This guide introduces key DQDL concepts to help you understand the language. It also provides a reference for DQDL rule types with syntax and examples. Before you use this guide, we recommend that you have familiarity with AWS Glue Data Quality. For more information, see AWS Glue Data Quality.

> **Note**
>
> DynamicRules are only supported in AWS Glue ETL.

DQDL syntax

A DQDL document is case sensitive and contains a *ruleset*, which groups individual data quality rules together. To construct a ruleset, you must create a list named `Rules` (capitalized), delimited by a pair of square brackets. The list should contain one or more comma-separated DQDL rules like the following example.

```
Rules = [
   IsComplete "order-id",
   IsUnique "order-id"
]
```

Rule structure

The structure of a DQDL rule depends on the rule type. However, DQDL rules generally fit the following format.

```
<RuleType> <Parameter> <Parameter> <Expression>
```

`RuleType` is the case-sensitive name of the rule type that you want to configure. For example, `IsComplete`, `IsUnique`, or `CustomSql`. Rule parameters differ for each rule type. For a complete reference of DQDL rule types and their parameters, see DQDL rule type reference.

Composite rules

DQDL supports the following logical operators that you can use to combine rules. These rules are called Composite Rules.

and

The logical `and` operator results in `true` if and only if the rules that it connects are `true`. Otherwise, the combined rule results in `false`. Each rule that you connect with the `and` operator must be surrounded by parentheses.

The following example uses the `and` operator to combine two DQDL rules.

```
(IsComplete "id") and (IsUnique "id")
```

or

The logical `or` operator results in `true` if and only if one or more of the rules that it connects are `true`. Each rule that you connect with the `or` operator must be surrounded by parentheses.

The following example uses the `or` operator to combine two DQDL rules.

```
(RowCount "id" > 100) or (IsPrimaryKey "id")
```

You can use the same operator to connect multiple rules, so the following rule combination is allowed.

```
(Mean "Star_Rating" > 3) and (Mean "Order_Total" > 500) and (IsComplete "Order_Id")
```

You can combine the logical operators into a single expression. For example:

```
(Mean "Star_Rating" > 3) and ((Mean "Order_Total" > 500) or (IsComplete "Order_Id"))
```

You can also author more complex, nested rules.

```
(RowCount > 0) or ((IsComplete "colA") and (IsUnique "colA"))
```

How Composite rules work

By default, Composite Rules are evaluated as individual rules across the entire dataset or table and then the results are combined. In other words, it evaluates the entire column first and then applies the operator. This default behaviour is explained below with an example:

```
# Dataset

+------+------+
|myCol1|myCol2|
+------+------+
|     2|     1|
|     0|     3|
+------+------+

# Overall outcome

+-------------------------------------------------------------+-------+
|Rule                                                         |Outcome|
+-------------------------------------------------------------+-------+
|(ColumnValues "myCol1" > 1) OR (ColumnValues "myCol2" > 2)|Failed |
+-------------------------------------------------------------+-------+
```

In the above example, AWS Glue Data Quality first evaluates `(ColumnValues "myCol1" > 1)` which will result in a failure. Then it will evaluate `(ColumnValues "myCol2" > 2)` which will also fail. The combination of both results will be noted as FAILED.

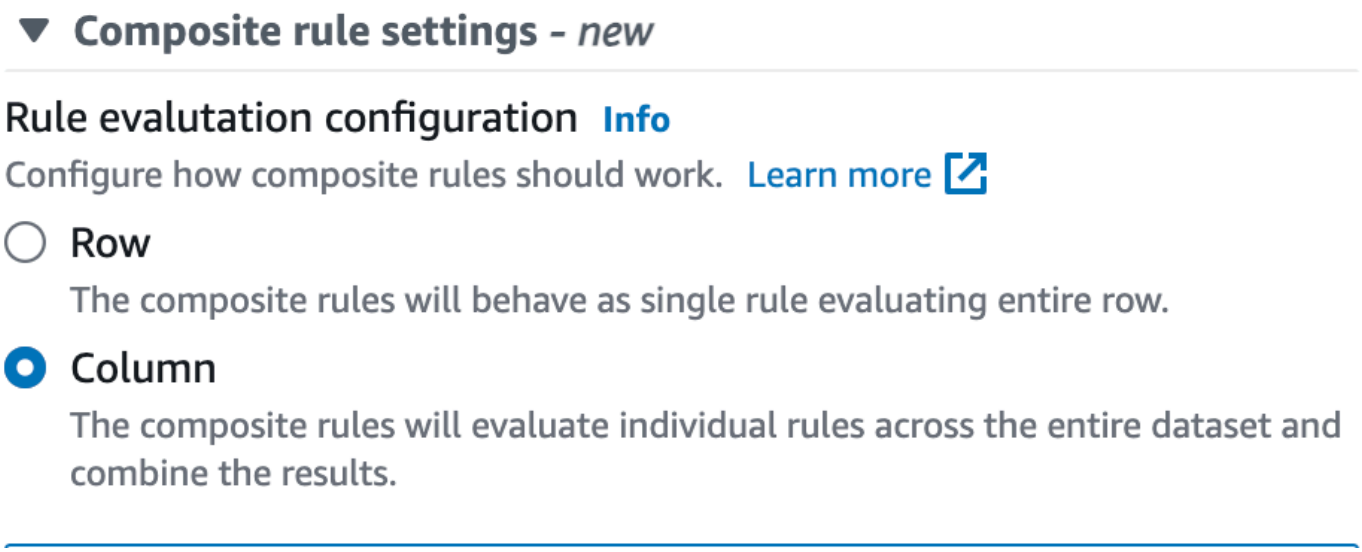
However, if you prefer an SQL like behaviour, where you need the entire row to be evaluated, you have to explicitly set the `ruleEvaluation.scope` parameter as shown in `additionalOptions` in the code snippet below.

```
object GlueApp {
  val datasource = glueContext.getCatalogSource(
    database="<db>",
    tableName="<table>",
    transformationContext="datasource"
  ).getDynamicFrame()
```

```
  val ruleset = """
    Rules = [
        (ColumnValues "age" >= 26) OR (ColumnLength "name" >= 4)
    ]
  """

  val dq_results = EvaluateDataQuality.processRows(
    frame=datasource,
    ruleset=ruleset,
    additionalOptions=JsonOptions("""
        {
          "compositeRuleEvaluation.method":"ROW"
        }
      """
    )
  )
}
```

In AWS Glue Data Catalog, you can easily configure this option in the user interface as shown below.



Once set, the composite rules will behave as a single rule evaluating the entire row. The following example illustrates this behaviour.

```
# Row Level outcome

+------+------+------------------------------------------------------------
+--------------------------+
|myCol1|myCol2|DataQualityRulesPass                                        |
DataQualityEvaluationResult|
+------+------+------------------------------------------------------------
+--------------------------+
|2     |1     |[(ColumnValues "myCol1" > 1) OR (ColumnValues "myCol2" > 2)]|Passed
                |
|0     |3     |[(ColumnValues "myCol1" > 1) OR (ColumnValues "myCol2" > 2)]|Passed
                |
+------+------+------------------------------------------------------------
+--------------------------+
```

Some rules cannot be supported in this feature because their overall outcome rely on thresholds or ratios. They are listed below.

Rules relying on ratios:

- Completeness
- DatasetMatch
- ReferentialIntegrity
- Uniqueness

Rules dependent on thresholds:

When the following rules include with threshold, they are not supported. However, rules that do not involve `with threshold` remain supported.

- ColumnDataType
- ColumnValues
- CustomSQL

Expressions

If a rule type doesn't produce a Boolean response, you must provide an expression as a parameter in order to create a Boolean response. For example, the following rule checks the mean (average) of all the values in a column against an expression to return a true or false result.

```
Mean "colA" between 80 and 100
```

Some rule types such as `IsUnique` and `IsComplete` already return a Boolean response.

The following table lists expressions that you can use in DQDL rules.

Supported DQDL expressions

Expression	Description	Example
=*x*	Resolves to `true` if the rule type response is equal to *x*.	`Completeness "colA" = "1.0", ColumnValues "colA" = "2022-06-30"`
!=*x*	x Resolves to true if the rule type response is not equal to *x*.	`ColumnValues "colA" != "a", ColumnValues "colA" != "2022-06-30"`
> *x*	Resolves to `true` if the rule type response is greater than *x*.	`ColumnValues "colA" > 10`
< *x*	Resolves to `true` if the rule type response is less than *x*.	`ColumnValues "colA" < 1000, ColumnValues "colA" < "2022-06-30"`
>= *x*	Resolves to `true` if the rule type response is greater than or equal to *x*.	`ColumnValues "colA" >= 10`

Expression	Description	Example
<= *x*	Resolves to `true` if the rule type response is less than or equal to *x*.	`ColumnValues "colA" <= 1000`
between *x* and *y*	Resolves to `true` if the rule type response falls in a specified range (exclusive). Only use this expression type for numeric and date types.	`Mean "colA" between 8 and 100, ColumnValues "colA" between "2022-05-31" and "2022-06-30"`
not between *x* and *y*	Resolves to true if the rule type response does not fall in a specified range (inclusive). You should only use this expression type for numeric and date types.	`ColumnValues "colA" not between "2022-05-31" and "2022-06-30"`
in [*a, b, c, ...*]	Resolves to `true` if the rule type response is in the specified set.	`ColumnValues "colA" in [ 1, 2, 3 ], ColumnValues "colA" in [ "a", "b", "c" ]`
not in [*a, b, c, ...*]	Resolves to `true` if the rule type response is not in the specified set.	`ColumnValues "colA" not in [ 1, 2, 3 ], ColumnValues "colA" not in [ "a", "b", "c" ]`
matches */ab+c/i*	Resolves to `true` if the rule type response matches a regular expression.	`ColumnValues "colA" matches "[a-zA-Z]*"`
not matches */ab+c/i*	Resolves to `true` if the rule type response does not match a regular expression.	`ColumnValues "colA" not matches "[a-zA-Z]*"`

Expression	Description	Example
now( )	Works only with the ColumnValues rule type to create a date expression.	`ColumnValues "load_date" > (now() - 3 days)`

matches/in [...]/not matches/not in [...] with threshold	Specifies the percentage of values that match the rule conditions. Works only with the ColumnValues , ColumnDataType , and CustomSQL rule types.	`ColumnValues "colA" in ["A", "B"] with threshold > 0.8,`
		`ColumnValues "colA" matches "[a-zA-Z]*" with threshold between 0.2 and 0.9`
		`ColumnDataType "colA" = "Timestamp" with threshold > 0.9`

Keywords for NULL, EMPTY and WHITESPACES_ONLY

If you want to validate if a string column has a null, empty or a string with only whitespaces you can use the following keywords:

- NULL / null – This keyword resolves to true for a null value in a string column.

  `ColumnValues "colA" != NULL with threshold > 0.5` would return true if more than 50% of your data does not have null values.

  `(ColumnValues "colA" = NULL) or (ColumnLength "colA" > 5)` would return true for all rows which either have a null value or have length >5. *Note that this will require the use of the "compositeRuleEvaluation.method" = "ROW" option.*
- EMPTY / empty – This keyword resolves to true for an empty string ("") value in a string column. Some data formats transform nulls in a string column to empty strings. This keyword helps filter out empty strings in your data.

  `(ColumnValues "colA" = EMPTY) or (ColumnValues "colA" in ["a", "b"])` would return true if a row is either empty, "a" or "b". *Note that this requires the use of the "compositeRuleEvaluation.method" = "ROW" option.*
- WHITESPACES_ONLY / whitespaces_only – This keyword resolves to true for a string with only whitespaces (" ") value in a string column.

`ColumnValues "colA" not in ["a", "b", WHITESPACES_ONLY]` would return true if a row is neither “a” or “b” nor just whitespaces.

Supported rules:

- ColumnValues

For a numeric or date based expression, if you want to validate if a column has a null you can use the following keywords.

- NULL / null – This keyword resolves to true for a null value in a string column.

  `ColumnValues "colA" in [NULL, "2023-01-01"]` would return true if a dates in your column are either `2023-01-01` or null.

  `(ColumnValues "colA" = NULL) or (ColumnValues "colA" between 1 and 9)` would return true for all rows which either have a null value or have values between 1 and 9. *Note that this will require the use of the “compositeRuleEvaluation.method” = “ROW” option.*

  Supported rules:

  - ColumnValues

Filtering with Where Clause

> **Note**
>
> Where Clause is only supported in AWS Glue 4.0.

You can filter your data when authoring rules. This is helpful when you want to apply conditional rules.

```
<DQDL Rule> where "<valid SparkSQL where clause> "
```

The filter must be specified with the `where` keyword, followed by a valid SparkSQL statement that is enclosed in quotes (`""`).

If the rule you wish to add the where clause to a rule with a threshold, the where clause should be specified before the threshold condition.

```
<DQDL Rule> where "valid SparkSQL statement>" with threshold <threshold condition>
```

With this syntax you can write rules like the following.

```
Completeness "colA" > 0.5 where "colB = 10"
ColumnValues "colB" in ["A", "B"] where "colC is not null" with threshold > 0.9
ColumnLength "colC" > 10 where "colD != Concat(colE, colF)"
```

We will validate that the SparkSQL statement provided is valid. If invalid, the rule evaluation will fail and we will throw the an `IllegalArgumentException` with the following format:

```
Rule <DQDL Rule> where "<invalid SparkSQL>" has provided an invalid where clause :
<SparkSQL Error>
```

Where clause behaviour when Row level error record identification is turned on

With AWS Glue Data Quality, you can identify specific records that failed. When applying a where clause to rules that support row level results, we will label the rows that are filtered out by the where clause as `Passed`.

If you prefer to separately label the filtered out rows as `SKIPPED`, you can set the following `additionalOptions` for the ETL job.

```
object GlueApp {
  val datasource = glueContext.getCatalogSource(
    database="<db>",
    tableName="<table>",
    transformationContext="datasource"
  ).getDynamicFrame()

  val ruleset = """
    Rules = [
       IsComplete "att2" where "att1 = 'a'"
    ]
  """

  val dq_results = EvaluateDataQuality.processRows(
    frame=datasource,
    ruleset=ruleset,
    additionalOptions=JsonOptions("""
```

```
        {
          "rowLevelConfiguration.filteredRowLabel":"SKIPPED"
        }
      """
    )
  )
}
```

As an example, refer to the following rule and dataframe:

```
IsComplete att2 where "att1 = 'a'"
```

id	att1	att2	Row-level Results (Default)	Row Level Results (Skipped Option)	Comments
1	a	f	PASSED	PASSED	
2	b	d	PASSED	SKIPPED	Row is filtered out, since `att1` is not `"a"`
3	a	null	FAILED	FAILED	
4	a	f	PASSED	PASSED	
5	b	null	PASSED	SKIPPED	Row is filtered out, since `att1` is not `"a"`
6	a	f	PASSED	PASSED	

Constants

In DQDL, you can define constant values and reference them throughout your script. This helps prevent issues related to query size limits—for example, when working with large SQL statements

that might exceed allowable boundaries. By assigning these values to Constants, you can simplify your DQDL and avoid hitting those limits.

The following example shows how to define and use a constant:

```
mySql = "select count(*) from primary"

Rules = [
    CustomSql $mySql between 0 and 100
]
```

In this example, the SQL query is assigned to the constant `mySql`, which is then referenced in the rule using the $ prefix.

Labels

Labels provide an effective way to organize and analyze data quality results. You can query results by specific labels to identify failing rules within particular categories, count rule outcomes by team or domain, and create focused reports for different stakeholders.

For example, you can apply all rules that pertain to the finance team with a label `"team=finance"` and generate a customized report to showcase quality metrics specific to the finance team. You can label high priority rules with `"criticality=high"` to prioritize remediation efforts. Labels can be authored as part of the DQDL. You can query the labels as part of rule outcomes, row-level results, and API responses, making it easy to integrate with your existing monitoring and reporting workflows.

> **Note**
>
> Labels are only available in AWS Glue ETL and are not available in AWS Glue Data Catalog based Data Quality.

Syntax for DQDL labels

DQDL supports both default and rule-specific labels. Default labels are defined at the ruleset level and automatically apply to all rules within that ruleset. Individual rules can also have their own labels, and since labels are implemented as key-value pairs, rule-specific labels can override the default labels when using the same key.

The following example shows how to use default and rule-specific labels:

```
DefaultLabels=["frequency"="monthly"]

Rules = [
    // Auto includes the default label ["frequency"="monthly"]
    ColumnValues "col" > 21,
    // Add ["foo"="bar"] to default label. Labels for this rule would be
 ["frequency"="monthly", "foo"="bar"]
    RowCount > 0 with threshold > 0.8 labels=["foo"="bar"],
    // Override default label. Labels for this rule would be ["frequency"="daily",
 "foo"="bar"]
    ColumnValues "colA" in ["A", "B"]  with threshold > 0.8 labels=["foo"="bar",
 "frequency"="daily"]
    // Labels must be applied to the entire composite rule (parentheses required)
    (isComplete "col" AND RowCount > 0) labels=["foo"="bar]
]
```

The following example shows invalid syntax with labels and composite rules:

```
        (isComplete "colA") AND (RowCount > 0) labels=["foo"="bar"]
        (isComplete "colA" labels=["foo"="bar"]) AND (RowCount > 0)
        isComplete "col" AND RowCount > 0 labels=["foo"="bar]
```

Label constraints

Labels have the following constraints:

- A maximum of 10 labels per DQDL rule.
- Labels are specified as a list of key-value pairs.
- The label key and label value are case sensitive.
- The maximum label key length is 128 characters. The label key must not be empty or null.
- The maximum label value length is 256 characters. The label value may be empty or null.

Retrieving DQDL labels

You can retrieve DQDL labels from rule outcomes, row-level results, and API responses.

Rule outcomes

DQDL labels are always visible in rule outcomes. No additional configuration is needed to enable them.

Row-level results

DQDL labels are disabled by default in row-level results but can be enabled using `AdditionalOptions` in `EvaluateDataQuality`.

The following example shows how to enable labels in row-level results:

```
val evaluateResult = EvaluateDataQuality.processRows(
    frame=AmazonS3_node1754591511068,
    ruleset=example_ruleset,
    publishingOptions=JsonOptions("""{
        "dataQualityEvaluationContext": "evaluateResult",
        "enableDataQualityCloudWatchMetrics": "true",
        "enableDataQualityResultsPublishing": "true"
    }"""),
    additionalOptions=JsonOptions("""{
        "performanceTuning.caching":"CACHE_NOTHING",
        "observations.scope":"ALL",
        "rowLevelConfiguration.ruleWithLabels":"ENABLED"
    }""")
)
```

When enabled, the row-level results dataframe includes labels for each rule in the `DataQualityRulesPass`, `DataQualityRulesFail`, and `DataQualityRulesSkip` columns.

API response

DQDL labels are always visible in API responses under a new field `Labels` in the `RuleResults` object.

The following example shows labels in an API response:

```
{
    "ResultId": "dqresult-example",
    "ProfileId": "dqprofile-example",
    "Score": 0.6666666666666666,
    "RulesetName": "EvaluateDataQuality_node1754591514205",
    "EvaluationContext": "EvaluateDataQuality_node1754591514205",
```

```
    "StartedOn": "2025-08-22T19:36:10.448000+00:00",
    "CompletedOn": "2025-08-22T19:36:16.368000+00:00",
    "JobName": "anniezc-test-labels",
    "JobRunId": "jr_068f6d7a45074d9105d14e4dee09db12c3b95664b45f6ee44fa29ed7e5619ba8",
    "RuleResults": [
        {
            "Name": "Rule_0",
            "Description": "IsComplete colA",
            "EvaluationMessage": "Input data does not include column colA!",
            "Result": "FAIL",
            "EvaluatedMetrics": {},
            "EvaluatedRule": "IsComplete colA",
            "Labels": {
                "frequency": "monthly"
            }
        },
        {
            "Name": "Rule_1",
            "Description": "Rule 1 with threshold > 0.8",
            "Result": "PASS",
            "EvaluatedMetrics": {},
            "EvaluatedRule": "Rule 1 with threshold > 0.8",
            "Labels": {
                "frequency": "monthly",
                "foo": "bar"
            }
        },
        {
            "Name": "Rule_3",
            "Description": "Rule 2 with threshold > 0.8",
            "Result": "PASS",
            "EvaluatedMetrics": {},
            "EvaluatedRule": "Rule 2 with threshold > 0.8",
            "Labels": {
                "frequency": "daily",
                "foo": "bar"
            }
        }
    ]
}
```

Dynamic rules

> **Note**
>
> Dynamic Rules are only supported in AWS Glue ETL and is not supported in AWS Glue Data Catalog.

You can now author dynamic rules to compare current metrics produced by your rules with their historical values. These historical comparisons are enabled by using the `last()` operator in expressions. For example, the rule `RowCount > last()` will succeed when the number of rows in the current run is greater than the most recent prior row count for the same dataset. `last()` takes an optional natural number argument describing how many prior metrics to consider; `last(k)` where `k >= 1` will reference the last `k` metrics.

- If no data points are available, `last(k)` will return the default value 0.0.
- If fewer than `k` metrics are available, `last(k)` will return all prior metrics.

To form valid expressions use `last(k)`, where `k > 1` requires an aggregation function to reduce multiple historical results to a single number. For example, `RowCount > avg(last(5))` will check whether the current dataset's row count is strictly greater than the average of the last five row counts for the same dataset. `RowCount > last(5)` will produce an error because the current dataset row count can't be meaningfully compared to a list.

Supported aggregation functions:

- `avg`
- `median`
- `max`
- `min`
- `sum`
- `std` (standard deviation)
- `abs` (absolute value)
- `index(last(k), i)` will allow for selecting the `i`th most recent value out of the last `k`. `i` is zero-indexed, so `index(last(3), 0)` will return the most recent datapoint and

`index(last(3), 3)` will result in an error as there are only three datapoints and we attempt to index the 4th most recent one.

Sample expressions

ColumnCorrelation

- `ColumnCorrelation "colA" "colB" < avg(last(10))`

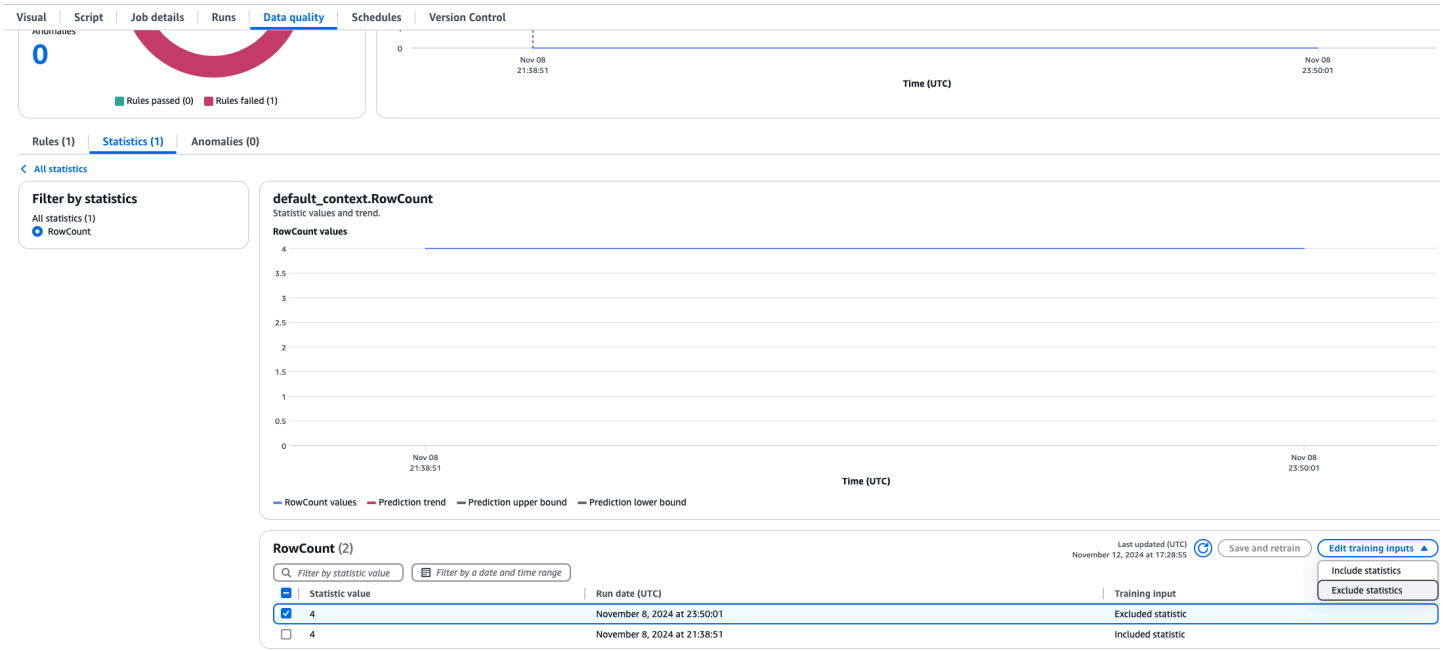
DistinctValuesCount

- `DistinctValuesCount "colA" between min(last(10))-1 and max(last(10))+1`

Most rule types with numeric conditions or thresholds support dynamic rules; see the provided table, Analyzers and Rules, to determine whether dynamic rules are supported for your rule type.

Excluding statistics from dynamic rules

Sometimes, you will need to exclude data statistics from your dynamic rule calculations. Lets say you did a historical data load and you don't want that to impact your averages. To do this, open the job in AWS Glue ETL and choose the **Data Quality** Tab, then choose **Statistics** and select the statistics that you want to exclude. You will be able to see a trend chart along with a table of statistics. Select the values you want to exclude and choose **Exclude Statistics**. Now the excluded statistics will not be included in the dynamic rule calculations.



Analyzers

> **Note**
>
> Analyzers are not supported in AWS Glue Data Catalog.

DQDL rules use functions called *analyzers* to gather information about your data. This information is employed by a rule's Boolean expression to determine whether the rule should succeed or fail. For example, the RowCount rule `RowCount > 5` will use a row count analyzer to discover the number of rows in your dataset, and compare that count with the expression `> 5` to check whether more than five rows exist in the current dataset.

Sometimes, instead of authoring rules, we recommend creating analyzers and then have them generate statistics that can be used to detect anomalies. For such instances, you can create analyzers. Analyzers differ from rules in the following ways.

Characteristic	Analyzers	Rules
Part of ruleset	Yes	Yes
Generates statistics	Yes	Yes

Characteristic	Analyzers	Rules
Generates observations	Yes	Yes
Can evaluate and assert a condition	No	Yes
You can configure actions such as stop the jobs on failure, continue processing job	No	Yes

Analyzers can independently exist without rules, so you can quickly configure them and progressively build data quality rules.

Some rule types can be input in the `Analyzers` block of your ruleset to run the rules required for analyzers and gather information without applying checks for any condition. Some analyzers aren't associated with rules and can only be input in the `Analyzers` block. The following table indicates whether each item is supported as a rule or a standalone analyzer, along with additional details for each rule type.

Example Ruleset with Analyzer

The following ruleset uses:

- a dynamic rule to check whether a dataset is growing over its trailing average for the last three job runs
- a `DistinctValuesCount` analyzer to record the number of distinct values in the dataset's `Name` column
- a `ColumnLength` analyzer to track minimum and maximum `Name` size over time

Analyzer metric results can be viewed in the Data Quality tab for your job run.

```
Rules = [
   RowCount > avg(last(3))
]
Analyzers = [
   DistinctValuesCount "Name",
```

```
   ColumnLength "Name"
]
```

AWS Glue Data Quality supports the following analyzers.

Analyzer name	Functionality
`RowCount`	Computes row counts for a dataset
`Completeness`	Computes the completeness percentage of a column
`Uniqueness`	Computes the uniqueness percentage of a column
`Mean`	Computes mean of a numeric column
`Sum`	Computes sum of a numeric column
`StandardDeviation`	Computes standard deviation of a numeric column
`Entropy`	Computes entropy of a numeric column
`DistinctValuesCount`	Computes the number of distinct values in a column
`UniqueValueRatio`	Computes the unique values ratio in a column
`ColumnCount`	Computes the number of columns in a dataset
`ColumnLength`	Computes the length of a column
`ColumnValues`	Computes the minimum, maximum for numerical columns. Computes Minimum ColumnLength and Maximum ColumnLength for non-numeric columns

Analyzer name	Functionality
`ColumnCorrelation`	Computes column correlations for given columns
`CustomSql`	Computes statistics returned by the CustomSQL
`AllStatistics`	Computes the following statistics: • RowCount, ColumnCount • Every column: Completeness, uniqueness • Numerical: Min, Max, Entropy, Mean, Standard Dev, Sum • String: MinLength, MaxLength

Comments

You can use the '#' character to add a comment to your DQDL document. Anything after the '#' character and until the end of the line is ignored by DQDL.

```
Rules = [
    # More items should generally mean a higher price, so correlation should be
 positive
    ColumnCorrelation "price" "num_items" > 0
]
```

DQDL rule type reference

This section provides a reference for each rule type that AWS Glue Data Quality supports.

Note

- DQDL doesn't currently support nested or list-type column data.
- Bracketed values in the below table will be replaced with the information provided in rule arguments.

- Rules typically require an additional argument for expression.

Ruletype	Description	Argumen	Reported Metrics	Support as Rule?	Support as Analyzer	Returns row-level Results?	Dynamic rule support?	Generate Observations	Supports Where Clause Syntax?
Aggrega Match	Checks if two datasets match by compari summary metrics like total sales amount. Useful for financial institutions to compare if all data is ingested from source systems.	One or more aggregat ons	When first and second aggregat on column names match: `Column [C olumn]. gregate tch` When first and second aggregat on column names different : `Column [C`	Yes	No	No	No	No	No

AggregateMatch

Checks the ratio of two column aggregations against a given expression. This ruletype works on multiple datasets. The two column aggregations are evaluated and a ratio is produced by dividing the result of the first column aggregation with the result of the second column aggregation. The ratio is checked against the provided expression to produce a boolean response.

Syntax

Column aggregation

```
AggregateMatch <AGG_OPERATION> (<OPTIONAL_REFERENCE_ALIAS>.<COL_NAME>)
```

- **AGG_OPERATION** – The operation to use for the aggregation. Currently, `sum` and `avg` are supported.

  Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short
- **OPTIONAL_REFERENCE_ALIAS** – This parameter needs to be provided if the column is from a reference dataset and not the primary dataset. If you are using this rule in the AWS Glue Data Catalog, your reference alias must follow the format "<database_name>.<table_name>.<column_name>

  Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short
- **COL_NAME** – The name of the column to aggregate.

  Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

Example: Average

```
"avg(rating)"
```

Example: Sum

```
"sum(amount)"
```

Example: Average of column in reference dataset

```
"avg(reference.rating)"
```

Rule

```
AggregateMatch <AGG_EXP_1> <AGG_EXP_2> <EXPRESSION>
```

- **AGG_EXP_1** – The first column aggregation.

  Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

  Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short
- **AGG_EXP_2** – The second column aggregation.

  Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

  Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short
- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see Expressions.

Example: Aggregate Match using sum

The following example rule checks whether the sum of the values in the `amount` column is exactly equal to the sum of the values in the `total_amount` column.

```
AggregateMatch "sum(amount)" "sum(total_amount)" = 1.0
```

Example: Aggregate Match using average

The following example rule checks whether the average of the values in the `ratings` column is equal to at least 90% of the average of the values in the `ratings` column in the `reference` dataset. The reference dataset is provided as an additional data source in the ETL or Data Catalog experience.

In AWS Glue ETL, you can use:

```
AggregateMatch "avg(ratings)" "avg(reference.ratings)" >= 0.9
```

In the AWS Glue Data Catalog, you can use:

```
AggregateMatch "avg(ratings)" "avg(database_name.tablename.ratings)" >= 0.9
```

Null behavior

The `AggregateMatch` rule will ignore rows with NULL values in the calculation of the aggregation methods (sum/mean). For example:

```
+---+-----------+
|id |units      |
+---+-----------+
|100|0          |
|101|null       |
|102|20         |
|103|null       |
|104|40         |
+---+-----------+
```

The mean of column `units` will be (0 + 20 + 40) / 3 = 20. Rows 101 and 103 are not considered in this calculation.

ColumnCorrelation

Checks the *correlation* between two columns against a given expression. AWS Glue Data Quality uses the Pearson correlation coefficient to measure the linear correlation between two columns. The result is a number between -1 and 1 that measures the strength and direction of the relationship.

Syntax

```
ColumnCorrelation <COL_1_NAME> <COL_2_NAME> <EXPRESSION>
```

- **COL_1_NAME** – The name of the first column that you want to evaluate the data quality rule against.

  Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short
- **COL_2_NAME** – The name of the second column that you want to evaluate the data quality rule against.

  Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short
- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see Expressions.

Example: Column correlation

The following example rule checks whether the correlation coefficient between the columns `height` and `weight` has a strong positive correlation (a coefficient value greater than 0.8).

```
ColumnCorrelation "height" "weight" > 0.8
```

```
ColumnCorrelation "weightinkgs" "Salary" > 0.8 where "weightinkgs > 40"
```

Sample dynamic rules

- `ColumnCorrelation "colA" "colB" between min(last(10)) and max(last(10))`
- `ColumnCorrelation "colA" "colB" < avg(last(5)) + std(last(5))`

Null behavior

The `ColumnCorrelation` rule will ignore rows with `NULL` values in the calculation of the correlation. For example:

```
+---+-----------+
|id |units      |
+---+-----------+
|100|0          |
|101|null       |
|102|20         |
|103|null       |
|104|40         |
+---+-----------+
```

Rows 101 and 103 will be ignored, and the `ColumnCorrelation` will be 1.0.

ColumnCount

Checks the column count of the primary dataset against a given expression. In the expression, you can specify the number of columns or a range of columns using operators like > and <.

Syntax

```
ColumnCount <EXPRESSION>
```

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see Expressions.

Example: Column count numeric check

The following example rule checks whether the column count is within a given range.

```
ColumnCount between 10 and 20
```

Sample dynamic rules

- `ColumnCount >= avg(last(10))`
- `ColumnCount between min(last(10))-1 and max(last(10))+1`

ColumnDataType

Checks if the values in a given column can be cast in Apache Spark to the provided type. Accepts a `with threshold` expression to check for a subset of the values in the column.

Syntax

```
ColumnDataType <COL_NAME> = <EXPECTED_TYPE>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

  Supported column types: String type

  Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short
- **EXPECTED_TYPE** – The expected type of the values in the column.

  Supported values: Boolean, Date, Timestamp, Integer, Double, Float, Long

  Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short
- **EXPRESSION** – An optional expression to specify the percentage of values that should be of the expected type.

  Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

Example: Column data type integers as strings

The following example rule checks whether the values in the given column, which is of type string, can be cast as integers.

```
ColumnDataType "colA" = "INTEGER"
```

Example: Column data type integers as strings check for a subset of the values

The following example rule checks whether more than 90% of the values in the given column, which is of type string, can be cast as integers.

```
ColumnDataType "colA" = "INTEGER" with threshold > 0.9
```

ColumnExists

Checks whether a column exists.

Syntax

```
ColumnExists <COL_NAME>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

  Supported column types: Any column type

Example: Column exists

The following example rule checks whether the column named `Middle_Name` exists.

```
ColumnExists "Middle_Name"
```

ColumnLength

Checks whether the length of each row in a column conforms to a given expression.

Syntax

```
ColumnLength <COL_NAME><EXPRESSION>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

  Supported column types: String

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see Expressions.

Example: Column row length

The following example rule checks whether the value in each row in the column named `Postal_Code` is 5 characters long.

```
ColumnLength "Postal_Code" = 5
ColumnLength "weightinkgs" = 2 where "weightinkgs > 10"
```

Null behavior

The `ColumnLength` rule treats `NULL`s as 0 length strings. For a `NULL` row:

```
ColumnLength "Postal_Code" > 4 # this will fail
```

```
ColumnLength "Postal_Code" < 6 # this will succeed
```

The following example compound rule provides a way to explicitly fail `NULL` values:

```
(ColumnLength "Postal_Code" > 4) AND (ColumnValues "Postal_Code" != NULL)
```

ColumnNamesMatchPattern

Checks whether the names of all columns in the primary dataset match the given regular expression.

Syntax

```
ColumnNamesMatchPattern <PATTERN>
```

- **PATTERN** – The pattern you want to evaluate the data quality rule against.

  Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

Example: Column names match pattern

The following example rule checks whether all columns start with the prefix "aws_"

```
ColumnNamesMatchPattern "aws_.*"
ColumnNamesMatchPattern "aws_.*" where "weightinkgs > 10"
```

ColumnValues

Runs an expression against the values in a column.

Syntax

```
ColumnValues <COL_NAME> <EXPRESSION>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

  Supported column types: Any column type
- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see Expressions.

Example: Allowed values

The following example rule checks whether each value in the specified column is in a set of allowed values (including null, empty, and strings with only whitespaces).

```
ColumnValues "Country" in [ "US", "CA", "UK", NULL, EMPTY, WHITESPACES_ONLY ]
ColumnValues "gender" in ["F", "M"] where "weightinkgs < 10"
```

Example: Regular expression

The following example rule checks the values in a column against a regular expression.

```
ColumnValues "First_Name" matches "[a-zA-Z]*"
```

Example: Date values

The following example rule checks the values in a date column against a date expression.

```
ColumnValues "Load_Date" > (now() - 3 days)
```

Example: Numeric values

The following example rule checks whether the column values match a certain numeric constraint.

```
ColumnValues "Customer_ID" between 1 and 2000
```

Null behavior

For all `ColumnValues` rules (other than `!=` and `NOT IN`), `NULL` rows will fail the rule. If the rule fails due to a null value, the failure reason will display the following:

```
Value: NULL does not meet the constraint requirement!
```

The following example compound rule provides a way to explicitly allow for `NULL` values:

```
(ColumnValues "Age" > 21) OR (ColumnValues "Age" = NULL)
```

Negated ColumnValues rules using the `!=` and `not in` syntax will pass for `NULL` rows. For example:

```
ColumnValues "Age" != 21
```

```
ColumnValues "Age" not in [21, 22, 23]
```

The following examples provide a way to explicitly fail `NULL` values

```
(ColumnValues "Age" != 21) AND (ColumnValues "Age" != NULL)
```

```
ColumnValues "Age" not in [21, 22, 23, NULL]
```

Completeness

Checks the percentage of complete (non-null) values in a column against a given expression.

Syntax

```
Completeness <COL_NAME> <EXPRESSION>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

  Supported column types: Any column type

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see Expressions.

Example: Null value percentage

The following example rules check if more than 95 percent of the values in a column are complete.

```
Completeness "First_Name" > 0.95
Completeness "First_Name" > 0.95 where "weightinkgs > 10"
```

Sample dynamic rules

- `Completeness "colA" between min(last(5)) - 1 and max(last(5)) + 1`
- `Completeness "colA" <= avg(last(10))`

Null behavior

Note on CSV Data Formats: Blank rows on CSV columns can display multiple behaviors.

- If a column is of `String` type, the blank row will be recognized as an empty string and will not fail the `Completeness` rule.
- If a column is of another data type like `Int`, the blank row will be recognized as `NULL` and will fail the `Completeness` rule.

CustomSQL

This rule type has been extended to support two use cases:

- Run a custom SQL statement against a dataset and checks the return value against a given expression.

- Run a custom SQL statement where you specify a column name in your SELECT statement against which you compare with some condition to get row-level results.

Syntax

```
CustomSql <SQL_STATEMENT> <EXPRESSION>
```

- **SQL_STATEMENT** – A SQL statement that returns a single numeric value, surrounded by double quotes.
- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see Expressions.

Example: Custom SQL to retrieve an overall rule outcome

This example rule uses a SQL statement to retrieve the record count for a data set. The rule then checks that the record count is between 10 and 20.

```
CustomSql "select count(*) from primary" between 10 and 20
```

Example: Custom SQL to retrieve row-level results

This example rule uses a SQL statement wherein you specify a column name in your SELECT statement against which you compare with some condition to get row level results. A threshold condition expression defines a threshold of how many records should fail for the entire rule to fail. Note that a rule may not contain both a condition and keyword together.

```
CustomSql "select Name from primary where Age  > 18"
```

or

```
CustomSql "select Name from primary where Age > 18" with threshold  > 3
```

Important

The `primary` alias stands in for the name of the data set that you want to evaluate. When you work with visual ETL jobs on the console, `primary` always represents the `DynamicFrame` being passed to the `EvaluateDataQuality.apply()` transform. When

you use the AWS Glue Data Catalog to run data quality tasks against a table, `primary` represents the table.

If you are in AWS Glue Data Catalog, you can also use the actual table names:

```
CustomSql "select count(*) from database.table" between 10 and 20
```

You can also join multiple tables to compare different data elements:

```
CustomSql "select count(*) from database.table inner join database.table2 on id1 = id2"
 between 10 and 20
```

In AWS Glue ETL, CustomSQL can identify records that failed the data quality checks. For this to work, you need to return records that are part of the primary table for which you are evaluating data quality. Records that are returned as part of the query are considered successful and records that are not returned are considered failed. This works by joining the result of your CustomSQL query with the original dataset. There may be performance implications based on the complexity of your SQL query.

To do this:

- You need to select at least 1 column from your primary table.
  - `select count(*) from primary` is a valid query for OVERALL CustomSQL DQ rule but not for Row Level Custom SQL.
  - This rule will throw an error during evaluation: `The output from CustomSQL must contain at least one column that matches the input dataset for AWS Glue Data Quality to provide row level results. The SQL query is a valid query but the columns from the SQL result are not present in the Input Dataset. Ensure that matching columns are returned from the SQL.`
- In your SQL query, select a `Primary Key` from your table or select a set of columns that form a composite key. Not doing so may result in inconsistent results due to matching of duplicate rows and degraded performance.
- Select keys ONLY from your primary table and not from your reference tables.

The following rule will ensure that records with age < 100 are identified as successful and records that are above are marked as failed.

```
CustomSql "select id from primary where age < 100"
```

This CustomSQL rule will pass when 50% of the records have age > 10 and will also identify records that failed. The records returned by this CustomSQL will be considered passed while the ones not returned will be considered failed.

```
CustomSQL "select ID, CustomerID from primary where age > 10" with threshold > 0.5
```

Note: CustomSQL rule will fail if you return records that are not available in the dataset.

DataFreshness

Checks the freshness of data in a column by evaluating the difference between the current time and the values of a date column. You can specify a time-based expression for this rule type to make sure that column values are up to date.

Syntax

```
DataFreshness <COL_NAME> <EXPRESSION>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

  Supported column types: Date
- **EXPRESSION** – A numeric expression in hours or days. You must specify the time unit in your expression.

Example: Data freshness

The following example rules check for data freshness.

```
DataFreshness "Order_Date" <= 24 hours
DataFreshness "Order_Date" between 2 days and 5 days
```

Null behavior

The `DataFreshness` rules will fail for rows with `NULL` values. If the rule fails due to a null value, the failure reason will display the following:

```
80.00 % of rows passed the threshold
```

where 20% of the rows that failed include the rows with NULL.

The following example compound rule provides a way to explicitly allow for NULL values:

```
(DataFreshness "Order_Date" <= 24 hours) OR (ColumnValues "Order_Date" = NULL)
```

Data Freshness for Amazon S3 objects

Sometimes you will need to validate the freshness of data based on the Amazon S3 file creating time. To do this, you can use the following code to get the timestamp and add it to your dataframe, and then apply Data Freshness checks.

```
df = glueContext.create_data_frame.from_catalog(database = "default", table_name =
 "mytable")
df = df.withColumn("file_ts", df["_metadata.file_modification_time"])

Rules = [
 DataFreshness "file_ts" < 24 hours
]
```

DatasetMatch

Checks if the data in the primary dataset matches the data in a reference dataset. The two datasets are joined using the provided key column mappings. Additional column mappings can be provided should you wish to check for the equality of the data in only those columns. Note that for **DataSetMatch** to work, your join keys should be unique and should not be NULL (must be a primary key). If you don't satisfy these conditions, you will get the error message, "Provided key map not suitable for given data frames". In cases where you can't have joined keys that are unique, consider using other ruletypes such as **AggregateMatch** to match on summary data.

Syntax

```
DatasetMatch <REFERENCE_DATASET_ALIAS> <JOIN CONDITION WITH
 MAPPING> <OPTIONAL_MATCH_COLUMN_MAPPINGS> <EXPRESSION>
```

- **REFERENCE_DATASET_ALIAS** – The alias of the reference dataset with which you compare data from the primary dataset.
- **KEY_COLUMN_MAPPINGS** – A comma-separated list of column names that form a key in the datasets. If the column names are not the same in both datasets, you must separated them with a ->

- **OPTIONAL_MATCH_COLUMN_MAPPINGS** – You can supply this parameter if you want to check for matching data only in certain columns. It uses the same syntax as the key column mappings. If this parameter is not provided, we will match the data in all remaining columns. The remaining, non-key columns must have the same names in both datasets.
- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see Expressions.

Example: Match set datasets using ID column

The following example rule checks that more than 90% of the primary dataset matches the reference dataset, using the "ID" column to join the two datasets. It compares all columns in this case.

```
DatasetMatch "reference" "ID" >= 0.9
```

Example: Match set datasets using multiple key columns

In the following example, the primary dataset and the reference dataset have different names for the key columns. `ID_1` and `ID_2` together form a composite key in the primary dataset. `ID_ref1` and `ID_ref2` together forms a composite key in the reference dataset. In this scenario, you can use the special syntax to supply the column names.

```
DatasetMatch "reference" "ID_1->ID_ref1,ID_2->ID_ref2" >= 0.9
```

Example: Match set datasets using multiple key columns and check that specific column matches

This example builds on the previous example. We want to check that only the column containing the amounts match. This column is named `Amount1` in the primary dataset and `Amount2` in the reference dataset. You want an exact match.

```
DatasetMatch "reference" "ID_1->ID_ref1,ID_2->ID_ref2" "Amount1->Amount2" >= 0.9
```

DistinctValuesCount

Checks the number of distinct values in a column against a given expression.

Syntax

```
DistinctValuesCount <COL_NAME> <EXPRESSION>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

  Supported column types: Any column type

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see Expressions.

Example: Distinct column value count

The following example rule checks that the column named `State` contains more than 3 distinct values.

```
DistinctValuesCount "State" > 3
DistinctValuesCount "Customer_ID" < 6  where "Customer_ID < 10"
```

Sample dynamic rules

- `DistinctValuesCount "colA" between avg(last(10))-1 and avg(last(10))+1`
- `DistinctValuesCount "colA" <= index(last(10),2) + std(last(5))`

Entropy

Checks whether the *entropy* value of a column matches a given expression. Entropy measures the level of information that's contained in a message. Given the probability distribution over values in a column, entropy describes how many bits are required to identify a value.

Syntax

```
Entropy <COL_NAME> <EXPRESSION>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

  Supported column types: Any column type

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see Expressions.

Example: Column entropy

The following example rule checks that the column named `Feedback` has an entropy value greater than one.

```
Entropy "Star_Rating" > 1
Entropy "First_Name" > 1  where "Customer_ID < 10"
```

Sample dynamic rules

- `Entropy "colA" < max(last(10))`
- `Entropy "colA" between min(last(10)) and max(last(10))`

IsComplete

Checks whether all of the values in a column are complete (non-null).

Syntax

```
IsComplete <COL_NAME>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

  Supported column types: Any column type

Example: Null values

The following example checks whether all of the values in a column named `email` are non-null.

```
IsComplete "email"
IsComplete "Email" where "Customer_ID between 1 and 50"
IsComplete "Customer_ID"  where "Customer_ID < 16 and Customer_ID != 12"
IsComplete "passenger_count" where "payment_type<>0"
```

Null behavior

Note on CSV Data Formats: Blank rows on CSV columns can display multiple behaviors.

- If a column is of `String` type, the blank row will be recognized as an empty string and will not fail the `Completeness` rule.
- If a column is of another data type like `Int`, the blank row will be recognized as `NULL` and will fail the `Completeness` rule.

IsPrimaryKey

Checks whether a column contains a primary key. A column contains a primary key if all of the values in the column are unique and complete (non-null). You can also check for primary keys with multiple columns.

Syntax

```
IsPrimaryKey <COL_NAME>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

  Supported column types: Any column type

Example: Primary key

The following example rule checks whether the column named `Customer_ID` contains a primary key.

```
IsPrimaryKey "Customer_ID"
IsPrimaryKey "Customer_ID" where "Customer_ID < 10"
```

Example: Primary key with multiple columns. Any of the following examples are valid.

```
IsPrimaryKey "colA" "colB"
IsPrimaryKey "colA" "colB" "colC"
IsPrimaryKey colA "colB" "colC"
```

IsUnique

Checks whether all of the values in a column are unique, and returns a Boolean value.

Syntax

```
IsUnique <COL_NAME>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

  Supported column types: Any column type

Examples

The following example rule checks whether all of the values in a column named `email` are unique.

```
IsUnique "email"
IsUnique "Customer_ID" where "Customer_ID < 10"]
```

The following example rule checks multiple columns.

```
IsUnique "vendorid" "tpep_pickup_datetime"
```

Mean

Checks whether the mean (average) of all the values in a column matches a given expression.

Syntax

```
Mean <COL_NAME> <EXPRESSION>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

  Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short
- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see Expressions.

Example: Average value

The following example rule checks whether the average of all of the values in a column exceeds a threshold.

```
Mean "Star_Rating" > 3
Mean "Salary" < 6200 where "Customer_ID < 10"
```

Sample dynamic rules

- `Mean "colA" > avg(last(10)) + std(last(2))`
- `Mean "colA" between min(last(5)) - 1 and max(last(5)) + 1`

Null behavior

The `Mean` rule will ignore rows with `NULL` values in the calculation of the mean. For example:

```
+---+-----------+
|id |units      |
+---+-----------+
|100|0          |
|101|null       |
|102|20         |
|103|null       |
|104|40         |
+---+-----------+
```

The mean of column `units` will be (0 + 20 + 40) / 3 = 20. Rows 101 and 103 are not considered in this calculation.

ReferentialIntegrity

Checks to what extent the values of a set of columns in the primary dataset are a subset of the values of a set of columns in a reference dataset.

Syntax

```
ReferentialIntegrity <PRIMARY_COLS> <REFERENCE_DATASET_COLS> <EXPRESSION>
```

- **PRIMARY_COLS** – A comma-separated list of column names in the primary dataset.

  Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short
- **REFERENCE_DATASET_COLS** – This parameter contains two parts separated by a period. The first part is the alias of the reference dataset. The second part is the comma-separated list of column names in the reference dataset enclosed in braces.

  Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see Expressions.

Example: Check the referential integrity of a zip code column

The following example rule checks that more than 90% of the values in the `zipcode` column in the primary dataset, are present in the `zipcode` column in the `reference` dataset.

```
ReferentialIntegrity "zipcode" "reference.zipcode" >= 0.9
```

Example: Check the referential integrity of the city and state columns

In the following example, columns containing city and state information exist in the primary dataset and the reference dataset. The names of the columns are different in both datasets. The rule checks if the set of values of the columns in the primary dataset is exactly equal to the set of values of the columns in the reference dataset.

```
ReferentialIntegrity "city,state" "reference.{ref_city,ref_state}" = 1.0
```

Sample dynamic rules

- `ReferentialIntegrity "city,state" "reference.{ref_city,ref_state}" > avg(last(10))`
- `ReferentialIntegrity "city,state" "reference.{ref_city,ref_state}" between min(last(10)) - 1 and max(last(10)) + 1`

RowCount

Checks the row count of a dataset against a given expression. In the expression, you can specify the number of rows or a range of rows using operators like > and <.

Syntax

```
RowCount <EXPRESSION>
```

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see Expressions.

Example: Row count numeric check

The following example rule checks whether the row count is within a given range.

```
RowCount between 10 and 100
RowCount between 1 and 50 where "Customer_ID < 10"
```

Sample dynamic rules

```
RowCount > avg(last(10)) *0.8
```

RowCountMatch

Checks the ratio of the row count of the primary dataset and the row count of a reference dataset against the given expression.

Syntax

```
RowCountMatch <REFERENCE_DATASET_ALIAS> <EXPRESSION>
```

- **REFERENCE_DATASET_ALIAS** – The alias of the reference dataset against which to compare row counts.

  Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short
- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see Expressions.

Example: Row count check against a reference dataset

The following example rule checks whether the row count of the primary dataset is at least 90% of the row count of the reference dataset.

```
RowCountMatch "reference" >= 0.9
```

StandardDeviation

Checks the standard deviation of all of the values in a column against a given expression.

Syntax

```
StandardDeviation <COL_NAME> <EXPRESSION>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

  Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short
- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see Expressions.

Example: Standard deviation

The following example rule checks whether the standard deviation of the values in a column named `colA` is less than a specified value.

```
StandardDeviation "Star_Rating" < 1.5
StandardDeviation "Salary" < 3500 where "Customer_ID < 10"
```

Sample dynamic rules

- `StandardDeviation "colA" > avg(last(10) + 0.1`
- `StandardDeviation "colA" between min(last(10)) - 1 and max(last(10)) + 1`

Null behavior

The `StandardDeviation` rule will ignore rows with `NULL` values in the calculation of standard deviation. For example:

```
+---+-----------+-----------+
|id |units1     |units2     |
+---+-----------+-----------+
|100|0          |0          |
|101|null       |0          |
|102|20         |20         |
|103|null       |0          |
|104|40         |40         |
+---+-----------+-----------+
```

The standard deviation of column `units1` will not consider rows 101 and 103 and result to 16.33. The standard deviation for column `units2` will result in 16.

Sum

Checks the sum of all the values in a column against a given expression.

Syntax

```
Sum <COL_NAME> <EXPRESSION>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

  Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short
- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see Expressions.

Example: Sum

The following example rule checks whether the sum of all of the values in a column exceeds a given threshold.

```
Sum "transaction_total" > 500000
Sum "Salary" < 55600 where "Customer_ID < 10"
```

Sample dynamic rules

- `Sum "ColA" > avg(last(10))`
- `Sum "colA" between min(last(10)) - 1 and max(last(10)) + 1`

Null behavior

The `Sum` rule will ignore rows with `NULL` values in the calculation of sum. For example:

```
+---+-----------+
|id |units      |
+---+-----------+
|100|0          |
|101|null       |
|102|20         |
|103|null       |
|104|40         |
```

```
+---+-----------+
```

The sum of column `units` will not consider rows 101 and 103 and result to (0 + 20 + 40) = 60.

SchemaMatch

Checks if the schema of the primary dataset matches the schema of a reference dataset. The schema check is done column by column. The schema of two columns match if the names are identical and the types are identical. The order of the columns does not matter.

Syntax

```
SchemaMatch <REFERENCE_DATASET_ALIAS> <EXPRESSION>
```

- **REFERENCE_DATASET_ALIAS** – The alias of the reference dataset against which to compare schemas.

  Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short
- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see Expressions.

Example: SchemaMatch

The following example rule checks whether the schema of the primary dataset exactly matches the schema of a reference dataset.

```
SchemaMatch "reference" = 1.0
```

Uniqueness

Checks the percentage of unique values in a column against a given expression. Unique values occur exactly once.

Syntax

```
Uniqueness <COL_NAME> <EXPRESSION>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

Supported column types: Any column type

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see Expressions.

Example

The following example rule checks whether the percentage of unique values in a column matches certain numeric criteria.

```
Uniqueness "email" = 1.0
Uniqueness "Customer_ID" != 1.0 where "Customer_ID < 10"
```

The following example rule checks multiple columns.

```
Uniqueness "vendorid" "tpep_pickup_datetime" = 1
```

Sample dynamic rules

- `Uniqueness "colA" between min(last(10)) and max(last(10))`
- `Uniqueness "colA" >= avg(last(10))`

UniqueValueRatio

Checks the *unique value ratio* of a column against a given expression. A unique value ratio is the fraction of unique values divided by the number of all distinct values in a column. Unique values occur exactly one time, while distinct values occur *at least* once.

For example, the set `[a, a, b]` contains one unique value (b) and two distinct values (a and b). So the unique value ratio of the set is ½ = 0.5.

Syntax

```
UniqueValueRatio <COL_NAME> <EXPRESSION>
```

- **COL_NAME** – The name of the column that you want to evaluate the data quality rule against.

Supported column types: Any column type

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see Expressions.

Example: Unique value ratio

This example checks the unique value ratio of a column against a range of values.

```
UniqueValueRatio "test_score" between 0 and 0.5
UniqueValueRatio "Customer_ID" between 0 and 0.9 where "Customer_ID < 10"
```

Sample dynamic rules

- `UniqueValueRatio "colA" > avg(last(10))`
- `UniqueValueRatio "colA" <= index(last(10),2) + std(last(5))`

DetectAnomalies

Detects anomalies for a given data quality rule. Every execution of DetectAnomalies rule result in saving evaluated value for the given rule. When there is enough data gathered, anomaly detection algorithm takes all historical data for that given rule and runs anomaly detection. DetectAnomalies rule fails when anomaly is detected. More info about what anomaly was detected can be obtained from Observations.

Syntax

```
DetectAnomalies <RULE_NAME> <RULE_PARAMETERS>
```

RULE_NAME – The name of the rule that you want to evaluate and detect anomalies for. Supported rules:

- "RowCount"
- "Completeness"
- "Uniqueness"

- "Mean"
- "Sum"
- "StandardDeviation"
- "Entropy"
- "DistinctValuesCount"
- "UniqueValueRatio"
- "ColumnLength"
- "ColumnValues"
- "ColumnCorrelation"
- "CustomSQL"
- "ColumnCount"

RULE_PARAMETERS – some rules require additional parameters to run. Refer to the given rule documentation to see required parameters.

Example: Anomalies for RowCount

For example, if we want to detect RowCount anomalies, we provide RowCount as a rule name.

```
DetectAnomalies "RowCount"
```

Example: Anomalies for ColumnLength

For example, if we want to detect ColumnLength anomalies, we provide ColumnLength as a rule name and the column name.

```
DetectAnomalies "ColumnLength" "id"
```

FileFreshness

FileFreshness ensures your data files are fresh based on the condition you provide. It uses your files' last modified time to ensure that data files or the entire folder is up-to-date.

This rule gathers two metrics:

- FileFreshness compliance based on the rule you set up

- The number of files that were scanned by the rule

```
Dataset.*.FileFreshness.Compliance: 1, Dataset.*.FileCount: 1
```

Anomaly detection does not consider these metrics.

Checking file freshness

The following rule ensures that tickets.parquet was created in the past 24 hours.

```
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/tickets.parquet" >
 (now() - 24 hours)
```

Checking folder freshness

The following rule passes if all files in the folder were created or modified in past 24 hours.

```
FileFreshness "s3://bucket/" >= (now() - 1 days)
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" >= (now() - 24 hours)
```

Checking folder or file freshness with threshold

The following rule passes if 10% of the files in the folder “tickets“ were created or modified in the past 10 days.

```
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" > (now() - 10 days)
 with threshold > 0.1
```

Checking files or folders with specific dates

You can check for file freshness for specific days.

```
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" > "2020-01-01"
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" between "2023-01-01"
 and "2024-01-01"
```

Checking files or folders with time

You can use FileFreshness to ensure that files have arrived based on certain times.

```
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" between (now() - 45
 minutes) and now()
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" between "9:30 AM" and
 "9:30 PM"
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" > (now() - 10 minutes)
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" > now()
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" between (now() - 2
 hours) and (now() + 15 minutes)
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" between (now() - 3
 days) and (now() + 15 minutes)
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" between "2001-02-07"
 and (now() + 15 minutes)
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" > "21:45"
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" > "2024-01-01"
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" between "02:30" and
 "04:30"
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" between "9:30 AM" and
 "22:15"
```

Key considerations:

- FileFreshness can evaluate files using days, hours, and minutes units
- For times, it supports AM / PM and 24-hour
- Times are calculated in UTC unless an override is specified
- Dates are calculated in UTC at time 00:00

FileFreshness that are time-based works as follows:

```
FileFreshness "s3://amzn-s3-demo-bucket/artifacts/file/tickets/" > "21:45"
```

- First, the time “21:45” is combined with today’s date in UTC format to create a date-time field
- Next, if a timezone override is specified, the date-time is converted to that timezone (otherwise UTC is used)
- Finally, the rule is evaluated

Optional File-based Rule Tags:

Tags allow you to control the rule behavior.

recentFiles

This tag limits the number of files processed by keeping the most recent file first.

```
FileFreshness "s3://amzn-s3-demo-bucket/" between (now() - 100 minutes) and (now() + 10
 minutes) with recentFiles = 1
```

uriRegex

> **Note**
>
> The `uriRegex` tag is available in AWS Glue 5.0 and later.

This tag filters files by applying a regex pattern to the file path. Only files whose paths match the pattern are processed. You can also use a negative lookahead to exclude files that match a pattern.

```
# Match only files with a .csv extension
FileFreshness "s3://amzn-s3-demo-bucket/" > (now() - 24 hours) with uriRegex = "\.csv$"
# Match Parquet files that contain "orders_" in the path
FileFreshness "s3://amzn-s3-demo-bucket/" > (now() - 24 hours) with uriRegex =
 ".*orders_.*\.parquet"
# Exclude files ending in .tmp using a negative lookahead
FileFreshness "s3://amzn-s3-demo-bucket/" > (now() - 24 hours) with uriRegex = "(?!.*
\.tmp$).*"
```

filterOrder

> **Note**
>
> The `filterOrder` tag is available in AWS Glue 5.0 and later.

When you use multiple filter tags such as `recentFiles` and `uriRegex` together, the `filterOrder` tag controls the order in which they are applied. The default order is `recentFiles` first, then `uriRegex`.

```
FileFreshness "s3://amzn-s3-demo-bucket/" > (now() - 24 hours) with recentFiles = 1
 with uriRegex = "inventory_" with filterOrder = ["uriRegex","recentFiles"]
```

In the example above, the `uriRegex` filter is applied first to select only files matching "inventory_", and then `recentFiles = 1` takes the most recent file from that filtered set. Without `filterOrder`, the default behavior would take the single most recent file first and then apply the regex, which could result in no files matching if the most recent file doesn't match the pattern.

> **Note**
>
> All values in the `filterOrder` list must reference other filter tags (`recentFiles` or `uriRegex`) that are also present on the same rule. Non-filter tags such as `timeZone` or `failFast` are not valid in `filterOrder`.

failFast

When set to `"true"`, the rule returns failure immediately on the first file that fails the freshness condition, instead of evaluating all files and computing a compliance ratio.

```
FileFreshness "s3://amzn-s3-demo-bucket/" > (now() - 24 hours) with failFast = "true"
```

timeZone

Accepted time zone overrides, see Allowed Time Zones for supported time zones.

```
FileFreshness "s3://path/" > "21:45" with timeZone = "America/New_York"
```

```
FileFreshness "s3://path/" > "21:45" with timeZone = "America/Chicago"
```

```
FileFreshness "s3://path/" > "21:45" with timeZone = "Europe/Paris"
```

```
FileFreshness "s3://path/" > "21:45" with timeZone = "Asia/Shanghai"
```

```
FileFreshness "s3://path/" > "21:45" with timeZone = "Australia/Darwin"
```

Inferring file names directly from data frames

You don't always have to provide a file path. For instance, when you are authoring the rule in the AWS Glue Data Catalog, it may be hard to find which folders the catalog tables are using. AWS Glue

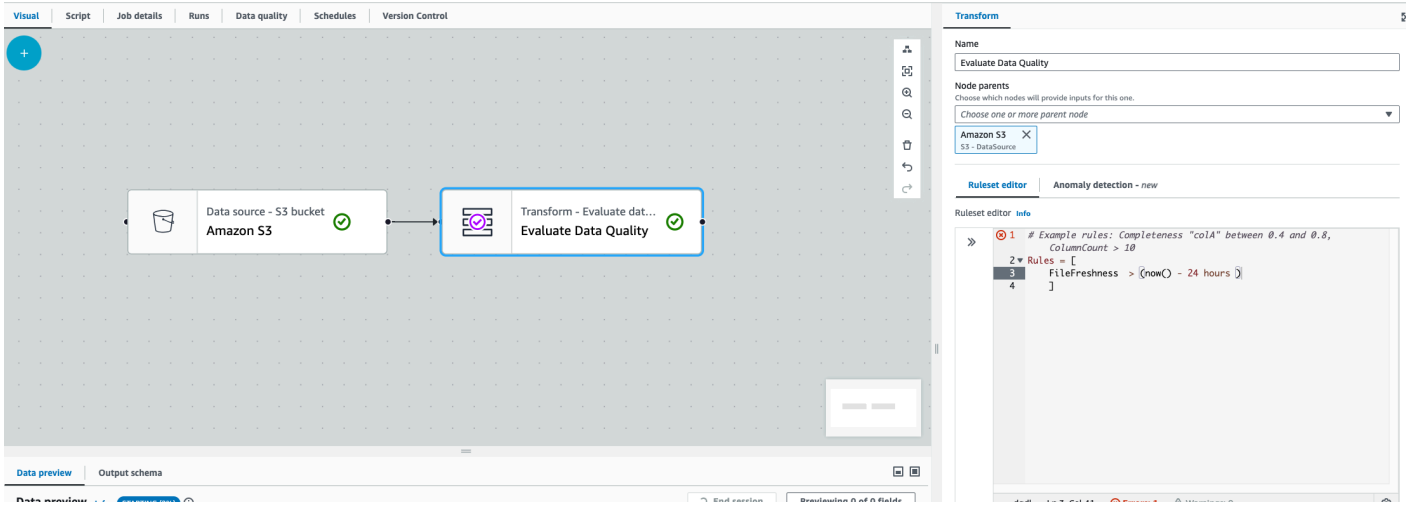
Data Quality can find the specific folders or files used to populate your dataframe and can detect if they are fresh.

> **Note**
>
> This feature will only work when files are successfully read into the DynamicFrame or DataFrame.

```
FileFreshness > (now() - 24 hours)
```

This rule will find the folder path or files that are used to populate the dynamic frame or data frame. This works for Amazon S3 paths or Amazon S3-based AWS Glue Data Catalog tables. There are a few considerations:

1. In AWS Glue ETL, you must have the **EvaluateDataQuality** Transform immediately after an Amazon S3 or AWS Glue Data Catalog transform.



2. This rule will not work in AWS Glue Interactive Sessions.

If you attempt this in both of the cases, or when AWS Glue can't find the files, AWS Glue will throw the following error: "`Unable to parse file path from DataFrame`"

FileMatch

The FileMatch rule allows you to compare files against other files or checksums. This can be useful in a few scenarios:

1. Validating files received from external sources: You can use FileMatch to ensure that you have received the correct files from external sources by comparing against checksums. This helps validate the integrity of the data you're ingesting.
2. Comparing data in two different folders: FileMatch can be used to compare files between two folders.

This rule gathers one metric: the number of files that were scanned by the rule.

```
Dataset.*.FileCount: 1
```

Validate file with a checksum:

FileMatch accepts a file and a set checksums to ensure that at least one checksums match the file.

```
FileMatch "s3://amzn-s3-demo-bucket/file.json" in ["3ee0d8617ac041793154713e5ef8f319"]
 with hashAlgorithm = "MD5"
FileMatch "s3://amzn-s3-demo-bucket/file.json" in ["3ee0d8617ac041793154713e5ef8f319"]
 with hashAlgorithm = "SHA-1"
FileMatch "s3://amzn-s3-demo-bucket/file.json" in ["3ee0d8617ac041793154713e5ef8f319"]
 with hashAlgorithm = "SHA-256"
FileMatch "s3://amzn-s3-demo-bucket/file.json" in ["3ee0d8617ac041793154713e5ef8f319"]
```

The following standard algorithms are supported:

- MD5
- SHA-1
- SHA-256

If you do not supply an algorithm, the default is SHA-256.

Validate all files in a folder with set of checksum:

```
FileMatch "s3://amzn-s3-demo-bucket /" in ["3ee0d8617ac041793154713e5ef8f319",
 "7e8617ac041793154713e5ef8f319"] with hashAlgorithm = "MD5"
FileMatch "s3://amzn-s3-demo-bucket /internal-folder/" in
 ["3ee0d8617ac041793154713e5ef8f319", "7e8617ac041793154713e5ef8f319"]
```

Compare files in different folders

```
# Compare all files across two buckets
FileMatch "s3://original_bucket/" "s3://archive_bucket/"
# Compare files within specific subfolders
FileMatch "s3://original_bucket/internal-folder/" "s3://original_bucket/other-folder/"
# Compare only .json files across two folders
FileMatch "s3://original_bucket/" "s3://archive_bucket/" with uriRegex = "\.json$"
# Compare only the 5 most recent .csv files
FileMatch "s3://original_bucket/" "s3://archive_bucket/" with recentFiles = 5 with
 uriRegex = "\.csv$" with filterOrder = ["uriRegex","recentFiles"]
```

FileMatch will check the contents of the files in `original_bucket` and ensure they match what's in `archive_bucket`. The rule will fail if they don't exactly match. It also can check the contents of internal folders or individual files.

FileMatch can also check individual files against each other.

```
FileMatch "s3://amzn-s3-demo-bucket /file_old.json" "s3://amzn-s3-demo-bucket /
file_new.json"
```

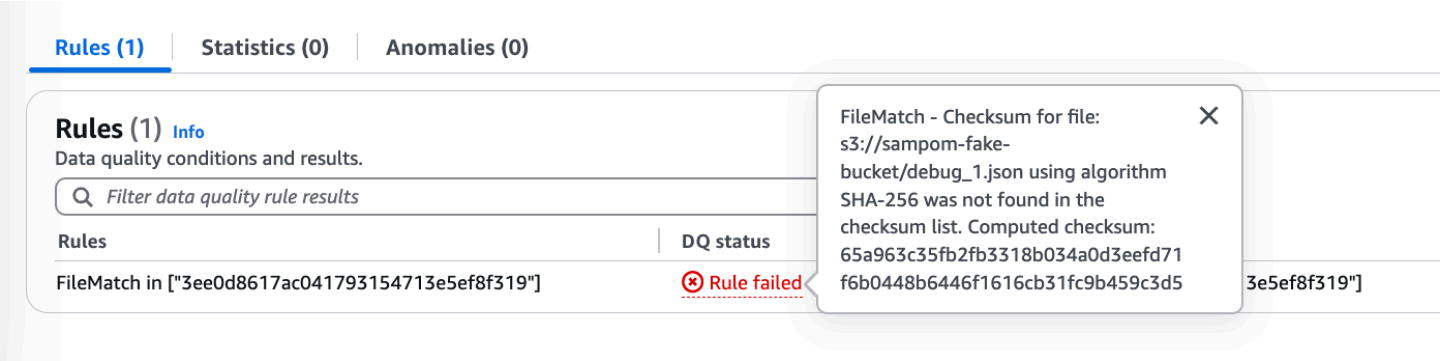
Inferring file names directly from data frames

You don't always have to provide a file path. For instance, when you are authoring the rule in the AWS Glue Data Catalog (backed by Amazon S3), it may be hard to find which folders the catalog tables are using. AWS Glue Data Quality can find the specific folders or files used to populate your data frame.

> **Note**
>
> This feature will only work when files are successfully read into the DynamicFrame or DataFrame.

```
FileMatch in ["3ee0d8617ac041793154713e5ef8f319"] with hashAlgorithm = "MD5"
FileMatch in ["3ee0d8617ac041793154713e5ef8f319"] with hashAlgorithm = "SHA-1"
FileMatch in ["3ee0d8617ac041793154713e5ef8f319"] with hashAlgorithm = "SHA-256"
FileMatch in ["3ee0d8617ac041793154713e5ef8f319"]
```

If the supplied checksum is different than what's computed, FileMatch will alert you to the difference.



Optional File-based Rule Tags:

Tags allow you to control the rule behaviour.

recentFiles

This tag limits the number of files processed by keeping the most recent file first.

```
FileMatch "s3://bucket/" in ["3ee0d8617ac04179sam4713e5ef8f319"] with recentFiles = 1
```

uriRegex

> **Note**
>
> The `uriRegex` tag is available in AWS Glue 5.0 and later.

This tag filters files by applying a regex pattern to the file path. Only files whose paths match the pattern are processed. You can also use a negative lookahead to exclude files that match a pattern.

```
# Match only files with a .json extension
FileMatch "s3://bucket/" in ["3ee0d8617ac04179sam4713e5ef8f319"] with uriRegex =
 "\.json$"
# Exclude files ending in .tmp using a negative lookahead
FileMatch "s3://bucket/" in ["3ee0d8617ac04179sam4713e5ef8f319"] with uriRegex = "(?!.*
\.tmp$).*"
```

filterOrder

> **Note**
>
> The `filterOrder` tag is available in AWS Glue 5.0 and later.

When you use multiple filter tags such as `recentFiles` and `uriRegex` together, the `filterOrder` tag controls the order in which they are applied. The default order is `recentFiles` first, then `uriRegex`.

```
FileMatch "s3://bucket/" in ["3ee0d8617ac04179sam4713e5ef8f319"] with recentFiles = 1
 with uriRegex = "\.json$" with filterOrder = ["uriRegex","recentFiles"]
```

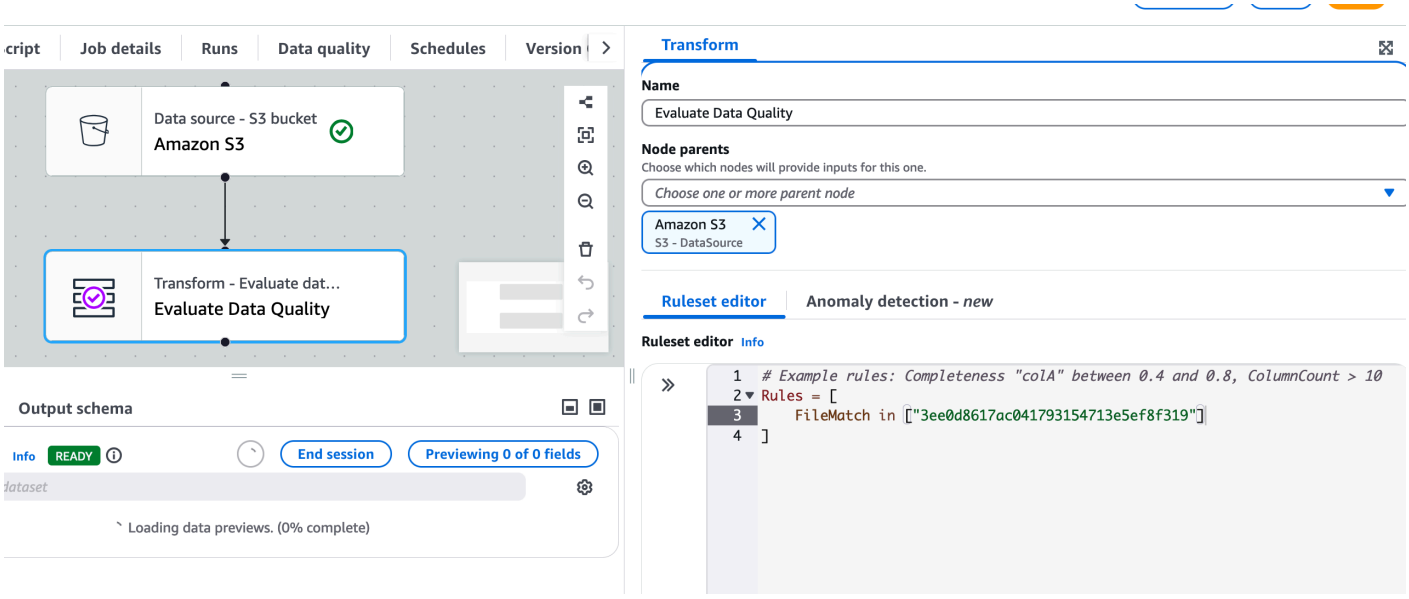
matchFileName

This tag ensures that files don't have duplicate names. Default behavior is false.

```
FileMatch "s3://amzn-s3-demo-bucket/file.json" in ["3ee0d8617ac04179sam4713e5ef8f319"]
 with matchFileName = "true"
```

There are a few considerations:

1. In AWS Glue ETL, you must have the **EvaluateDataQuality** Transform immediately after an Amazon S3 or AWS Glue Data Catalog transform.



2. This rule will not work in AWS Glue Interactive Sessions.

FileUniqueness

File Uniqueness allows you to ensure that there are no duplicate files in the data you have received from your data producers.

It gathers the following data statistics:

1. The number of files that were scanned by the rule
2. The Uniqueness Ratio of the files

```
Dataset.*.FileUniquenessRatio: 1.00, Dataset.*.FileCount: 8
```

Find duplicate files in a folder:

```
FileUniqueness "s3://bucket/" > 0.5
FileUniqueness "s3://bucket/folder/" = 1
```

Inferring folder names directly from data frames to detect duplicates:

You don't always have to provide a file path. For instance, when you are authoring the rule in the AWS Glue Data Catalog, it may be hard to find which folders the catalog tables are using. AWS Glue Data Quality can find the specific folders or files used to populate your data frame.

> **Note**
>
> When using inference, file-based rules can only detect files successfully read into the DynamicFrame or DataFrame.

```
FileUniqueness > 0.5
```

Optional File-based Rule Tags:

Tags allow you to control the rule behaviour.

recentFiles

This tag limits the number of files processed by keeping the most recent file first.

```
FileUniqueness "s3://amzn-s3-demo-bucket/" > 0.5 with recentFiles = 1
```

uriRegex

> **Note**
>
> The `uriRegex` tag is available in AWS Glue 5.0 and later.

This tag filters files by applying a regex pattern to the file path. Only files whose paths match the pattern are processed. You can also use a negative lookahead to exclude files that match a pattern.

```
# Match only files with a .csv extension
FileUniqueness "s3://bucket/" > 0.5 with uriRegex = "\.csv$"
# Exclude files ending in .tmp using a negative lookahead
FileUniqueness "s3://bucket/" > 0.5 with uriRegex = "(?!.*\.tmp$).*"
```

filterOrder

> **Note**
>
> The `filterOrder` tag is available in AWS Glue 5.0 and later.

When you use multiple filter tags such as `recentFiles` and `uriRegex` together, the `filterOrder` tag controls the order in which they are applied. The default order is `recentFiles` first, then `uriRegex`.

```
FileUniqueness "s3://bucket/" > 0.5 with recentFiles = 5 with uriRegex = "\.csv$" with
 filterOrder = ["uriRegex","recentFiles"]
```

matchFileName

This tag ensures that files don't have duplicate names. Default behavior is false.

```
FileUniqueness "s3://amzn-s3-demo-bucket/" > 0.5 with matchFileName = "true"
```

There are a few considerations:

1. In AWS Glue ETL, you must have the **EvaluateDataQuality** Transform immediately after an Amazon S3 or AWS Glue Data Catalog transform.
2. This rule will not work in AWS Glue Interactive Sessions.

FileSize

The FileSize ruletype allows you to ensure that files meet a certain file size criteria. This is useful for following use cases:

1. Ensure that producers are not sending empty or substantially smaller files for processing.
2. Ensure that your target buckets don't have smaller files which may lead to performance issues.

FileSize gathers the following metrics:

1. Compliance: returns the % of files that meet the rule threshold you have established
2. File Count: the number of files that were scanned by the rule
3. Minimum file size in bytes
4. Maximum file size in bytes

```
Dataset.*.FileSize.Compliance: 1, Dataset.*.FileCount: 8, Dataset.*.MaximumFileSize:
 327413121, Dataset.*.MinimumFileSize: 204558920
```

Anomaly detection is not supported for these metrics.

Validate size of files

This rule will pass when file.dat is greater than 2 MB.

```
FileSize "s3://amzn-s3-demo-bucket/file.dat" > 2 MB
```

The supported units include B (bytes), KB (kilobytes), MB (megabytes), GB (gigabytes) and TB (terabytes).

Validate size of files in folders

```
FileSize "s3://bucket/" > 5 B
```

```
FileSize "s3://bucket/" < 2 GB
```

This rule will pass if 70% of the files in s3://amzn-s3-demo-bucket is between 2 GB and 1 TB.

```
FileSize "s3://amzn-s3-demo-bucket/" between 2 GB and 1 TB with threshold > 0.7
```

Inferring file names directly from data frames

You don't always have to provide a file path. For instance, when you are authoring the rule in the Data Catalog, it may be hard to find which folders the catalog tables are using. AWS Glue Data Quality can find the specific folders or files used to populate your data frame.

> **Note**
>
> This feature will only work when files are successfully read into the DynamicFrame or DataFrame.

```
FileSize < 10 MB with threshold > 0.7
```

Optional File-based Rule Tags:

Tags allow you to control the rule behaviour.

recentFiles

This tag limits the number of files processed by keeping the most recent file first.

```
FileSize "s3://amzn-s3-demo-bucket/" > 5 B with recentFiles = 1
```

uriRegex

> **Note**
>
> The `uriRegex` tag is available in AWS Glue 5.0 and later.

This tag filters files by applying a regex pattern to the file path. Only files whose paths match the pattern are processed. You can also use a negative lookahead to exclude files that match a pattern.

```
# Match only files with a .dat extension
FileSize "s3://bucket/" > 5 B with uriRegex = "\.dat$"
# Exclude files ending in .tmp using a negative lookahead
FileSize "s3://bucket/" > 5 B with uriRegex = "(?!.*\.tmp$).*"
```

filterOrder

> **Note**
>
> The `filterOrder` tag is available in AWS Glue 5.0 and later.

When you use multiple filter tags such as `recentFiles` and `uriRegex` together, the `filterOrder` tag controls the order in which they are applied. The default order is `recentFiles` first, then `uriRegex`.

```
FileSize "s3://bucket/" > 5 B with recentFiles = 5 with uriRegex = "\.dat$" with
 filterOrder = ["uriRegex","recentFiles"]
```

failFast

When set to `"true"`, the rule returns failure immediately on the first file that fails the size condition, instead of evaluating all files and computing a compliance ratio.

```
FileSize "s3://bucket/" > 2 MB with failFast = "true"
```

There are a few considerations:

1. In AWS Glue ETL, you must have Evaluate DataQuality Transform immediately after the Amazon S3 or Data Catalog transform.
2. This rule will not work in AWS Glue Interactive Sessions.

Using APIs to measure and manage data quality

This topic describes how to use APIs to measure and manage data quality.

Contents

- Prerequisites
- Working with AWS Glue Data Quality recommendations
- Working with AWS Glue Data Quality rulesets
- Working with AWS Glue Data Quality runs
- Working with AWS Glue Data Quality results

Prerequisites

- Make sure your boto3 version is up to date so that it includes the latest AWS Glue Data Quality API.
- Make sure your AWS CLI version is up to date, so as to include the latest CLI.

If you're using an AWS Glue job to run these APIs, you can use the following option to update the boto3 library to the latest version:

```
–additional-python-modules boto3==<version>
```

Working with AWS Glue Data Quality recommendations

To start an AWS Glue Data Quality recommendation run:

```
class GlueWrapper:
    """Encapsulates AWS Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 AWS Glue client.
        """
        self.glue_client = glue_client

    def start_data_quality_rule_recommendation_run(self, database_name, table_name,
 role_arn):
        """
        Starts a recommendation run that is used to generate rules when you don't know
 what rules to write. AWS Glue Data Quality
        analyzes the data and comes up with recommendations for a potential ruleset.
 You can then triage the ruleset
        and modify the generated ruleset to your liking.
```

```
        :param database_name: The name of the AWS Glue database which contains the
dataset.
        :param table_name: The name of the AWS Glue table against which we want a
recommendation
        :param role_arn: The Amazon Resource Name (ARN) of an AWS Identity and Access
Management (IAM) role that grants permission to let AWS Glue access the resources it
needs.

        """
        try:
            response = self.client.start_data_quality_rule_recommendation_run(
                DataSource={
                    'GlueTable': {
                        'DatabaseName': database_name,
                        'TableName': table_name
                    }
                },
                Role=role_arn
            )
        except ClientError as err:
            logger.error(
                "Couldn't start data quality recommendation run %s. Here's why: %s:
%s", name,
                err.response['Error']['Code'], err.response['Error']['Message'])
            raise
        else:
            return response['RunId']
```

For a recommendation run, you are able to use your `pushDownPredicates` or `catalogPartitionPredicates` to improve performance and run recommendations only on specific partitions of your catalog sources.

```
client.start_data_quality_rule_recommendation_run(
            DataSource={
                'GlueTable': {
                    'DatabaseName': database_name,
                    'TableName': table_name,
                    'AdditionalOptions': {
                        'pushDownPredicate': "year=2022"
                    }
                }
            },
            Role=role_arn,
```

```
            NumberOfWorkers=2,
            CreatedRulesetName='<rule_set_name>'
  )
```

To get results of an AWS Glue Data Quality recommendation run:

```
class GlueWrapper:
    """Encapsulates AWS Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 AWS Glue client.
        """
        self.glue_client = glue_client

    def get_data_quality_rule_recommendation_run(self, run_id):
        """
        Gets the specified recommendation run that was used to generate rules.

        :param run_id: The id of the data quality recommendation run

        """
        try:
            response =
 self.client.get_data_quality_rule_recommendation_run(RunId=run_id)
        except ClientError as err:
            logger.error(
                "Couldn't get data quality recommendation run %. Here's why: %s: %s",
 run_id,
                err.response['Error']['Code'], err.response['Error']['Message'])
            raise
        else:
            return response
```

From the above response object, you can extract the RuleSet that was recommended by the run, to use in further steps:

```
print(response['RecommendedRuleset'])

Rules = [
    RowCount between 2000 and 8000,
    IsComplete "col1",
    IsComplete "col2",
    StandardDeviation "col3" between 58138330.8 and 64258155.09,
```

```
    ColumnValues "col4" between 1000042965 and 1214474826,
    IsComplete "col5"
]
```

To get a list of all your recommendation runs that can be filtered and listed:

```
response = client.list_data_quality_rule_recommendation_runs(
    Filter={
        'DataSource': {
            'GlueTable': {
                'DatabaseName': '<database_name>',
                'TableName': '<table_name>'
            }
        }
)
```

To cancel existing AWS Glue Data Quality recommendation tasks:

```
response = client.cancel_data_quality_rule_recommendation_run(
    RunId='dqrun-d4b6b01957fdd79e59866365bf9cb0e40fxxxxxxx'
)
```

Working with AWS Glue Data Quality rulesets

To create an AWS Glue Data Quality ruleset:

```
response = client.create_data_quality_ruleset(
    Name='<ruleset_name>',
    Ruleset='Rules = [IsComplete "col1", IsPrimaryKey "col2", RowCount between 2000 and
 8000]',
    TargetTable={
        'TableName': '<table_name>',
        'DatabaseName': '<database_name>'
    }
)
```

To get a data quality ruleset:

```
response = client.get_data_quality_ruleset(
    Name='<ruleset_name>'
```

```
)
print(response)
```

You can use this API to then extract the rule set:

```
print(response['Ruleset'])
```

To list all the data quality rulesets for a table:

```
response = client.list_data_quality_rulesets()
```

You can use the filter condition within the API to filter all rulesets attached to a specific database or table:

```
response = client.list_data_quality_rulesets(
    Filter={
        'TargetTable': {
            'TableName': '<table_name>',
            'DatabaseName': '<database_name>'
        }
    },
)
```

To update a data quality ruleset:

```
class GlueWrapper:
    """Encapsulates AWS Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 AWS Glue client.
        """
        self.glue_client = glue_client

    def update_data_quality_ruleset(self, ruleset_name, ruleset_string):
        """
        Update an AWS Glue Data Quality Ruleset

        :param ruleset_name: The name of the AWS Glue Data Quality ruleset to update
        :param ruleset_string: The DQDL ruleset string to update the ruleset with

        """
```

```
        try:
            response = self.client.update_data_quality_ruleset(
                Name=ruleset_name,
                Ruleset=ruleset_string
            )
        except ClientError as err:
            logger.error(
                "Couldn't update the AWS Glue Data Quality ruleset. Here's why: %s:
 %s",
                err.response['Error']['Code'], err.response['Error']['Message'])
            raise
        else:
            return response
```

To delete a data quality ruleset:

```
class GlueWrapper:
    """Encapsulates AWS Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 AWS Glue client.
        """
        self.glue_client = glue_client

    def delete_data_quality_ruleset(self, ruleset_name):
        """
        Delete a AWS Glue Data Quality Ruleset

        :param ruleset_name: The name of the AWS Glue Data Quality ruleset to delete

        """
        try:
            response = self.client.delete_data_quality_ruleset(
                Name=ruleset_name
            )
        except ClientError as err:
            logger.error(
                "Couldn't delete the AWS Glue Data Quality ruleset. Here's why: %s:
 %s",
                err.response['Error']['Code'], err.response['Error']['Message'])
            raise
        else:
            return response
```

Working with AWS Glue Data Quality runs

To start an AWS Glue Data Quality run:

```
class GlueWrapper:
    """Encapsulates AWS Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 AWS Glue client.
        """
        self.glue_client = glue_client

    def start_data_quality_ruleset_evaluation_run(self, database_name, table_name,
 role_name, ruleset_list):
        """
        Start an AWS Glue Data Quality evaluation run

        :param database_name: The name of the AWS Glue database which contains the
 dataset.
        :param table_name: The name of the AWS Glue table against which we want to
 evaluate.
        :param role_arn: The Amazon Resource Name (ARN) of an AWS Identity and Access
 Management (IAM) role that grants permission to let AWS Glue access the resources it
 needs.
        :param ruleset_list: The list of AWS Glue Data Quality ruleset names to
 evaluate.

        """
        try:
            response = client.start_data_quality_ruleset_evaluation_run(
                DataSource={
                    'GlueTable': {
                        'DatabaseName': database_name,
                        'TableName': table_name
                    }
                },
                Role=role_name,
                RulesetNames=ruleset_list
            )
        except ClientError as err:
            logger.error(
                "Couldn't start the AWS Glue Data Quality Run. Here's why: %s: %s",
                err.response['Error']['Code'], err.response['Error']['Message'])
```

```
            raise
        else:
            return response['RunId']
```

Remember that you can pass a `pushDownPredicate` or `catalogPartitionPredicate` parameter to ensure your data quality run only targets a specific set of partition within your catalog table. For example:

```
response = client.start_data_quality_ruleset_evaluation_run(
    DataSource={
        'GlueTable': {
            'DatabaseName': '<database_name>',
            'TableName': '<table_name>',
            'AdditionalOptions': {
                'pushDownPredicate': 'year=2023'
            }
        }
    },
    Role='<role_name>',
    NumberOfWorkers=5,
    Timeout=123,
    AdditionalRunOptions={
        'CloudWatchMetricsEnabled': False
    },
    RulesetNames=[
        '<ruleset_name>',
    ]
)
```

You can also configure how composite rules in your ruleset are evaluated, either at the ROW or COLUMN level. For more information on how composite rules work, please refer to How composite rules work in the documentation.

Example on how to set the composite rule evaluation method in your request:

```
response = client.start_data_quality_ruleset_evaluation_run(
    DataSource={
        'GlueTable': {
            'DatabaseName': '<database_name>',
            'TableName': '<table_name>',
            'AdditionalOptions': {
                'pushDownPredicate': 'year=2023'
```

```
            }
        }
    },
    Role='<role_name>',
    NumberOfWorkers=5,
    Timeout=123,
    AdditionalRunOptions={
        'CompositeRuleEvaluationMethod':ROW
    },
    RulesetNames=[
        '<ruleset_name>',
    ]
)
```

To get information about an AWS Glue Data Quality run:

```
class GlueWrapper:
    """Encapsulates AWS Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 AWS Glue client.
        """
        self.glue_client = glue_client

    def get_data_quality_ruleset_evaluation_run(self, run_id):
        """
        Get details about an AWS Glue Data Quality Run

        :param run_id: The AWS Glue Data Quality run ID to look up

        """
        try:
            response = self.client.get_data_quality_ruleset_evaluation_run(
                RunId=run_id
            )
        except ClientError as err:
            logger.error(
                "Couldn't look up the AWS Glue Data Quality run ID. Here's why: %s:
 %s",
                err.response['Error']['Code'], err.response['Error']['Message'])
            raise
        else:
            return response
```

To get the results from an AWS Glue Data Quality run:

For a given AWS Glue Data Quality run, you can extract the results of the run's evaluation using the following method:

```
response = client.get_data_quality_ruleset_evaluation_run(
    RunId='d4b6b01957fdd79e59866365bf9cb0e40fxxxxxxx'
)

resultID = response['ResultIds'][0]

response = client.get_data_quality_result(
    ResultId=resultID
)

print(response['RuleResults'])
```

To list all your AWS Glue Data Quality runs:

```
class GlueWrapper:
    """Encapsulates AWS Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 AWS Glue client.
        """
        self.glue_client = glue_client

    def list_data_quality_ruleset_evaluation_runs(self, database_name, table_name):
        """
        Lists all the AWS Glue Data Quality runs against a given table

        :param database_name: The name of the database where the data quality runs
        :param table_name: The name of the table against which the data quality runs
 were created

        """
        try:
            response = self.client.list_data_quality_ruleset_evaluation_runs(
                Filter={
                    'DataSource': {
                        'GlueTable': {
                            'DatabaseName': database_name,
                            'TableName': table_name
```

```
                    }
                }
            }
        )
    except ClientError as err:
        logger.error(
            "Couldn't list the AWS Glue Quality runs. Here's why: %s: %s",
            err.response['Error']['Code'], err.response['Error']['Message'])
        raise
    else:
        return response
```

You can modify the filter clause to only show results between specific times or running against specific tables.

To stop an ongoing AWS Glue Data Quality run:

```
class GlueWrapper:
    """Encapsulates AWS Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 AWS Glue client.
        """
        self.glue_client = glue_client

    def cancel_data_quality_ruleset_evaluation_run(self, result_id):
        """
        Cancels a given AWS Glue Data Quality run

        :param result_id: The result id of a AWS Glue Data Quality run to cancel

        """
        try:
            response = self.client.cancel_data_quality_ruleset_evaluation_run(
                ResultId=result_id
            )
        except ClientError as err:
            logger.error(
                "Couldn't cancel the AWS Glue Data Quality run. Here's why: %s: %s",
                err.response['Error']['Code'], err.response['Error']['Message'])
            raise
        else:
            return response
```

Working with AWS Glue Data Quality results

To get your AWS Glue Data Quality run results:

```
class GlueWrapper:
    """Encapsulates AWS Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 AWS Glue client.
        """
        self.glue_client = glue_client

    def get_data_quality_result(self, result_id):
        """
        Outputs the result of an AWS Glue Data Quality Result

        :param result_id: The result id of an AWS Glue Data Quality run

        """
        try:
            response = self.client.get_data_quality_result(
                ResultId=result_id
            )
        except ClientError as err:
            logger.error(
                "Couldn't get the AWS Glue Data Quality result. Here's why: %s: %s",
                err.response['Error']['Code'], err.response['Error']['Message'])
            raise
        else:
            return response
```

To view the statistics gathered for a given data quality result:

```
import boto3
from botocore.exceptions import ClientError
import logging

logger = logging.getLogger(__name__)
class GlueWrapper:
    """Encapsulates AWS Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 AWS Glue client.
```

```
        """
        self.glue_client = glue_client

    def get_profile_for_data_quality_result(self, result_id):
        """
        Outputs the statistic profile for a AWS Glue Data Quality Result

        :param result_id: The result id of a AWS Glue Data Quality run

        """
        try:
            response = self.glue_client.get_data_quality_result(
                ResultId=result_id
            )

            # the profile contains all statistics gathered for the result
            profile_id = response['ProfileId']
            profile = self.glue_client.list_data_quality_statistics(
                ProfileId = profile_id
            )
            return profile
        except ClientError as err:
            logger.error(
                "Couldn't retrieve Data Quality profile. Here's why: %s: %s",
                err.response['Error']['Code'], err.response['Error']['Message'])
            raise
```

To view the timeseries for a statistic gathered across multiple data quality runs:

```
class GlueWrapper:
    """Encapsulates AWS Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 AWS Glue client.
        """
        self.glue_client = glue_client

    def get_statistics_for_data_quality_result(self, profile_id):
        """
        Outputs an array of datapoints for each statistic in the input result.

        :param result_id: The profile id of a AWS Glue Data Quality run
```

```
        """
        try:
            profile = self.glue_client.list_data_quality_statistics(
                ProfileId = profile_id
            )
            statistics = [self.glue_client.list_data_quality_statistics(
                StatisticId = s['StatisticId']
            ) for s in profile['Statistics']]
            return statistics
        except ClientError as err:
            logger.error(
                "Couldn't retrieve Data Quality statistics. Here's why: %s: %s",
                err.response['Error']['Code'], err.response['Error']['Message'])
            raise
```

To view the anomaly detection model for a specific statistic:

```
class GlueWrapper:
    """Encapsulates AWS Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 AWS Glue client.
        """
        self.glue_client = glue_client

    def get_model_training_result_for_statistic(self, statistic_id, profile_id):
        """
        Outputs the details (bounds) of anomaly detection training for the given
 statistic at the given profile.

        :param statistic_id the model's statistic (the timeseries it is tracking)
        :param profile_id the profile associated with the model (a point in the
 timeseries)

        """
        try:
            model = self.glue_client.get_data_quality_model_result(
                ProfileId = profile_id, StatisticId = statistic_id
            )
            return model
        except ClientError as err:
            logger.error(
                "Couldn't retrieve Data Quality model results. Here's why: %s: %s",
```

```
                err.response['Error']['Code'], err.response['Error']['Message'])
            raise
```

To exclude a datapoint from its statistic model's anomaly detection baseline:

```
class GlueWrapper:
    """Encapsulates AWS Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 AWS Glue client.
        """
        self.glue_client = glue_client

    def apply_exclusions_to_statistic(self, statistic_id, profile_ids):
        """
        Annotate some points along a given statistic timeseries.

        This example excludes the provided values; INCLUDE can also be used to undo
 this action.

        :param statistic_id the statistic timeseries to annotate
        :param profile_id the profiles we want to exclude (points in the timeseries)

        """

        try:
            response = self.glue_client.batch_put_data_quality_statistic_annotation(
                    InclusionAnnotations = [
                        {'ProfileId': prof_id,
                        'StatisticId': statistic_id,
                        'InclusionAnnotation': 'EXCLUDE'} for prof_id in profile_ids
                    ]
            )
            return response['FailedInclusionAnnotations']
        except ClientError as err:
            logger.error(
                "Couldn't store Data Quality annotations. Here's why: %s: %s",
                err.response['Error']['Code'], err.response['Error']['Message'])
            raise
```

To view the status of anomaly detection model training for a specific statistic:

```
class GlueWrapper:
```

```
    """Encapsulates AWS Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 AWS Glue client.
        """
        self.glue_client = glue_client

    def get_model_training_status_for_statistic(self, statistic_id, profile_id):
        """
        Outputs the status of anomaly detection training for the given statistic at the
 given profile.

        :param statistic_id the model's statistic (the timeseries it is tracking)
        :param profile_id the profile associated with the model (a point in the
 timeseries)

        """
        try:
            model = self.glue_client.get_data_quality_model(
                ProfileId = profile_id, StatisticId = statistic_id
            )
            return model
        except ClientError as err:
            logger.error(
                "Couldn't retrieve Data Quality statistics. Here's why: %s: %s",
                err.response['Error']['Code'], err.response['Error']['Message'])
            raise
```

To exclude all results from a specific data quality run from anomaly detection baselines:

```
class GlueWrapper:
    """Encapsulates AWS Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 AWS Glue client.
        """
        self.glue_client = glue_client

    def apply_exclusions_to_profile(self, profile_id):
        """
        Exclude datapoints produced by a run across statistic timeseries.
```

```
        This example excludes the provided values; INCLUDE can also be used to undo
 this action.

        :param profile_id the profiles we want to exclude (points in the timeseries)

        """
        try:
            response = self.glue_client.put_data_quality_profile_annotation(
                    ProfileId = profile_id,
                    InclusionAnnotation = "EXCLUDE"
            )
            return response
        except ClientError as err:
            logger.error(
                "Couldn't store Data Quality annotations. Here's why: %s: %s",
                err.response['Error']['Code'], err.response['Error']['Message'])
            raise
```

To get the results from a given data quality run and display the results:

With a AWS Glue Data Quality `runID`, you can extract the `resultID` to then get the actual results, as shown below:

```
response = client.get_data_quality_ruleset_evaluation_run(
    RunId='dqrun-abca77ee126abe1378c1da1ae0750d7dxxxx'
)

resultID = response['ResultIds'][0]

response = client.get_data_quality_result(
    ResultId=resultID
)

print(resp['RuleResults'])
```

Setting up alerts, deployments, and scheduling

This topic describes how to set up alerts, deployments, and scheduling for AWS Glue Data Quality.

Contents

- Setting up alerts and notifications in Amazon EventBridge integration

- Additional configuration options for the event pattern
- Formatting notifications as emails
- Set up alerts and notifications in CloudWatch integration
- Querying data quality results to build dashboards
- Deploying data quality rules using AWS CloudFormation
- Scheduling data quality rules

Setting up alerts and notifications in Amazon EventBridge integration

AWS Glue Data Quality supports the publishing of EventBridge events, which are emitted upon completion of a Data Quality ruleset evaluation run. With this, you can easily setup alerts when data quality rules fail.

Here is a sample event when you evaluate data quality rulesets in the Data Catalog. With this information, you can review the data that is made available with Amazon EventBridge. You can issue additional API calls to get more details. For example, call the `get_data_quality_result` API with the result ID to get the details of a particular execution.

```
{

        "rulesSkipped": 0
    }
}
```

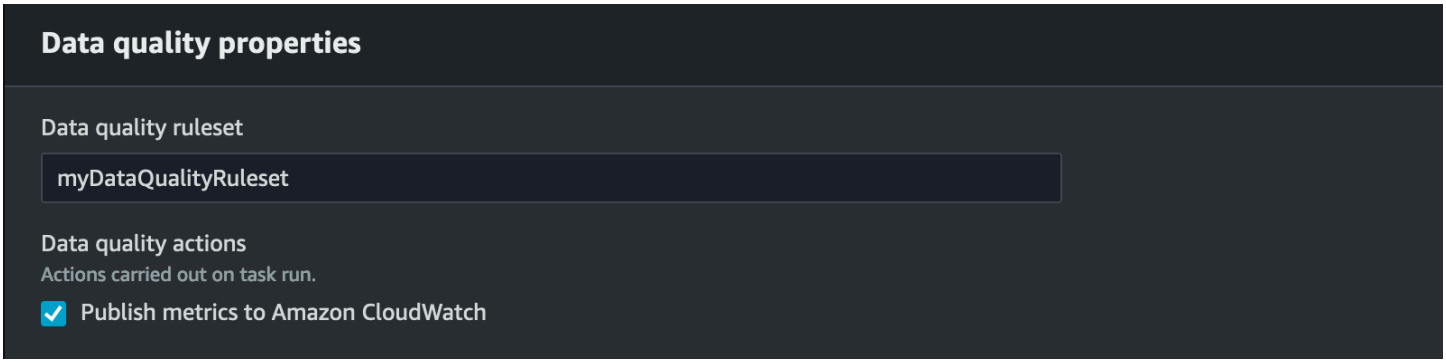
For Data Quality evaluation runs both in the Data Catalog and in ETL jobs, the **Publish metrics to Amazon CloudWatch** option, which is selected by default, must remain selected for EventBridge publishing to work.

Setting up EventBridge notifications



To receive the emitted events and define targets, you must configure Amazon EventBridge rules. To create rules:

1. Open the Amazon EventBridge console.
2. Choose **Rules** under the **Buses** section of the navigation bar.
3. Choose **Create Rule**.
4. On **Define Rule Detail**:
   a. For Name, enter `myDQRule`.
   b. Enter the description (optional).
   c. For event bus, select your event bus. If you don't have one, leave it as default.
   d. For Rule type select **Rule with an event pattern** then choose **Next**.
5. On **Build Event Pattern**:
   a. For event source select **AWS events or EventBridge partner events**.
   b. Skip the sample event section.
   c. For creation method select **Use pattern form**.
   d. For event pattern:
      i. Select **AWS services** for Event source.
      ii. Select **Glue Data Quality** for AWS service.
      iii. Select **Data Quality Evaluation Results Available** for Event type.
      iv. Select **FAILED** for Specific state(s). Then you see an event pattern similar to the following:

```
{
  "source": ["aws.glue-dataquality"],
  "detail-type": ["Data Quality Evaluation Results Available"],
  "detail": {
    "state": ["FAILED"]
```

```
  }
}
```

v. For more configuration options see Additional configuration options for the event pattern.

6. On **Select Target(s)**:
   a. For **Target Types** select **AWS service**.
   b. Use the **Select a target** dropdown to choose your desired AWS service to connect to (SNS, Lambda, SQS, etc.), then choose **Next**.
7. On **Configure tag(s)** click **Add new tags** to add optional tags then choose **Next**.
8. You see a summary page of all the selections. Choose **Create rule** at the bottom.

Additional configuration options for the event pattern

In addition to filtering your event on success or failure, you may want to further filter events on different parameters.

To do this, go to the Event Pattern section, and select **Edit pattern** to specify additional parameters. Note that fields in the event pattern are case sensitive. The following are examples of configuring the event pattern.

To capture events from a particular table evaluating specific rulesets use this type of pattern:

```
{
  "source": ["aws.glue-dataquality"],
  "detail-type": ["Data Quality Evaluation Results Available"],
  "detail": {
    "context": {
      "contextType": ["GLUE_DATA_CATALOG"],
      "databaseName": "db-123",
       "tableName": "table-123",
    },
    "rulesetNames": ["ruleset1", "ruleset2"]
    "state": ["FAILED"]
  }
}
```

To capture events from specific jobs in the ETL experience use this type of pattern:

```
{
```

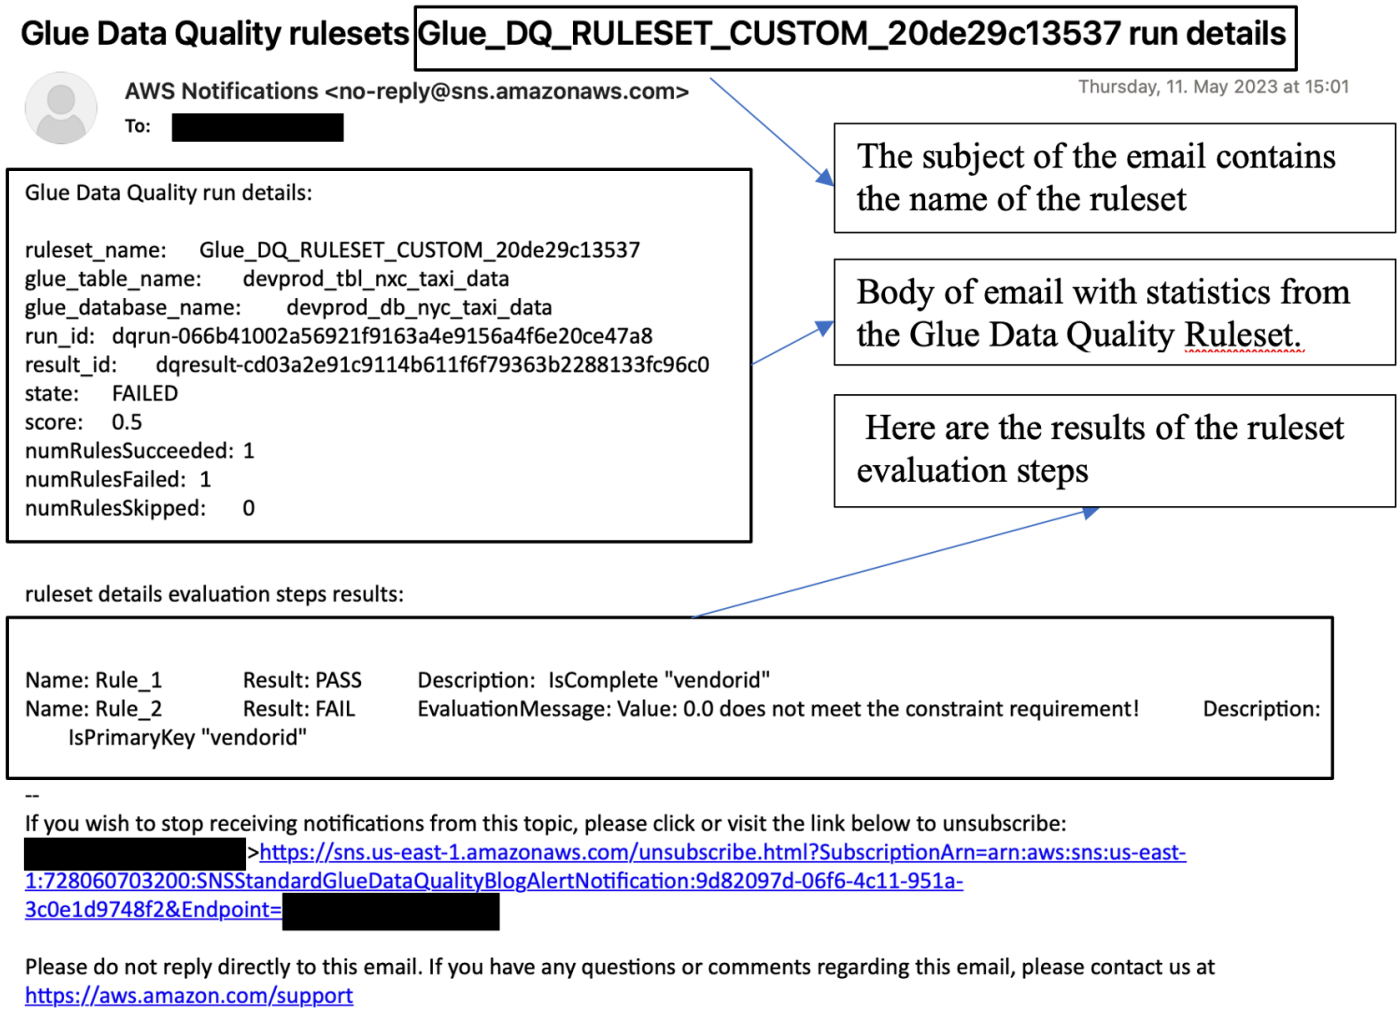
```
  "source": ["aws.glue-dataquality"],
  "detail-type": ["Data Quality Evaluation Results Available"],
  "detail": {
    "context": {
      "contextType": ["GLUE_JOB"],
      "jobName": ["dq_evaluation_job1", "dq_evaluation_job2"]
    },
    "state": ["FAILED"]
  }
}
```

To capture events with a score under a specific threshold (e.g. 70%):

```
{
  "source": ["aws.glue-dataquality"],
  "detail-type": ["Data Quality Evaluation Results Available"],
  "detail": {
    "score": [{
      "numeric": ["<=", 0.7]
    }]
  }
}
```

Formatting notifications as emails

Sometimes you need to send a well-formatted email notification to your business teams. You can use Amazon EventBridge and AWS Lambda to achieve this.



The following sample code can be used to format your data quality notifications to generate emails.

```
import boto3
import json
from datetime import datetime

sns_client = boto3.client('sns')
glue_client = boto3.client('glue')

sns_topic_arn = 'arn:aws:sns:<region-code>:<account-id>:<sns-topic-name>'

def lambda_handler(event, context):
    log_metadata = {}
```

```
    message_text = ""
    subject_text = ""

    if event['detail']['context']['contextType'] == 'GLUE_DATA_CATALOG':
        log_metadata['ruleset_name'] = str(event['detail']['rulesetNames'][0])
        log_metadata['tableName'] = str(event['detail']['context']['tableName'])
        log_metadata['databaseName'] = str(event['detail']['context']['databaseName'])
        log_metadata['runId'] = str(event['detail']['context']['runId'])
        log_metadata['resultId'] = str(event['detail']['resultId'])
        log_metadata['state'] = str(event['detail']['state'])
        log_metadata['score'] = str(event['detail']['score'])
        log_metadata['numRulesSucceeded'] = str(event['detail']['numRulesSucceeded'])
        log_metadata['numRulesFailed'] = str(event['detail']['numRulesFailed'])
        log_metadata['numRulesSkipped'] = str(event['detail']['numRulesSkipped'])

        message_text += "Glue Data Quality run details:\n"
        message_text += "ruleset_name: {}\n".format(log_metadata['ruleset_name'])
        message_text += "glue_table_name: {}\n".format(log_metadata['tableName'])
        message_text += "glue_database_name: {}\n".format(log_metadata['databaseName'])
        message_text += "run_id: {}\n".format(log_metadata['runId'])
        message_text += "result_id: {}\n".format(log_metadata['resultId'])
        message_text += "state: {}\n".format(log_metadata['state'])
        message_text += "score: {}\n".format(log_metadata['score'])
        message_text += "numRulesSucceeded:
{}\n".format(log_metadata['numRulesSucceeded'])
        message_text += "numRulesFailed: {}\n".format(log_metadata['numRulesFailed'])
        message_text += "numRulesSkipped: {}\n".format(log_metadata['numRulesSkipped'])

        subject_text = "Glue Data Quality ruleset {} run
details".format(log_metadata['ruleset_name'])

    else:
        log_metadata['ruleset_name'] = str(event['detail']['rulesetNames'][0])
        log_metadata['jobName'] = str(event['detail']['context']['jobName'])
        log_metadata['jobId'] = str(event['detail']['context']['jobId'])
        log_metadata['resultId'] = str(event['detail']['resultId'])
        log_metadata['state'] = str(event['detail']['state'])
        log_metadata['score'] = str(event['detail']['score'])

        log_metadata['numRulesSucceeded'] = str(event['detail']['numRulesSucceeded'])
        log_metadata['numRulesFailed'] = str(event['detail']['numRulesFailed'])
        log_metadata['numRulesSkipped'] = str(event['detail']['numRulesSkipped'])

        message_text += "Glue Data Quality run details:\n"
```

```
        message_text += "ruleset_name: {}\n".format(log_metadata['ruleset_name'])
        message_text += "glue_job_name: {}\n".format(log_metadata['jobName'])
        message_text += "job_id: {}\n".format(log_metadata['jobId'])
        message_text += "result_id: {}\n".format(log_metadata['resultId'])
        message_text += "state: {}\n".format(log_metadata['state'])
        message_text += "score: {}\n".format(log_metadata['score'])
        message_text += "numRulesSucceeded:
{}\n".format(log_metadata['numRulesSucceeded'])
        message_text += "numRulesFailed: {}\n".format(log_metadata['numRulesFailed'])
        message_text += "numRulesSkipped: {}\n".format(log_metadata['numRulesSkipped'])

        subject_text = "Glue Data Quality ruleset {} run
details".format(log_metadata['ruleset_name'])

    resultID = str(event['detail']['resultId'])
    response = glue_client.get_data_quality_result(ResultId=resultID)
    RuleResults = response['RuleResults']
    message_text += "\n\nruleset details evaluation steps results:\n\n"
    subresult_info = []

    for dic in RuleResults:
        subresult = "Name: {}\t\tResult: {}\t\tDescription: \t{}".format(dic['Name'],
dic['Result'], dic['Description'])
        if 'EvaluationMessage' in dic:
            subresult += "\t\tEvaluationMessage: {}".format(dic['EvaluationMessage'])
        subresult_info.append({
            'Name': dic['Name'],
            'Result': dic['Result'],
            'Description': dic['Description'],
            'EvaluationMessage': dic.get('EvaluationMessage', '')
        })
        message_text += "\n" + subresult

    log_metadata['resultrun'] = subresult_info

    sns_client.publish(
        TopicArn=sns_topic_arn,
        Message=message_text,
        Subject=subject_text
    )

    return {
```

```
        'statusCode': 200,
        'body': json.dumps('Message published to SNS topic')
    }
```

Set up alerts and notifications in CloudWatch integration

Our recommended approach is to set up data quality alerts using Amazon EventBridge, because Amazon EventBridge requires a one-time setup to alert customers. However, some customers prefer Amazon CloudWatch due to familiarity. For such customers, we offer integration with Amazon CloudWatch.

Each AWS Glue Data Quality evaluation emits a pair of metrics named `glue.data.quality.rules.passed` (indicating a number of rules that passed) and `glue.data.quality.rules.failed` (indicating the number of failed rules) per data quality run. You can use this emitted metric to create alarms to alert users if a given data quality run falls below a threshold. To get started with setting up an alarm that would send an email via an Amazon SNS notification, follow the steps below:

To get started with setting up an alarm that would send an email via an Amazon SNS notification, follow the steps below:

1. Open the Amazon CloudWatch console.
2. Choose **All metrics** under **Metrics**. You will see an additional namespace under Custom namespaces titled Glue Data Quality.

   > **Note**
   >
   > When starting an AWS Glue Data Quality run, make sure the **Publish metrics to Amazon CloudWatch** checkbox is enabled. Otherwise, metrics for that particular run will not be published to Amazon CloudWatch.

   Under the `Glue Data Quality` namespace, you can see metrics being emitted per table, per ruleset. For the purpose of this topic, we will use the `glue.data.quality.rules.failed` rule and alarm if this value goes over 1 (indicating that, if we see a number of failed rule evaluations greater than 1, we want to be notified).
3. To create the alarm, choose **All alarms** under **Alarms**.

4. Choose **Create alarm**.
5. Choose **Select metric**.
6. Select the `glue.data.quality.rules.failed` metric corresponding to the table you've created, then choose **Select metric**.
7. Under the **Specify metric and conditions** tab, under the **Metrics** section:
   a. For **Statistic**, choose **Sum**.
   b. For **Period**, choose **1 minute**.
8. Under the **Conditions** section:
   a. For **Threshold type**, choose **Static**.
   b. For **Whenever glue.data.quality.rules.failed is...**, select **Greater/Equal**.
   c. For **than...**, enter **1** as the threshold value.

   These selections imply that if the `glue.data.quality.rules.failed` metric emits a value greater than or equal to 1, we will trigger an alarm. However, if there is no data, we will treat it as acceptable.
9. Choose **Next**.
10. On **Configure actions**:
    a. For the **Alarm state trigger** section, choose **In alarm**.
    b. For **Send a notification to the following SNS topic** section, choose **Create a new topic to send a notification via a new SNS topic**.
    c. For **Email endpoints that will receive the notification** enter your email address. Then click **Create Topic**.
    d. Choose **Next**.
11. For **Alarm name**, enter `myFirstDQAlarm`, then choose **Next**.
12. You see a summary page of all the selections. Choose **Create alarm** at the bottom.

You can now see the alarm being created from the Amazon CloudWatch alarms dashboard.

Querying data quality results to build dashboards

You may want to build a dashboard to display your data quality results. There are two ways to do this:

Set up Amazon EventBridge with the following code to write the data to Amazon S3:

```
import boto3
import json
from datetime import datetime

s3_client = boto3.client('s3')
glue_client = boto3.client('glue')

s3_bucket = 's3-bucket-name'

def write_logs(log_metadata):
    try:
        filename = datetime.now().strftime("%m%d%Y%H%M%S") + ".json"
        key_opts = {
            'year': datetime.now().year,
            'month': "{:02d}".format(datetime.now().month),
            'day': "{:02d}".format(datetime.now().day),
            'filename': filename
        }
        s3key = "gluedataqualitylogs/year={year}/month={month}/day={day}/
{filename}".format(**key_opts)
        s3_client.put_object(Bucket=s3_bucket, Key=s3key,
 Body=json.dumps(log_metadata))
    except Exception as e:
        print(f'Error writing logs to S3: {e}')

def lambda_handler(event, context):
    log_metadata = {}
    message_text = ""
    subject_text = ""

    if event['detail']['context']['contextType'] == 'GLUE_DATA_CATALOG':
        log_metadata['ruleset_name'] = str(event['detail']['rulesetNames'][0])
        log_metadata['tableName'] = str(event['detail']['context']['tableName'])
        log_metadata['databaseName'] = str(event['detail']['context']['databaseName'])
        log_metadata['runId'] = str(event['detail']['context']['runId'])
        log_metadata['resultId'] = str(event['detail']['resultId'])
        log_metadata['state'] = str(event['detail']['state'])
        log_metadata['score'] = str(event['detail']['score'])
        log_metadata['numRulesSucceeded'] = str(event['detail']['numRulesSucceeded'])
        log_metadata['numRulesFailed'] = str(event['detail']['numRulesFailed'])
```

```
        log_metadata['numRulesSkipped'] = str(event['detail']['numRulesSkipped'])

        message_text += "Glue Data Quality run details:\n"
        message_text += "ruleset_name: {}\n".format(log_metadata['ruleset_name'])
        message_text += "glue_table_name: {}\n".format(log_metadata['tableName'])
        message_text += "glue_database_name: {}\n".format(log_metadata['databaseName'])
        message_text += "run_id: {}\n".format(log_metadata['runId'])
        message_text += "result_id: {}\n".format(log_metadata['resultId'])
        message_text += "state: {}\n".format(log_metadata['state'])
        message_text += "score: {}\n".format(log_metadata['score'])
        message_text += "numRulesSucceeded:
{}\n".format(log_metadata['numRulesSucceeded'])
        message_text += "numRulesFailed: {}\n".format(log_metadata['numRulesFailed'])
        message_text += "numRulesSkipped: {}\n".format(log_metadata['numRulesSkipped'])

        subject_text = "Glue Data Quality ruleset {} run
details".format(log_metadata['ruleset_name'])

    else:
        log_metadata['ruleset_name'] = str(event['detail']['rulesetNames'][0])
        log_metadata['jobName'] = str(event['detail']['context']['jobName'])
        log_metadata['jobId'] = str(event['detail']['context']['jobId'])
        log_metadata['resultId'] = str(event['detail']['resultId'])
        log_metadata['state'] = str(event['detail']['state'])
        log_metadata['score'] = str(event['detail']['score'])

        log_metadata['numRulesSucceeded'] = str(event['detail']['numRulesSucceeded'])
        log_metadata['numRulesFailed'] = str(event['detail']['numRulesFailed'])
        log_metadata['numRulesSkipped'] = str(event['detail']['numRulesSkipped'])

        message_text += "Glue Data Quality run details:\n"
        message_text += "ruleset_name: {}\n".format(log_metadata['ruleset_name'])
        message_text += "glue_job_name: {}\n".format(log_metadata['jobName'])
        message_text += "job_id: {}\n".format(log_metadata['jobId'])
        message_text += "result_id: {}\n".format(log_metadata['resultId'])
        message_text += "state: {}\n".format(log_metadata['state'])
        message_text += "score: {}\n".format(log_metadata['score'])
        message_text += "numRulesSucceeded:
{}\n".format(log_metadata['numRulesSucceeded'])
        message_text += "numRulesFailed: {}\n".format(log_metadata['numRulesFailed'])
        message_text += "numRulesSkipped: {}\n".format(log_metadata['numRulesSkipped'])

        subject_text = "Glue Data Quality ruleset {} run
details".format(log_metadata['ruleset_name'])
```

```
    resultID = str(event['detail']['resultId'])
    response = glue_client.get_data_quality_result(ResultId=resultID)
    RuleResults = response['RuleResults']
    message_text += "\n\nruleset details evaluation steps results:\n\n"
    subresult_info = []

    for dic in RuleResults:
        subresult = "Name: {}\t\tResult: {}\t\tDescription: \t{}".format(dic['Name'],
dic['Result'], dic['Description'])
        if 'EvaluationMessage' in dic:
            subresult += "\t\tEvaluationMessage: {}".format(dic['EvaluationMessage'])
        subresult_info.append({
            'Name': dic['Name'],
            'Result': dic['Result'],
            'Description': dic['Description'],
            'EvaluationMessage': dic.get('EvaluationMessage', '')
        })
        message_text += "\n" + subresult

    log_metadata['resultrun'] = subresult_info

    write_logs(log_metadata)

    return {
        'statusCode': 200,
        'body': json.dumps('Message published to SNS topic')
    }
```

After writing to Amazon S3, you can use AWS Glue crawlers to register to Athena and query the tables.

Configure an Amazon S3 location during a data quality evaluation::

When running data quality tasks in the AWS Glue Data Catalog or AWS Glue ETL, you can provide an Amazon S3 location to write the data quality results to Amazon S3. You can use the syntax below to create a table by referencing the target to read the data quality results.

Note that you must run the `CREATE EXTERNAL TABLE` and `MSCK REPAIR TABLE` queries separately.

```
CREATE EXTERNAL TABLE <my_table_name>(
    catalogid string,
    databasename string,
    tablename string,
    dqrunid string,
    evaluationstartedon timestamp,
    evaluationcompletedon timestamp,
    rule string,
    outcome string,
    failurereason string,
    evaluatedmetrics string)
PARTITIONED BY (
    `year` string,
    `month` string,
    `day` string)
ROW FORMAT SERDE 'org.openx.data.jsonserde.JsonSerDe'
WITH SERDEPROPERTIES (

 'paths'='catalogId,databaseName,dqRunId,evaluatedMetrics,evaluationCompletedOn,evaluationStart
STORED AS INPUTFORMAT 'org.apache.hadoop.mapred.TextInputFormat'
OUTPUTFORMAT 'org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat'
LOCATION 's3://glue-s3-dq-bucket-us-east-2-results/'
TBLPROPERTIES (
    'classification'='json',
    'compressionType'='none',
    'typeOfData'='file');
```

```
MSCK REPAIR TABLE <my_table_name>;
```

Once you create the above table, you can run analytical queries using Amazon Athena.

Deploying data quality rules using AWS CloudFormation

You can use AWS CloudFormation to create data quality rules. For more information, see AWS CloudFormation for AWS Glue.

Scheduling data quality rules

You can schedule data quality rules using the following methods:

- Schedule data quality rules from the Data Catalog: no code users can use this option to easily schedule their data quality scans. AWS Glue Data Quality will create the schedule in Amazon EventBridge. To schedule data quality rules:
  - Navigate to the ruleset and click **Run**.
  - In the **Run frequency**, select the desired schedule and provide a **Task Name**. This Task Name is the name of your schedule in EventBridge.
- Use Amazon EventBridge and AWS Step Functions to orchestrate evaluations and recommendations for data quality rules.

Data encryption at rest for AWS Glue Data Quality

AWS Glue Data Quality provides encryption by default to protect sensitive customer data at rest using AWS owned encryption keys.

AWS owned keys

AWS Glue Data Quality uses these keys to automatically encrypt customers' Data Quality assets. You cannot view, manage, or use AWS owned keys, or audit their use. However, you don't need to take any action or change any programs to protect the keys that encrypt your data. For more information, see AWS owned keys in the AWS KMS Developer Guide.

Encryption of data at rest by default helps reduce the operational overhead and complexity involved in protecting sensitive data. At the same time, it enables you to build secure applications that meet strict encryption compliance and regulatory requirements.

While you can't disable this layer of encryption or select an alternate encryption type, you can add a second layer of encryption over the existing AWS owned encryption keys by choosing a customer-managed key when you create your Data Quality resources.

Customer managed keys

Customer managed keys: AWS Glue Data Quality supports the use of a symmetric customer-managed key that you create, own, and manage. This adds a second layer of encryption over the existing AWS owned encryption. Because you have full control of this layer of encryption, you can perform tasks such as:

- Establishing and maintaining key policies

- Establishing and maintaining IAM policies
- Enabling and disabling key policies
- Rotating key cryptographic material
- Adding tags
- Creating key aliases
- Scheduling keys for deletion

For more information, see Customer managed keys in the AWS KMS Developer Guide.

The following table summarizes how AWS Glue Data Quality encrypts different Data Quality assets.

Data type	AWS owned key encryption	Customer managed key encryption
Data Quality Ruleset DQDL ruleset string that is referenced by the persisted DQ ruleset. These persisted rulesets are only used in the AWS Glue Data Catalog experience for now.	Enabled	Enabled
Data Quality Rule/Analyzer Results Result artifacts that contains the pass/fail status of each rule in a ruleset as well as metrics collected by both rules and analyzers.	Enabled	Enabled
Observations Observations are generated when an anomaly is detected in the data. It contains	Enabled	Enabled

Data type	AWS owned key encryption	Customer managed key encryption
information on the expected upper and lower bound and a suggested rule based on these bounds. If generated, they are displayed with the Data Quality Results.		
Statistics Contains information on metrics collected after evaluating the data given a ruleset, such as the value of the metric (e.g. RowCount, Completeness), column names, and other metadata.	Enabled	Enabled
Anomaly Detection Statistic Models The statistic models contain the time series of upper and lower bounds for a given metric generated based off of previous evaluations of the customer data.	Enabled	Enabled

Note

AWS Data Quality automatically enables encryption at rest using AWS owned keys to protect personally identifiable data at no charge. However, AWS KMS charges apply for using a customer managed key. For more information about pricing, see AWS KMS Pricing. For more information on AWS KMS, see AWS KMS.

Create a Customer Managed Key

You can create a symmetric customer managed key by using the AWS Management Console, or the AWS KMS APIs.

To create a symmetric customer managed key:

- Follow the steps for Creating symmetric encryption AWS KMS keys in the AWS Key Management Service Developer Guide.

Key policy

Key policies control access to your customer managed key. Every customer managed key must have exactly one key policy, which contains statements that determine who can use the key and how they can use it. When you create your customer managed key, you can specify a key policy. For more information, see Key policies in AWS KMS keys in the AWS Key Management Service Developer Guide.

To use your customer managed key with your Data Quality resources, the following API operations must be permitted in the key policy:

- `kms:Decrypt` – Decrypts ciphertext that was encrypted by an AWS KMS key using `GenerateDataKeyWithoutPlaintext`
- `kms:DescribeKey` – Provides the customer managed key details to allow Amazon Location to validate the key.
- `kms:GenerateDataKeyWithoutPlaintext` – Returns a unique symmetric data key for use outside of AWS KMS. This operation returns a data key that is encrypted under a symmetric encryption KMS key that you specify. The bytes in the key are random; they are not related to the caller or to the KMS key. Used to reduce KMS calls the customer has to make.
- `kms:ReEncrypt*` – Decrypts ciphertext and then reencrypts it entirely within AWS KMS. You can use this operation to change the KMS key under which data is encrypted, such as when you manually rotate a KMS key or change the KMS key that protects a ciphertext. You can also use it to reencrypt ciphertext under the same KMS key, such as to change the encryption context of a ciphertext.

The following are policy statement examples you can add for Amazon Location:

```
"Statement" : [
    {
        "Sid" : "Allow access to principals authorized to use AWS Glue Data Quality",
        "Effect" : "Allow",
        "Principal" : {
            "AWS": "arn:aws:iam::<account_id>:role/ExampleRole"
        },
        "Action" : [
            "kms:Decrypt",
            "kms:DescribeKey",
            "kms:GenerateDataKeyWithoutPlaintext",
            "kms:ReEncrypt*"
        ],
        "Resource" : "*",
        "Condition" : {
            "StringEquals" : {
                "kms:ViaService" : "glue.amazonaws.com",
                "kms:CallerAccount" : "111122223333"
            }
        },
    {
        "Sid": "Allow access for key administrators",
        "Effect": "Allow",
        "Principal": {
            "AWS": "arn:aws:iam::111122223333:root"
          },
        "Action" : [
            "kms:*"
         ],
        "Resource": "arn:aws:kms:region:111122223333:key/key_ID"
    },
    {
        "Sid" : "Allow read-only access to key metadata to the account",
        "Effect" : "Allow",
        "Principal" : {
            "AWS" : "arn:aws:iam::111122223333:root"
        },
        "Action" : [
            "kms:Describe*",
            "kms:Get*",
            "kms:List*",
        ],
        "Resource" : "*"
```

```
    }
]
```

Notes about using KMS Keys in AWS Glue Data Quality

AWS Glue Data Quality does not support key transitions. This means that if you encrypt your Data Quality assets with Key A and decide to switch to Key B, we will not re-encrypt the data that was encrypted with Key A to use Key B. You can still switch to Key B, but will need to maintain access to Key A to access data previously encrypted with Key A.

For more information about specifying permissions in a policy, see Permissions for AWS services in key policies in the AWS Key Management Service Developer Guide.

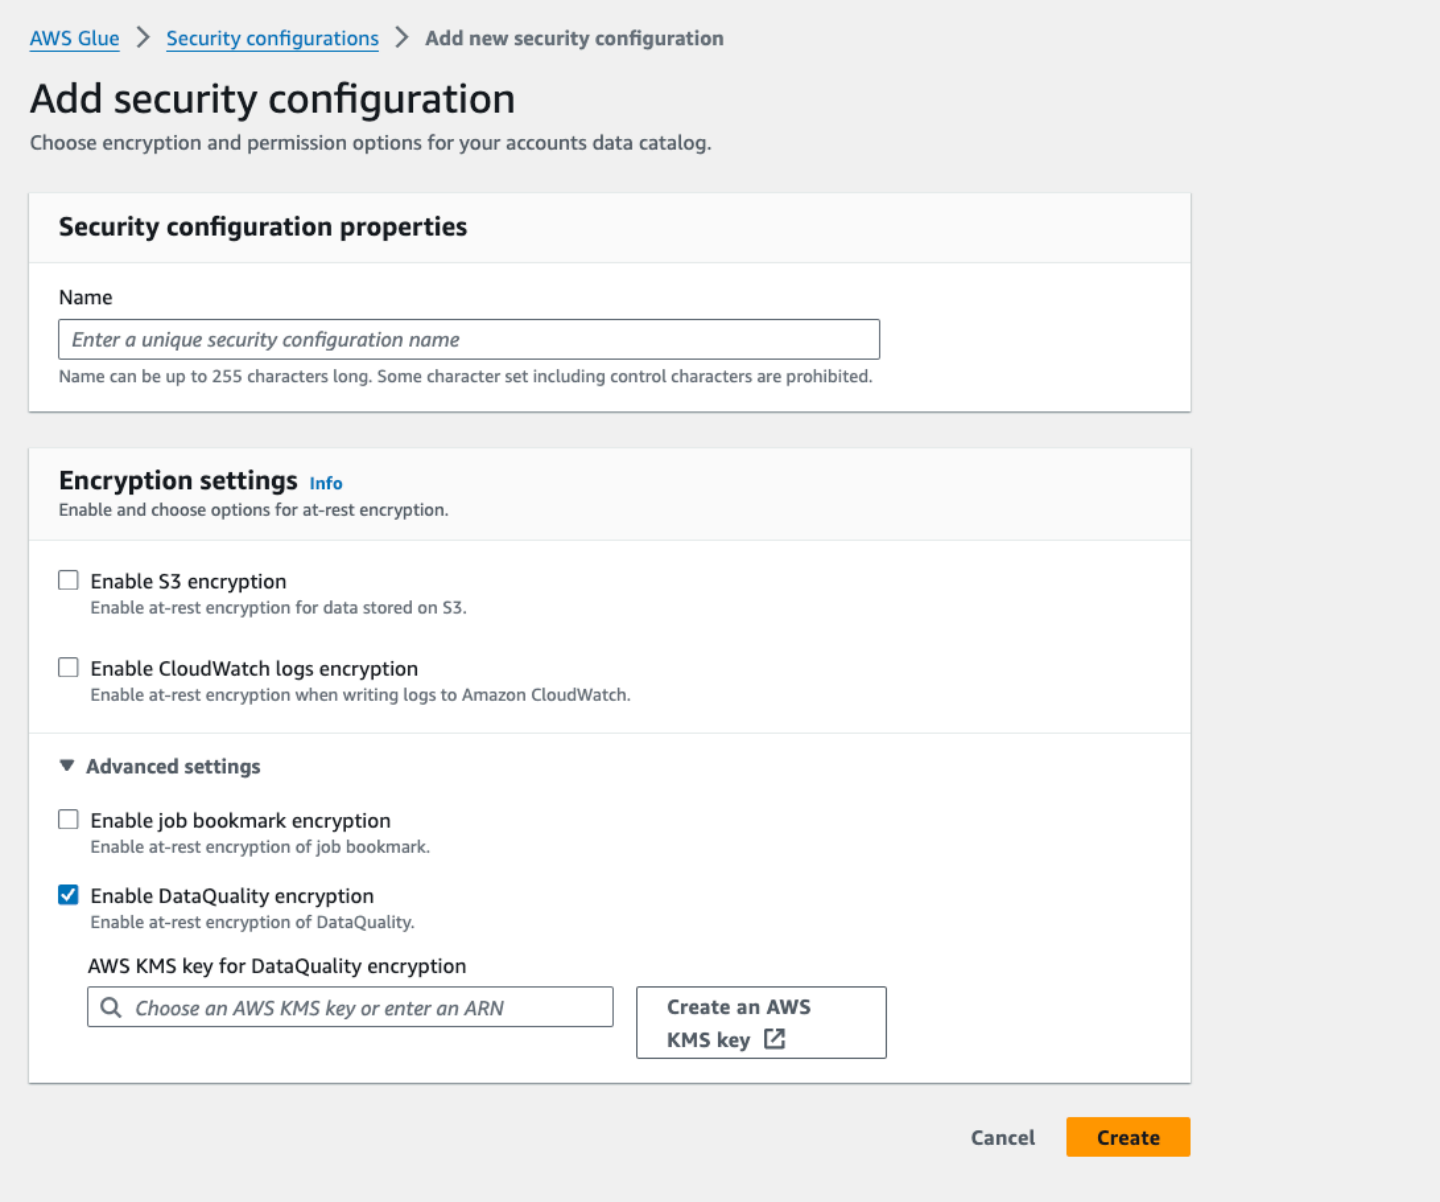
For more information about troubleshooting key access, see Troubleshooting key access in the AWS Key Management Service Developer Guide.

Create a security configuration

In AWS Glue the Security Configurations resource contains properties that are needed when you write encrypted data.

To encrypt your data quality assets:

1. In **Encryption settings**, under **Advanced settings**, choose **Enable Data Quality Encryption**
2. Select your KMS key or choose **Create an AWS KMS key**



AWS Glue Data Quality encryption context

An encryption context is an optional set of key-value pairs that contain additional contextual information about the data.

AWS KMS uses the encryption context as additional authenticated data to support authenticated encryption. When you include an encryption context in a request to encrypt data, AWS KMS binds the encryption context to the encrypted data. To decrypt data, you include the same encryption context in the request.

AWS Glue Data Quality encryption context example

```
"encryptionContext": {
    "kms-arn": "arn:aws:kms:us-
east-1:111122223333:key/1234abcd-12ab-34cd-56ef-123456SAMPLE",
    "branch-key-id": "111122223333+arn:aws:kms:us-
east-1:111122223333:key/1234abcd-12ab-34cd-56ef-123456SAMPLE",
    "hierarchy-version": "1",
    "aws-crypto-ec:aws:glue:securityConfiguration": "111122223333:customer-security-
configuration-name",
    "create-time": "2024-06-07T13:47:23:000861Z",
    "tablename": "AwsGlueMlEncryptionKeyStore",
    "type": "beacon:ACTIVE"
}
```

Using encryption context for monitoring

When you use a symmetric customer managed key to encrypt your tracker or geofence collection, you can also use the encryption context in audit records and logs to identify how the customer managed key is being used. The encryption context also appears in logs generated by AWS CloudTrail or Amazon CloudWatch Logs.

Monitoring your encryption keys for AWS Glue Data Quality

When you use an AWS KMS customer managed key with your AWS Glue Data Quality resources, you can use AWS CloudTrail or Amazon CloudWatch Logs to track requests that AWS Glue Data Quality sends to AWS KMS.

The following examples are AWS CloudTrail events for `GenerateDataKeyWithoutPlainText` and `Decrypt` to monitor KMS operations called by AWS Glue Data Quality to access data encrypted by your customer managed key.

Decrypt

```
{
    "eventVersion": "1.09",
    "userIdentity": {
        "type": "AssumedRole",
        "arn": "arn:aws:sts::111122223333:role/CustomerRole",
        "accountId": "111122223333",
        "invokedBy": "glue.amazonaws.com"
    },
```

```
    "eventTime": "2024-07-02T20:03:10Z",

- For more information about Security best practices for AWS Key Management Service see the AWS Key Management Service Developer Guide.

Troubleshooting AWS Glue Data Quality errors

If you encounter errors in AWS Glue Data Quality, use the following solutions to help you find the source of the problems and fix them.

Contents

- Error: missing AWS Glue Data Quality module
- Error: insufficient AWS Lake Formation permissions
- Error: rulesets are not uniquely named
- Error: tables with special characters
- Error: overflow error with a large ruleset
- Error: overall rule status is failed
- AnalysisException: Unable to verify existence of default database
- Error Message: Provided key map not suitable for given data frames
- Exception in User Class: java.lang.RuntimeException : Failed to fetch data. Check the logs in CloudWatch to get more details
- LAUNCH ERROR: Error downloading from S3 for bucket
- InvalidInputException (status: 400): DataQuality rules cannot be parsed
- Error: Eventbridge is not triggering Glue DQ jobs based on the schedule I setup
- CustomSQL errors
- Dynamic Rules
- Exception in User Class: org.apache.spark.sql.AnalysisException: org.apache.hadoop.hive.ql.metadata.HiveException
- UNCLASSIFIED_ERROR; IllegalArgumentException: Parsing Error: No rules or analyzers provided., no viable alternative at input

Error: missing AWS Glue Data Quality module

Error message: No module named 'awsgluedq'.

Resolution: This error occurs when you run AWS Glue Data Quality in an unsupported version. AWS Glue Data Quality is supported only in Glue version 3.0 and later.

Error: insufficient AWS Lake Formation permissions

Error message: Exception in User Class: `com.amazonaws.services.glue.model.AccessDeniedException`: Insufficient Lake Formation permission(s) on impact_sdg_involvement (Service: AWS Glue; Status Code: 400; Error Code: AccessDeniedException; Request ID: 465ae693-b7ba-4df0-a4e4-6b17xxxxxxxx; Proxy: null).

Resolution: You must provide sufficient permissions in AWS Lake Formation.

Error: rulesets are not uniquely named

Error message: Exception in User Class: ...services.glue.model.AlreadyExistsException: Another ruleset with the same name already exists.

Resolution: Rulesets are global and must be unique.

Error: tables with special characters

Error message: Exception in User Class: org.apache.spark.sql.AnalysisException: cannot resolve "C" given input columns: [primary.data_end_time, primary.data_start_time, primary.end_time, primary.last_updated, primary.message, primary.process_date, primary.rowhash, primary.run_by, primary.run_id, primary.start_time, primary.status]; line 1 pos 44;.

Resolution: There is a current limitation that AWS Glue Data Quality cannot be executed on tables that have special characters such as ".".

Error: overflow error with a large ruleset

Error message: Exception in User Class: java.lang.StackOverflowError.

Resolution: If you have a large ruleset of greater than 2K rules, you may encounter this issue. Break your rules into multiple rulesets.

Error: overall rule status is failed

Error condition: My Ruleset is successful, but my overall rule status is failed.

Resolution: This error most likely occurred because you chose the option to publish metrics to Amazon CloudWatch while publishing. If your dataset is in a VPC, your VPC may not allow AWS Glue to publish metrics to Amazon CloudWatch. In this case, you >must set up an endpoint for your VPC to access Amazon CloudWatch.

AnalysisException: Unable to verify existence of default database

Error condition: AnalysisException: Unable to verify existence of default database: com.amazonaws.services.glue.model.AccessDeniedException: Insufficient Lake Formation permission(s) on default (Service: AWS Glue; Status Code: 400; Error Code: AccessDeniedException; Request ID: XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX; Proxy: null)

Resolution: In AWS Glue job's catalog integration, AWS Glue always tries to check whether default database exists or not using AWS Glue `GetDatabase API`. When the `DESCRIBE` Lake Formation permission is not granted, or `GetDatabase IAM` permission is granted, then the job fails when verifying existence of the default database.

To resolve:

1. Add the `DESCRIBE` permission in Lake Formation for the default database.
2. Configure the IAM role attached to the AWS Glue job as Database Creator in Lake Formation. This will automatically create a default database and grant required Lake Formation permissions for the role.
3. Disable `--enable-data-catalog` option. (It is shown as **Use Data Catalog as the Hive metastore** in AWS Glue Studio).

   If you do not need Spark SQL Data Catalog integration in the job, you can disable it.

Error Message: Provided key map not suitable for given data frames

Error condition: Provided key map not suitable for given data frames.

Resolution: You are using **DataSetMatch** ruletype and the join keys have duplicates. Your join keys must be unique and must not be NULL. In cases where you can't have join keys that are unique, consider using other ruletypes such as **AggregateMatch** to match on summary data.

Exception in User Class: java.lang.RuntimeException : Failed to fetch data. Check the logs in CloudWatch to get more details

Error condition: Exception in User Class: java.lang.RuntimeException : Failed to fetch data. Check the logs in CloudWatch to get more details.

Resolution: This happens when you are creating DQ rules on an Amazon S3-based table that compares against Amazon RDS or Amazon Redshift. In these cases, AWS Glue cannot load the connection. Instead, try to set up DQ rule on the Amazon Redshift or Amazon RDS dataset. This is a known bug.

LAUNCH ERROR: Error downloading from S3 for bucket

Error condition: LAUNCH ERROR: Error downloading from S3 for bucket: `aws-glue-ml-data-quality-assets-us-east-1, key: jars/aws-glue-ml-data-quality-etl.jar.Access Denied (Service: Amazon S3; Status Code: 403; Please refer logs for details) .`

Resolution: The permissions in the role passed to AWS Glue Data Quality must permit reading from the preceding Amazon S3 location. This IAM policy should be attached to the role:

```
{
  "Sid": "allowS3",
  "Effect": "Allow",
  "Action": "s3:GetObject",
  "Resource": "arn:aws:s3:::aws-glue-ml-data-quality-assets-<region>/*"
}
```

Refer to Data Quality authorization for detailed permissions. These libraries are required to evaluate data quality for your datasets.

InvalidInputException (status: 400): DataQuality rules cannot be parsed

Error condition: InvalidInputException (status: 400): DataQuality rules cannot be parsed.

Resolution: There are many possibilities for this error. One possibility is that your rules may have single quotes. Verify that they are in double quotes. For example:

```
Rules = [
```

```
ColumnValues "tipo_vinculo" in ["CODO", "DOCO", "COCO", "DODO"] AND "categoria" = 'ES'
    AND "cod_bandera" = 'CEP'
```

Change this to:

```
Rules = [
(ColumnValues "tipovinculo" in [ "CODO", "DOCO", "COCO", "DODO"]) AND (ColumnValues
 "categoria" = "ES")
    AND (ColumnValues "codbandera" = "CEP")
]
```

Error: Eventbridge is not triggering Glue DQ jobs based on the schedule I setup

Error condition: Eventbridge is not triggering AWS Glue Data Quality jobs based on the schedule I setup.

Resolution: The role triggering the job may not have the right permissions. Make sure that the role that you are using to start the jobs has the permissions mentioned in IAM setup required for scheduling evaluation runs .

CustomSQL errors

Error condition: `The output from CustomSQL must contain at least one column that matches the input dataset for AWS Glue Data Quality to provide row level results. The SQL query is a valid query but no columns from the SQL result are present in the Input Dataset. Ensure that matching columns are returned from the SQL.`

Resolution: The SQL query is valid but verify that you're selecting only columns from the primary table. Selecting aggregate functions like sum, count on the columns from the primary can result in this error.

Error condition: `There was a problem when executing your SQL statement: cannot resolve "Col".`

Resolution: This column is not present in the primary table.

Error condition: `The columns that are returned from the SQL statement should only belong to the primary table. "In this case, some columns ( Col ) belong to reference table".`

Resolution: In SQL queries when you're joining the primary table with other reference tables, verify that your select statement has only column names from your primary table to generate row level results for the primary table.

Dynamic Rules

Error condition: `Dynamic rules require job context, and cannot be evaluated in interactive session or data preview..`

Cause: This error message might appear in your data preview results, or in other interactive sessions, when dynamic DQ rules are present in your ruleset. Dynamic rules reference historical metrics associated with a particular job name and evaluation context, so they can't be evaluated in interactive sessions.

Resolution: Running your AWS Glue job will produce historical metrics, which can be referenced in later job runs for the same job.

Error condition:

- `[RuleType] rule only supports simple atomic operands in thresholds..`
- `Function last not yet implemented for [RuleType] rule.`

Resolution: Dynamic rules are generally supported for all DQDL ruletypes in numeric expressions (see DQDL Reference). However, some rules that produce multiple metrics, ColumnValues and ColumnLength, are not yet supported.

Error condition: `Binary expression operands must resolve to a single number..`

Cause: Dynamic rules support binary expressions, like `RowCount > avg(last(5)) * 0.9`. Here, the binary expression is `avg(last(5)) * 0.9`. This rule is valid because both operands `avg(last(5))` and `0.9` resolve to a single number. An incorrect example is `RowCount > last(5) * 0.9`, because `last(5)` will produce a list that can't be meaningfully compared to the current row count.

Resolution: Use aggregation functions to reduce a list-valued operand to a single number.

Error condition:

- `Rule threshold results in list, and a single value is expected. Use aggregation functions to produce a single value. Valid example: sum(last(10)), avg(last(10)).`
- `Rule threshold results in empty list, and a single value is expected.`

Cause: Dynamic rules can be used to compare some feature of your dataset with its historical values. The last function allows for the retrieval of multiple historical values, if a positive integer argument is provided. For example, `last(5)` will retrieve the last five most recent values observed in job runs for your rule.

Resolution: An aggregation function must be used to reduce these values to a single number to make a meaningful comparison with the value observed in the current job run.

Valid examples:

- `RowCount >= avg(last(5))`
- `RowCount > last(1)`
- `RowCount < last()`

Invalid example: `RowCount > last(5)`.

Error condition:

- `Function index used in threshold requires positive integer argument.`
- `Index argument must be an integer. Valid syntax example: RowCount > index(last(10, 2)), which means RowCount must be greater than third most recent execution from last 10 job runs.`

Resolution: When authoring dynamic rules, you can use the `index` aggregation function to select one historical value from a list. For example, `RowCount > index(last(5), 1)` will check whether the row count observed in the current job is strictly greater than the second most recent row count observed for your job. `index` is zero-indexed.

Error condition: `IllegalArgumentException: Parsing Error: Rule Type: DetectAnomalies is not valid`.

Resolution: Anomaly detection is only available in AWS Glue 4.0.

Error condition: `IllegalArgumentException: Parsing Error: Unexpected condition for rule of type ... no viable alternative at input ....`

Note: `...` is dynamic. Example: `IllegalArgumentException: Parsing Error: Unexpected condition for rule of type RowCount with number return type, line 4:19 no viable alternative at input '>last'`.

Resolution: Anomaly detection is only available in AWS Glue 4.0.

Exception in User Class: org.apache.spark.sql.AnalysisException: org.apache.hadoop.hive.ql.metadata.HiveException

Error condition: `Exception in User Class: org.apache.spark.sql.AnalysisException: org.apache.hadoop.hive.ql.metadata.HiveException: Unable to fetch table mailpiece_submitted. StorageDescriptor#InputFormat cannot be null for table: mailpiece_submitted (Service: null; Status Code: 0; Error Code: null; Request ID: null; Proxy: null)`

Cause: You are using Apache Iceberg in AWS Glue Data Catalog and the Input Format attribute in AWS Glue Data Catalog is empty.

Resolution: This issue occurs when you are using CustomSQL ruletype in your DQ rule. One way to fix this is to use “primary“ or add catalog name `glue_catalog.` to `<database>.<table>` in `Custom ruletype`.

UNCLASSIFIED_ERROR; IllegalArgumentException: Parsing Error: No rules or analyzers provided., no viable alternative at input

Error condition: `UNCLASSIFIED_ERROR; IllegalArgumentException: Parsing Error: No rules or analyzers provided., no viable alternative at input`

Resolution: DQDL is not parsable. There are a few instances where this can occur. If you are using composite rules, makes sure they have right parenthesis.

```
(RowCount >= avg(last(10)) * 0.6) and (RowCount <= avg(last(10)) * 1.4) instead of
      RowCount >= avg(last(10)) * 0.6 and RowCount <= avg(last(10)) * 1.4
```

Amazon Q data integration in AWS Glue

Amazon Q data integration in AWS Glue is a new generative AI capability of AWS Glue that enables data engineers and ETL developers to build data integration jobs using natural language. Engineers and developers can ask Amazon Q to author jobs, troubleshoot issues, and answer questions about AWS Glue and data integration.

What is Amazon Q?

> **Note**
>
> Powered by Amazon Bedrock: AWS implements automated abuse detection. Because Amazon Q data integration is built on Amazon Bedrock, users can take full advantage of the controls implemented in Amazon Bedrock to enforce safety, security, and the responsible use of artificial intelligence (AI).

Amazon Q is a generative artificial intelligence (AI) powered conversational assistant that can help you understand, build, extend, and operate AWS applications. The model that powers Amazon Q has been augmented with high quality AWS content to get you more complete, actionable, and referenced answers to accelerate your building on AWS. For more information, see What is Amazon Q?

What is Amazon Q data integration in AWS Glue?

Amazon Q data integration in AWS Glue includes the following capabilities:

- **Chat** – Amazon Q data integration in AWS Glue can answer natural language questions in English about AWS Glue and data integration domains like AWS Glue source and destination connectors, AWS Glue ETL jobs, Data Catalog, crawlers and AWS Lake Formation, and other feature documentation, and best practices. Amazon Q data integration in AWS Glue responds with step-by-step instructions, and includes references to its information sources.
- **Data integration code generation** – Amazon Q data integration in AWS Glue can answer questions about AWS Glue ETL scripts, and generate new code given a natural language question in English.

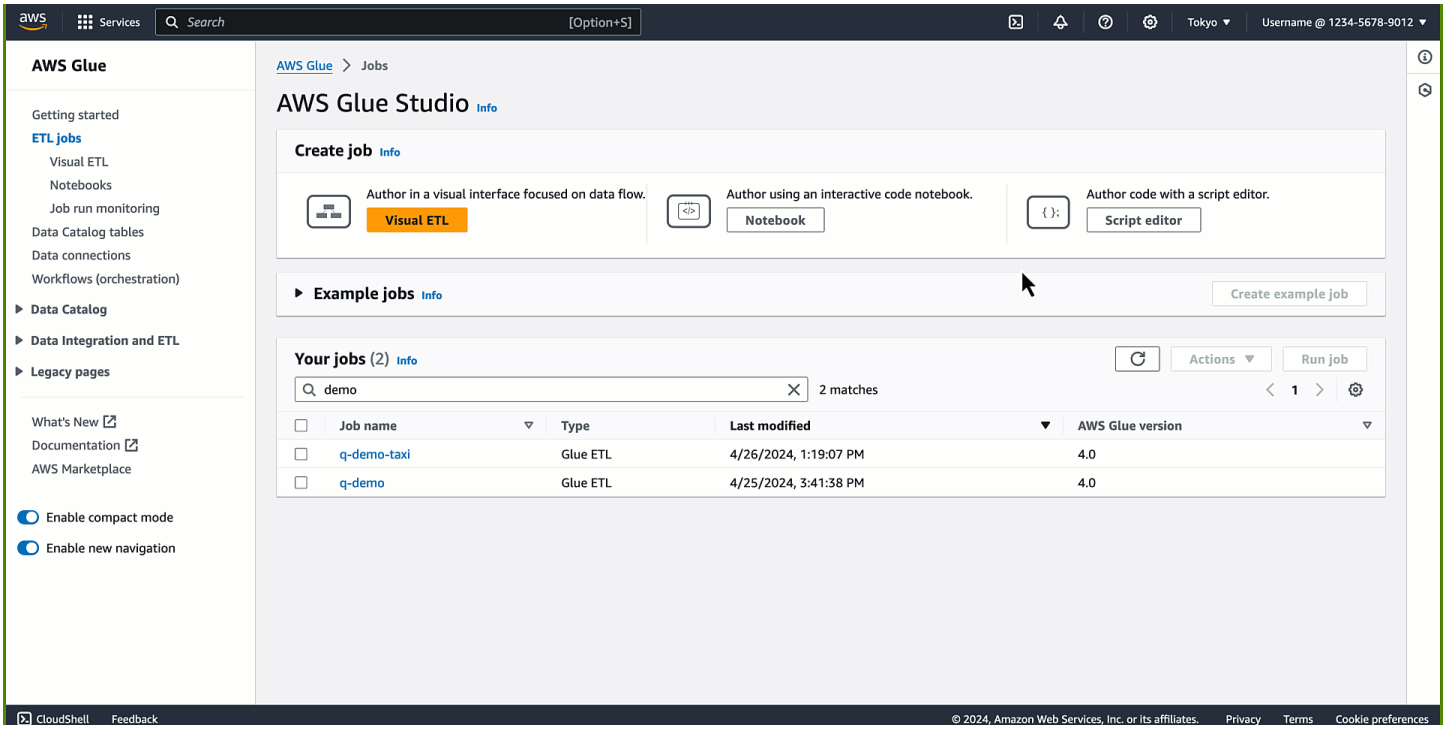
- **Troubleshoot** – Amazon Q data integration in AWS Glue is purpose built to help you understand errors in AWS Glue jobs and provides step-by-step instructions, to root cause and resolve your issues.

> **Note**
>
> Amazon Q data integration in AWS Glue does not use the context of your conversation to inform future responses for the duration of your conversation. Each conversation with Amazon Q data integration in AWS Glue is independent of your prior or future conversations.

Working with Amazon Q data integration in AWS Glue?

In the Amazon Q panel you can request Amazon Q generate code for an AWS Glue ETL script, or answer a question on AWS Glue features or troubleshooting an error. The response is an ETL script in PySpark with step-by-step instructions to customize the script, review and execute it. For questions, the response is generated based on the data integration knowledge base with a summary and source URL for references.

For example, you can ask Amazon Q to "*Please provide a Glue script that reads from Snowflake, renames the fields, and writes to Redshift*" and in response, Amazon Q data integration in AWS Glue will return an AWS Glue job script that can perform the requested action. You can review the generated code to ensure that it fulfills the requested intent. If satisfied, you can deploy it as an AWS Glue job in production. You can troubleshoot jobs by asking the integration to explain errors and failures, and to propose solutions. Amazon Q can answer questions about AWS Glue or data integration best practices.



The following are example questions that demonstrate how Amazon Q data integration in AWS Glue can help you build on AWS Glue:

AWS Glue ETL code generation:

- Write an AWS Glue script that reads JSON from S3, transforms fields using apply mapping and writes to Amazon Redshift
- How do I write an AWS Glue script for reading from DynamoDB, applying the DropNullFields transform and writing to S3 as Parquet?
- Give me an AWS Glue script that reads from MySQL, drops some fields based on my business logic, and writes to Snowflake
- Write an AWS Glue job to read from DynamoDB and write to S3 as JSON
- Help me develop an AWS Glue script for AWS Glue Data Catalog to S3
- Write an AWS Glue job to read JSON from S3, drop nulls and write to Redshift

AWS Glue feature explanations:

- How do I use AWS Glue Data Quality?
- How to use AWS Glue job bookmarks?
- How do I enable AWS Glue autoscaling?

- What is the difference between AWS Glue dynamic frames and Spark data frames?
- What are the different types of connections supported by AWS Glue?

AWS Glue troubleshooting:

- How to troubleshoot Out Of Memory (OOM) errors on AWS Glue jobs?
- What are some error messages you may see when setting up AWS Glue Data Quality and how can you fix them?
- How do I fix an AWS Glue job with the error Amazon S3 access denied?
- How do I resolve issues with data shuffle on AWS Glue jobs?

Best practices for interacting with Amazon Q data integration

The following are best practices for interacting with Amazon Q data integration:

- When interacting with Amazon Q data integration, ask specific questions, iterate when you have complex requests, and verify the answers for accuracy.
- When providing data integration prompts in natural language, be as specific as possible to help the assistant understand exactly what you need. Instead of asking "extract data from S3," provide more details like “write an AWS Glue script that extracts JSON files from S3.”
- Review the generated script before running it to ensure accuracy. If the generated script has errors or does not match your intent, provide instructions to the assistant on how to correct it.
- Generative AI technology is new and there can be mistakes, sometimes called hallucinations, in the responses. Test and review all code for errors and vulnerabilities before using it in your environment or workload.

Amazon Q data integration in AWS Glue service improvement

To help Amazon Q data integration in AWS Glue provide the most relevant information about AWS services, we may use certain content from Amazon Q, such as questions that you ask Amazon Q and its responses, for service improvement.

For information about what content we use and how to opt out, see Amazon Q Developer service improvement in the *Amazon Q Developer User Guide*.

Considerations

Consider the following items before you use Amazon Q data integration in AWS Glue:

- Currently, the code generation only works with PySpark kernel. The generated code is for AWS Glue jobs based on Python Spark.
- For information about the supported combinations of code generation abilities of Amazon Q data integration in AWS Glue, see Supported code generation abilities.

Setting up Amazon Q data integration in AWS Glue

The following sections provide information setting up Amazon Q data integration in AWS Glue.

Topics

- Configuring IAM permissions

Configuring IAM permissions

This topic describes the IAM permissions that you configure for the Amazon Q chat experience, and the AWS Glue Studio notebook experience.

Topics

- Configuring IAM permissions for Amazon Q chat
- Configuring IAM permissions for AWS Glue Studio notebooks

Configuring IAM permissions for Amazon Q chat

Granting permissions to the APIs used by Amazon Q data integration in AWS Glue requires appropriate AWS Identity and Access Management (IAM) permissions. You can obtain permissions by attaching the following custom AWS policy to your IAM identity (such as a user, role, or group):

JSON

```
{
  "Version":"2012-10-17",
```

```
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:StartCompletion",
        "glue:GetCompletion"
      ],
      "Resource": [
        "arn:aws:glue:*:*:completion/*"
      ]
    }
  ]
}
```

Configuring IAM permissions for AWS Glue Studio notebooks

To enable Amazon Q data integration in AWS Glue Studio notebooks, ensure the following permission is attached to the notebook IAM role:

> **Note**
>
> The `codewhisperer` prefix is a legacy name from a service that merged with Amazon Q Developer. For more information, see Amazon Q Developer rename - Summary of changes.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:StartCompletion",
        "glue:GetCompletion"
      ],
      "Resource": [
        "arn:aws:glue:*:*:completion/*"
      ]
    },
```

```
    {
      "Sid": "AmazonQDeveloperPermissions",
      "Effect": "Allow",
      "Action": [
        "codewhisperer:GenerateRecommendations"
      ],
      "Resource": "*"
    }
  ]
}
```

> **Note**
>
> Amazon Q data integration in AWS Glue does not have APIs available through the AWS SDK that you can use programmatically. The following two APIs are used in the IAM policy for enabling this experience through the Amazon Q chat panel or AWS Glue Studio notebooks: `StartCompletion` and `GetCompletion`.

Assigning permissions

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center: Create a permission set. Follow the instructions in Create a permission set in the *AWS IAM Identity Center User Guide*.
- Users managed in IAM through an identity provider: Create a role for identity federation. Follow the instructions in Creating a role for a third-party identity provider (federation) in the *IAM User Guide*.
- IAM users:
  - Create a role that your user can assume. Follow the instructions in Creating a role for an IAM user in the *IAM User Guide*.
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in Adding permissions to a user (console) in the *IAM User Guide*.

Supported code generation abilities

The following are the combinations of the code generation abilities of Amazon Q data integration.

Sources and Targets	Transformation
S3 with the following format types: json, csv, parquet, hudi, delta	Drop
AWS Glue Data Catalog	Aggregate
Redlake	DropDuplicates
Amazon DynamoDB	Join
MySQL	Filter
Oracle	RenameColumns
PostgresSQL	FillNull
Microsoft SQL Server	DropNull
Amazon DocumentDB / MongoDB	WithColumns
Snowflake	SQL Query
Google BigQuery	Union
Teradata	Select
Amazon OpenSearch Service	
Vertica	
SAP HANA	
Amazon Redshift	

Example interactions

Amazon Q data integration in AWS Glue allows you enter your question in the Amazon Q panel. You can enter a question regarding data integration functionality provided by AWS Glue. A detailed answer, together with reference documents, will be returned.

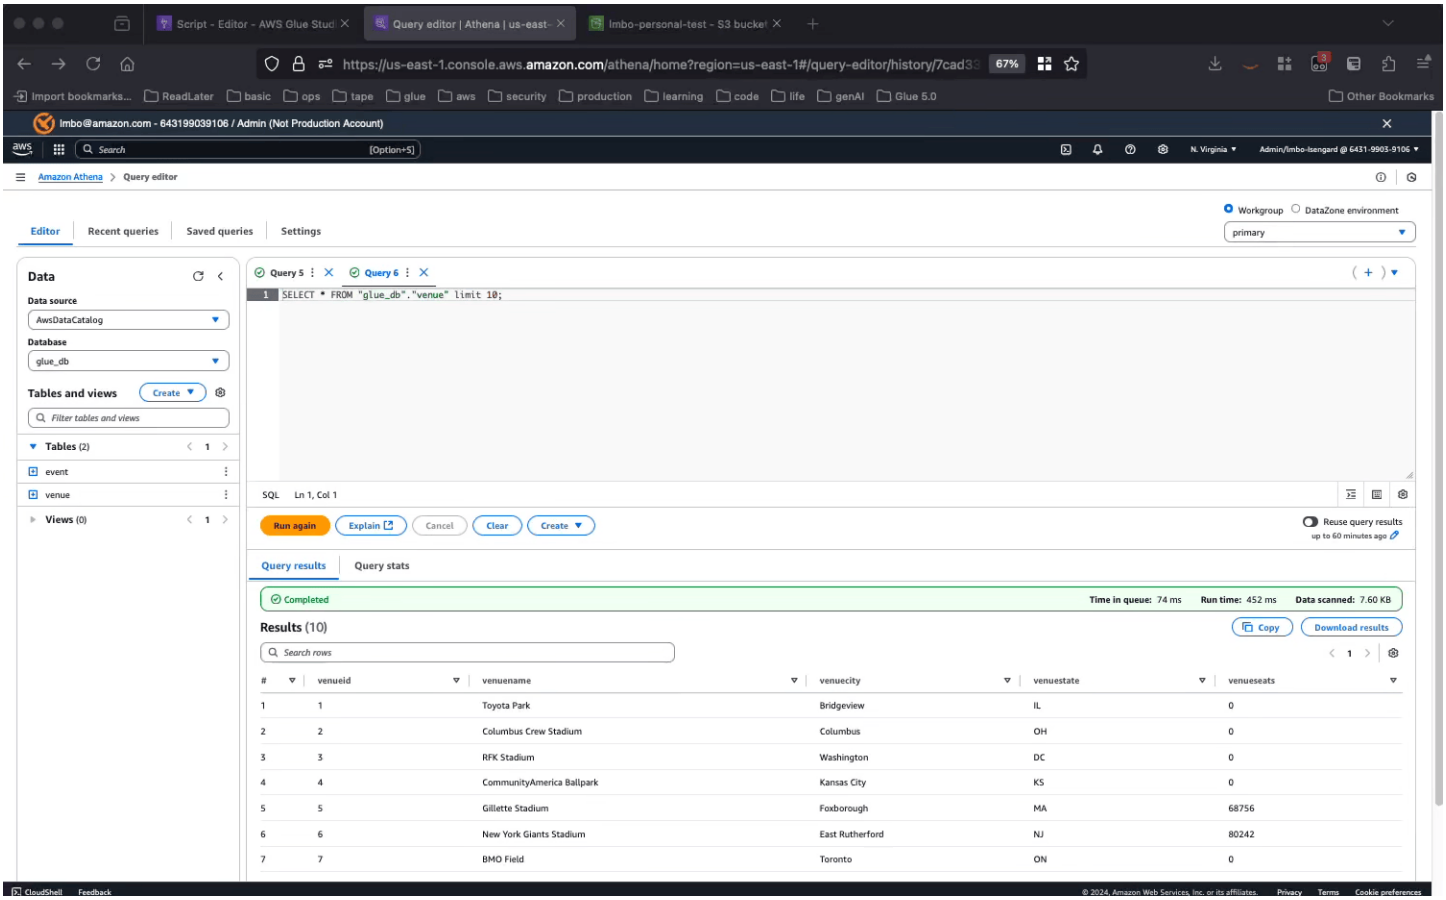
Another use case is generating AWS Glue ETL job scripts. You can ask a question regarding how to perform a data extract, transform, load job. A generated PySpark script will be returned.

Topics

- Amazon Q chat interactions
- AWS Glue Studio notebook interactions

Amazon Q chat interactions

On the AWS Glue console, start authoring a new job, and ask Amazon Q: *"Create a Glue ETL flow connect to two Glue catalog tables venue and event in my database glue_db, join the results on the venue's venueid and event's e_venueid, and then filter on venue state with condition as venuestate=='DC' and write to s3://amzn-s3-demo-bucket/codegen/BDB-9999/output/ in CSV format.""*



You will notice that the code is generated. With this response, you can learn and understand how you can author AWS Glue code for your purpose. You can copy/paste the generated code to the script editor and configure placeholders. After you configure an IAM role and AWS Glue

connections on the job, save and run the job. When the job is complete, you can verify the summary data is persisted to Amazon S3 as expected and can be used by your downstream workloads.

AWS Glue Studio notebook interactions

> **Note**
>
> The Amazon Q Data integration experience in AWS Glue Studio notebook still focuses on DynamicFrame-based data integration flow.

Add a new cell and enter your comment to describe what you want to achieve. After you press **Tab** and **Enter**, the recommended code is shown.

First intent is to extract the data: *"Give me code that reads a Glue Data Catalog table"*, followed by *"Give me code to apply a filter transform with star_rating>3"* and *"Give me code that writes the frame into S3 as Parquet"*.

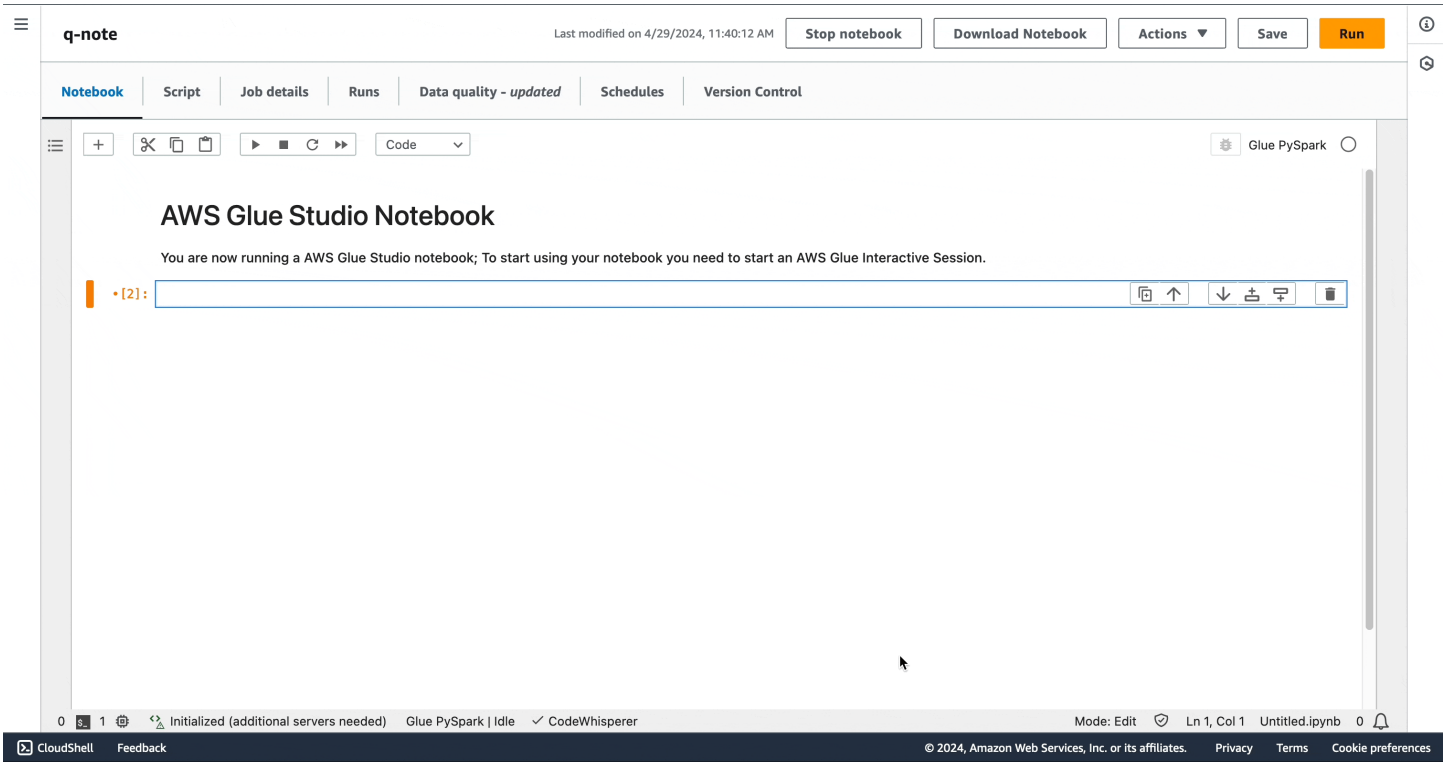
Similar to the Amazon Q chat experience, the code is recommended. If you press **Tab**, then the recommended code is chosen.

You can run each cell by filling in the appropriate options for your sources in the generated code. At any point in the runs, you can also preview a sample of your dataset by using the `show( )` method.

You can run the notebook as a job, either programmatically or by choosing **Run**.

Complex prompts

You can generate a full script with a single complex prompt. *"I have JSON data in S3 and data in Oracle that needs combining. Please provide a Glue script that reads from both sources, does a join, and then writes results to Redshift."*



You may notice that, on the notebook, Amazon Q data integration in AWS Glue generated the same code snippet that was generated in the Amazon Q chat.

You can run the notebook as a job, either by choosing **Run** or programmatically.

Using context awareness with Amazon Q Data Integration in AWS Glue

You can now create data processing jobs more efficiently with query based context-aware and PySpark DataFrame code generation in Amazon Q Data Integration. For example, you can use this prompt to generate PySpark code: “create a job to load sales data from Redshift table ‘analytics.salesorder’ using connection ‘erp_conn’, filter order_amount below 50 dollars, and save to Amazon S3 in parquet format.”

Amazon Q will generate the script based on your prompt and setup data integration workflow setup with the details provided from your question, such as connection configurations, schema details, database/table names, and column specifications for transformations. Sensitive information, such as connection option passwords, continue to be redacted.

If required information is not provided from your prompt, Amazon Q will put placeholders, which you have to update the generated code with the appropriate values before running the code.

The following are examples on how to use context awareness.

Example: interactions

Reading an Amazon S3 file and writing to an Amazon S3 bucket

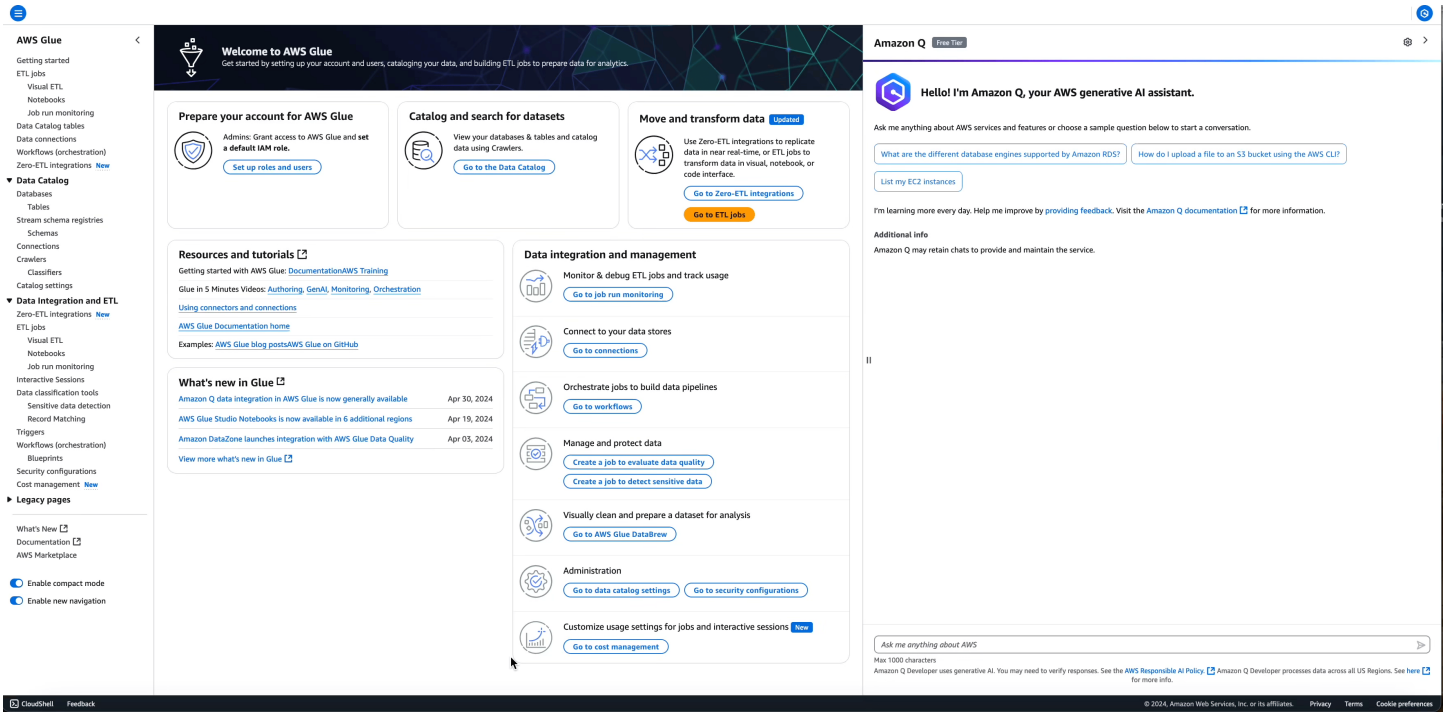
Prompt: `Create an AWS Glue spark job that reads a file s3://amzn-s3-demo-bucket-input-bucket-name/input-filename.csv and saves it into the parquet file under directory s3://amzn-s3-demo-bucket-output-bucket-name/output-s3-prefix/`

```
import sys
from awsglue.transforms import *
from pyspark.context import SparkContext
from pyspark.sql import SparkSession

sc = SparkContext.getOrCreate()
spark = SparkSession.builder.getOrCreate()

# Script generated for node S3DataSource
S3DataSource_dsource1 = spark.read.format("csv").load(
    "s3://amzn-s3-demo-bucket-input-bucket-name/input-filename.csv"
)
```

```
# Script generated for node S3DataSink
S3DataSource_dsource1.write.format("parquet").mode("append").save(
    "s3://amzn-s3-demo-bucket-output-bucket-name/output-s3-prefix/"
)
```



Get data from Lakehouse and write to database

Prompt: `write an ETL script to read from a Lakehouse table my-table in database my-database and write it to a RDS MySQL table my-target-table`

For fields where you did not provide information (for example, the connectionName required is for MySQL data sink and default with a placehoder <connection-name> in the generated code), a placeholder is kept for you to fill in the required information before run the script.

Generated script:

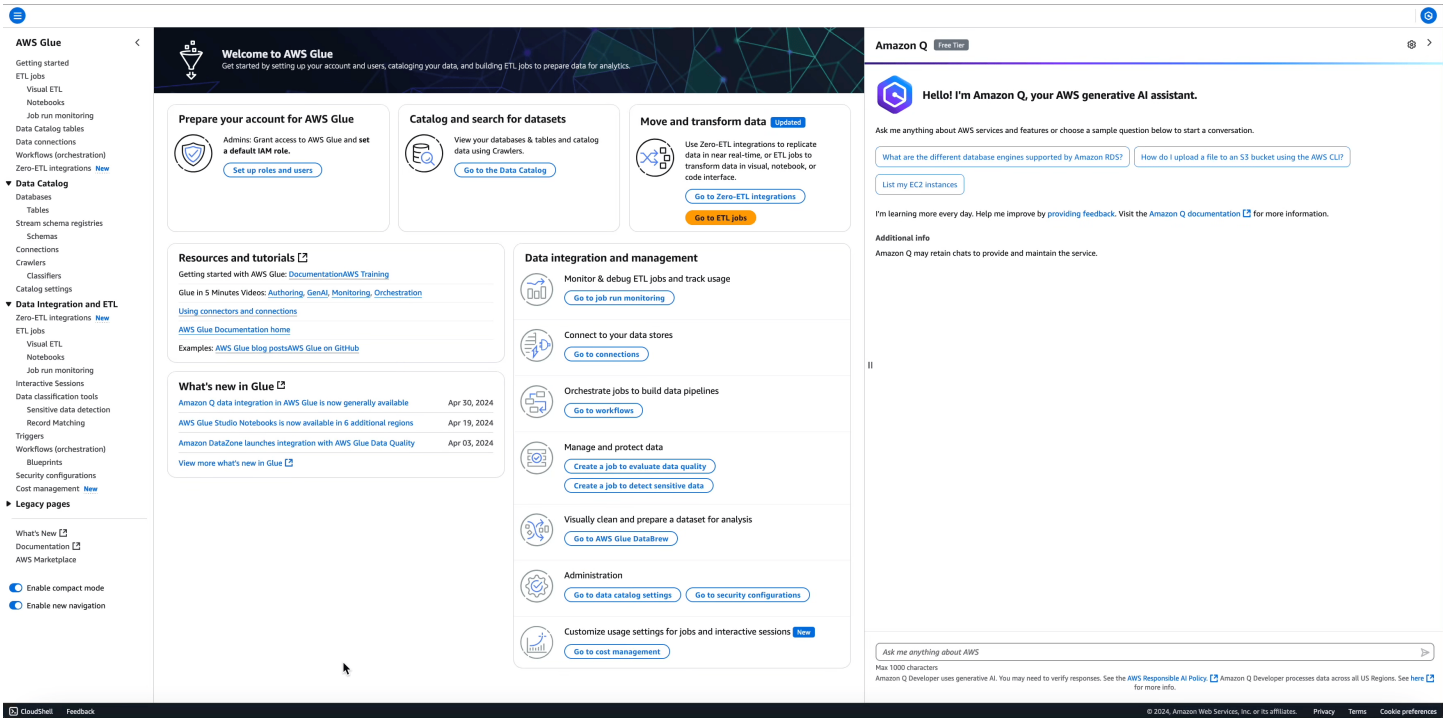
```
import sys
from awsglue.transforms import *
from pyspark.context import SparkContext
from pyspark.sql import SparkSession
from connectivity.adapter import CatalogConnectionHelper

sc = SparkContext.getOrCreate()
```

```
spark = SparkSession.builder.getOrCreate()

# Script generated for node S3DataSource
S3DataSource_dsource1 = spark.read.format("parquet").load(
    "s3://amzn-lakehouse-demo-bucket/my-database/my-table"
)

# Script generated for node ConnectionV2DataSink
ConnectionV2DataSink_dsink1_additional_options = {"dbtable": "my-target-table"}
CatalogConnectionHelper(spark).write(
    S3DataSource_dsource1,
    "mysql",
    "<connection-name>",
    ConnectionV2DataSink_dsink1_additional_options,
)
```



Example: Full ETL workflow

The following example demonstrates how you can ask AWS Glue to create a AWS Glue script to complete a full ETL workflow with the following prompt: `Create a AWS Glue ETL Script read from two AWS Glue Data Catalog tables venue and event in my database glue_db_4fthqih3vvk1if, join the results on the field venueid, filter on venue state with condition as venuestate=='DC' after joining the results`

`and write output to an Amazon S3 S3 location s3://amz-s3-demo-bucket/output/ in CSV format.`

The workflow contains reading from different data sources (two AWS Glue Data Catalog tables), and a couple of transforms after the reading by join the result from two readings, filter based on some condition and write the transformed output to an Amazon S3 destination in CSV format.

The generated job will fill in the detailed information to the data source, transform and sink operation with corresponding information extracted from user question as below.

```
import sys
from awsglue.transforms import *
from pyspark.context import SparkContext
from pyspark.sql import SparkSession

sc = SparkContext.getOrCreate()
spark = SparkSession.builder.getOrCreate()

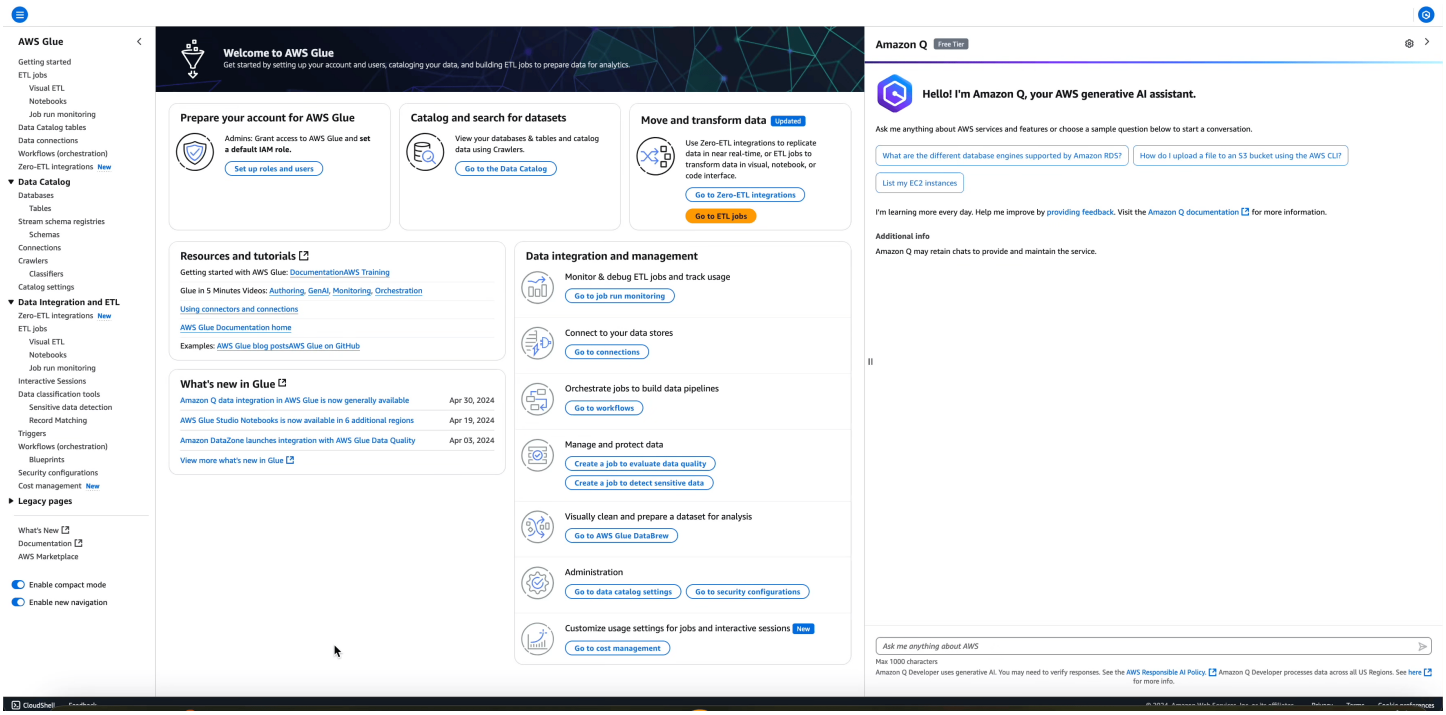
# Script generated for node CatalogDataSource
CatalogDataSource_dsource1 = spark.sql("select * from
 `glue_db_4fthqih3vvk1if`.`venue`")

# Script generated for node CatalogDataSource
CatalogDataSource_dsource2 = spark.sql("select * from
 `glue_db_4fthqih3vvk1if`.`event`")

# Script generated for node JoinTransform
JoinTransform_transform1 = CatalogDataSource_dsource1.join(
    CatalogDataSource_dsource2,
    (CatalogDataSource_dsource1["venueid"] == CatalogDataSource_dsource2["venueid"]),
    "inner",
)

# Script generated for node FilterTransform
FilterTransform_transform2 = JoinTransform_transform1.filter("venuestate=='DC'")

# Script generated for node S3DataSink
FilterTransform_transform2.write.format("csv").mode("append").save(
    "s3://amz-s3-demo-bucket/output//output/"
)
```



Limitations

- Context carryover:
  - The context-awareness feature only carries over context from the previous user query within the same conversation. It does not retain context beyond the immediate preceding query.
- Support for node configurations:
  - Currently, context-awareness supports only a subset of required configurations for various nodes.
  - Support for optional fields is planned in upcoming releases.
- Availability:
  - Context-awareness and DataFrame support are available in Q Chat and SageMaker Unified Studio notebooks. However, these features are not yet available in AWS Glue Studio notebooks.

Orchestration in AWS Glue

The following sections provide information on orchestration of jobs in AWS Glue.

Topics

- Starting jobs and crawlers using triggers
- Performing complex ETL activities using blueprints and workflows in AWS Glue
- Developing blueprints in AWS Glue

Starting jobs and crawlers using triggers

In AWS Glue, you can create Data Catalog objects called triggers, which you can use to either manually or automatically start one or more crawlers or extract, transform, and load (ETL) jobs. Using triggers, you can design a chain of dependent jobs and crawlers.

> **Note**
>
> You can accomplish the same thing by defining *workflows*. Workflows are preferred for creating complex multi-job ETL operations. For more information, see the section called "Performing complex ETL activities using blueprints and workflows".

Topics

- AWS Glue triggers
- Adding triggers
- Activating and deactivating triggers

AWS Glue triggers

When *fired*, a trigger can start specified jobs and crawlers. A trigger fires on demand, based on a schedule, or based on a combination of events.

> **Note**
>
> Only two crawlers can be activated by a single trigger. If you want to crawl multiple data stores, use multiple sources for each crawler instead of running multiple crawlers simultaneously.

A trigger can exist in one of several states. A trigger is either `CREATED`, `ACTIVATED`, or `DEACTIVATED`. There are also transitional states, such as `ACTIVATING`. To temporarily stop a trigger from firing, you can deactivate it. You can then reactivate it later.

There are three types of triggers:

Scheduled

A time-based trigger based on `cron`.

You can create a trigger for a set of jobs or crawlers based on a schedule. You can specify constraints, such as the frequency that the jobs or crawlers run, which days of the week they run, and at what time. These constraints are based on `cron`. When you're setting up a schedule for a trigger, consider the features and limitations of cron. For example, if you choose to run your crawler on day 31 each month, keep in mind that some months don't have 31 days. For more information about cron, see Time-based schedules for jobs and crawlers.

Conditional

A trigger that fires when a previous job or crawler or multiple jobs or crawlers satisfy a list of conditions.

When you create a conditional trigger, you specify a list of jobs and a list of crawlers to watch. For each watched job or crawler, you specify a status to watch for, such as succeeded, failed, timed out, and so on. The trigger fires if the watched jobs or crawlers end with the specified statuses. You can configure the trigger to fire when any or all of the watched events occur.

For example, you could configure a trigger T1 to start job J3 when both job J1 and job J2 successfully complete, and another trigger T2 to start job J4 if either job J1 or job J2 fails.

The following table lists the job and crawler completion states (events) that triggers watch for.

Job completion states	Crawler completion states
• SUCCEEDED • STOPPED • FAILED • TIMEOUT	• SUCCEEDED • FAILED • CANCELLED

On-demand

A trigger that fires when you activate it. On-demand triggers never enter the ACTIVATED or DEACTIVATED state. They always remain in the CREATED state.

So that they are ready to fire as soon as they exist, you can set a flag to activate scheduled and conditional triggers when you create them.

> **Important**
>
> Jobs or crawlers that run as a result of other jobs or crawlers completing are referred to as *dependent*. Dependent jobs or crawlers are only started if the job or crawler that completes was started by a trigger. All jobs or crawlers in a dependency chain must be descendants of a single **scheduled** or **on-demand** trigger.

Passing job parameters with triggers

A trigger can pass parameters to the jobs that it starts. Parameters include job arguments, timeout value, security configuration, and more. If the trigger starts multiple jobs, the parameters are passed to each job.

The following are the rules for job arguments passed by a trigger:

- If the key in the key-value pair matches a default job argument, the passed argument overrides the default argument. If the key doesn't match a default argument, then the argument is passed as an additional argument to the job.
- If the key in the key-value pair matches a non-overridable argument, the passed argument is ignored.

For more information, see the section called "Triggers" in the AWS Glue API.

Adding triggers

You can add a trigger using the AWS Glue console, the AWS Command Line Interface (AWS CLI), or the AWS Glue API.

To add a trigger (console)

1. Sign in to the AWS Management Console and open the AWS Glue console at https://console.aws.amazon.com/glue/.
2. In the navigation pane, under **ETL**, choose **Triggers**. Then choose **Add trigger**.
3. Provide the following properties:

   Name

   Give your trigger a unique name.

   Trigger type

   Specify one of the following:

   - **Schedule:** The trigger fires at a specific frequency and time.
   - **Job events:** A conditional trigger. The trigger fires when any or all jobs in the list match their designated statuses. For the trigger to fire, the watched jobs must have been started by triggers. For any job you choose, you can only watch one job event (completion status).
   - **On-demand:** The trigger fires when it is activated.
4. Complete the trigger wizard. On the **Review** page, you can activate **Schedule** and **Job events** (conditional) triggers immediately by selecting **Enable trigger on creation**.

To add a trigger (AWS CLI)

- Enter a command similar to the following.

```
aws glue create-trigger --name MyTrigger --type SCHEDULED --schedule  "cron(0 12 *
 * ? *)" --actions CrawlerName=MyCrawler --start-on-creation
```

This command creates a schedule trigger named `MyTrigger`, which runs every day at 12:00pm UTC and starts a crawler named `MyCrawler`. The trigger is created in the activated state.

For more information, see the section called "AWS Glue triggers".

Time-based schedules for jobs and crawlers

You can define a time-based schedule for your crawlers and jobs in AWS Glue. The definition of these schedules uses the Unix-like cron syntax. You specify time in Coordinated Universal Time (UTC), and the minimum precision for a schedule is 5 minutes.

To learn more about configuring jobs and crawlers to run using a schedule, see Starting jobs and crawlers using triggers.

Cron expressions

Cron expressions have six required fields, which are separated by white space.

Syntax

```
cron(Minutes Hours Day-of-month Month Day-of-week Year)
```

Fields	Values	Wildcards
Minutes	0–59	, - * /
Hours	0–23	, - * /
Day-of-month	1–31	, - * ? / L W
Month	1–12 or JAN-DEC	, - * /
Day-of-week	1–7 or SUN-SAT	, - * ? / L
Year	1970–2199	, - * /

Wildcards

- The **,** (comma) wildcard includes additional values. In the `Month` field, `JAN,FEB,MAR` would include January, February, and March.
- The **-** (dash) wildcard specifies ranges. In the `Day` field, 1–15 would include days 1 through 15 of the specified month.
- The ***** (asterisk) wildcard includes all values in the field. In the `Hours` field, ***** would include every hour.
- The **/** (forward slash) wildcard specifies increments. In the `Minutes` field, you could enter **`1/10`** to specify every 10th minute, starting from the first minute of the hour (for example, the 11th, 21st, and 31st minute).
- The **?** (question mark) wildcard specifies one or another. In the `Day-of-month` field you could enter **7**, and if you didn't care what day of the week the seventh was, you could enter **?** in the Day-of-week field.
- The **L** wildcard in the `Day-of-month` or `Day-of-week` fields specifies the last day of the month or week.
- The **W** wildcard in the `Day-of-month` field specifies a weekday. In the `Day-of-month` field, `3W` specifies the day closest to the third weekday of the month.

Limits

- You can't specify the `Day-of-month` and `Day-of-week` fields in the same cron expression. If you specify a value in one of the fields, you must use a **?** (question mark) in the other.
- Cron expressions that lead to rates faster than 5 minutes are not supported.

Examples

When creating a schedule, you can use the following sample cron strings.

Minutes	Hours	Day of month	Month	Day of week	Year	Meaning
0	10	*	*	?	*	Run at 10:00

Minutes	Hours	Day of month	Month	Day of week	Year	Meaning
						am (UTC) every day
15	12	*	*	?	*	Run at 12:15 pm (UTC) every day
0	18	?	*	MON-FRI	*	Run at 6:00 pm (UTC) every Monday through Friday
0	8	1	*	?	*	Run at 8:00 am (UTC) every first day of the month
0/15	*	*	*	?	*	Run every 15 minutes
0/10	*	?	*	MON-FRI	*	Run every 10 minutes Monday through Friday

Minutes	Hours	Day of month	Month	Day of week	Year	Meaning
0/5	8–17	?	*	MON-FRI	*	Run every 5 minutes Monday through Friday between 8:00 am and 5:55 pm (UTC)

For example to run on a schedule of every day at 12:15 UTC, specify:

```
cron(15 12 * * ? *)
```

Activating and deactivating triggers

You can activate or deactivate a trigger using the AWS Glue console, the AWS Command Line Interface (AWS CLI), or the AWS Glue API.

To activate or deactivate a trigger (console)

1. Sign in to the AWS Management Console and open the AWS Glue console at https://console.aws.amazon.com/glue/.
2. In the navigation pane, under **ETL**, choose **Triggers**.
3. Select the check box next to the desired trigger, and on the **Action** menu choose **Enable trigger** to activate the trigger or **Disable trigger** to deactivate the trigger.

To activate or deactivate a trigger (AWS CLI)

- Enter one of the following commands.

```
aws glue start-trigger --name MyTrigger
```

```
aws glue stop-trigger --name MyTrigger
```

Starting a trigger activates it, and stopping a trigger deactivates it. When you activate an on-demand trigger, it fires immediately.

For more information, see the section called "AWS Glue triggers".

Performing complex ETL activities using blueprints and workflows in AWS Glue

Some of your organization's complex extract, transform, and load (ETL) processes might best be implemented by using multiple, dependent AWS Glue jobs and crawlers. Using AWS Glue *workflows*, you can design a complex multi-job, multi-crawler ETL process that AWS Glue can run and track as single entity. After you create a workflow and specify the jobs, crawlers, and triggers in the workflow, you can run the workflow on demand or on a schedule.

Overview of workflows in AWS Glue

In AWS Glue, you can use workflows to create and visualize complex extract, transform, and load (ETL) activities involving multiple crawlers, jobs, and triggers. Each workflow manages the

execution and monitoring of all its jobs and crawlers. As a workflow runs each component, it records execution progress and status. This provides you with an overview of the larger task and the details of each step. The AWS Glue console provides a visual representation of a workflow as a graph.

You can create a workflow from an AWS Glue blueprint, or you can manually build a workflow a component at a time using the AWS Management Console or the AWS Glue API. For more information about blueprints, see the section called “Overview of blueprints”.

Triggers within workflows can start both jobs and crawlers and can be fired when jobs or crawlers complete. By using triggers, you can create large chains of interdependent jobs and crawlers. In addition to triggers within a workflow that define job and crawler dependencies, each workflow has a *start trigger*. There are three types of start triggers:

- **Schedule** – The workflow is started according to a schedule that you define. The schedule can be daily, weekly, monthly, and so on, or can be a custom schedule based on a `cron` expression.
- **On demand** – The workflow is started manually from the AWS Glue console, API, or AWS CLI.
- **EventBridge event** – The workflow is started upon the occurrence of a single Amazon EventBridge event or a batch of Amazon EventBridge events. With this trigger type, AWS Glue can be an event consumer in an event-driven architecture. Any EventBridge event type can start a workflow. A common use case is the arrival of a new object in an Amazon S3 bucket (the S3 `PutObject` operation).

  Starting a workflow with a batch of events means waiting until a specified number of events have been received or until a specified amount of time has passed. When you create the EventBridge event trigger, you can optionally specify batch conditions. If you specify batch conditions, you must specify the batch size (number of events), and can optionally specify a batch window (number of seconds). The default and maximum batch window is 900 seconds (15 minutes). The batch condition that is met first starts the workflow. The batch window starts when the first event arrives. If you don't specify batch conditions when creating a trigger, the batch size defaults to 1.

  When the workflow starts, the batch conditions are reset and the event trigger begins watching for the next batch condition to be met to start the workflow again.

  The following table shows how batch size and batch window operate together to trigger a workflow.

Batch size	Batch window	Resulting triggering condition
10		The workflow is triggered upon the arrival of 10 EventBridge events, or 15 minutes after the arrival of the first event, whichever occurs first. (If windows size isn't specified, it defaults to 15 minutes.)
10	2 mins	The workflow is triggered upon the arrival of 10 EventBridge events, or 2 minutes after the arrival of the first event, whichever occurs first.
1		The workflow is triggered upon the arrival of the first event. Window size is irrelevant. The batch size defaults to 1 if you don't specify batch conditions when you create the EventBridge event trigger.

The `GetWorkflowRun` API operation returns the batch condition that triggered the workflow.

Regardless of how a workflow is started, you can specify the maximum number of concurrent workflow runs when you create the workflow.

If an event or batch of events starts a workflow run that eventually fails, that event or batch of events is no longer considered for starting a workflow run. A new workflow run is started only when the next event or batch of events arrives.

Important

Limit the total number of jobs, crawlers, and triggers within a workflow to 100 or less. If you include more than 100, you might get errors when trying to resume or stop workflow runs.

A workflow run will not be started if it would exceed the concurrency limit set for the workflow, even though the event condition is met. It's advisable to adjust workflow concurrency limits based on the expected event volume. AWS Glue does not retry workflow runs that fail due to exceeded

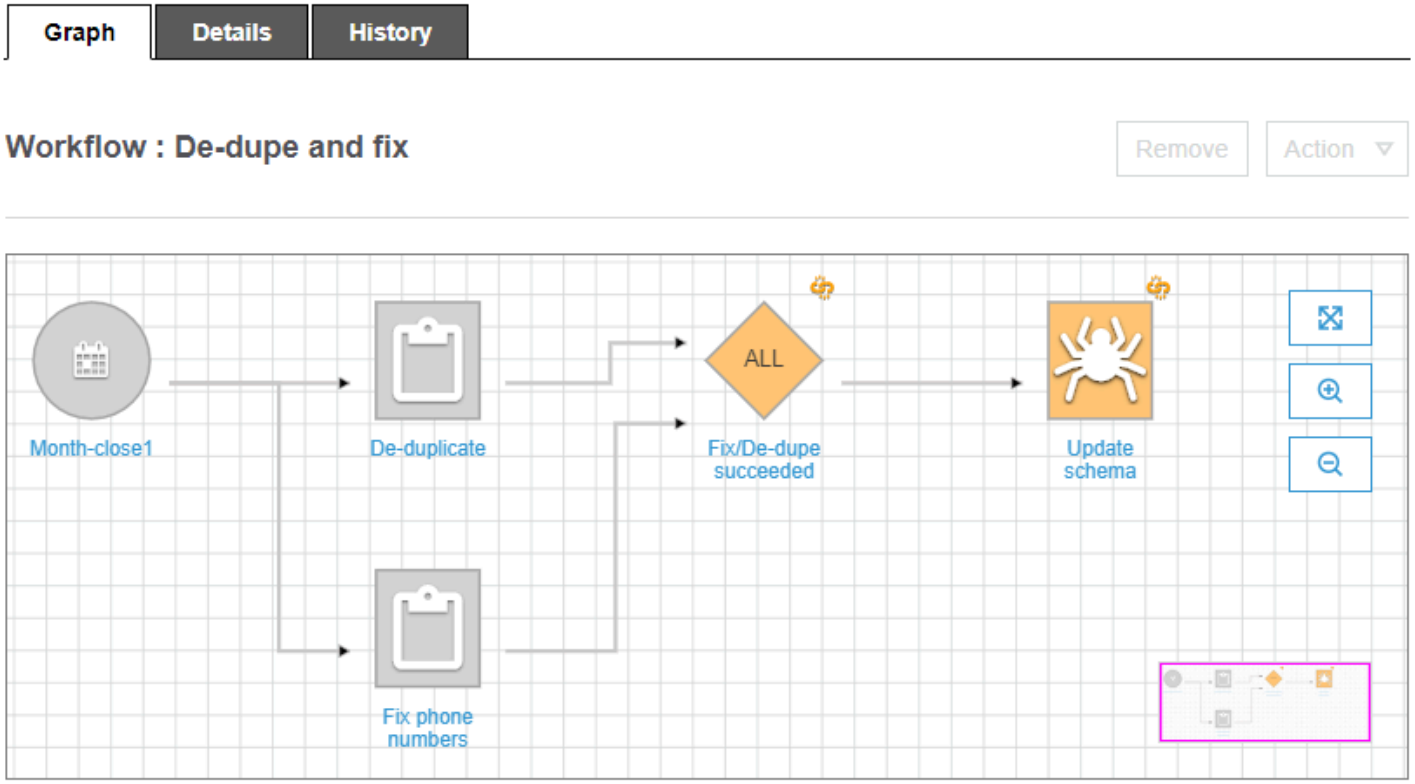
concurrency limits. Likewise, it's advisable to adjust concurrency limits for jobs and crawlers within workflows based on expected event volume.

Workflow run properties

To share and manage state throughout a workflow run, you can define default workflow run properties. These properties, which are name/value pairs, are available to all the jobs in the workflow. Using the AWS Glue API, jobs can retrieve the workflow run properties and modify them for jobs that come later in the workflow.

Workflow graph

The following image shows the graph of a very basic workflow on the AWS Glue console. Your workflow could have dozens of components.



This workflow is started by a schedule trigger, `Month-close1`, which starts two jobs, `De-duplicate` and `Fix phone numbers`. Upon successful completion of both jobs, an event trigger, `Fix/De-dupe succeeded`, starts a crawler, `Update schema`.

Static and dynamic workflow views

For each workflow, there is the notion of *static view* and *dynamic view*. The static view indicates the design of the workflow. The dynamic view is a runtime view that includes the latest run information for each of the jobs and crawlers. Run information includes success status and error details.

When a workflow is running, the console displays the dynamic view, graphically indicating the jobs that have completed and that are yet to be run. You can also retrieve a dynamic view of a running workflow using the AWS Glue API. For more information, see Querying workflows using the AWS Glue API.

- the section called "Creating and building out a workflow manually"
- Workflows (for the workflows API)

Creating and building out a workflow manually in AWS Glue

You can use the AWS Glue console to manually create and build out a workflow one node at a time.

A workflow contains jobs, crawlers, and triggers. Before manually creating a workflow, create the jobs and crawlers that the workflow is to include. It's best to specify run-on-demand crawlers for workflows. You can create new triggers while you are building out your workflow, or you can *clone* existing triggers into the workflow. When you clone a trigger, all the catalog objects associated with the trigger—the jobs or crawlers that fire it and the jobs or crawlers that it starts—are added to the workflow.

Important

Limit the total number of jobs, crawlers, and triggers within a workflow to 100 or less. If you include more than 100, you might get errors when trying to resume or stop workflow runs.

You build out your workflow by adding triggers to the workflow graph, and defining the watched events and actions for each trigger. You begin with a *start trigger*, which can be either an on-demand or schedule trigger, and complete the graph by adding event (conditional) triggers.

Step 1: Create the workflow

1. Sign in to the AWS Management Console and open the AWS Glue console at https://console.aws.amazon.com/glue/.
2. In the navigation pane, under **ETL**, choose **Workflows**.
3. Choose **Add workflow** and complete the **Add a new ETL workflow** form.

   Any optional default run properties that you add are made available as arguments to all jobs in the workflow. For more information, see Getting and setting workflow run properties in AWS Glue.
4. Choose **Add workflow**.

   The new workflow appears in the list on the **Workflows** page.

Step 2: Add a start trigger

1. On the **Workflows** page, select your new workflow. Then, at the bottom of the page, ensure that the **Graph** tab is selected.
2. Choose **Add trigger**, and in the **Add trigger** dialog box, do one of the following:

   - Choose **Clone existing**, and choose a trigger to clone. Then choose **Add**.

     The trigger appears on the graph, along with the jobs and crawlers that it watches and the jobs and crawlers that it starts.

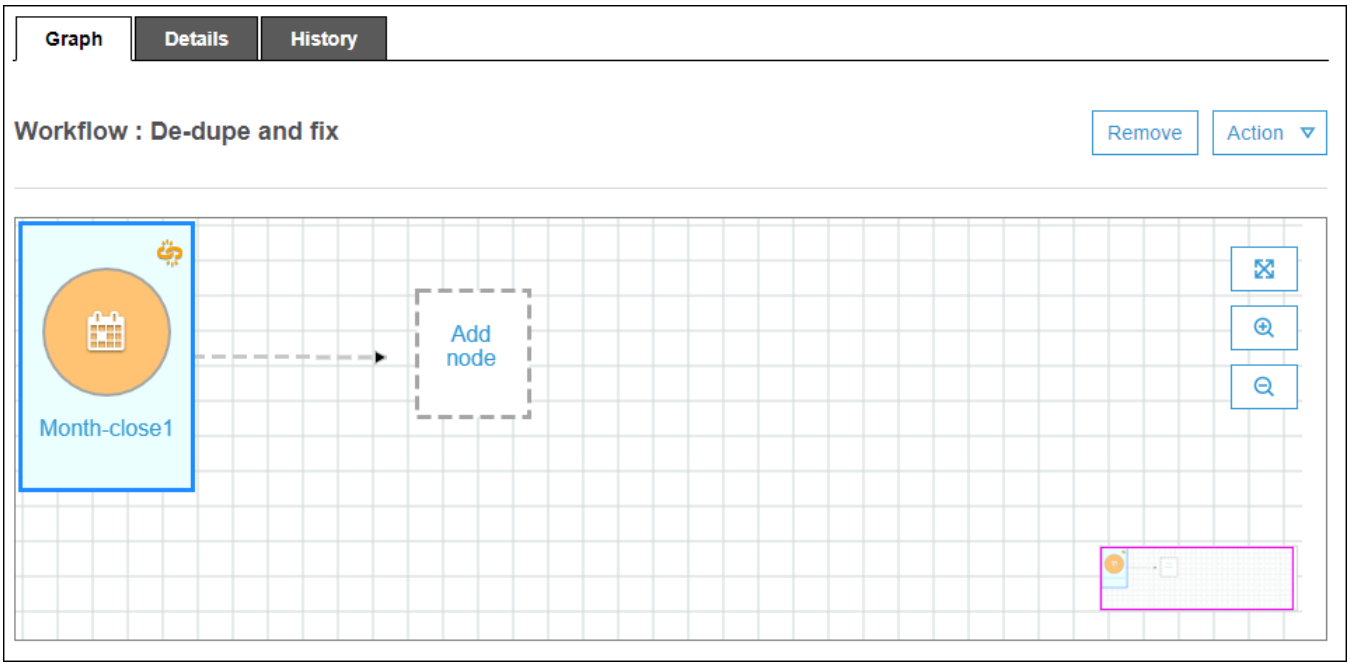
     If you mistakenly selected the wrong trigger, select the trigger on the graph, and then choose **Remove**.
   - Choose **Add new**, and complete the **Add trigger** form.
     1. For **Trigger type**, select **Schedule**, **On demand**, or **EventBridge event**.

        For trigger type **Schedule**, choose one of the **Frequency** options. Choose **Custom** to enter a `cron` expression.

        For trigger type **EventBridge event**, enter **Number of events** (batch size), and optionally enter **Time delay** (batch window). If you omit **Time delay**, the batch window defaults to 15 minutes. For more information, see Overview of workflows in AWS Glue.
     2. Choose **Add**.

The trigger appears on the graph, along with a placeholder node (labeled **Add node**). In the example below, the start trigger is a schedule trigger named `Month-close1`.

At this point, the trigger isn't saved yet.



3. If you added a new trigger, complete these steps:

   a. Do one of the following:

   - Choose the placeholder node (**Add node**).
   - Ensure that the start trigger is selected, and on the **Action** menu above the graph, choose **Add jobs/crawlers to trigger**.

   b. In the **Add jobs(s) and crawler(s) to trigger** dialog box, select one or more jobs or crawlers, and then choose **Add**.

   The trigger is saved, and the selected jobs or crawlers appear on the graph with connectors from the trigger.

   If you mistakenly added the wrong jobs or crawlers, you can select either the trigger or a connector and choose **Remove**.

Step 3: Add more triggers

Continue to build out your workflow by adding more triggers of type **Event**. To zoom in or out or to enlarge the graph canvas, use the icons to the right of the graph. For each trigger to add, complete the following steps:

> **Note**
>
> There is no action to save the workflow. After you add your last trigger and assign actions to the trigger, the workflow is complete and saved. You can always come back later and add more nodes.

1. Do one of the following:

   - To clone an existing trigger, ensure that no node on the graph is selected, and on the **Action** menu, choose **Add trigger**.
   - To add a new trigger that watches a particular job or crawler on the graph, select the job or crawler node, and then choose the **Add trigger** placeholder node.

     You can add more jobs or crawlers to watch for this trigger in a later step.

2. In the **Add trigger** dialog box, do one of the following:

   - Choose **Add new**, and complete the **Add trigger** form. Then choose **Add**.

     The trigger appears on the graph. You will complete the trigger in a later step.
   - Choose **Clone existing**, and choose a trigger to clone. Then choose **Add**.

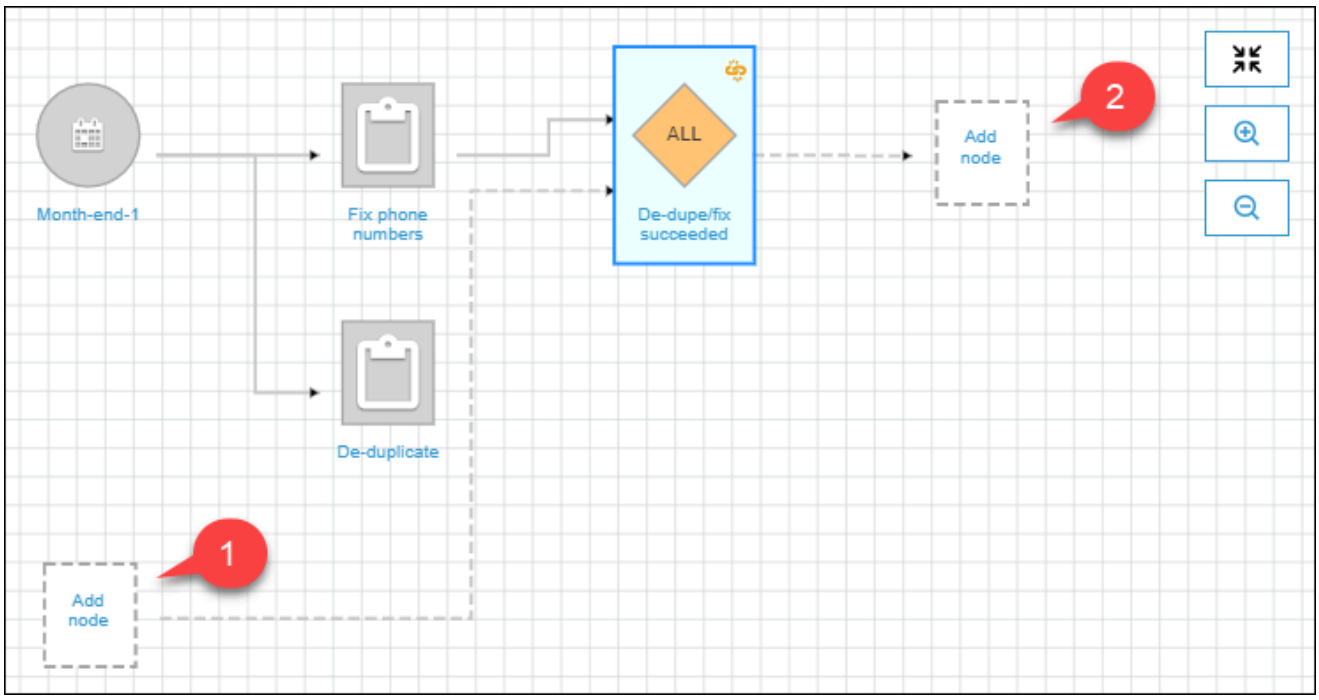
     The trigger appears on the graph, along with the jobs and crawlers that it watches and the jobs and crawlers that it starts.

     If you mistakenly chose the wrong trigger, select the trigger on the graph, and then choose **Remove**.

3. If you added a new trigger, complete these steps:

   a. Select the new trigger.

      As the following graph shows, the trigger `De-dupe/fix succeeded` is selected, and placeholder nodes appear for (1) events to watch and (2) actions.



b. (Optional if the trigger already watches an event and you want to add more jobs or crawlers to watch.) Choose the events-to-watch placeholder node, and in the **Add job(s) and crawler(s) to watch** dialog box, select one or more jobs or crawlers. Choose an event to watch (SUCCEEDED, FAILED, etc.), and choose **Add**.

c. Ensure that the trigger is selected, and choose the actions placeholder node.

d. In the **Add job(s) and crawler(s) to watch dialog** box, select one or more jobs or crawlers, and choose **Add**.

   The selected jobs and crawlers appear on the graph, with connectors from the trigger.

For more information on workflows and blueprints, see the following topics.

- Overview of workflows in AWS Glue
- Running and monitoring a workflow in AWS Glue
- Creating a workflow from a blueprint in AWS Glue

Starting an AWS Glue workflow with an Amazon EventBridge event

Amazon EventBridge, also known as CloudWatch Events, enables you to automate your AWS services and respond automatically to system events such as application availability issues or resource changes. Events from AWS services are delivered to EventBridge in near real time. You can

write simple rules to indicate which events are of interest to you, and what automated actions to take when an event matches a rule.

With EventBridge support, AWS Glue can serve as an event producer and consumer in an event-driven architecture. For workflows, AWS Glue supports any type of EventBridge event as a consumer. The likely most common use case is the arrival of a new object in an Amazon S3 bucket. If you have data arriving in irregular or undefined intervals, you can process this data as close to its arrival as possible.

> **Note**
>
> AWS Glue does not provide guaranteed delivery of EventBridge messages. AWS Glue performs no deduplication if EventBridge delivers duplicate messages. You must manage idempotency based on your use case.
> Be sure to configure EventBridge rules correctly to avoid sending unwanted events.

Before you begin

If you want to start a workflow with Amazon S3 data events, you must ensure that events for the S3 bucket of interest are logged to AWS CloudTrail and EventBridge. To do so, you must create a CloudTrail trail. For more information, see Creating a trail for your AWS account.

To start a workflow with an EventBridge event

> **Note**
>
> In the following commands, replace:
>
> - *<workflow-name>* with the name to assign to the workflow.
> - *<trigger-name>* with the name to assign to the trigger.
> - *<bucket-name>* with the name of the Amazon S3 bucket.
> - *<account-id>* with a valid AWS account ID.
> - *<region>* with the name of the Region (for example, `us-east-1`).
> - *<rule-name>* with the name to assign to the EventBridge rule.

1. Ensure that you have AWS Identity and Access Management (IAM) permissions to create and view EventBridge rules and targets. The following is a sample policy that you can attach. You might want to scope it down to put limits on the operations and resources.

   JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "events:PutRule",
        "events:DisableRule",
        "events:DeleteRule",
        "events:PutTargets",
        "events:RemoveTargets",
        "events:EnableRule",
        "events:List*",
        "events:Describe*"
      ],
      "Resource": "*"
    }
  ]
}
```

2. Create an IAM role that the EventBridge service can assume when passing an event to AWS Glue.

   a. On the **Create role** page of the IAM console, choose **AWS Service**. Then choose the service **CloudWatch Events**.

   b. Complete the **Create role** wizard. The wizard automatically attaches the `CloudWatchEventsBuiltInTargetExecutionAccess` and `CloudWatchEventsInvocationAccess` policies.

   c. Attach the following inline policy to the role. This policy allows the EventBridge service to direct events to AWS Glue.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:notifyEvent"
      ],
      "Resource": [
        "arn:aws:glue:us-east-1:111122223333:workflow/workflow-name"
      ]
    }
  ]
}
```

3. Enter the following command to create the workflow.

   See create-workflow in the *AWS CLI Command Reference* for information about additional optional command-line parameters.

   ```
   aws glue create-workflow --name <workflow-name>
   ```

4. Enter the following command to create an EventBridge event trigger for the workflow. This will be the start trigger for the workflow. Replace *<actions>* with the actions to perform (the jobs and crawlers to start).

   See create-trigger in the *AWS CLI Command Reference* for information about how to code the `actions` argument.

   ```
   aws glue create-trigger --workflow-name <workflow-name> --type EVENT --
   name <trigger-name> --actions <actions>
   ```

   If you want the workflow to be triggered by a batch of events instead of a single EventBridge event, enter the following command instead.

```
aws glue create-trigger --workflow-name <workflow-name> --type EVENT
 --name <trigger-name> --event-batching-condition BatchSize=<number-of-
events>,BatchWindow=<seconds> --actions <actions>
```

For the `event-batching-condition` argument, `BatchSize` is required and `BatchWindow` is optional. If `BatchWindow` is omitted, the window defaults to 900 seconds, which is the maximum window size.

Example

The following example creates a trigger that starts the `eventtest` workflow after three EventBridge events have arrived, or five minutes after the first event arrives, whichever comes first.

```
aws glue create-trigger --workflow-name eventtest --type EVENT --name objectArrival
 --event-batching-condition BatchSize=3,BatchWindow=300 --actions JobName=test1
```

5. Create a rule in Amazon EventBridge.

   a. Create the JSON object for the rule details in your preferred text editor.

      The following example specifies Amazon S3 as the event source, `PutObject` as the event name, and the bucket name as a request parameter. This rule starts a workflow when a new object arrives in the bucket.

```
{
  "source": [
    "aws.s3"
  ],
  "detail-type": [
    "AWS API Call via CloudTrail"
  ],
  "detail": {
    "eventSource": [
      "s3.amazonaws.com"
    ],
    "eventName": [
      "PutObject"
    ],
    "requestParameters": {
```

```
      "bucketName": [
        "<bucket-name>"
      ]
    }
  }
}
```

To start the workflow when a new object arrives in a folder within the bucket, you can substitute the following code for `requestParameters`.

```
    "requestParameters": {
      "bucketName": [
        "<bucket-name>"
      ]
      "key" : [{ "prefix" : "<folder1>/<folder2>/*"}}]
  }
```

b. Use your preferred tool to convert the rule JSON object to an escaped string.

```
{\n  \"source\": [\n    \"aws.s3\"\n  ],\n  \"detail-type\": [\n    \"AWS API
 Call via CloudTrail\"\n  ],\n  \"detail\": {\n    \"eventSource\": [\n
 \"s3.amazonaws.com\"\n    ],\n    \"eventName\": [\n      \"PutObject\"\n
  ],\n    \"requestParameters\": {\n      \"bucketName\": [\n        \"<bucket-
name>\"\n      ]\n    }\n  }\n}
```

c. Run the following command to create a JSON parameter template that you can edit to specify input parameters to a subsequent `put-rule` command. Save the output in a file. In this example, the file is called `ruleCommand`.

```
aws events put-rule --name <rule-name> --generate-cli-skeleton >ruleCommand
```

For more information about the `--generate-cli-skeleton` parameter, see Generating AWS CLI skeleton and input parameters from a JSON or YAML input file in the *AWS Command Line Interface User Guide*.

The output file should look like the following.

```
{
    "Name": "",
    "ScheduleExpression": "",
    "EventPattern": "",
```

```
    "State": "ENABLED",
    "Description": "",
    "RoleArn": "",
    "Tags": [
        {
            "Key": "",
            "Value": ""
        }
    ],
    "EventBusName": ""
}
```

d. Edit the file to optionally remove parameters and to specify at a minimum the `Name`, `EventPattern`, and `State` parameters. For the `EventPattern` parameter, provide the escaped string for the rule details that you created in a previous step.

```
{
    "Name": "<rule-name>",
    "EventPattern": "{\n  \"source\": [\n    \"aws.s3\"\n  ],\n  \"detail-
type\": [\n    \"AWS API Call via CloudTrail\"\n  ],\n  \"detail\": {\n
 \"eventSource\": [\n      \"s3.amazonaws.com\"\n    ],\n    \"eventName\": [\n
      \"PutObject\"\n    ],\n    \"requestParameters\": {\n      \"bucketName
\": [\n        \"<bucket-name>\"\n      ]\n    }\n  }\n}",
    "State": "DISABLED",
    "Description": "Start an AWS Glue workflow upon new file arrival in an
 Amazon S3 bucket"
}
```

> **Note**
>
> It is best to leave the rule disabled until you finish building out the workflow.

e. Enter the following `put-rule` command, which reads input parameters from the file `ruleCommand`.

```
aws events put-rule --name <rule-name> --cli-input-json file://ruleCommand
```

The following output indicates success.

```
{
    "RuleArn": "<rule-arn>"
```

```
}
```

6. Enter the following command to attach the rule to a target. The target is the workflow in AWS Glue. Replace *<role-name>* with the role that you created at the beginning of this procedure.

```
aws events put-targets --rule <rule-name> --targets
 "Id"="1","Arn"="arn:aws:glue:<region>:<account-id>:workflow/<workflow-
name>","RoleArn"="arn:aws:iam::<account-id>:role/<role-name>" --region <region>
```

   The following output indicates success.

```
{
    "FailedEntryCount": 0,
    "FailedEntries": []
}
```

7. Confirm successful connection of the rule and target by entering the following command.

```
aws events list-rule-names-by-target --target-arn arn:aws:glue:<region>:<account-
id>:workflow/<workflow-name>
```

   The following output indicates success, where *<rule-name>* is the name of the rule that you created.

```
{
    "RuleNames": [
        "<rule-name>"
    ]
}
```

8. Sign in to the AWS Management Console and open the AWS Glue console at https://console.aws.amazon.com/glue/.
9. Select the workflow, and verify that the start trigger and its actions—the jobs or crawlers that it starts— appear on the workflow graph. Then continue with the procedure in Step 3: Add more triggers. Or add more components to the workflow by using the AWS Glue API or AWS Command Line Interface.
10. When the workflow is completely specified, enable the rule.

```
aws events enable-rule --name <rule-name>
```

The workflow is now ready to be started by an EventBridge event or event batch.

- Creating and building out a workflow manually in AWS Glue

Viewing the EventBridge events that started a workflow

You can view the event ID of the Amazon EventBridge event that started your workflow. If your workflow was started by a batch of events, you can view the event IDs of all events in the batch.

For workflows with a batch size greater than one, you can also see which batch condition started the workflow: the arrival of the number of events in the batch size, or the expiration of the batch window.

To view the EventBridge events that started a workflow (console)

1. Sign in to the AWS Management Console and open the AWS Glue console at https://console.aws.amazon.com/glue/.
2. In the navigation pane, choose **Workflows**.
3. Select the workflow. Then at the bottom, choose the **History** tab.
4. Select a workflow run, and then choose **View run details**.
5. On the run details page, locate the **Run properties** field, and look for the **aws:eventIds** key.

   The value for that key is a list of EventBridge event IDs.

To view the EventBridge events that started a workflow (AWS API)

- Include the following code in your Python script.

```
workflow_params =
 glue_client.get_workflow_run_properties(Name=workflow_name,RunId=workflow_run_id)
batched_events = workflow_params['aws:eventIds']
```

`batched_events` will be a list of strings, where each string is an event ID.

- *Amazon EventBridge User Guide*
- the section called "Overview of workflows"

Running and monitoring a workflow in AWS Glue

If the start trigger for a workflow is an on-demand trigger, you can start the workflow from the AWS Glue console. Complete the following steps to run and monitor a workflow. If the workflow fails, you can view the run graph to determine the node that failed. To help troubleshoot, if the workflow was created from a blueprint, you can view the blueprint run to see the blueprint parameter values that were used to create the workflow. For more information, see the section called "Viewing blueprint runs".

You can run and monitor a workflow by using the AWS Glue console, API, or AWS Command Line Interface (AWS CLI).

To run and monitor a workflow (console)

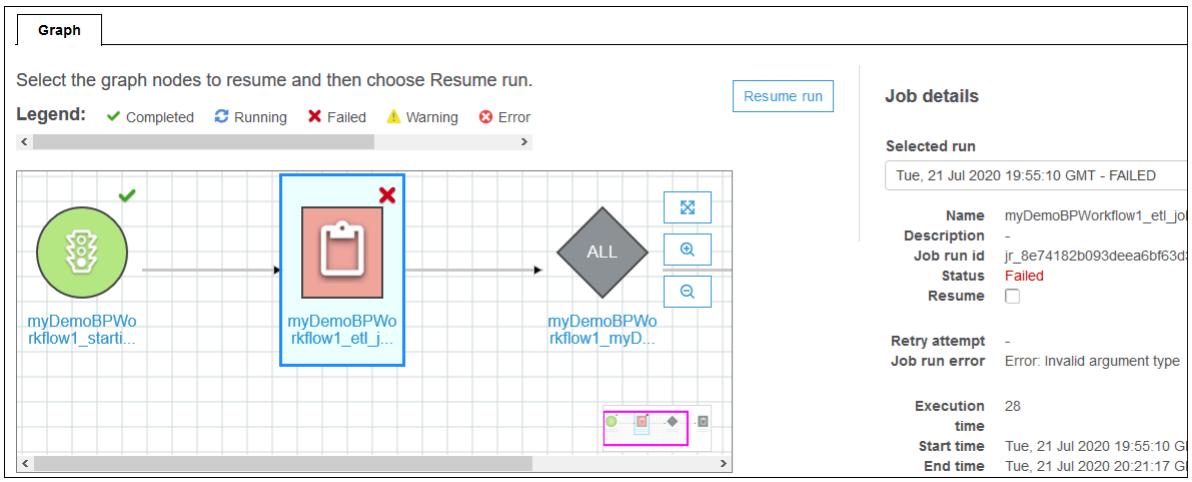
1. Open the AWS Glue console at https://console.aws.amazon.com/glue/.
2. In the navigation pane, under **ETL**, choose **Workflows**.
3. Select a workflow. On the **Actions** menu, choose **Run**.
4. Check the **Last run status** column in the workflows list. Choose the refresh button to view ongoing workflow status.
5. While the workflow is running or after it has completed (or failed), view the run details by completing the following steps.

   a. Ensure that the workflow is selected, and choose the **History** tab.

   b. Choose the current or most recent workflow run, and then choose **View run details**.

   The workflow runtime graph shows the current run status.

   c. Choose any node in the graph to view details and status of the node.



To run and monitor a workflow (AWS CLI)

1. Enter the following command. Replace *<workflow-name>* with the workflow to run.

```
aws glue start-workflow-run --name <workflow-name>
```

   If the workflow is successfully started, the command returns the run ID.

2. View workflow run status by using the `get-workflow-run` command. Supply the workflow name and run ID.

```
aws glue get-workflow-run --name myWorkflow --run-id
 wr_d2af14217e8eae775ba7b1fc6fc7a42c795aed3cbcd8763f9415452e2dbc8705
```

   The following is sample command output.

```
{
    "Run": {
        "Name": "myWorkflow",
        "WorkflowRunId":
 "wr_d2af14217e8eae775ba7b1fc6fc7a42c795aed3cbcd8763f9415452e2dbc8705",
        "WorkflowRunProperties": {
            "run_state": "COMPLETED",
            "unique_id": "fee63f30-c512-4742-a9b1-7c8183bdaae2"
        },
        "StartedOn": 1578556843.049,
        "CompletedOn": 1578558649.928,
        "Status": "COMPLETED",
```

```
        "Statistics": {
            "TotalActions": 11,
            "TimeoutActions": 0,
            "FailedActions": 0,
            "StoppedActions": 0,
            "SucceededActions": 9,
            "RunningActions": 0,
            "ErroredActions": 0
        }
    }
}
```

Stopping a workflow run

You can use the AWS Glue console, AWS Command Line Interface (AWS CLI) or AWS Glue API to stop a workflow run. When you stop a workflow run, all running jobs and crawlers are immediately terminated, and jobs and crawlers that are not yet started never start. It might take up to a minute for all running jobs and crawlers to stop. The workflow run status goes from **Running** to **Stopping**, and when the workflow run is completely stopped, the status goes to **Stopped**.

After the workflow run is stopped, you can view the run graph to see which jobs and crawlers completed and which never started. You can then determine if you must perform any steps to ensure data integrity. Stopping a workflow run causes no automatic rollback operations to be performed.

To stop a workflow run (console)

1. Open the AWS Glue console at https://console.aws.amazon.com/glue/.
2. In the navigation pane, under **ETL**, choose **Workflows**.
3. Choose a running workflow, and then choose the **History** tab.
4. Choose the workflow run, and then choose **Stop run**.

The run status changes to **Stopping**.

5. (Optional) Choose the workflow run, choose **View run details**, and review the run graph.

To stop a workflow run (AWS CLI)

- Enter the following command. Replace *<workflow-name>* with the name of the workflow and *<run-id>* with the run ID of the workflow run to stop.

```
aws glue stop-workflow-run --name <workflow-name> --run-id <run-id>
```

The following is an example of the **stop-workflow-run** command.

```
aws glue stop-workflow-run --name my-workflow --run-id
 wr_137b88917411d128081069901e4a80595d97f719282094b7f271d09576770354
```

Repairing and resuming a workflow run

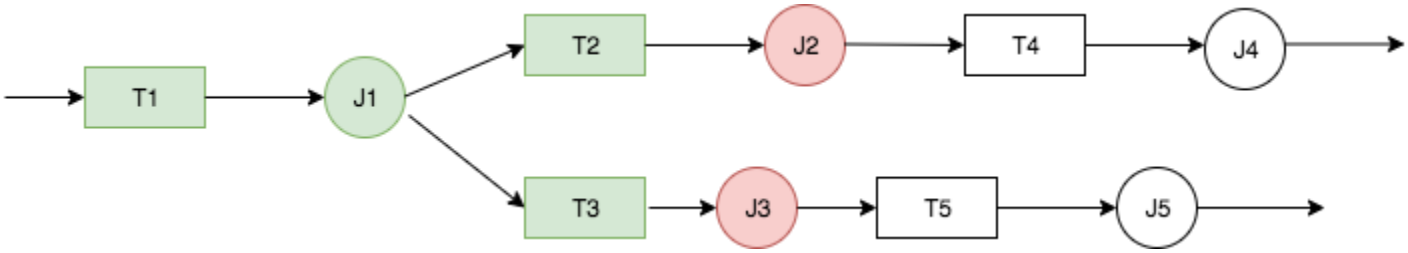
If one or more nodes (jobs or crawlers) in a workflow do not successfully complete, this means that the workflow only partially ran. After you find the root causes and make corrections, you can select one or more nodes to resume the workflow run from, and then resume the workflow run. The selected nodes and all nodes that are downstream from those nodes are then run.

Topics

- Resuming a workflow run: How it works
- Resuming a workflow run
- Notes and limitations for resuming workflow runs

Resuming a workflow run: How it works

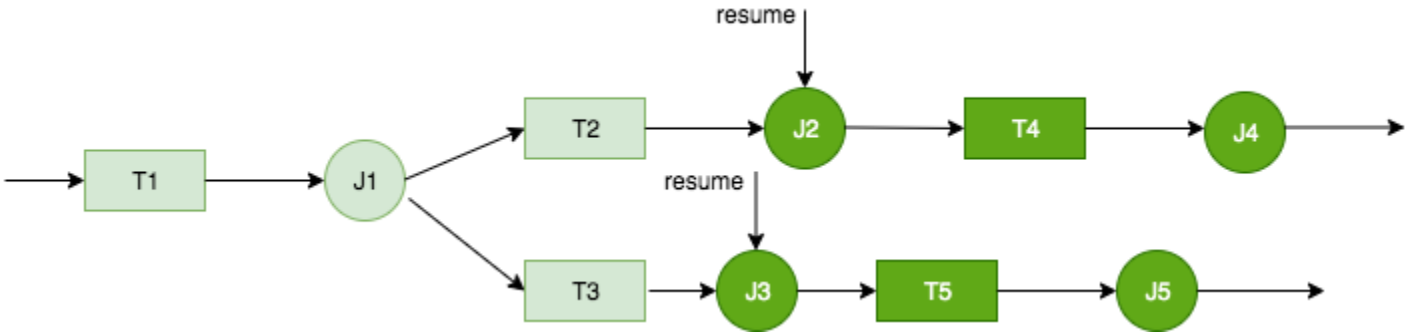
Consider the workflow W1 in the following diagram.



The workflow run proceeds as follows:

1. Trigger T1 starts job J1.
2. Successful completion of J1 fires triggers T2 and T3, which run jobs J2 and J3, respectively.
3. Jobs J2 and J3 fail.
4. Triggers T4 and T5 depend on the successful completion of J2 and J3, so they don't fire, and jobs J4 and J5 don't run. Workflow W1 is only partially run.

Now assume that the issues that caused J2 and J3 to fail are corrected. J2 and J3 are selected as the starting points to resume the workflow run from.



The workflow run resumes as follows:

1. Jobs J2 and J3 run successfully.
2. Triggers T4 and T5 fire.
3. Jobs J4 and J5 run successfully.

The resumed workflow run is tracked as a separate workflow run with a new run ID. When you view the workflow history, you can view the previous run ID for any workflow run. In the example in the following screenshot, the workflow run with run ID `wr_c7a22...` (the second row) had a node that did not complete. The user fixed the problem and resumed the workflow run, which resulted in run ID `wr_a07e55...` (the first row).

> **Note**
>
> For the rest of this discussion, the term "resumed workflow run" refers to the workflow run that was created when the previous workflow run was resumed. The "original workflow run" refers to the workflow run that only partially ran and that needed to be resumed.

Resumed workflow run graph

In a resumed workflow run, although only a subset of nodes are run, the run graph is a complete graph. That is, the nodes that didn't run in the resumed workflow are copied from the run graph of the original workflow run. Copied job and crawler nodes that ran in the original workflow run include run details.

Consider again the workflow W1 in the previous diagram. When the workflow run is resumed starting with J2 and J3, the run graph for the resumed workflow run shows all jobs, J1 though J5, and all triggers, T1 through T5. The run details for J1 are copied from the original workflow run.

Workflow run snapshots

When a workflow run is started, AWS Glue takes a snapshot of the workflow design graph at that point in time. That snapshot is used for the duration of the workflow run. If you make changes to any triggers after the run starts, those changes don't affect the current workflow run. Snapshots ensure that workflow runs proceed in a consistent manner.

Snapshots make only triggers immutable. Changes that you make to downstream jobs and crawlers during the workflow run take effect for the current run.

Resuming a workflow run

Follow these steps to resume a workflow run. You can resume a workflow run by using the AWS Glue console, API, or AWS Command Line Interface (AWS CLI).

To resume a workflow run (console)

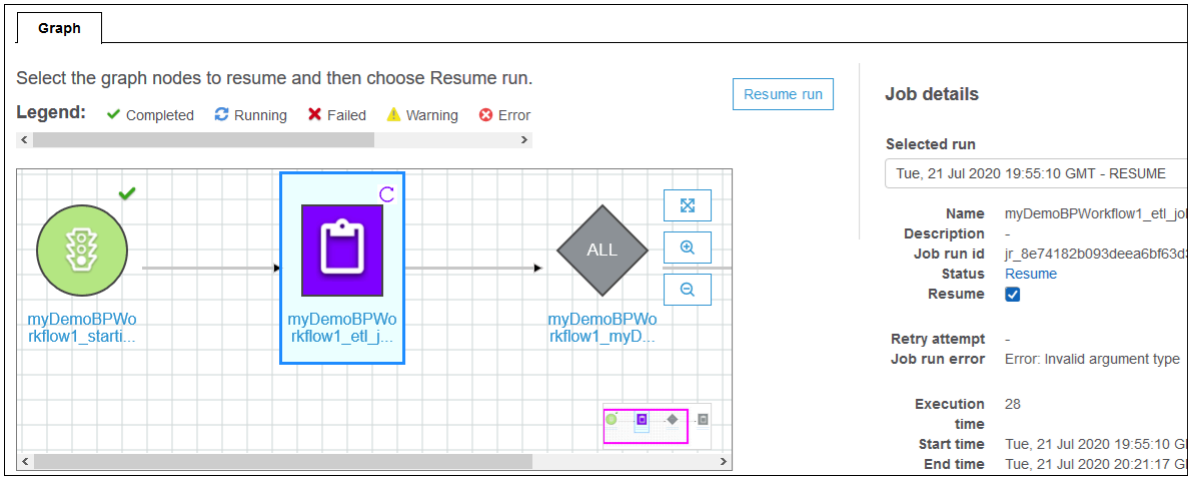
1. Open the AWS Glue console at https://console.aws.amazon.com/glue/.

   Sign in as a user who has permissions to view workflows and resume workflow runs.

   > **Note**
   >
   > To resume workflow runs, you need the `glue:ResumeWorkflowRun` AWS Identity and Access Management (IAM) permission.

2. In the navigation pane, choose **Workflows**.
3. Select a workflow, and then choose the **History** tab.
4. Select the workflow run that only partially ran, and then choose **View run details**.
5. In the run graph, select the first (or only) node that you want to restart and that you want to resume the workflow run from.
6. In the details pane to the right of the graph, select the **Resume** check box.

   The node changes color and shows a small resume icon at the upper right.



7. Complete the previous two steps for any additional nodes to restart.
8. Choose **Resume run**.

To resume a workflow run (AWS CLI)

1. Ensure that you have the `glue:ResumeWorkflowRun` IAM permission.
2. Retrieve the node IDs for the nodes that you want to restart.

   a. Run the `get-workflow-run` command for the original workflow run. Supply the workflow name and run ID, and add the `--include-graph` option, as shown in the following example. Get the run ID from the **History** tab on the console, or by running the `get-workflow` command.

   ```
   aws glue get-workflow-run --name cloudtrailtest1 --run-id
    wr_a07e55f2087afdd415a404403f644a4265278f68b13ba3da08c71924ebe3c3a8 --include-
   graph
   ```

   The command returns the nodes and edges of the graph as a large JSON object.

   b. Locate the nodes of interest by the `Type` and `Name` properties of the node objects.

   The following is an example node object from the output.

   ```
   {
       "Type": "JOB",
       "Name": "test1_post_failure_4592978",
       "UniqueId":
    "wnode_d1b2563c503078b153142ee76ce545fe5ceef66e053628a786ddd74a05da86fd",
   ```

```
    "JobDetails": {
        "JobRuns": [
            {
                "Id":
 "jr_690b9f7fc5cb399204bc542c6c956f39934496a5d665a42de891e5b01f59e613",
                "Attempt": 0,
                "TriggerName": "test1_aggregate_failure_649b2432",
                "JobName": "test1_post_failure_4592978",
                "StartedOn": 1595358275.375,
                "LastModifiedOn": 1595358298.785,
                "CompletedOn": 1595358298.785,
                "JobRunState": "FAILED",
                "PredecessorRuns": [],
                "AllocatedCapacity": 0,
                "ExecutionTime": 16,
                "Timeout": 2880,
                "MaxCapacity": 0.0625,
                "LogGroupName": "/aws-glue/python-jobs"
            }
        ]
    }
}
```

c. Get the node ID from the `UniqueId` property of the node object.

3. Run the `resume-workflow-run` command. Provide the workflow name, run ID, and list of node IDs separated by spaces, as shown in the following example.

```
aws glue resume-workflow-run --name cloudtrailtest1 --run-id
 wr_a07e55f2087afdd415a404403f644a4265278f68b13ba3da08c71924ebe3c3a8 --node-
ids wnode_ca1f63e918fb855e063aed2f42ec5762ccf71b80082ae2eb5daeb8052442f2f3
 wnode_d1b2563c503078b153142ee76ce545fe5ceef66e053628a786ddd74a05da86fd
```

The command outputs the run ID of the resumed (new) workflow run and a list of nodes that will be started.

```
{
    "RunId": "wr_2ada0d3209a262fc1156e4291134b3bd643491bcfb0ceead30bd3e4efac24de9",
    "NodeIds": [
        "wnode_ca1f63e918fb855e063aed2f42ec5762ccf71b80082ae2eb5daeb8052442f2f3"
    ]
}
```

Note that although the example `resume-workflow-run` command listed two nodes to restart, the example output indicated that only one node would be restarted. This is because one node was downstream of the other node, and the downstream node would be restarted anyway by the normal flow of the workflow.

Notes and limitations for resuming workflow runs

Keep the following notes and limitations in mind when resuming workflow runs.

- You can resume a workflow run only if it's in the `COMPLETED` state.

> **Note**
>
> Even if one ore more nodes in a workflow run don't complete, the workflow run state is shown as `COMPLETED`. Be sure to check the run graph to discover any nodes that didn't successfully complete.

- You can resume a workflow run from any job or crawler node that the original workflow run attempted to run. You can't resume a workflow run from a trigger node.
- Restarting a node does not reset its state. Any data that was partially processed is not rolled back.
- You can resume a failed workflow run multiple times. However, a resumed run can only be resumed once more. For additional retries, resume the original failed run instead
- If you select two nodes to restart and they're dependent upon each other, the upstream node is run before the downstream node. In fact, selecting the downstream node is redundant, because it will be run according to the normal flow of the workflow.

Getting and setting workflow run properties in AWS Glue

Use workflow run properties to share and manage state among the jobs in your AWS Glue workflow. You can set default run properties when you create the workflow. Then, as your jobs run, they can retrieve the run property values and optionally modify them for input to jobs that are later in the workflow. When a job modifies a run property, the new value exists only for the workflow run. The default run properties aren't affected.

If your AWS Glue job is not part of a workflow, these properties will not be set.

The following sample Python code from an extract, transform, and load (ETL) job demonstrates how to get the workflow run properties.

```
import sys
import boto3
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from awsglue.context import GlueContext
from pyspark.context import SparkContext

glue_client = boto3.client("glue")
args = getResolvedOptions(sys.argv, ['JOB_NAME','WORKFLOW_NAME', 'WORKFLOW_RUN_ID'])
workflow_name = args['WORKFLOW_NAME']
workflow_run_id = args['WORKFLOW_RUN_ID']
workflow_params = glue_client.get_workflow_run_properties(Name=workflow_name,
                                       RunId=workflow_run_id)["RunProperties"]

target_database = workflow_params['target_database']
target_s3_location = workflow_params['target_s3_location']
```

The following code continues by setting the `target_format` run property to `'csv'`.

```
workflow_params['target_format'] = 'csv'
glue_client.put_workflow_run_properties(Name=workflow_name, RunId=workflow_run_id,
 RunProperties=workflow_params)
```

For more information, see the following:

- GetWorkflowRunProperties action (Python: get_workflow_run_properties)
- PutWorkflowRunProperties action (Python: put_workflow_run_properties)

Querying workflows using the AWS Glue API

AWS Glue provides a rich API for managing workflows. You can retrieve a static view of a workflow or a dynamic view of a running workflow using the AWS Glue API. For more information, see Workflows.

Topics

- Querying static views
- Querying dynamic views

Querying static views

Use the `GetWorkflow` API operation to get a static view that indicates the design of a workflow. This operation returns a directed graph consisting of nodes and edges, where a node represents a trigger, a job, or a crawler. Edges define the relationships between nodes. They are represented by connectors (arrows) on the graph in the AWS Glue console.

You can also use this operation with popular graph-processing libraries such as NetworkX, igraph, JGraphT, and the Java Universal Network/Graph (JUNG) Framework. Because all these libraries represent graphs similarly, minimal transformations are needed.

The static view returned by this API is the most up-to-date view according to the latest definition of triggers associated with the workflow.

Graph definition

A workflow graph G is an ordered pair (N, E), where N is a set of nodes and E a set of edges. *Node* is a vertex in the graph identified by a unique number. A node can be of type trigger, job, or crawler. For example: `{name:T1, type:Trigger, uniqueId:1}, {name:J1, type:Job, uniqueId:2}`.

Edge is a 2-tuple of the form (`src, dest`), where `src` and `dest` are nodes and there is a directed edge from `src` to `dest`.

Example of querying a static view

Consider a conditional trigger T, which triggers job J2 upon completion of job J1.

```
J1 ---> T ---> J2
```

Nodes: J1, T, J2

Edges: (J1, T), (T, J2)

Querying dynamic views

Use the `GetWorkflowRun` API operation to get a dynamic view of a running workflow. This operation returns the same static view of the graph along with metadata related to the workflow run.

For run, nodes representing jobs in the `GetWorkflowRun` call have a list of job runs initiated as part of the latest run of the workflow. You can use this list to display the run status of each job in the graph itself. For downstream dependencies that are not yet run, this field is set to `null`. The graphed information makes you aware of the current state of any workflow at any point of time.

The dynamic view returned by this API is based on the static view that was present when the workflow run was started.

Runtime nodes example: `{name:T1, type: Trigger, uniqueId:1}`, `{name:J1, type:Job, uniqueId:2, jobDetails:{jobRuns}}`, `{name:C1, type:Crawler, uniqueId:3, crawlerDetails:{crawls}}`

Example 1: Dynamic view

The following example illustrates a simple two-trigger workflow.

- Nodes: t1, j1, t2, j2
- Edges: (t1, j1), (j1, t2), (t2, j2)

The `GetWorkflow` response contains the following.

```
{
    Nodes : [
        {
            "type" : Trigger,
            "name" : "t1",
            "uniqueId" : 1
        },
        {
            "type" : Job,
            "name" : "j1",
            "uniqueId" : 2
        },
        {
            "type" : Trigger,
            "name" : "t2",
            "uniqueId" : 3
        },
        {
            "type" : Job,
            "name" : "j2",
```

```
            "uniqueId" : 4
        }
    ],
    Edges : [
        {
            "sourceId" : 1,
            "destinationId" : 2
        },
        {
            "sourceId" : 2,
            "destinationId" : 3
        },
        {
            "sourceId" : 3,
            "destinationId" : 4
        }
}
```

The `GetWorkflowRun` response contains the following.

```
{
    Nodes : [
        {
            "type" : Trigger,
            "name" : "t1",
            "uniqueId" : 1,
            "jobDetails" : null,
            "crawlerDetails" : null
        },
        {
            "type" : Job,
            "name" : "j1",
            "uniqueId" : 2,
            "jobDetails" : [
                {
                    "id" : "jr_12334",
                    "jobRunState" : "SUCCEEDED",
                    "errorMessage" : "error string"
                }
            ],
            "crawlerDetails" : null
        },
        {
```

```
            "type" : Trigger,
            "name" : "t2",
            "uniqueId" : 3,
            "jobDetails" : null,
            "crawlerDetails" : null
        },
        {
            "type" : Job,
            "name" : "j2",
            "uniqueId" : 4,
            "jobDetails" : [
                {
                    "id" : "jr_1233sdf4",
                    "jobRunState" : "SUCCEEDED",
                    "errorMessage" : "error string"
                }
            ],
            "crawlerDetails" : null
        }
    ],
    Edges : [
        {
            "sourceId" : 1,
            "destinationId" : 2
        },
        {
            "sourceId" : 2,
            "destinationId" : 3
        },
        {
            "sourceId" : 3,
            "destinationId" : 4
        }
}
```

Example 2: Multiple jobs with a conditional trigger

The following example shows a workflow with multiple jobs and a conditional trigger (t3).

```
Consider Flow:
T(t1) ---> J(j1) ---> T(t2) ---> J(j2)
             |                    |
             |                    |
             >+------> T(t3) <-----+
```

```
                          |
                          |
                        J(j3)

Graph generated:
Nodes: t1, t2, t3, j1, j2, j3
Edges: (t1, j1), (j1, t2), (t2, j2), (j1, t3), (j2, t3), (t3, j3)
```

Blueprint and workflow restrictions in AWS Glue

The following are restrictions for blueprints and workflows.

Blueprint restrictions

Keep the following blueprint restrictions in mind:

- The blueprint must be registered in the same AWS Region where the Amazon S3 bucket resides in.
- To share blueprints across AWS accounts you must give read permissions on the blueprint ZIP archive in Amazon S3. Customers who have read permission on a blueprint ZIP archive can register the blueprint in their AWS account and use it.
- The set of blueprint parameters is stored as a single JSON object. The maximum length of this object is 128 KB.
- The maximum uncompressed size of the blueprint ZIP archive is 5 MB. The maximum compressed size is 1 MB.
- Limit the total number of jobs, crawlers, and triggers within a workflow to 100 or less. If you include more than 100, you might get errors when trying to resume or stop workflow runs.

Workflow restrictions

Keep the following workflow restrictions in mind. Some of these comments are directed more at a user creating workflows manually.

- The maximum batch size for an Amazon EventBridge event trigger is 100. The maximum window size is 900 seconds (15 minutes).
- A trigger can be associated with only one workflow.
- Only one starting trigger (on-demand or schedule) is permitted.

- If a job or crawler in a workflow is started by a trigger that is outside the workflow, any triggers inside the workflow that depend on job or crawler completion (succeeded or otherwise) do not fire.
- Similarly, if a job or crawler in a workflow has triggers that depend on job or crawler completion (succeeded or otherwise) both within the workflow and outside the workflow, and if the job or crawler is started from within a workflow, only the triggers inside the workflow fire upon job or crawler completion.

Troubleshooting blueprint errors in AWS Glue

If you encounter errors when using AWS Glue blueprints, use the following solutions to help you find the source of the problems and fix them.

Topics

- Error: missing PySpark module
- Error: missing blueprint config file
- Error: missing imported file
- Error: not authorized to perform iamPassRole on resource
- Error: invalid cron schedule
- Error: a trigger with the same name already exists
- Error: workflow with name: foo already exists.
- Error: module not found in specified layoutGenerator path
- Error: validation error in Connections field

Error: missing PySpark module

AWS Glue returns the error "Unknown error executing layout generator function ModuleNotFoundError: No module named 'pyspark'".

When you unzip the blueprint archive it could be like either of the following:

```
$ unzip compaction.zip
Archive:  compaction.zip
   creating: compaction/
  inflating: compaction/blueprint.cfg
  inflating: compaction/layout.py
```

```
  inflating: compaction/README.md
  inflating: compaction/compaction.py

$ unzip compaction.zip
Archive:  compaction.zip
  inflating: blueprint.cfg
  inflating: compaction.py
  inflating: layout.py
  inflating: README.md
```

In the first case, all the files related to the blueprint were placed under a folder named compaction and it was then converted into a zip file named *compaction.zip*.

In the second case, all the files required for the blueprint were not included into a folder and were added as root files under the zip file *compaction.zip*.

Creating a file in either of the above formats is allowed. However make sure that `blueprint.cfg` has the correct path to the name of the function in the script that generates the layout.

Examples

In case 1: `blueprint.cfg` should have `layoutGenerator` as the following:

```
layoutGenerator": "compaction.layout.generate_layout"
```

In case 2: `blueprint.cfg` should have `layoutGenerator` as the following

```
layoutGenerator": "layout.generate_layout"
```

If this path is not included correctly, you could see an error as indicated. For example, if you have the folder structure as mentioned in case 2 and you have the `layoutGenerator` indicated as in case 1, you can see the above error.

Error: missing blueprint config file

AWS Glue returns the error "Unknown error executing layout generator function FileNotFoundError: [Errno 2] No such file or directory: '/tmp/compaction/blueprint.cfg'".

The blueprint.cfg should be placed at the root level of the ZIP archive or within a folder which has the same name as the ZIP archive.

When we extract the blueprint ZIP archive, blueprint.cfg is expected to be found in one of the following paths. If it is not found in one of the following paths, you can see the above error.

```
$ unzip compaction.zip
Archive:  compaction.zip
   creating: compaction/
  inflating: compaction/blueprint.cfg

$ unzip compaction.zip
Archive:  compaction.zip
  inflating: blueprint.cfg
```

Error: missing imported file

AWS Glue returns the error "Unknown error executing layout generator function FileNotFoundError: [Errno 2] No such file or directory:* *'demo-project/foo.py'".

If your layout generation script has functionality to read other files, make sure you give a full path for the file to be imported. For example, the Conversion.py script may be referenced in Layout.py. For more information, see Sample blueprint Project.

Error: not authorized to perform iamPassRole on resource

AWS Glue returns the error "User: arn:aws:sts::123456789012:assumed-role/AWSGlueServiceRole/GlueSession is not authorized to perform: iam:PassRole on resource: arn:aws:iam::123456789012:role/AWSGlueServiceRole"

If the jobs and crawlers in the workflow assume the same role as the role passed to create workflow from the blueprint, then the blueprint role needs to include the `iam:PassRole` permission on itself.

If the jobs and crawlers in the workflow assume a role other than the role passed to create the entities of the workflow from the blueprint, then the blueprint role needs to include the `iam:PassRole` permission on that other role instead of on the blueprint role.

For more information, see Permissions for blueprint Roles.

Error: invalid cron schedule

AWS Glue returns the error "The schedule cron(0 0 * * * *) is invalid."

Provide a valid cron expression. For more information, see Time-Based Schedules for Jobs and Crawlers.

Error: a trigger with the same name already exists

AWS Glue returns the error "Trigger with name 'foo_starting_trigger' already submitted with different configuration".

A blueprint does not require you to define triggers in the layout script for workflow creation. Trigger creation is managed by the blueprint library based on the dependencies defined between two actions.

The naming for the triggers is as follows:

- For the starting trigger in the workflow the naming is <workflow_name>_starting_trigger.
- For a node(job/crawler) in the workflow that depends on the completion of either one or multiple upstream nodes; AWS Glue defines a trigger with the name <workflow_name>_<node_name>_trigger

This error means a trigger with same name already exists. You can delete the existing trigger and re-run the workflow creation.

> **Note**
>
> Deleting a workflow doesn't delete the nodes within the workflow. It is possible that though the workflow is deleted, triggers are left behind. Due to this, you may not receive a 'workflow already exists' error, but you may receive a 'trigger already exists' error in a case where you create a workflow, delete it and then try to re-create it with the same name from same blueprint.

Error: workflow with name: foo already exists.

The workflow name should be unique. Please try with a different name.

Error: module not found in specified layoutGenerator path

AWS Glue returns the error "Unknown error executing layout generator function ModuleNotFoundError: No module named 'crawl_s3_locations'".

```
layoutGenerator": "crawl_s3_locations.layout.generate_layout"
```

For example, if you have the above layoutGenerator path, then when you unzip the blueprint archive, it needs to look like the following:

```
$ unzip crawl_s3_locations.zip
Archive:  crawl_s3_locations.zip
   creating: crawl_s3_locations/
  inflating: crawl_s3_locations/blueprint.cfg
  inflating: crawl_s3_locations/layout.py
  inflating: crawl_s3_locations/README.md
```

When you unzip the archive, if the blueprint archive looks like the following, then you can get the above error.

```
$ unzip crawl_s3_locations.zip
Archive:  crawl_s3_locations.zip
  inflating: blueprint.cfg
  inflating: layout.py
  inflating: README.md
```

You can see that there is no folder named `crawl_s3_locations` and when the `layoutGenerator` path refers to the layout file via the module `crawl_s3_locations`, you can get the above error.

Error: validation error in Connections field

AWS Glue returns the error "Unknown error executing layout generator function TypeError: Value ['foo'] for key Connections should be of type <class 'dict'>!".

This is a validation error. The `Connections` field in the `Job` class is expecting a dictionary and instead a list of values are provided causing the error.

```
User input was list of values
Connections= ['string']

Should be a dict like the following
Connections*=*{'Connections': ['string']}
```

To avoid these run time errors while creating a workflow from a blueprint, you can validate the workflow, job and crawler definitions as outlined in Testing a blueprint.

Refer to the syntax in AWS Glue blueprint Classes Reference for defining the AWS Glue job, crawler and workflow in the layout script.

Permissions for personas and roles for AWS Glue blueprints

The following are the typical personas and suggested AWS Identity and Access Management (IAM) permissions policies for personas and roles for AWS Glue blueprints.

Topics

- Blueprint personas
- Permissions for blueprint personas
- Permissions for blueprint roles

Blueprint personas

The following are the personas typically involved in the lifecycle of AWS Glue blueprints.

Persona	Description
AWS Glue developer	Develops, tests, and publishes blueprints.
AWS Glue administrator	Registers, maintains, and grants permissions on blueprints.
Data analyst	Runs blueprints to create workflows.

For more information, see the section called “Overview of blueprints”.

Permissions for blueprint personas

The following are the suggested permissions for each blueprint persona.

AWS Glue developer permissions for blueprints

The AWS Glue developer must have write permissions on the Amazon S3 bucket that is used to publish the blueprint. Often, the developer registers the blueprint after uploading it. In that

case, the developer needs the permissions listed in the section called "AWS Glue administrator permissions for blueprints". Additionally, if the developer wishes to test the blueprint after its registered, he or she also needs the permissions listed in the section called "Data analyst permissions for blueprints".

AWS Glue administrator permissions for blueprints

The following policy grants permissions to register, view, and maintain AWS Glue blueprints.

> **Important**
>
> In the following policy, replace *<s3-bucket-name>* and *<prefix>* with the Amazon S3 path to uploaded blueprint ZIP archives to register.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:CreateBlueprint",
        "glue:UpdateBlueprint",
        "glue:DeleteBlueprint",
        "glue:GetBlueprint",
        "glue:ListBlueprints",
        "glue:BatchGetBlueprints"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject"
      ],
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/prefix/*"
    }
  ]
}
```

Data analyst permissions for blueprints

The following policy grants permissions to run blueprints and to view the resulting workflow and workflow components. It also grants `PassRole` on the role that AWS Glue assumes to create the workflow and workflow components.

The policy grants permissions on any resource. If you want to configure fine-grained access to individual blueprints, use the following format for blueprint ARNs:

```
arn:aws:glue:<region>:<account-id>:blueprint/<blueprint-name>
```

> **Important**
>
> In the following policy, replace *<account-id>* with a valid AWS account and replace *<role-name>* with the name of the role used to run a blueprint. See the section called "Permissions for blueprint roles" for the permissions that this role requires.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:ListBlueprints",
        "glue:GetBlueprint",
        "glue:StartBlueprintRun",
        "glue:GetBlueprintRun",
        "glue:GetBlueprintRuns",
        "glue:GetCrawler",
        "glue:ListTriggers",
        "glue:ListJobs",
        "glue:BatchGetCrawlers",
        "glue:GetTrigger",
        "glue:BatchGetWorkflows",
        "glue:BatchGetTriggers",
        "glue:BatchGetJobs",
        "glue:BatchGetBlueprints",
        "glue:GetWorkflowRun",
```

```
        "glue:GetWorkflowRuns",
        "glue:ListCrawlers",
        "glue:ListWorkflows",
        "glue:GetJob",
        "glue:GetWorkflow",
        "glue:StartWorkflowRun"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": "arn:aws:iam::111122223333:role/role-name"
    }
  ]
}
```

Permissions for blueprint roles

The following are the suggested permissions for the IAM role used to create a workflow from a blueprint. The role has to have a trust relationship with `glue.amazonaws.com`.

> **Important**
>
> In the following policy, replace *<account-id>* with a valid AWS account, and replace *<role-name>* with the name of the role.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:CreateJob",
        "glue:GetCrawler",
        "glue:GetTrigger",
        "glue:DeleteCrawler",
```

```
        "glue:CreateTrigger",
        "glue:DeleteTrigger",
        "glue:DeleteJob",
        "glue:CreateWorkflow",
        "glue:DeleteWorkflow",
        "glue:GetJob",
        "glue:GetWorkflow",
        "glue:CreateCrawler"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": "arn:aws:iam::111122223333:role/role-name"
    }
  ]
}
```

> **Note**
>
> If the jobs and crawlers in the workflow assume a role other than this role, this policy must include the `iam:PassRole` permission on that other role instead of on the blueprint role.

Developing blueprints in AWS Glue

Your organization might have a set of similar ETL use cases that could benefit from being able to parametrize a single workflow to handle them all. To address this need, AWS Glue enables you to define *blueprints*, which you can use to generate workflows. A blueprint accepts parameters, so that from a single blueprint, a data analyst can create different workflows to handle similar ETL use cases. After you create a blueprint, you can reuse it for different departments, teams, and projects.

Overview of blueprints in AWS Glue

> **Note**
>
> The blueprints feature is currently unavailable in the following Regions in the AWS Glue console: Asia Pacific (Jakarta) and Middle East (UAE).

AWS Glue blueprints provide a way to create and share AWS Glue workflows. When there is a complex ETL process that could be used for similar use cases, rather than creating an AWS Glue workflow for each use case, you can create a single blueprint.

The blueprint specifies the jobs and crawlers to include in a workflow, and specifies parameters that the workflow user supplies when they run the blueprint to create a workflow. The use of parameters enables a single blueprint to generate workflows for the various similar use cases. For more information about workflows, see Overview of workflows in AWS Glue.

The following are example use cases for blueprints:

- You want to partition an existing dataset. The input parameters to the blueprint are Amazon Simple Storage Service (Amazon S3) source and target paths and a list of partition columns.
- You want to snapshot an Amazon DynamoDB table into a SQL data store like Amazon Redshift. The input parameters to the blueprint are the DynamoDB table name and an AWS Glue connection, which designates an Amazon Redshift cluster and destination database.
- You want to convert CSV data in multiple Amazon S3 paths to Parquet. You want the AWS Glue workflow to include a separate crawler and job for each path. The input parameters are the destination database in the AWS Glue Data Catalog and a comma-delimited list of Amazon S3 paths. Note that in this case, the number of crawlers and jobs that the workflow creates is variable.

Blueprint components

A blueprint is a ZIP archive that contains the following components:

- A Python layout generator script

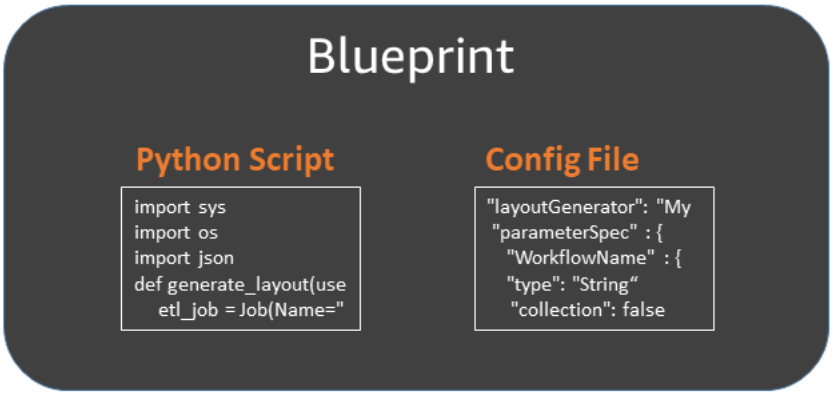
  Contains a function that specifies the workflow *layout*—the crawlers and jobs to create for the workflow, the job and crawler properties, and the dependencies between the jobs and crawlers. The function accepts blueprint parameters and returns a workflow structure (JSON object) that AWS Glue uses to generate the workflow. Because you use a Python script to generate the workflow, you can add your own logic that is suitable for your use cases.

- A configuration file

  Specifies the fully qualified name of the Python function that generates the workflow layout. Also specifies the names, data types, and other properties of all blueprint parameters used by the script.

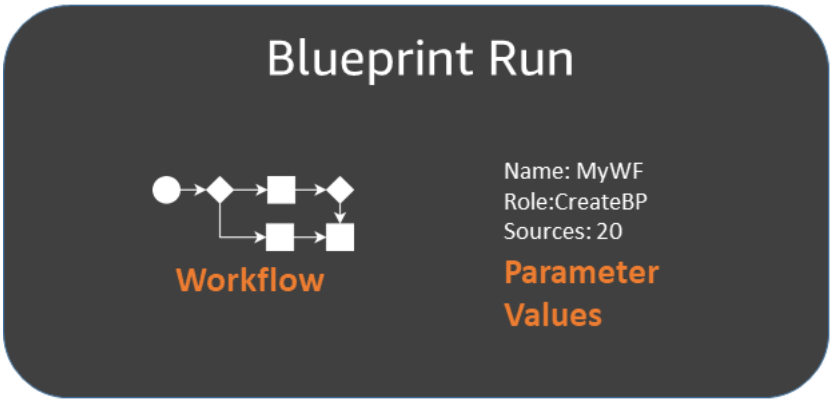
- (Optional) ETL scripts and supporting files

  As an advanced use case, you can parameterize the location of the ETL scripts that your jobs use. You can include job script files in the ZIP archive and specify a blueprint parameter for an Amazon S3 location where the scripts are to be copied to. The layout generator script can copy the ETL scripts to the designated location and specify that location as the job script location property. You can also include any libraries or other supporting files, provided that your script handles them.



Blueprint runs

When you create a workflow from a blueprint, AWS Glue runs the blueprint, which starts an asynchronous process to create the workflow and the jobs, crawlers, and triggers that the workflow encapsulates. AWS Glue uses the blueprint run to orchestrate the creation of the workflow and its components. You view the status of the creation process by viewing the blueprint run status. The blueprint run also stores the values that you supplied for the blueprint parameters.



You can view blueprint runs using the AWS Glue console or AWS Command Line Interface (AWS CLI). When viewing or troubleshooting a workflow, you can always return to the blueprint run to view the blueprint parameter values that were used to create the workflow.

Lifecycle of a blueprint

blueprints are developed, tested, registered with AWS Glue, and run to create workflows. There are typically three personas involved in the blueprint lifecycle.

Persona	Tasks
AWS Glue developer	• Writes the workflow layout script and creates the configuration file. • Tests the blueprint locally using libraries provided by the AWS Glue service. • Creates a ZIP archive of the script, configuration file, and supporting files and publishes the archive to a location in Amazon S3. • Adds a bucket policy to the Amazon S3 bucket that grants read permissions on bucket objects to the AWS Glue administrator's AWS account. • Grants IAM read permissions on the ZIP archive in Amazon S3 to the AWS Glue administrator.
AWS Glue administrator	• *Registers* the blueprint with AWS Glue. AWS Glue makes a copy of the ZIP archive into a reserved Amazon S3 location.

Persona	Tasks
	• Grants IAM permissions on the blueprint to data analysts.
Data analyst	• Runs the blueprint to create a workflow, and provides blueprint parameter values. Checks the blueprint run status to ensure that the workflow and workflow components were successfully generated. • Runs and troubleshoots the workflow. Before running the workflow, can verify the workflow by viewing the workflow design graph on the AWS Glue console.

Overview of developing blueprints

The first step in your development process is to identify a common use case that would benefit from a blueprint. A typical use case involves a recurring ETL problem that you believe should be solved in a general manner. Next, design a blueprint that implements the generalized use case, and define the blueprint input parameters that together can define a specific use case from the generalized use case.

A blueprint consists of a project that contains a blueprint parameter configuration file and a script that defines the *layout* of the workflow to generate. The layout defines the jobs and crawlers (or *entities* in blueprint script terminology) to create.

You do not directly specify any triggers in the layout script. Instead you write code to specify the dependencies between the jobs and crawlers that the script creates. AWS Glue generates the triggers based on your dependency specifications. The output of the layout script is a workflow object, which contains specifications for all workflow entities.

You build your workflow object using the following AWS Glue blueprint libraries:

- `awsglue.blueprint.base_resource` – A library of base resources used by the libraries.
- `awsglue.blueprint.workflow` – A library for defining a `Workflow` class.
- `awsglue.blueprint.job` – A library for defining a `Job` class.
- `awsglue.blueprint.crawler` – A library for defining a `Crawler` class.

The only other libraries that are supported for layout generation are those libraries that are available for the Python shell.

Before publishing your blueprint, you can use methods defined in the blueprint libraries to test the blueprint locally.

When you're ready to make the blueprint available to data analysts, you package the script, the parameter configuration file, and any supporting files, such as additional scripts and libraries, into

a single deployable asset. You then upload the asset to Amazon S3 and ask an administrator to register it with AWS Glue.

For information about more sample blueprint projects, see Sample blueprint project and Blueprint samples.

Prerequisites for developing blueprints

To develop blueprints, you should be familiar with using AWS Glue and writing scripts for Apache Spark ETL jobs or Python shell jobs. In addition, you must complete the following setup tasks.

- Download four AWS Python libraries to use in your blueprint layout scripts.
- Set up the AWS SDKs.
- Set up the AWS CLI.

Download the Python libraries

Download the following libraries from GitHub, and install them into your project:

- https://github.com/awslabs/aws-glue-blueprint-libs/tree/master/awsglue/blueprint/base_resource.py
- https://github.com/awslabs/aws-glue-blueprint-libs/tree/master/awsglue/blueprint/workflow.py
- https://github.com/awslabs/aws-glue-blueprint-libs/tree/master/awsglue/blueprint/crawler.py
- https://github.com/awslabs/aws-glue-blueprint-libs/tree/master/awsglue/blueprint/job.py

Set up the AWS Java SDK

For the AWS Java SDK, you must add a `jar` file that includes the API for blueprints.

1. If you haven't already done so, set up the AWS SDK for Java.
   - For Java 1.x, follow the instructions in Set up the AWS SDK for Java in the *AWS SDK for Java Developer Guide*.
   - For Java 2.x, follow the instructions in Setting up the AWS SDK for Java 2.x in the *AWS SDK for Java 2.x Developer Guide*.
2. Download the client `jar` file that has access to the APIs for blueprints.

- For Java 1.x: s3://awsglue-custom-blueprints-preview-artifacts/awsglue-java-sdk-preview/AWSGlueJavaClient-1.11.x.jar
- For Java 2.x: s3://awsglue-custom-blueprints-preview-artifacts/awsglue-java-sdk-v2-preview/AwsJavaSdk-Glue-2.0.jar

3. Add the client `jar` to the front of the Java classpath to override the AWS Glue client provided by the AWS Java SDK.

```
export CLASSPATH=<path-to-preview-client-jar>:$CLASSPATH
```

4. (Optional) Test the SDK with the following Java application. The application should output an empty list.

   Replace `accessKey` and `secretKey` with your credentials, and replace `us-east-1` with your Region.

```
import com.amazonaws.auth.AWSCredentials;
import com.amazonaws.auth.AWSCredentialsProvider;
import com.amazonaws.auth.AWSStaticCredentialsProvider;
import com.amazonaws.auth.BasicAWSCredentials;
import com.amazonaws.services.glue.AWSGlue;
import com.amazonaws.services.glue.AWSGlueClientBuilder;
import com.amazonaws.services.glue.model.ListBlueprintsRequest;

public class App{
    public static void main(String[] args) {
        AWSCredentials credentials = new BasicAWSCredentials("accessKey",
 "secretKey");
        AWSCredentialsProvider provider = new
 AWSStaticCredentialsProvider(credentials);
        AWSGlue glue = AWSGlueClientBuilder.standard().withCredentials(provider)
                .withRegion("us-east-1").build();
        ListBlueprintsRequest request = new
 ListBlueprintsRequest().withMaxResults(2);
        System.out.println(glue.listBlueprints(request));
    }
}
```

Set up the AWS Python SDK

The following steps assume that you have Python version 2.7 or later, or version 3.9 or later installed on your computer.

1. Download the following boto3 wheel file. If prompted to open or save, save the file. s3://awsglue-custom-blueprints-preview-artifacts/aws-python-sdk-preview/boto3-1.17.31-py2.py3-none-any.whl
2. Download the following botocore wheel file: s3://awsglue-custom-blueprints-preview-artifacts/aws-python-sdk-preview/botocore-1.20.31-py2.py3-none-any.whl
3. Check your Python version.

   ```
   python --version
   ```

4. Depending on your Python version, enter the following commands (for Linux):

   - For Python 2.7 or later.

     ```
     python3 -m pip install --user virtualenv
     source env/bin/activate
     ```

   - For Python 3.9 or later.

     ```
     python3 -m venv python-sdk-test
     source python-sdk-test/bin/activate
     ```

5. Install the botocore wheel file.

   ```
   python3 -m pip install <download-directory>/botocore-1.20.31-py2.py3-none-any.whl
   ```

6. Install the boto3 wheel file.

   ```
   python3 -m pip install <download-directory>/boto3-1.17.31-py2.py3-none-any.whl
   ```

7. Configure your credentials and default region in the `~/.aws/credentials` and `~/.aws/config` files. For more information, see Configuring the AWS CLI in the *AWS Command Line Interface User Guide*.
8. (Optional) Test your setup. The following commands should return an empty list.

   Replace `us-east-1` with your Region.

```
$ python
>>> import boto3
>>> glue = boto3.client('glue', 'us-east-1')
>>> glue.list_blueprints()
```

Set up the preview AWS CLI

1. If you haven't already done so, install and/or update the AWS Command Line Interface (AWS CLI) on your computer. The easiest way to do this is with `pip`, the Python installer utility:

   ```
   pip install awscli --upgrade --user
   ```

   You can find complete installation instructions for the AWS CLI here: Installing the AWS Command Line Interface.
2. Download the AWS CLI wheel file from: s3://awsglue-custom-blueprints-preview-artifacts/awscli-preview-build/awscli-1.19.31-py2.py3-none-any.whl
3. Install the AWS CLI wheel file.

   ```
   python3 -m pip install awscli-1.19.31-py2.py3-none-any.whl
   ```
4. Run the `aws configure` command. Configure your AWS credentials (including access key, and secret key) and AWS Region. You can find information on configuring the AWS CLI here: Configuring the AWS CLI.
5. Test the AWS CLI. The following command should return an empty list.

   Replace `us-east-1` with your Region.

   ```
   aws glue list-blueprints --region us-east-1
   ```

Writing the blueprint code

Each blueprint project that you create must contain at a minimum the following files:

- A Python layout script that defines the workflow. The script contains a function that defines the entities (jobs and crawlers) in a workflow, and the dependencies between them.
- A configuration file, `blueprint.cfg`, which defines:

- The full path of the workflow layout definition function.
- The parameters that the blueprint accepts.

Topics

- Creating the blueprint layout script
- Creating the configuration file
- Specifying blueprint parameters

Creating the blueprint layout script

The blueprint layout script must include a function that generates the entities in your workflow. You can name this function whatever you like. AWS Glue uses the configuration file to determine the fully qualified name of the function.

Your layout function does the following:

- (Optional) Instantiates the `Job` class to create `Job` objects, and passes arguments such as `Command` and `Role`. These are job properties that you would specify if you were creating the job using the AWS Glue console or API.
- (Optional) Instantiates the `Crawler` class to create `Crawler` objects, and passes name, role, and target arguments.
- To indicate dependencies between the objects (workflow entities), passes the `DependsOn` and `WaitForDependencies` additional arguments to `Job()` and `Crawler()`. These arguments are explained later in this section.
- Instantiates the `Workflow` class to create the workflow object that is returned to AWS Glue, passing a `Name` argument, an `Entities` argument, and an optional `OnSchedule` argument. The `Entities` argument specifies all of the jobs and crawlers to include in the workflow. To see how to construct an `Entities` object, see the sample project later in this section.
- Returns the `Workflow` object.

For definitions of the `Job`, `Crawler`, and `Workflow` classes, see AWS Glue blueprint classes reference.

The layout function must accept the following input arguments.

Argument	Description
`user_params`	Python dictionary of blueprint parameter names and values. For more information, see Specifying blueprint parameters.
`system_params`	Python dictionary containing two properties: `region` and `accountId` .

Here is a sample layout generator script in a file named `Layout.py`:

```
import argparse
import sys
import os
import json
from awsglue.blueprint.workflow import *
from awsglue.blueprint.job import *
from awsglue.blueprint.crawler import *

def generate_layout(user_params, system_params):

    etl_job = Job(Name="{}_etl_job".format(user_params['WorkflowName']),
                  Command={
                      "Name": "glueetl",
                      "ScriptLocation": user_params['ScriptLocation'],
                      "PythonVersion": "2"
                  },
                  Role=user_params['PassRole'])
    post_process_job = Job(Name="{}_post_process".format(user_params['WorkflowName']),
                           Command={
                               "Name": "pythonshell",
                               "ScriptLocation": user_params['ScriptLocation'],
                               "PythonVersion": "2"
                           },
                           Role=user_params['PassRole'],
                           DependsOn={
                               etl_job: "SUCCEEDED"
                           },
                           WaitForDependencies="AND")
    sample_workflow = Workflow(Name=user_params['WorkflowName'],
                           Entities=Entities(Jobs=[etl_job, post_process_job]))
```

```
    return sample_workflow
```

The sample script imports the required blueprint libraries and includes a `generate_layout` function that generates a workflow with two jobs. This is a very simple script. A more complex script could employ additional logic and parameters to generate a workflow with many jobs and crawlers, or even a variable number of jobs and crawlers.

Using the DependsOn argument

The `DependsOn` argument is a dictionary representation of a dependency that this entity has on other entities within the workflow. It has the following form.

```
DependsOn = {dependency1 : state, dependency2 : state, ...}
```

The keys in this dictionary represent the object reference, not the name, of the entity, while the values are strings that correspond to the state to watch for. AWS Glue infers the proper triggers. For the valid states, see Condition Structure.

For example, a job might depend on the successful completion of a crawler. If you define a crawler object named `crawler2` as follows:

```
crawler2 = Crawler(Name="my_crawler", ...)
```

Then an object depending on `crawler2` would include a constructor argument such as:

```
DependsOn = {crawler2 : "SUCCEEDED"}
```

For example:

```
job1 = Job(Name="Job1", ..., DependsOn = {crawler2 : "SUCCEEDED", ...})
```

If `DependsOn` is omitted for an entity, that entity depends on the workflow start trigger.

Using the WaitForDependencies argument

The `WaitForDependencies` argument defines whether a job or crawler entity should wait until *all* entities on which it depends complete or until *any* completes.

The allowable values are "AND" or "ANY".

Using the OnSchedule argument

The `OnSchedule` argument for the `Workflow` class constructor is a `cron` expression that defines the starting trigger definition for a workflow.

If this argument is specified, AWS Glue creates a schedule trigger with the corresponding schedule. If it isn't specified, the starting trigger for the workflow is an on-demand trigger.

Creating the configuration file

The blueprint configuration file is a required file that defines the script entry point for generating the workflow, and the parameters that the blueprint accepts. The file must be named `blueprint.cfg`.

Here is a sample configuration file.

```
{
    "layoutGenerator": "DemoBlueprintProject.Layout.generate_layout",
    "parameterSpec" : {
           "WorkflowName" : {
                "type": "String",
                "collection": false
           },
           "WorkerType" : {
                "type": "String",
                "collection": false,
                "allowedValues": ["G1.X", "G2.X"],
                "defaultValue": "G1.X"
           },
           "Dpu" : {
                "type" : "Integer",
                "allowedValues" : [2, 4, 6],
                "defaultValue" : 2
           },
           "DynamoDBTableName": {
                "type": "String",
                "collection" : false
           },
           "ScriptLocation" : {
                "type": "String",
                "collection": false
```

```
     }
    }
}
```

The `layoutGenerator` property specifies the fully qualified name of the function in the script that generates the layout.

The `parameterSpec` property specifies the parameters that this blueprint accepts. For more information, see Specifying blueprint parameters.

> **Important**
>
> Your configuration file must include the workflow name as a blueprint parameter, or you must generate a unique workflow name in your layout script.

Specifying blueprint parameters

The configuration file contains blueprint parameter specifications in a `parameterSpec` JSON object. `parameterSpec` contains one or more parameter objects.

```
"parameterSpec": {
    "<parameter_name>": {
      "type": "<parameter-type>",
      "collection": true|false,
      "description": "<parameter-description>",
      "defaultValue": "<default value for the parameter if value not specified>"
      "allowedValues": "<list of allowed values>"
    },
    "<parameter_name>": {
       ...
    }
  }
```

The following are the rules for coding each parameter object:

- The parameter name and `type` are mandatory. All other properties are optional.
- If you specify the `defaultValue` property, the parameter is optional. Otherwise the parameter is mandatory and the data analyst who is creating a workflow from the blueprint must provide a value for it.

- If you set the `collection` property to `true`, the parameter can take a collection of values. Collections can be of any data type.
- If you specify `allowedValues`, the AWS Glue console displays a dropdown list of values for the data analyst to choose from when creating a workflow from the blueprint.

The following are the permitted values for `type`:

Parameter data type	Notes
`String`	-
`Integer`	-
`Double`	-
`Boolean`	Possible values are `true` and `false`. Generates a check box on the **Create a workflow from <blueprint>** page on the AWS Glue console.
`S3Uri`	Complete Amazon S3 path, beginning with `s3://`. Generates a text field and **Browse** button on the **Create a workflow from <blueprint>** page.
`S3Bucket`	Amazon S3 bucket name only. Generates a bucket picker on the **Create a workflow from <blueprint>** page.
`IAMRoleArn`	Amazon Resource Name (ARN) of an AWS Identity and Access Management (IAM) role. Generates a role picker on the **Create a workflow from <blueprint>** page.
`IAMRoleName`	Name of an IAM role. Generates a role picker on the **Create a workflow from <blueprint>** page.

Sample blueprint project

Data format conversion is a frequent extract, transform, and load (ETL) use case. In typical analytic workloads, column-based file formats like Parquet or ORC are preferred over text formats like CSV or JSON. This sample blueprint enables you to convert data from CSV/JSON/etc. into Parquet for files on Amazon S3.

This blueprint takes a list of S3 paths defined by a blueprint parameter, converts the data to Parquet format, and writes it to the S3 location specified by another blueprint parameter. The layout script creates a crawler and job for each path. The layout script also uploads the ETL script in `Conversion.py` to an S3 bucket specified by another blueprint parameter. The layout script then specifies the uploaded script as the ETL script for each job. The ZIP archive for the project contains the layout script, the ETL script, and the blueprint configuration file.

For information about more sample blueprint projects, see Blueprint samples.

The following is the layout script, in the file `Layout.py`.

```
from awsglue.blueprint.workflow import *
from awsglue.blueprint.job import *
from awsglue.blueprint.crawler import *
import boto3

s3_client = boto3.client('s3')

# Ingesting all the S3 paths as Glue table in parquet format
def generate_layout(user_params, system_params):
    #Always give the full path for the file
    with open("ConversionBlueprint/Conversion.py", "rb") as f:
        s3_client.upload_fileobj(f, user_params['ScriptsBucket'], "Conversion.py")
    etlScriptLocation = "s3://{}/Conversion.py".format(user_params['ScriptsBucket'])

    crawlers = []
    jobs = []
    workflowName = user_params['WorkflowName']
    for path in user_params['S3Paths']:
      tablePrefix = "source_"
      crawler = Crawler(Name="{}_crawler".format(workflowName),
                        Role=user_params['PassRole'],
                        DatabaseName=user_params['TargetDatabase'],
                        TablePrefix=tablePrefix,
                        Targets= {"S3Targets": [{"Path": path}]})
      crawlers.append(crawler)
      transform_job = Job(Name="{}_transform_job".format(workflowName),
                          Command={"Name": "glueetl",
                                   "ScriptLocation": etlScriptLocation,
                                   "PythonVersion": "3"},
                          Role=user_params['PassRole'],
                          DefaultArguments={"--database_name":
 user_params['TargetDatabase'],
```

```
                                            "--table_prefix": tablePrefix,
                                            "--region_name": system_params['region'],
                                            "--output_path":
 user_params['TargetS3Location']},
                         DependsOn={crawler: "SUCCEEDED"},
                         WaitForDependencies="AND")
      jobs.append(transform_job)
    conversion_workflow = Workflow(Name=workflowName, Entities=Entities(Jobs=jobs,
 Crawlers=crawlers))
    return conversion_workflow
```

The following is the corresponding blueprint configuration file `blueprint.cfg`.

```
{
    "layoutGenerator": "ConversionBlueprint.Layout.generate_layout",
    "parameterSpec" : {
        "WorkflowName" : {
            "type": "String",
            "collection": false,
            "description": "Name for the workflow."
        },
        "S3Paths" : {
            "type": "S3Uri",
            "collection": true,
            "description": "List of Amazon S3 paths for data ingestion."
        },
        "PassRole" : {
            "type": "IAMRoleName",
            "collection": false,
            "description": "Choose an IAM role to be used in running the job/crawler"
        },
        "TargetDatabase": {
            "type": "String",
            "collection" : false,
            "description": "Choose a database in the Data Catalog."
        },
        "TargetS3Location": {
            "type": "S3Uri",
            "collection" : false,
            "description": "Choose an Amazon S3 output path: ex:s3://<target_path>/."
        },
        "ScriptsBucket": {
            "type": "S3Bucket",
```

```
            "collection": false,
            "description": "Provide an S3 bucket name(in the same AWS Region) to store
 the scripts."
        }
    }
}
```

The following script in the file `Conversion.py` is the uploaded ETL script. Note that it preserves the partitioning scheme during conversion.

```
import sys
from pyspark.sql.functions import *
from pyspark.context import SparkContext
from awsglue.transforms import *
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions
import boto3

args = getResolvedOptions(sys.argv, [
    'JOB_NAME',
    'region_name',
    'database_name',
    'table_prefix',
    'output_path'])
databaseName = args['database_name']
tablePrefix = args['table_prefix']
outputPath = args['output_path']

glue = boto3.client('glue', region_name=args['region_name'])

glue_context = GlueContext(SparkContext.getOrCreate())
spark = glue_context.spark_session
job = Job(glue_context)
job.init(args['JOB_NAME'], args)

def get_tables(database_name, table_prefix):
    tables = []
    paginator = glue.get_paginator('get_tables')
    for page in paginator.paginate(DatabaseName=database_name, Expression=table_prefix
+"*"):
        tables.extend(page['TableList'])
    return tables
```

```
for table in get_tables(databaseName, tablePrefix):
    tableName = table['Name']
    partitionList = table['PartitionKeys']
    partitionKeys = []
    for partition in partitionList:
        partitionKeys.append(partition['Name'])

    # Create DynamicFrame from Catalog
    dyf = glue_context.create_dynamic_frame.from_catalog(
        name_space=databaseName,
        table_name=tableName,
        additional_options={
            'useS3ListImplementation': True
        },
        transformation_ctx='dyf'
    )

    # Resolve choice type with make_struct
    dyf = ResolveChoice.apply(
        frame=dyf,
        choice='make_struct',
        transformation_ctx='resolvechoice_' + tableName
    )

    # Drop null fields
    dyf = DropNullFields.apply(
        frame=dyf,
        transformation_ctx="dropnullfields_" + tableName
    )

    # Write DynamicFrame to S3 in glueparquet
    sink = glue_context.getSink(
        connection_type="s3",
        path=outputPath,
        enableUpdateCatalog=True,
        partitionKeys=partitionKeys
    )
    sink.setFormat("glueparquet")

    sink.setCatalogInfo(
        catalogDatabase=databaseName,
        catalogTableName=tableName[len(tablePrefix):]
    )
```

```
    sink.writeFrame(dyf)

job.commit()
```

> **Note**
>
> Only two Amazon S3 paths can be supplied as an input to the sample blueprint. This is because AWS Glue triggers are limited to invoking only two crawler actions.

Testing a blueprint

While you develop your code, you should perform local testing to verify that the workflow layout is correct.

Local testing doesn't generate AWS Glue jobs, crawlers, or triggers. Instead, you run the layout script locally and use the `to_json()` and `validate()` methods to print objects and find errors. These methods are available in all three classes defined in the libraries.

There are two ways to handle the `user_params` and `system_params` arguments that AWS Glue passes to your layout function. Your test-bench code can create a dictionary of sample blueprint parameter values and pass that to the layout function as the `user_params` argument. Or, you can remove the references to `user_params` and replace them with hardcoded strings.

If your code makes use of the `region` and `accountId` properties in the `system_params` argument, you can pass in your own dictionary for `system_params`.

To test a blueprint

1. Start a Python interpreter in a directory with the libraries, or load the blueprint files and the supplied libraries into your preferred integrated development environment (IDE).
2. Ensure that your code imports the supplied libraries.
3. Add code to your layout function to call `validate()` or `to_json()` on any entity or on the `Workflow` object. For example, if your code creates a `Crawler` object named `mycrawler`, you can call `validate()` as follows.

   ```
   mycrawler.validate()
   ```

   You can print `mycrawler` as follows:

```
print(mycrawler.to_json())
```

If you call `to_json` on an object, there is no need to also call `validate()`, because `to_json()` calls `validate()`.

It is most useful to call these methods on the workflow object. Assuming that your script names the workflow object `my_workflow`, validate and print the workflow object as follows.

```
print(my_workflow.to_json())
```

For more information about `to_json()` and `validate()`, see Class methods.

You can also import `pprint` and pretty-print the workflow object, as shown in the example later in this section.

4. Run the code, fix errors, and finally remove any calls to `validate()` or `to_json()`.

Example

The following example shows how to construct a dictionary of sample blueprint parameters and pass it in as the `user_params` argument to layout function `generate_compaction_workflow`. It also shows how to pretty-print the generated workflow object.

```
from pprint import pprint
from awsglue.blueprint.workflow import *
from awsglue.blueprint.job import *
from awsglue.blueprint.crawler import *

USER_PARAMS = {"WorkflowName": "compaction_workflow",
               "ScriptLocation": "s3://amzn-s3-demo-bucket/scripts/threaded-
compaction.py",
               "PassRole": "arn:aws:iam::111122223333:role/GlueRole-ETL",
               "DatabaseName": "cloudtrial",
               "TableName": "ct_cloudtrail",
               "CoalesceFactor": 4,
               "MaxThreadWorkers": 200}

def generate_compaction_workflow(user_params: dict, system_params: dict) -> Workflow:
    compaction_job = Job(Name=f"{user_params['WorkflowName']}_etl_job",
```

```
                        Command={"Name": "glueetl",
                                 "ScriptLocation": user_params['ScriptLocation'],
                                 "PythonVersion": "3"},
                        Role="arn:aws:iam::111122223333:role/
AWSGlueServiceRoleDefault",
                        DefaultArguments={"DatabaseName": user_params['DatabaseName'],
                                          "TableName": user_params['TableName'],
                                          "CoalesceFactor":
 user_params['CoalesceFactor'],
                                          "max_thread_workers":
 user_params['MaxThreadWorkers']})

    catalog_target = {"CatalogTargets": [{"DatabaseName": user_params['DatabaseName'],
 "Tables": [user_params['TableName']]}]}

    compacted_files_crawler = Crawler(Name=f"{user_params['WorkflowName']}_post_crawl",
                                      Targets = catalog_target,
                                      Role=user_params['PassRole'],
                                      DependsOn={compaction_job: "SUCCEEDED"},
                                      WaitForDependencies="AND",
                                      SchemaChangePolicy={"DeleteBehavior": "LOG"})

    compaction_workflow = Workflow(Name=user_params['WorkflowName'],
                                   Entities=Entities(Jobs=[compaction_job],

 Crawlers=[compacted_files_crawler]))
    return compaction_workflow

generated = generate_compaction_workflow(user_params=USER_PARAMS, system_params={})
gen_dict = generated.to_json()

pprint(gen_dict)
```

Publishing a blueprint

After you develop a blueprint, you must upload it to Amazon S3. You must have write permissions on the Amazon S3 bucket that you use to publish the blueprint. You must also make sure that the AWS Glue administrator, who will register the blueprint, has read access to the Amazon S3 bucket. For the suggested AWS Identity and Access Management (IAM) permissions policies for personas and roles for AWS Glue blueprints, see Permissions for personas and roles for AWS Glue blueprints.

To publish a blueprint

1. Create the necessary scripts, resources, and blueprint configuration file.
2. Add all files to a ZIP archive and upload the ZIP file to Amazon S3. Use an S3 bucket that is in the same Region as the Region in which users will register and run the blueprint.

   You can create a ZIP file from the command line using the following command.

   ```
   zip -r folder.zip folder
   ```

3. Add a bucket policy that grants read permissions to the AWS desired account. The following is a sample policy.

   JSON

   ```
   {
     "Version":"2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
           "AWS": "arn:aws:iam::111122223333:root"
         },
         "Action": "s3:GetObject",
         "Resource": "arn:aws:s3:::my-blueprints/*"
       }
     ]
   }
   ```

4. Grant the IAM `s3:GetObject` permission on the Amazon S3 bucket to the AWS Glue administrator or to whoever will be registering blueprints. For a sample policy to grant to administrators, see AWS Glue administrator permissions for blueprints.

After you have completed local testing of your blueprint, you may also want to test a blueprint on AWS Glue. To test a blueprint on AWS Glue, it must be registered. You can limit who sees the registered blueprint using IAM authorization, or by using separate testing accounts.

AWS Glue blueprint classes reference

The libraries for AWS Glue blueprints define three classes that you use in your workflow layout script: `Job`, `Crawler`, and `Workflow`.

Topics

- Job class
- Crawler class
- Workflow class
- Class methods

Job class

The `Job` class represents an AWS Glue ETL job.

Mandatory constructor arguments

The following are mandatory constructor arguments for the `Job` class.

Argument name	Type	Description
`Name`	`str`	Name to assign to the job. AWS Glue adds a randomly generated suffix to the name to distinguish the job from those created by other blueprint runs.
`Role`	`str`	Amazon Resource Name (ARN) of the role that the job should assume while executing.
`Command`	`dict`	Job command, as specified in the JobCommand structure in the API documentation.

Optional constructor arguments

The following are optional constructor arguments for the `Job` class.

Argument name	Type	Description
`DependsOn`	`dict`	List of workflow entities that the job depends on. For more information, see Using the DependsOn argument.
`WaitForDependencies`	`str`	Indicates whether the job should wait until *all* entities on which it depends complete before executing or until *any* completes. For more information, see Using the WaitForDependencies argument. Omit if the job depends on only one entity.
(Job properties)	-	Any of the job properties listed in Job structure in the AWS Glue API documentation (except `CreatedOn` and `LastModifiedOn`).

Crawler class

The `Crawler` class represents an AWS Glue crawler.

Mandatory constructor arguments

The following are mandatory constructor arguments for the `Crawler` class.

Argument name	Type	Description
`Name`	`str`	Name to assign to the crawler. AWS Glue adds a randomly generated suffix to the name to distinguish the crawler from those created by other blueprint runs.
`Role`	`str`	ARN of the role that the crawler should assume while running.

Argument name	Type	Description
`Targets`	`dict`	Collection of targets to crawl. `Targets` class constructor arguments are defined in the CrawlerTargets structure in the API documentation. All `Targets` constructor arguments are optional, but you must pass at least one.

Optional constructor arguments

The following are optional constructor arguments for the `Crawler` class.

Argument name	Type	Description
`DependsOn`	`dict`	List of workflow entities that the crawler depends on. For more information, see Using the DependsOn argument.
`WaitForDependencies`	`str`	Indicates whether the crawler should wait until *all* entities on which it depends complete before running or until *any* completes. For more information, see Using the WaitForDependencies argument. Omit if the crawler depends on only one entity.
(Crawler properties)	-	Any of the crawler properties listed in Crawler structure in the AWS Glue API documentation, with the following exceptions: • `State` • `CrawlElapsedTime` • `CreationTime` • `LastUpdated` • `LastCrawl` • `Version`

Workflow class

The `Workflow` class represents an AWS Glue workflow. The workflow layout script returns a `Workflow` object. AWS Glue creates a workflow based on this object.

Mandatory constructor arguments

The following are mandatory constructor arguments for the `Workflow` class.

Argument name	Type	Description
`Name`	`str`	Name to assign to the workflow.
`Entities`	`Entities`	A collection of entities (jobs and crawlers) to include in the workflow. The `Entities` class constructor accepts a `Jobs` argument, which is a list of `Job` objects, and a `Crawlers` argument, which is a list of `Crawler` objects.

Optional constructor arguments

The following are optional constructor arguments for the `Workflow` class.

Argument name	Type	Description
`Description`	`str`	See Workflow structure.
`DefaultRunProperties`	`dict`	See Workflow structure.
`OnSchedule`	`str`	A `cron` expression.

Class methods

All three classes include the following methods.

validate()

Validates the properties of the object and if errors are found, outputs a message and exits. Generates no output if there are no errors. For the `Workflow` class, calls itself on every entity in the workflow.

to_json()

Serializes the object to JSON. Also calls `validate()`. For the `Workflow` class, the JSON object includes job and crawler lists, and a list of triggers generated by the job and crawler dependency specifications.

Blueprint samples

There are a number of sample blueprint projects available on the AWS Glue blueprint Github repository. These samples are for reference only and are not intended for production use.

The titles of the sample projects are:

- Compaction: this blueprint creates a job that compacts input files into larger chunks based on desired file size.
- Conversion: this blueprint converts input files in various standard file formats into Apache Parquet format, which is optimized for analytic workloads.
- Crawling Amazon S3 locations: this blueprint crawls multiple Amazon S3 locations to add metadata tables to the Data Catalog.
- Custom connection to Data Catalog: this blueprint accesses data stores using AWS Glue custom connectors, reads the records, and populates the table definitions in the AWS Glue Data Catalog based on the record schema.
- Encoding: this blueprint converts your non-UTF files into UTF encoded files.
- Partitioning: this blueprint creates a partitioning job that places output files into partitions based on specific partition keys.
- Importing Amazon S3 data into a DynamoDB table: this blueprint imports data from Amazon S3 into a DynamoDB table.
- Standard table to governed: this blueprint imports an AWS Glue Data Catalog table into a Lake Formation table.

Registering a blueprint in AWS Glue

After the AWS Glue developer has coded the blueprint and uploaded a ZIP archive to Amazon Simple Storage Service (Amazon S3), an AWS Glue administrator must register the blueprint. Registering the blueprint makes it available for use.

When you register a blueprint, AWS Glue copies the blueprint archive to a reserved Amazon S3 location. You can then delete the archive from the upload location.

To register a blueprint, you need read permissions on the Amazon S3 location that contains the uploaded archive. You also need the AWS Identity and Access Management (IAM) permission `glue:CreateBlueprint`. For the suggested permissions for an AWS Glue administrator who must register, view, and maintain blueprints, see AWS Glue administrator permissions for blueprints.

You can register a blueprint by using the AWS Glue console, AWS Glue API, or AWS Command Line Interface (AWS CLI).

To register a blueprint (console)

1. Ensure that you have read permissions (`s3:GetObject`) on the blueprint ZIP archive in Amazon S3.
2. Open the AWS Glue console at https://console.aws.amazon.com/glue/.

   Sign in as a user that has permissions to register a blueprint. Switch to the same AWS Region as the Amazon S3 bucket that contains the blueprint ZIP archive.
3. In the navigation pane, choose **blueprints**. Then on the **blueprints** page, choose **Add blueprint**.
4. Enter a blueprint name and optional description.
5. For **ZIP archive location (S3)**, enter the Amazon S3 path of the uploaded blueprint ZIP archive. Include the archive file name in the path and begin the path with `s3://`.
6. (Optional) Add tag one or more tags.
7. Choose **Add blueprint**.

   The **blueprints** page returns and shows that the blueprint status is `CREATING`. Choose the refresh button until the status changes to `ACTIVE` or `FAILED`.
8. If the status is `FAILED`, select the blueprint, and on the **Actions** menu, choose **View**.

The detail page shows the reason for the failure. If the error message is "Unable to access object at location..." or "Access denied on object at location...", review the following requirements:

- The user that you are signed in as must have read permission on the blueprint ZIP archive in Amazon S3.
- The Amazon S3 bucket that contains the ZIP archive must have a bucket policy that grants read permission on the object to your AWS account ID. For more information, see Developing blueprints in AWS Glue.
- The Amazon S3 bucket that you're using must be in the same Region as the Region that you're signed into on the console.

9. Ensure that data analysts have permissions on the blueprint.

   The suggested IAM policy for data analysts is shown in Data analyst permissions for blueprints. This policy grants `glue:GetBlueprint` on any resource. If your policy is more fine-grained at the resource level, then grant data analysts permissions on this newly created resource.

To register a blueprint (AWS CLI)

1. Enter the following command.

```
aws glue create-blueprint --name <blueprint-name> [--description <description>] --
blueprint-location s3://<s3-path>/<archive-filename>
```

2. Enter the following command to check the blueprint status. Repeat the command until the status goes to `ACTIVE` or `FAILED`.

```
aws glue get-blueprint --name <blueprint-name>
```

   If the status is `FAILED` and the error message is "Unable to access object at location..." or "Access denied on object at location...", review the following requirements:

- The user that you are signed in as must have read permission on the blueprint ZIP archive in Amazon S3.
- The Amazon S3 bucket containing the ZIP archive must have a bucket policy that grants read permission on the object to your AWS account ID. For more information, see Publishing a blueprint.

- The Amazon S3 bucket that you're using must be in the same Region as the Region that you're signed into on the console.

Viewing blueprints in AWS Glue

View a blueprint to review the blueprint description, status, and parameter specifications, and to download the blueprint ZIP archive.

You can view a blueprint by using the AWS Glue console, AWS Glue API, or AWS Command Line Interface (AWS CLI).

To view a blueprint (console)

1. Open the AWS Glue console at https://console.aws.amazon.com/glue/.
2. In the navigation pane, choose **blueprints**.
3. On the **blueprints** page, select a blueprint. Then on the **Actions** menu, choose **View**.

To view a blueprint (AWS CLI)

- Enter the following command to view just the blueprint name, description, and status. Replace *<blueprint-name>* with the name of the blueprint to view.

```
aws glue get-blueprint --name <blueprint-name>
```

The command output looks something like the following.

```
{
    "Blueprint": {
        "Name": "myDemoBP",
        "CreatedOn": 1587414516.92,
        "LastModifiedOn": 1587428838.671,
        "BlueprintLocation": "s3://amzn-s3-demo-bucket1/demo/
DemoBlueprintProject.zip",
```

```
        "Status": "ACTIVE"
    }
}
```

Enter the following command to also view the parameter specifications.

```
aws glue get-blueprint --name <blueprint-name>  --include-parameter-spec
```

The command output looks something like the following.

```
{
    "Blueprint": {
        "Name": "myDemoBP",
        "CreatedOn": 1587414516.92,
        "LastModifiedOn": 1587428838.671,
        "ParameterSpec": "{\"WorkflowName\":{\"type\":\"String\",\"collection
\":false,\"description\":null,\"defaultValue\":null,\"allowedValues\":null},
\"PassRole\":{\"type\":\"String\",\"collection\":false,\"description\":null,
\"defaultValue\":null,\"allowedValues\":null},\"DynamoDBTableName\":{\"type
\":\"String\",\"collection\":false,\"description\":null,\"defaultValue\":null,
\"allowedValues\":null},\"ScriptLocation\":{\"type\":\"String\",\"collection
\":false,\"description\":null,\"defaultValue\":null,\"allowedValues\":null}}",
        "BlueprintLocation": "s3://awsexamplebucket1/demo/
DemoBlueprintProject.zip",
        "Status": "ACTIVE"
    }
}
```

Add the `--include-blueprint` argument to include a URL in the output that you can paste into your browser to download the blueprint ZIP archive that AWS Glue stored.

- Overview of blueprints in AWS Glue

Updating a blueprint in AWS Glue

You can update a blueprint if you have a revised layout script, a revised set of blueprint parameters, or revised supporting files. Updating a blueprint creates a new version.

Updating a blueprint doesn't affect existing workflows created from the blueprint.

You can update a blueprint by using the AWS Glue console, AWS Glue API, or AWS Command Line Interface (AWS CLI).

The following procedure assumes that the AWS Glue developer has created and uploaded an updated blueprint ZIP archive to Amazon S3.

To update a blueprint (console)

1. Ensure that you have read permissions (`s3:GetObject`) on the blueprint ZIP archive in Amazon S3.
2. Open the AWS Glue console at https://console.aws.amazon.com/glue/.

   Sign in as a user that has permissions to update a blueprint. Switch to the same AWS Region as the Amazon S3 bucket that contains the blueprint ZIP archive.
3. In the navigation pane, choose **blueprints**.
4. On the **blueprints** page, select a blueprint, and on the **Actions** menu, choose **Edit**.
5. On the **Edit a blueprint** page, update the blueprint **Description** or **ZIP archive location (S3)**. Be sure to include the archive file name in the path.
6. Choose **Save**.

   The **blueprints** page returns and shows that the blueprint status is `UPDATING`. Choose the refresh button until the status changes to `ACTIVE` or `FAILED`.
7. If the status is `FAILED`, select the blueprint, and on the **Actions** menu, choose **View**.

   The detail page shows the reason for the failure. If the error message is "Unable to access object at location..." or "Access denied on object at location...", review the following requirements:

   - The user that you are signed in as must have read permission on the blueprint ZIP archive in Amazon S3.

- The Amazon S3 bucket that contains the ZIP archive must have a bucket policy that grants read permission on the object to your AWS account ID. For more information, see Publishing a blueprint.
- The Amazon S3 bucket that you're using must be in the same Region as the Region that you're signed into on the console.

> **Note**
>
> If the update fails, the next blueprint run uses the latest version of the blueprint that was successfully registered or updated.

To update a blueprint (AWS CLI)

1. Enter the following command.

```
aws glue update-blueprint --name <blueprint-name> [--description <description>] --
blueprint-location s3://<s3-path>/<archive-filename>
```

2. Enter the following command to check the blueprint status. Repeat the command until the status goes to `ACTIVE` or `FAILED`.

```
aws glue get-blueprint --name <blueprint-name>
```

   If the status is `FAILED` and the error message is "Unable to access object at location..." or "Access denied on object at location...", review the following requirements:

   - The user that you are signed in as must have read permission on the blueprint ZIP archive in Amazon S3.
   - The Amazon S3 bucket containing the ZIP archive must have a bucket policy that grants read permission on the object to your AWS account ID. For more information, see Publishing a blueprint.
   - The Amazon S3 bucket that you're using must be in the same Region as the Region that you're signed into on the console.

Creating a workflow from a blueprint in AWS Glue

You can create an AWS Glue workflow manually, adding one component at a time, or you can create a workflow from an AWS Glue blueprint. AWS Glue includes blueprints for common use cases. Your AWS Glue developers can create additional blueprints.

Important

Limit the total number of jobs, crawlers, and triggers within a workflow to 100 or less. If you include more than 100, you might get errors when trying to resume or stop workflow runs.

When you use a blueprint, you can quickly generate a workflow for a specific use case based on the generalized use case defined by the blueprint. You define the specific use case by providing values for the blueprint parameters. For example, a blueprint that partitions a dataset could have the Amazon S3 source and target paths as parameters.

AWS Glue creates a workflow from a blueprint by *running* the blueprint. The blueprint run saves the parameter values that you supplied, and is used to track the progress and outcome of the creation of the workflow and its components. When troubleshooting a workflow, you can view the blueprint run to determine the blueprint parameter values that were used to create a workflow.

To create and view workflows, you require certain IAM permissions. For a suggested IAM policy, see Data analyst permissions for blueprints.

You can create a workflow from a blueprint by using the AWS Glue console, AWS Glue API, or AWS Command Line Interface (AWS CLI).

To create a workflow from a blueprint (console)

1. Open the AWS Glue console at https://console.aws.amazon.com/glue/.

   Sign in as a user that has permissions to create a workflow.

2. In the navigation pane, choose **blueprints**.
3. Select a blueprint, and on the **Actions** menu, choose **Create workflow**.
4. On the **Create a workflow from <blueprint-name>** page, enter the following information:

   Blueprint parameters

   These vary depending on the blueprint design. For questions about the parameters, see the developer. blueprints typically include a parameter for the workflow name.

   IAM role

   The role that AWS Glue assumes to create the workflow and its components. The role must have permissions to create and delete workflows, jobs, crawlers, and triggers. For a suggested policy for the role, see Permissions for blueprint roles.
5. Choose **Submit**.

   The **Blueprint Details** page appears, showing a list of blueprint runs at the bottom.
6. In the blueprint runs list, check the topmost blueprint run for workflow creation status.

   The initial status is `RUNNING`. Choose the refresh button until the status goes to `SUCCEEDED` or `FAILED`.
7. Do one of the following:

   - If the completion status is `SUCCEEDED`, you can go to the **Workflows** page, select the newly created workflow, and run it. Before running the workflow, you can review the design graph.
   - If the completion status is `FAILED`, select the blueprint run, and on the **Actions** menu, choose **View** to see the error message.

For more information on workflows and blueprints, see the following topics.

- Overview of workflows in AWS Glue
- Updating a blueprint in AWS Glue
- Creating and building out a workflow manually in AWS Glue

Viewing blueprint runs in AWS Glue

View a blueprint run to see the following information:

- Name of the workflow that was created.
- blueprint parameter values that were used to create the workflow.
- Status of the workflow creation operation.

You can view a blueprint run by using the AWS Glue console, AWS Glue API, or AWS Command Line Interface (AWS CLI).

To view a blueprint run (console)

1. Open the AWS Glue console at https://console.aws.amazon.com/glue/.
2. In the navigation pane, choose **blueprints**.
3. On the **blueprints** page, select a blueprint. Then on the **Actions** menu, choose **View**.
4. At the bottom of the **Blueprint Details** page, select a blueprint run, and on the **Actions** menu, choose **View**.

To view a blueprint run (AWS CLI)

- Enter the following command. Replace *<blueprint-name>* with the name of the blueprint. Replace *<blueprint-run-id>* with the blueprint run ID.

```
aws glue get-blueprint-run --blueprint-name <blueprint-name> --run-id <blueprint-run-id>
```

AWS CloudFormation for AWS Glue

CloudFormation is a service that can create many AWS resources. AWS Glue provides API operations to create objects in the AWS Glue Data Catalog. However, it might be more convenient to define and create AWS Glue objects and other related AWS resource objects in an CloudFormation template file. Then you can automate the process of creating the objects.

CloudFormation provides a simplified syntax—either JSON (JavaScript Object Notation) or YAML (YAML Ain't Markup Language)—to express the creation of AWS resources. You can use CloudFormation templates to define Data Catalog objects such as databases, tables, partitions, crawlers, classifiers, and connections. You can also define ETL objects such as jobs, triggers, and development endpoints. You create a template that describes all the AWS resources you want, and CloudFormation takes care of provisioning and configuring those resources for you.

For more information, see What Is AWS CloudFormation? and Working with AWS CloudFormation Templates in the *AWS CloudFormation User Guide*.

If you plan to use CloudFormation templates that are compatible with AWS Glue, as an administrator, you must grant access to CloudFormation and to the AWS services and actions on which it depends. To grant permissions to create CloudFormation resources, attach the following policy to users that work with CloudFormation:

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "cloudformation:*"
      ],
      "Resource": "*"
    }
  ]
}
```

The following table contains the actions that an CloudFormation template can perform on your behalf. It includes links to information about the AWS resource types and their property types that you can add to an CloudFormation template.

AWS Glue resource	CloudFormation template	AWS Glue samples
Classifier	AWS::Glue::Classifier	Grok classifier, JSON classifier, XML classifier
Connection	AWS::Glue::Connection	MySQL connection
Crawler	AWS::Glue::Crawler	Amazon S3 crawler, MySQL crawler
Database	AWS::Glue::Database	Empty database, Database with tables
Development endpoint	AWS::Glue::DevEndpoint	Development endpoint
Integration	AWS::Glue::Integration	Zero-ETL integration
Integration Resource Property	AWS::Glue::IntegrationResourceProperty	Zero-ETL integration with integration resource property
Job	AWS::Glue::Job	Amazon S3 job, JDBC job
Machine learning transform	AWS::Glue::MLTransform	Machine learning transform
Data quality ruleset	AWS::Glue::DataQualityRuleset	Data quality ruleset, Data quality ruleset with EventBridge scheduler
Partition	AWS::Glue::Partition	Partitions of a table
Table	AWS::Glue::Table	Table in a database
Trigger	AWS::Glue::Trigger	On-demand trigger, Scheduled trigger, Conditional trigger

To get started, use the following sample templates and customize them with your own metadata. Then use the CloudFormation console to create an CloudFormation stack to add objects to AWS Glue and any associated services. Many fields in an AWS Glue object are optional. These templates illustrate the fields that are required or are necessary for a working and functional AWS Glue object.

An CloudFormation template can be in either JSON or YAML format. In these examples, YAML is used for easier readability. The examples contain comments (#) to describe the values that are defined in the templates.

CloudFormation templates can include a `Parameters` section. This section can be changed in the sample text or when the YAML file is submitted to the CloudFormation console to create a stack. The `Resources` section of the template contains the definition of AWS Glue and related objects. CloudFormation template syntax definitions might contain properties that include more detailed property syntax. Not all properties might be required to create an AWS Glue object. These samples show example values for common properties to create an AWS Glue object.

Sample CloudFormation template for an AWS Glue database

An AWS Glue database in the Data Catalog contains metadata tables. The database consists of very few properties and can be created in the Data Catalog with an CloudFormation template. The following sample template is provided to get you started and to illustrate the use of CloudFormation stacks with AWS Glue. The only resource created by the sample template is a database named `cfn-mysampledatabase`. You can change it by editing the text of the sample or changing the value on the CloudFormation console when you submit the YAML.

The following shows example values for common properties to create an AWS Glue database. For more information about the CloudFormation database template for AWS Glue, see AWS::Glue::Database.

```
---
AWSTemplateFormatVersion: '2010-09-09'
# Sample CloudFormation template in YAML to demonstrate creating a database named
 mysampledatabase
# The metadata created in the Data Catalog points to the flights public S3 bucket
#
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
Parameters:
```

```
  CFNDatabaseName:
    Type: String
    Default: cfn-mysampledatabse

# Resources section defines metadata for the Data Catalog
Resources:
# Create an AWS Glue database
  CFNDatabaseFlights:
    Type: AWS::Glue::Database
    Properties:
      # The database is created in the Data Catalog for your account
      CatalogId: !Ref AWS::AccountId
      DatabaseInput:
        # The name of the database is defined in the Parameters section above
        Name: !Ref CFNDatabaseName
        Description: Database to hold tables for flights data
        LocationUri: s3://crawler-public-us-east-1/flight/2016/csv/
        #Parameters: Leave AWS database parameters blank
```

Sample CloudFormation template for an AWS Glue database, table, and partition

An AWS Glue table contains the metadata that defines the structure and location of data that you want to process with your ETL scripts. Within a table, you can define partitions to parallelize the processing of your data. A partition is a chunk of data that you defined with a key. For example, using month as a key, all the data for January is contained in the same partition. In AWS Glue, databases can contain tables, and tables can contain partitions.

The following sample shows how to populate a database, a table, and partitions using an CloudFormation template. The base data format is `csv` and delimited by a comma (,). Because a database must exist before it can contain a table, and a table must exist before partitions can be created, the template uses the `DependsOn` statement to define the dependency of these objects when they are created.

The values in this sample define a table that contains flight data from a publicly available Amazon S3 bucket. For illustration, only a few columns of the data and one partitioning key are defined. Four partitions are also defined in the Data Catalog. Some fields to describe the storage of the base data are also shown in the `StorageDescriptor` fields.

```
---
AWSTemplateFormatVersion: '2010-09-09'
# Sample CloudFormation template in YAML to demonstrate creating a database, a table,
 and partitions
# The metadata created in the Data Catalog points to the flights public S3 bucket
#
# Parameters substituted in the Resources section
# These parameters are names of the resources created in the Data Catalog
Parameters:
  CFNDatabaseName:
    Type: String
    Default: cfn-database-flights-1
  CFNTableName1:
    Type: String
    Default: cfn-manual-table-flights-1
# Resources to create metadata in the Data Catalog
Resources:
###
# Create an AWS Glue database
  CFNDatabaseFlights:
    Type: AWS::Glue::Database
    Properties:

          InputFormat: org.apache.hadoop.mapred.TextInputFormat
          Location: s3://crawler-public-us-east-1/flight/2016/csv/mon=4/
          SerdeInfo:
            Parameters:
              field.delim: ","
            SerializationLibrary: org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe
```

Sample CloudFormation template for an AWS Glue grok classifier

An AWS Glue classifier determines the schema of your data. One type of custom classifier uses a grok pattern to match your data. If the pattern matches, then the custom classifier is used to create your table's schema and set the `classification` to the value set in the classifier definition.

This sample creates a classifier that creates a schema with one column named `message` and sets the classification to `greedy`.

```
---
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating a classifier
#
# Parameters section contains names that are substituted in the Resources section
```

```
# These parameters are the names the resources created in the Data Catalog
Parameters:

# The name of the classifier to be created
  CFNClassifierName:
    Type: String
    Default: cfn-classifier-grok-one-column-1

#
#
# Resources section defines metadata for the Data Catalog
Resources:
# Create classifier that uses grok pattern to put all data in one column and classifies
 it as "greedy".
  CFNClassifierFlights:
    Type: AWS::Glue::Classifier
    Properties:
      GrokClassifier:
        #Grok classifier that puts all data in one column
        Name: !Ref CFNClassifierName
        Classification: greedy

        GrokPattern: "%{GREEDYDATA:message}"
        #CustomPatterns: none
```

Sample CloudFormation template for an AWS Glue JSON classifier

An AWS Glue classifier determines the schema of your data. One type of custom classifier uses a `JsonPath` string defining the JSON data for the classifier to classify. AWS Glue supports a subset of the operators for `JsonPath`, as described in Writing JsonPath Custom Classifiers.

If the pattern matches, then the custom classifier is used to create your table's schema.

This sample creates a classifier that creates a schema with each record in the `Records3` array in an object.

```
---
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating a JSON classifier
#
```

```
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
Parameters:

# The name of the classifier to be created
  CFNClassifierName:
    Type: String
    Default: cfn-classifier-json-one-column-1

#
#
# Resources section defines metadata for the Data Catalog
Resources:
# Create classifier that uses a JSON pattern.
  CFNClassifierFlights:
    Type: AWS::Glue::Classifier
    Properties:
      JSONClassifier:
        #JSON classifier
        Name: !Ref CFNClassifierName
        JsonPath: $.Records3[*]
```

Sample CloudFormation template for an AWS Glue XML classifier

An AWS Glue classifier determines the schema of your data. One type of custom classifier specifies an XML tag to designate the element that contains each record in an XML document that is being parsed. If the pattern matches, then the custom classifier is used to create your table's schema and set the `classification` to the value set in the classifier definition.

This sample creates a classifier that creates a schema with each record in the `Record` tag and sets the classification to `XML`.

```
---
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating an XML classifier
#
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
```

```
Parameters:

# The name of the classifier to be created
  CFNClassifierName:
    Type: String
    Default: cfn-classifier-xml-one-column-1

#
#
# Resources section defines metadata for the Data Catalog
Resources:
# Create classifier that uses the XML pattern and classifies it as "XML".
  CFNClassifierFlights:
    Type: AWS::Glue::Classifier
    Properties:
      XMLClassifier:
        #XML classifier
        Name: !Ref CFNClassifierName
        Classification: XML
        RowTag: <Records>
```

Sample CloudFormation template for an AWS Glue crawler for Amazon S3

An AWS Glue crawler creates metadata tables in your Data Catalog that correspond to your data. You can then use these table definitions as sources and targets in your ETL jobs.

This sample creates a crawler, the required IAM role, and an AWS Glue database in the Data Catalog. When this crawler is run, it assumes the IAM role and creates a table in the database for the public flights data. The table is created with the prefix "`cfn_sample_1_`". The IAM role created by this template allows global permissions; you might want to create a custom role. No custom classifiers are defined by this classifier. AWS Glue built-in classifiers are used by default.

When you submit this sample to the CloudFormation console, you must confirm that you want to create the IAM role.

```
---
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating a crawler
#

Sample CloudFormation template for an AWS Glue connection

An AWS Glue connection in the Data Catalog contains the JDBC and network information that is required to connect to a JDBC database. This information is used when you connect to a JDBC database to crawl or run ETL jobs.

This sample creates a connection to an Amazon RDS MySQL database named `devdb`. When this connection is used, an IAM role, database credentials, and network connection values must also be supplied. See the details of necessary fields in the template.

```

Sample CloudFormation template for an AWS Glue zero-ETL integration

AWS zero-ETL is a set of fully managed integrations that minimize the need to build ETL data pipelines for common ingestion and replication use cases.

This sample creates a zero-ETL integration from the given source to the target.

```
---
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating a zero-ETL integration in AWS Glue
#
# Parameters section contains names that are substituted in the Resources section
#
Parameters:

  # The name of the zero-ETL integration to be created
  IntegrationName:
    Type: String
  # The ARN for the source of the zero-ETL integration
  SourceArn:
    Type: String
  # The ARN for the target of the zero-ETL integration
  TargetArn:
    Type: String
#
#
Resources:
# Create an AWS Glue zero-ETL integration
  GlueIntegration:
    Type: AWS::Glue::Integration
    Properties:
      IntegrationName: !Ref IntegrationName
      Description: "AWS Glue zero-ETL integration"
      SourceArn: !Ref SourceArn
      TargetArn: !Ref TargetArn
      DataFilter: "include:table1"
      Tags:
```

```
        - Key: Purpose
          Value: GlueZeroETLIntegration
```

Sample CloudFormation template for an AWS Glue zero-ETL integration with integration resource properties

An AWS Glue zero-ETL integration requires resource properties to be defined for the source and the target. For the source, the only property that needs to be defined is the IAM role that the integration will use to access the AWS Glue connection or DynamoDB database. For the target, the properties that can be configured include the IAM role that will be used to access the target, the VPC network that the integration should be created in, the event bus that will be used to setup event notifications for the integration and the KMS key that will be used for data encryption.

The below sample defines the source and target resource properties and then creates a zero-ETL integration from the source to the target.

```
---
AWSTemplateFormatVersion: '2010-09-09'

```

Sample CloudFormation template for an AWS Glue crawler for JDBC

An AWS Glue crawler creates metadata tables in your Data Catalog that correspond to your data. You can then use these table definitions as sources and targets in your ETL jobs.

This sample creates a crawler, required IAM role, and an AWS Glue database in the Data Catalog. When this crawler is run, it assumes the IAM role and creates a table in the database for the public flights data that has been stored in a MySQL database. The table is created with the prefix "`cfn_jdbc_1_`". The IAM role created by this template allows global permissions; you might want to create a custom role. No custom classifiers can be defined for JDBC data. AWS Glue built-in classifiers are used by default.

When you submit this sample to the CloudFormation console, you must confirm that you want to create the IAM role.

```

Sample CloudFormation template for an AWS Glue job for Amazon S3 to Amazon S3

An AWS Glue job in the Data Catalog contains the parameter values that are required to run a script in AWS Glue.

This sample creates a job that reads flight data from an Amazon S3 bucket in `csv` format and writes it to an Amazon S3 Parquet file. The script that is run by this job must already exist. You can generate an ETL script for your environment with the AWS Glue console. When this job is run, an IAM role with the correct permissions must also be supplied.

Common parameter values are shown in the template. For example, `AllocatedCapacity` (DPUs) defaults to 5.

```

            JobName: !Ref CFNJobName2
            State: SUCCEEDED
```

Sample CloudFormation template for an AWS Glue development endpoint

An AWS Glue machine learning transform is a custom transform to cleanse your data. There is currently one available transform named FindMatches. The FindMatches transform enables you to identify duplicate or matching records in your dataset, even when the records do not have a common unique identifier and no fields match exactly.

This sample creates a machine learning transform. For more information about the parameters that you need to create a machine learning transform, see Record matching with AWS Lake Formation FindMatches.

Sample CloudFormation template for an AWS Glue Data Quality ruleset

An AWS Glue Data Quality ruleset contains rules that can be evaluated on a table within the Data Catalog. Once the ruleset is placed on your targeted table you can go into the Data Catalog and run an evaluation which runs your data against those rules within the ruleset. These rules can vary from evaluating the row count to evaluating referential integrity on your data.

The following sample is a CloudFormation template which creates a ruleset with a variety of rules on the specified target table.

```
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating a DataQualityRuleset
#
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
Parameters:
```

```
  # The name of the ruleset to be created
  RulesetName:
    Type: String
    Default: "CFNRulesetName"
  RulesetDescription:
    Type: String
    Default: "CFN DataQualityRuleset"
  # Rules that will be associated with this ruleset
  Rules:
    Type: String
    Default: 'Rules = [
        RowCount > 100,
        IsUnique "id",
        IsComplete "nametype"
        ]'
  # Name of database and table within Data Catalog which the ruleset will
  # be applied too
  DatabaseName:
    Type: String
    Default: "ExampleDatabaseName"
  TableName:
    Type: String
    Default: "ExampleTableName"

# Resources section defines metadata for the Data Catalog
Resources:
  # Creates a Data Quality ruleset under specified rules
  DQRuleset:
    Type: AWS::Glue::DataQualityRuleset
    Properties:
      Name: !Ref RulesetName
      Description: !Ref RulesetDescription
      # The String within rules must be formatted in DQDL, a language
      # used specifically to make rules
      Ruleset: !Ref Rules
      # The targeted table must exist within Data Catalog alongside
      # the correct database
      TargetTable:
        DatabaseName: !Ref DatabaseName
        TableName: !Ref TableName
```

Sample CloudFormation template for an AWS Glue Data Quality ruleset with EventBridge scheduler

An AWS Glue Data Quality ruleset contains rules that can be evaluated on a table within the Data Catalog. Once the ruleset is placed on your targeted table you can go into the Data Catalog and run an evaluation which runs your data against those rules within the ruleset. Instead of having to manually go into the Data Catalog to evaluate the ruleset, you can also add an EventBridge Scheduler within our CloudFormation template to schedule these ruleset evaluations for you on a timed interval.

The following sample is a CloudFormation template which creates a Data Quality ruleset and a EventBridge Scheduler to evaluate the aforementioned ruleset every five minutes.

```
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating a DataQualityRuleset
#
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
Parameters:

  # The name of the ruleset to be created
  RulesetName:
    Type: String
    Default: "CFNRulesetName"
  # Rules that will be associated with this Ruleset
  Rules:
    Type: String
    Default: 'Rules = [
        RowCount > 100,
        IsUnique "id",
        IsComplete "nametype"
        ]'
  # The name of the Schedule to be created
  ScheduleName:
    Type: String
    Default: "ScheduleDQRulsetEvaluation"
  # This expression determines the rate at which the Schedule will evaluate
  # your data using the above ruleset
  ScheduleRate:
    Type: String
    Default: "rate(5 minutes)"
```

```
  # The Request that being sent must match the details of the Data Quality Ruleset
  ScheduleRequest:
    Type: String
    Default: '
        { "DataSource": { "GlueTable": { "DatabaseName": "ExampleDatabaseName",
         "TableName": "ExampleTableName" } },
         "Role": "role/AWSGlueServiceRoleDefault",
          "RulesetNames": [ ""CFNRulesetName"" ] }
        '

# Resources section defines metadata for the Data Catalog

        '
```

Sample CloudFormation template for an AWS Glue development endpoint

An AWS Glue development endpoint is an environment that you can use to develop and test your AWS Glue scripts.

This sample creates a development endpoint with the minimal network parameter values required to successfully create it. For more information about the parameters that you need to set up a development endpoint, see Setting up networking for development for AWS Glue.

You provide an existing IAM role ARN (Amazon Resource Name) to create the development endpoint. Supply a valid RSA public key and keep the corresponding private key available if you plan to create a notebook server on the development endpoint.

> **Note**
>
> For any notebook server that you create that is associated with a development endpoint, you manage it. Therefore, if you delete the development endpoint, to delete the notebook server, you must delete the CloudFormation stack on the CloudFormation console.

```
---
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating a development endpoint
#
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
Parameters:

# The name of the crawler to be created
  CFNEndpointName:
```

```
    Type: String
    Default: cfn-devendpoint-1
  CFNIAMRoleArn:
    Type: String
    Default: arn:aws:iam::123456789012/role/AWSGlueServiceRoleGA

```

AWS Glue programming guide

A script contains the code that extracts data from sources, transforms it, and loads it into targets. AWS Glue runs a script when it starts a job.

AWS Glue ETL scripts are coded in Python or Scala. While all job types can be written in Python, AWS Glue for Spark jobs can be written in Scala as well. When you automatically generate the source code logic for your job in AWS Glue Studio, a script is created. You can edit this script, or you can provide your own script to process your ETL work.

Providing your own custom scripts

Scripts perform the extract, transform, and load (ETL) work in AWS Glue. A script is created when you automatically generate the source code logic for a job. You can either edit this generated script, or you can provide your own custom script.

To provide your own custom script in AWS Glue, follow these general steps:

1. Sign in to the AWS Management Console and open the AWS Glue console at https://console.aws.amazon.com/glue/.
2. Choose the **ETL Jobs** tab, and then view the **Create job** section. Choose a **script editor** option.
3. Under **This job runs**, choose one of the following:
   - **Create a new script with boilerplate code**
   - **Upload and edit an existing script**
4. On the **Job details** page, choose the **IAM role** that is required for your custom script to run. For more information, see Identity and access management for AWS Glue.
5. Choose any connections that your script references. These objects are needed to connect to the necessary JDBC data stores.

   An elastic network interface is a virtual network interface that you can attach to an instance in a virtual private cloud (VPC). Choose the elastic network interface that is required to connect to the data store that's used in the script.
6. Provide additional configuration, including parameters, specific to your job type. For more information about configuration for your job type, see the *Building visual ETL jobs* section.

7. On the **Script** tab, paste or write your custom script.

Use the content in this section to guide the process of writing your custom script.

For more information about adding jobs in AWS Glue, see *Building visual ETL jobs*.

For step-by-step guidance, see the **Add job** tutorial in the AWS Glue console.

Programming Spark scripts

AWS Glue makes it easy to write or autogenerate extract, transform, and load (ETL) scripts, in addition to testing and running them. This section describes the extensions to Apache Spark that AWS Glue has introduced, and provides examples of how to code and run ETL scripts in Python and Scala.

> **Important**
>
> Different versions of AWS Glue support different versions of Apache Spark. Your custom script must be compatible with the supported Apache Spark version. For information about AWS Glue versions, see the Glue version job property.

Topics

- Tutorial: Writing an AWS Glue for Spark script
- Program AWS Glue ETL scripts in PySpark
- Programming AWS Glue ETL scripts in Scala
- Features and optimizations for programming AWS Glue for Spark ETL scripts

Tutorial: Writing an AWS Glue for Spark script

This tutorial introduces you to the process of writing AWS Glue scripts. You can run scripts on a schedule with jobs, or interactively with interactive sessions. For more information about jobs, see *Building visual ETL jobs*. For more information about interactive sessions, see the section called "Overview of AWS Glue interactive sessions".

The AWS Glue Studio visual editor offers a graphical, no-code interface for building AWS Glue jobs. AWS Glue scripts back visual jobs. They give you access to the expanded set of tools available to

work with Apache Spark programs. You can access native Spark APIs, as well as AWS Glue libraries that facilitate extract, transform, and load (ETL) workflows from within an AWS Glue script.

In this tutorial, you extract, transform, and load a dataset of parking tickets. The script that does this work is identical in form and function to the one generated in Making ETL easier with AWS Glue Studio on the AWS Big Data Blog, which introduces the AWS Glue Studio visual editor. By running this script in a job, you can compare it to visual jobs and see how AWS Glue ETL scripts work. This prepares you to use additional functionalities that aren't yet available in visual jobs.

You use the Python language and libraries in this tutorial. Similar functionality is available in Scala. After going through this tutorial, you should be able to generate and inspect a sample Scala script to understand how to perform the Scala AWS Glue ETL script writing process.

Prerequisites

This tutorial has the following prerequisites:

- The same prerequisites as the AWS Glue Studio blog post, which instructs you to run a CloudFormation template.

  This template uses the AWS Glue Data Catalog to manage the parking ticket dataset available in `s3://aws-bigdata-blog/artifacts/gluestudio/`. It creates the following resources which will be referenced:
- **AWS Glue StudioRole** – IAM role to run AWS Gluejobs
- **AWS Glue StudioAmazon S3Bucket** – Name of the Amazon S3 bucket to store blog-related files
- **AWS Glue StudioTicketsYYZDB** – AWS Glue Data Catalog database
- **AWS Glue StudioTableTickets** – Data Catalog table to use as a source
- **AWS Glue StudioTableTrials** – Data Catalog table to use as a source
- **AWS Glue StudioParkingTicketCount** – Data Catalog table to use as the destination
- The script generated in the AWS Glue Studio blog post. If the blog post changes, the script is also available in the following text.

Generate a sample script

You can use the AWS Glue Studio visual editor as a powerful code generation tool to create a scaffold for the script you want to write. You will use this tool to create a sample script.

If you want to skip these steps, the script is provided.

Tutorial sample script

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
job.init(args["JOB_NAME"], args)

# Script generated for node S3 bucket
S3bucket_node1 = glueContext.create_dynamic_frame.from_catalog(
    database="yyz-tickets", table_name="tickets", transformation_ctx="S3bucket_node1"
)

# Script generated for node ApplyMapping
ApplyMapping_node2 = ApplyMapping.apply(
    frame=S3bucket_node1,
    mappings=[
        ("tag_number_masked", "string", "tag_number_masked", "string"),
        ("date_of_infraction", "string", "date_of_infraction", "string"),
        ("ticket_date", "string", "ticket_date", "string"),
        ("ticket_number", "decimal", "ticket_number", "float"),
        ("officer", "decimal", "officer_name", "decimal"),
        ("infraction_code", "decimal", "infraction_code", "decimal"),
        ("infraction_description", "string", "infraction_description", "string"),
        ("set_fine_amount", "decimal", "set_fine_amount", "float"),
        ("time_of_infraction", "decimal", "time_of_infraction", "decimal"),
    ],
    transformation_ctx="ApplyMapping_node2",
)

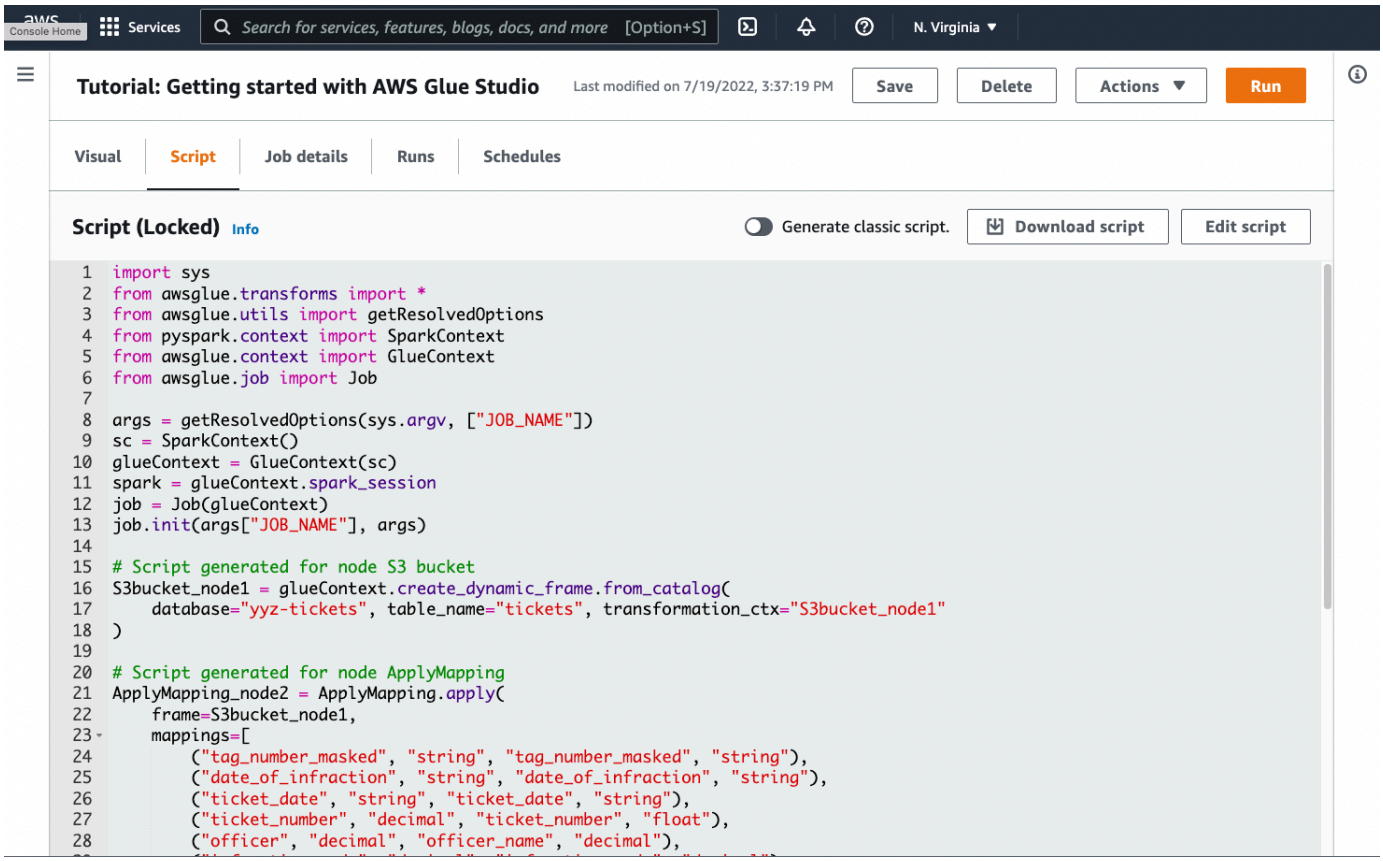
# Script generated for node S3 bucket
S3bucket_node3 = glueContext.write_dynamic_frame.from_options(
    frame=ApplyMapping_node2,
    connection_type="s3",
    format="glueparquet",
    connection_options={"path": "s3://DOC-EXAMPLE-BUCKET", "partitionKeys": []},
```

```
    format_options={"compression": "gzip"},
    transformation_ctx="S3bucket_node3",
)

job.commit()
```

To generate a sample script

1. Complete the AWS Glue Studio tutorial. To complete this tutorial, see Creating a job in AWS Glue Studio from an example job.
2. Navigate to the **Script** tab on the job page, as shown in the following screenshot:



3. Copy the complete contents of the **Script** tab. By setting the script language in **Job details**, you can switch back and forth between generating Python or Scala code.

Step 1. Create a job and paste your script

In this step, you create an AWS Glue job in the AWS Management Console. This sets up a configuration that allows AWS Glue to run your script. It also creates a place for you to store and edit your script.

To create a job

1. In the AWS Management Console, navigate to the AWS Glue landing page.
2. In the side navigation pane, choose **Jobs**.
3. Choose **Spark script editor** in **Create job**, and then choose **Create**.
4. **Optional** - Paste the full text of your script into the **Script** pane. Alternatively, you can follow along with the tutorial.

Step 2. Import AWS Glue libraries

You need to set your script up to interact with code and configuration that are defined outside of the script. This work is done behind the scenes in AWS Glue Studio.

In this step, you perform the following actions.

- Import and initialize a `GlueContext` object. This is the most important import, from the script writing perspective. This exposes standard methods for defining source and target datasets, which is the starting point for any ETL script. To learn more about the `GlueContext` class, see GlueContext class.
- Initialize a `SparkContext` and `SparkSession`. These allow you to configure the Spark engine available inside the AWS Glue job. You won't need to use them directly within introductory AWS Glue scripts.
- Call `getResolvedOptions` to prepare your job arguments for use within the script. For more information about resolving job parameters, see the section called “getResolvedOptions”.
- Initialize a `Job`. The `Job` object sets configuration and tracks the state of various optional AWS Glue features. Your script can run without a `Job` object, but the best practice is to initialize it so that you don't encounter confusion if those features are later integrated.

  One of these features is job bookmarks, which you can optionally configure in this tutorial. You can learn about job bookmarks in the following section, the section called “Optional - Enable job bookmarks”.

In this procedure, you write the following code. This code is a portion of the generated sample script.

```
from awsglue.transforms import *
```

```
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
job.init(args["JOB_NAME"], args)
```

To import AWS Glue libraries

- Copy this section of code and paste it into the **Script** editor.

> **Note**
>
> You might consider copying code to be a bad engineering practice. In this tutorial, we suggest this to encourage you to consistently name your core variables across all AWS Glue ETL scripts.

Step 3. Extract data from a source

In any ETL process, you first need to define a source dataset that you want to change. In the AWS Glue Studio visual editor, you provide this information by creating a **Source** node.

In this step, you provide the `create_dynamic_frame.from_catalog` method a `database` and `table_name` to extract data from a source configured in the AWS Glue Data Catalog.

In the previous step, you initialized a `GlueContext` object. You use this object to find methods that are used to configure sources, such as `create_dynamic_frame.from_catalog`.

In this procedure, you write the following code using `create_dynamic_frame.from_catalog`. This code is a portion of the generated sample script.

```
S3bucket_node1 = glueContext.create_dynamic_frame.from_catalog(
    database="yyz-tickets", table_name="tickets", transformation_ctx="S3bucket_node1"
    )
```

To extract data from a source

1. Examine the documentation to find a method on `GlueContext` to extract data from a source defined in the AWS Glue Data Catalog. These methods are documented in the section called "GlueContext". Choose the create_dynamic_frame.from_catalog method. Call this method on `glueContext`.
2. Examine the documentation for `create_dynamic_frame.from_catalog`. This method requires `database` and `table_name` parameters. Provide the necessary parameters to `create_dynamic_frame.from_catalog`.

   The AWS Glue Data Catalog stores information about the location and format of your source data, and was set up in the prerequisite section. You don't have to directly provide your script with that information.
3. **Optional** – Provide the `transformation_ctx` parameter to the method in order to support job bookmarks. You can learn about job bookmarks in the following section, the section called "Optional - Enable job bookmarks".

> **Note**
>
> **Common methods for extracting data**
> the section called "create_dynamic_frame_from_catalog" is used to connect to tables in the AWS Glue Data Catalog.
> If you need to directly provide your job with configuration that describes the structure and location of your source, see the the section called "create_dynamic_frame_from_options" method. You will need to provide more detailed parameters describing your data than when using `create_dynamic_frame.from_catalog`.
> Refer to the supplemental documentation about `format_options` and `connection_parameters` to identify your required parameters. For an explanation of how to provide your script information about your source data format, see the section called "Data format options". For an explanation of how to provide your script information about your source data location, see the section called "Connection parameters".
> If you're reading information from a streaming source, you provide your job with source information through the the section called "create_data_frame_from_catalog" or the section called "create_data_frame_from_options" methods. Note that these methods return Apache Spark `DataFrames`.

Our generated code calls `create_dynamic_frame.from_catalog` while the reference documentation refers to `create_dynamic_frame_from_catalog`. These methods ultimately call the same code, and are included so you can write cleaner code. You can verify this by viewing the source for our Python wrapper, available at aws-glue-libs.

Step 4. Transform data with AWS Glue

After extracting source data in an ETL process, you need to describe how you want to change your data. You provide this information by creating a **Transform** node in the AWS Glue Studio visual editor.

In this step, you provide the `ApplyMapping` method with a map of current and desired field names and types to transform your `DynamicFrame`.

You perform the following transformations.

- Drop the four `location` and `province` keys.
- Change the name of `officer` to `officer_name`.
- Change the type of `ticket_number` and `set_fine_amount` to `float`.

`create_dynamic_frame.from_catalog` provides you with a `DynamicFrame` object. A `DynamicFrame` represents a dataset in AWS Glue. AWS Glue transforms are operations that change `DynamicFrames`.

Note

What is a `DynamicFrame`?
A `DynamicFrame` is an abstraction that allows you to connect a dataset with a description of the names and types of entries in the data. In Apache Spark, a similar abstraction exists called a DataFrame. For an explanation of DataFrames, see Spark SQL Guide.
With `DynamicFrames`, you can describe dataset schemas dynamically. Consider a dataset with a price column, where some entries store price as a string, and others store price as a double. AWS Glue computes a schema on-the-fly—it creates a self-describing record for each row.
Inconsistent fields (like price) are explicitly represented with a type (`ChoiceType`) in the schema for the frame. You can address your inconsistent fields by dropping them with `DropFields` or resolving them with `ResolveChoice`. These are transforms that are

available on the DynamicFrame. You can then write your data back to your data lake with writeDynamicFrame.
You can call many of the same transforms from methods on the DynamicFrame class, which can lead to more readable scripts. For more information about DynamicFrame, see the section called “DynamicFrame”.

In this procedure, you write the following code using ApplyMapping. This code is a portion of the generated sample script.

```
ApplyMapping_node2 = ApplyMapping.apply(
    frame=S3bucket_node1,
    mappings=[
        ("tag_number_masked", "string", "tag_number_masked", "string"),
        ("date_of_infraction", "string", "date_of_infraction", "string"),
        ("ticket_date", "string", "ticket_date", "string"),
        ("ticket_number", "decimal", "ticket_number", "float"),
        ("officer", "decimal", "officer_name", "decimal"),
        ("infraction_code", "decimal", "infraction_code", "decimal"),
        ("infraction_description", "string", "infraction_description", "string"),
        ("set_fine_amount", "decimal", "set_fine_amount", "float"),
        ("time_of_infraction", "decimal", "time_of_infraction", "decimal"),
    ],
    transformation_ctx="ApplyMapping_node2",
)
```

To transform data with AWS Glue

1. Examine the documentation to identify a transform to change and drop fields. For details, see the section called “GlueTransform”. Choose the ApplyMapping transform. For more information about ApplyMapping, see the section called “ApplyMapping”. Call apply on the ApplyMapping transform object.

   Note

   What is ApplyMapping?
   ApplyMapping takes a DynamicFrame and transforms it. It takes a list of tuples that represent transformations on fields—a "mapping". The first two tuple elements, a field name and type, are used to identify a field in the frame. The second two parameters are also a field name and type.

ApplyMapping converts the source field to the target name and type in a new `DynamicFrame`, which it returns. Fields that aren't provided are dropped in the return value.
Rather than calling `apply`, you can call the same transform with the `apply_mapping` method on the `DynamicFrame` to create more fluent, readable code. For more information, see the section called “apply_mapping”.

2. Examine the documentation for `ApplyMapping` to identify required parameters. See the section called “ApplyMapping”. You will find that this method requires `frame` and `mappings` parameters. Provide the necessary parameters to `ApplyMapping`.
3. **Optional** – Provide `transformation_ctx` to the method to support job bookmarks. You can learn about job bookmarks in the following section, the section called “Optional - Enable job bookmarks”.

> **Note**
>
> **Apache Spark functionality**
> We provide transforms to streamline ETL workflows within your job. You also have access to the libraries that are available in a Spark program in your job, built for more general purposes. In order to use them, you convert between `DynamicFrame` and `DataFrame`. You can create a `DataFrame` with the section called “toDF”. Then, you can use methods available on the DataFrame to transform your dataset. For more information on these methods, see DataFrame. You can then convert backwards with the section called “fromDF” to use AWS Glue operations for loading your frame to a target.

Step 5. Load data into a target

After you transform your data, you typically store the transformed data in a different place from the source. You perform this operation by creating a **target** node in the AWS Glue Studio visual editor.

In this step, you provide the `write_dynamic_frame.from_options` method a `connection_type`, `connection_options`, `format`, and `format_options` to load data into a target bucket in Amazon S3.

In Step 1, you initialized a `GlueContext` object. In AWS Glue, this is where you will find methods that are used to configure targets, much like sources.

In this procedure, you write the following code using `write_dynamic_frame.from_options`. This code is a portion of the generated sample script.

```
S3bucket_node3 = glueContext.write_dynamic_frame.from_options(
    frame=ApplyMapping_node2,
    connection_type="s3",
    format="glueparquet",
    connection_options={"path": "s3://amzn-s3-demo-bucket", "partitionKeys": []},
    format_options={"compression": "gzip"},
    transformation_ctx="S3bucket_node3",
    )
```

To load data into a target

1. Examine the documentation to find a method to load data into a target Amazon S3 bucket. These methods are documented in the section called "GlueContext". Choose the the section called "write_dynamic_frame_from_options" method. Call this method on `glueContext`.

   > **Note**
   >
   > **Common methods for loading data**
   > `write_dynamic_frame.from_options` is the most common method used to load data. It supports all targets that are available in AWS Glue.
   > If you're writing to a JDBC target defined in an AWS Glue connection, use the the section called "write_dynamic_frame_from_jdbc_conf" method. AWS Glue connections store information about how to connect to a data source. This removes the need to provide that information in `connection_options`. However, you still need to use `connection_options` to provide `dbtable`.
   > `write_dynamic_frame.from_catalog` is not a common method for loading data. This method updates the AWS Glue Data Catalog without updating the underlying dataset, and is used in combination with other processes that change the underlying dataset. For more information, see the section called "Updating the schema and adding new partitions".

2. Examine the documentation for the section called "write_dynamic_frame_from_options". This method requires `frame`, `connection_type`, `format`, `connection_options`, and `format_options`. Call this method on `glueContext`.

   a. Refer to the supplemental documentation about `format_options` and `format` to identify the parameters you need. For an explanation of data formats, see the section called "Data format options".

   b. Refer to the supplemental documentation about `connection_type` and `connection_options` to identify the parameters you need. For an explanation of connections, see the section called "Connection parameters".

   c. Provide the necessary parameters to `write_dynamic_frame.from_options`. This method has a similar configuration to `create_dynamic_frame.from_options`.

3. **Optional** – Provide `transformation_ctx` to `write_dynamic_frame.from_options` to support job bookmarks. You can learn about job bookmarks in the following section, the section called "Optional - Enable job bookmarks".

Step 6. Commit the Job object

You initialized a `Job` object in Step 1. You may need to manually conclude its lifecycle at the end of your script if certain optional features need this to function properly, such as when using Job Bookmarks. This work is done behind the scenes in AWS Glue Studio.

In this step, call the `commit` method on the `Job` object.

In this procedure, you write the following code. This code is a portion of the generated sample script.

```
job.commit()
```

To commit the Job object

1. If you have not yet done this, perform the optional steps outlined in previous sections to include `transformation_ctx`.
2. Call `commit`.

Optional - Enable job bookmarks

In every prior step, you have been instructed to set `transformation_ctx` parameters. This is related to a feature called job bookmarks.

With job bookmarks, you can save time and money with jobs that run on a recurring basis, against datasets where previous work can easily be tracked. Job bookmarks track the progress of an AWS Glue transform across a dataset from previous runs. By tracking where previous runs ended, AWS Glue can limit its work to rows it hasn't processed before. For more information about job bookmarks, see the section called “Tracking processed data using job bookmarks”.

To enable job bookmarks, first add the `transformation_ctx` statements into our provided functions, as described in the previous examples. Job bookmark state is persisted across runs. `transformation_ctx` parameters are keys used to access that state. On their own, these statements will do nothing. You also need to activate the feature in the configuration for your job.

In this procedure, you enable job bookmarks using the AWS Management Console.

To enable job bookmarks

1. Navigate to the **Job details** section of your corresponding job.
2. Set **Job bookmark** to **Enable**.

Step 7. Run your code as a job

In this step, you run your job to verify that you successfully completed this tutorial. This is done with the click of a button, as in the AWS Glue Studio visual editor.

To run your code as a job

1. Choose **Untitled job** on the title bar to edit and set your job name.
2. Navigate to the **Job details** tab. Assign your job an **IAM Role**. You can use the one created by the CloudFormation template in the prerequisites for the AWS Glue Studio tutorial. If you have completed that tutorial, it should be available as `AWS Glue StudioRole`.
3. Choose **Save** to save your script.
4. Choose **Run** to run your job.
5. Navigate to the **Runs** tab to verify that your job completes.

6. Navigate to *amzn-s3-demo-bucket*, the target for `write_dynamic_frame.from_options`. Confirm that the output matches your expectations.

For more information about configuring and managing jobs, see the section called "Providing your own custom scripts".

More information

Apache Spark libraries and methods are available in AWS Glue scripts. You can look at the Spark documentation to understand what you can do with those included libraries. For more information, see the examples section of the Spark source repository.

AWS Glue 2.0+ includes several common Python libraries by default. There are also mechanisms for loading your own dependencies into an AWS Glue job in a Scala or Python environment. For information about Python dependencies, see the section called "Python libraries".

For more examples of how to use AWS Glue features in Python, see the section called "Python samples". Scala and Python jobs have feature parity, so our Python examples should give you some thoughts about how to perform similar work in Scala.

Program AWS Glue ETL scripts in PySpark

You can find Python code examples and utilities for AWS Glue in the AWS Glue samples repository on the GitHub website.

Using Python with AWS Glue

AWS Glue supports an extension of the PySpark Python dialect for scripting extract, transform, and load (ETL) jobs. This section describes how to use Python in ETL scripts and with the AWS Glue API.

- Setting up to use Python with AWS Glue
- Calling AWS Glue APIs in Python
- Using Python libraries with AWS Glue
- AWS Glue Python code samples

AWS Glue PySpark extensions

AWS Glue has created the following extensions to the PySpark Python dialect.

- Accessing parameters using `getResolvedOptions`
- PySpark extension types
- DynamicFrame class
- DynamicFrameCollection class
- DynamicFrameWriter class
- DynamicFrameReader class
- GlueContext class

AWS Glue PySpark transforms

AWS Glue has created the following transform Classes to use in PySpark ETL operations.

- GlueTransform base class
- ApplyMapping class
- DropFields class
- DropNullFields class
- ErrorsAsDynamicFrame class
- FillMissingValues class
- Filter class
- FindIncrementalMatches class
- FindMatches class
- FlatMap class
- Join class
- Map class
- MapToCollection class
- mergeDynamicFrame
- Relationalize class
- RenameField class
- ResolveChoice class
- SelectFields class
- SelectFromCollection class

- Spigot class
- SplitFields class
- SplitRows class
- Unbox class
- UnnestFrame class

Setting up to use Python with AWS Glue

Use Python to develop your ETL scripts for Spark jobs. The supported Python versions for ETL jobs depend on the AWS Glue version of the job. For more information on AWS Glue versions, see the Glue version job property.

To set up your system for using Python with AWS Glue

Follow these steps to install Python and to be able to invoke the AWS Glue APIs.

1. If you don't already have Python installed, download and install it from the Python.org download page.
2. Install the AWS Command Line Interface (AWS CLI) as documented in the AWS CLI documentation.

   The AWS CLI is not directly necessary for using Python. However, installing and configuring it is a convenient way to set up AWS with your account credentials and verify that they work.
3. Install the AWS SDK for Python (Boto 3), as documented in the Boto3 Quickstart .

   Boto 3 resource APIs are not yet available for AWS Glue. Currently, only the Boto 3 client APIs can be used.

   For more information about Boto 3, see AWS SDK for Python (Boto3) Getting Started.

You can find Python code examples and utilities for AWS Glue in the AWS Glue samples repository on the GitHub website.

Calling AWS Glue APIs in Python

Note that Boto 3 resource APIs are not yet available for AWS Glue. Currently, only the Boto 3 client APIs can be used.

AWS Glue API names in Python

AWS Glue API names in Java and other programming languages are generally CamelCased. However, when called from Python, these generic names are changed to lowercase, with the parts of the name separated by underscore characters to make them more "Pythonic". In the *AWS Glue API* reference documentation, these Pythonic names are listed in parentheses after the generic CamelCased names.

However, although the AWS Glue API names themselves are transformed to lowercase, their parameter names remain capitalized. It is important to remember this, because parameters should be passed by name when calling AWS Glue APIs, as described in the following section.

Passing and accessing Python parameters in AWS Glue

In Python calls to AWS Glue APIs, it's best to pass parameters explicitly by name. For example:

```
job = glue.create_job(Name='sample', Role='Glue_DefaultRole',
                      Command={'Name': 'glueetl',
                               'ScriptLocation': 's3://my_script_bucket/scripts/
my_etl_script.py'})
```

It is helpful to understand that Python creates a dictionary of the name/value tuples that you specify as arguments to an ETL script in a Job structure or JobRun structure. Boto 3 then passes them to AWS Glue in JSON format by way of a REST API call. This means that you cannot rely on the order of the arguments when you access them in your script.

For example, suppose that you're starting a JobRun in a Python Lambda handler function, and you want to specify several parameters. Your code might look something like the following:

```
from datetime import datetime, timedelta

client = boto3.client('glue')

def lambda_handler(event, context):
  last_hour_date_time = datetime.now() - timedelta(hours = 1)
  day_partition_value = last_hour_date_time.strftime("%Y-%m-%d")
  hour_partition_value = last_hour_date_time.strftime("%-H")

  response = client.start_job_run(
               JobName = 'my_test_Job',
               Arguments = {
                 '--day_partition_key':   'partition_0',
```

```
                  '--hour_partition_key':  'partition_1',
                  '--day_partition_value':  day_partition_value,
                  '--hour_partition_value': hour_partition_value } )
```

To access these parameters reliably in your ETL script, specify them by name using AWS Glue's `getResolvedOptions` function and then access them from the resulting dictionary:

```
import sys
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv,
                          ['JOB_NAME',
                           'day_partition_key',
                           'hour_partition_key',
                           'day_partition_value',
                           'hour_partition_value'])
print "The day partition key is: ", args['day_partition_key']
print "and the day partition value is: ", args['day_partition_value']
```

If you want to pass an argument that is a nested JSON string, to preserve the parameter value as it gets passed to your AWS Glue ETL job, you must encode the parameter string before starting the job run, and then decode the parameter string before referencing it your job script. For example, consider the following argument string:

```
glue_client.start_job_run(JobName = "gluejobname", Arguments={
"--my_curly_braces_string": '{"a": {"b": {"c": [{"d": {"e": 42}}]}}}'
})
```

To pass this parameter correctly, you should encode the argument as a Base64 encoded string.

```
import base64
...
sample_string='{"a": {"b": {"c": [{"d": {"e": 42}}]}}}'
sample_string_bytes = sample_string.encode("ascii")

base64_bytes = base64.b64encode(sample_string_bytes)
base64_string = base64_bytes.decode("ascii")
...
glue_client.start_job_run(JobName = "gluejobname", Arguments={
"--my_curly_braces_string": base64_bytes})
...
sample_string_bytes = base64.b64decode(base64_bytes)
```

```
sample_string = sample_string_bytes.decode("ascii")
print(f"Decoded string: {sample_string}")
...
```

Example: Create and run a job

The following example shows how call the AWS Glue APIs using Python, to create and run an ETL job.

To create and run a job

1. Create an instance of the AWS Glue client:

```
import boto3
glue = boto3.client(service_name='glue', region_name='us-east-1',
              endpoint_url='https://glue.us-east-1.amazonaws.com')
```

2. Create a job. You must use `glueetl` as the name for the ETL command, as shown in the following code:

```
myJob = glue.create_job(Name='sample', Role='Glue_DefaultRole',
                        Command={'Name': 'glueetl',
                                 'ScriptLocation': 's3://my_script_bucket/
scripts/my_etl_script.py'})
```

3. Start a new run of the job that you created in the previous step:

```
myNewJobRun = glue.start_job_run(JobName=myJob['Name'])
```

4. Get the job status:

```
status = glue.get_job_run(JobName=myJob['Name'], RunId=myNewJobRun['JobRunId'])
```

5. Print the current state of the job run:

```
print(status['JobRun']['JobRunState'])
```

Using Python libraries with AWS Glue

You can install additional Python modules and libraries for use with AWS Glue ETL. For AWS Glue 2.0 and above, AWS Glue uses the Python Package Installer (pip3) to install additional

modules used by AWS Glue ETL. AWS Glue provides multiple options to bring the additional Python modules to your AWS Glue job environment. You can use the `--additional-python-modules` parameter to bring in new modules using zip files containing bundled Python wheels (also known as "zip of wheels", available for AWS Glue 5.0 and above), individual Python wheel files, requirements files (requirements.txt, available for AWS Glue 5.0 and above), or a list of comma-separated Python modules. It could also be used to change the version of the python modules provided in the AWS Glue environment (see Python modules already provided in AWS Glue for more details).

Topics

- Installing additional Python modules with pip in AWS Glue 2.0 or later
- Including Python files with PySpark native features
- Programming scripts that use visual transforms
- Zipping libraries for inclusion
- Loading Python libraries in AWS Glue Studio notebooks
- Loading Python libraries in a development endpoint in AWS Glue 0.9/1.0
- Using Python libraries in a job or JobRun
- Proactively analyze Python dependencies
- Python modules already provided in AWS Glue
- Appendix A: Creating a Zip of Wheels Artifact
- Appendix B: AWS Glue environment details

Installing additional Python modules with pip in AWS Glue 2.0 or later

AWS Glue uses the Python Package Installer (pip3) to install additional modules to be used by AWS Glue ETL. You can use the `--additional-python-modules` parameter with a list of comma-separated Python modules to add a new module or change the version of an existing module. You can install built wheel artifacts either through a zip of wheels or a standalone wheel artifact by uploading the file to Amazon S3, then including the path to the Amazon S3 object in your list of modules. For more information about setting job parameters, see Using job parameters in AWS Glue jobs.

You can pass additional options to pip3 with the `--python-modules-installer-option` parameter. For example, you could pass `--only-binary` to force pip to install only pre-built

artifacts for the packages specified by `--additional-python-modules`. For more examples, see Building Python modules from a wheel for Spark ETL workloads using AWS Glue 2.0 .

Best Practices for Python Dependency Management

For production workloads, AWS Glue recommend packaging all your Python dependencies as wheel files in a single zip artifact. This approach provides:

- **Deterministic execution**: Exact control over which package versions are installed
- **Reliability**: No dependency on external package repositories during job execution
- **Performance**: Single download operation instead of multiple network calls
- **Offline installation**: Works in private VPC environments without internet access

Important Considerations

Under the AWS shared responsibility model, you are responsible for managing additional Python modules, libraries, and their dependencies. This includes:

- **Security updates**: Regularly updating packages to address security vulnerabilities
- **Version compatibility**: Ensuring packages are compatible with your AWS Glue version
- **Testing**: Validating that your packaged dependencies work correctly in the Glue environment

If you have minimal dependencies, you may consider using individual wheel files instead.

(Recommended) Installing additional Python libraries in AWS Glue 5.0 or above using Zip of Wheels

AWS Glue 5.0 and above supports packaging multiple wheel files into a single zip artifact containing bundled Python wheels for more reliable and deterministic dependency management. To use this approach, create a zip file containing all your wheel dependencies and their transitive dependencies with the `.gluewheels.zip` suffix, upload it to Amazon S3, and reference it using the `--additional-python-modules` parameter. Be sure to add `--no-index` to the `--python-modules-installer-option` job parameter. With this configuration, the zip of wheels file essentially acts as a local index for pip to resolve dependencies from at runtime. This eliminates dependencies on external package repositories like PyPI during job execution, providing greater stability and consistency for production workloads. For example:

```
--additional-python-modules s3://amzn-s3-demo-bucket/path/to/zip-of-
wheels-1.0.0.gluewheels.zip
--python-modules-installer-option --no-index
```

For Instructions on how to create a zip of wheels file, see Appendix A: Creating a Zip of Wheels Artifact.

Installing additional Python libraries using Wheel

AWS Glue supports installing custom Python packages using wheel (.whl) files stored in Amazon S3. To include wheel files in your AWS Glue jobs, provide a comma-separated list of your wheel files stored in s3 to the `--additional-python-modules` job parameter. For example:

```
--additional-python-modules s3://amzn-s3-demo-bucket/path/to/package-1.0.0-py3-none-
any.whl,s3://your-bucket/path/to/another-package-2.1.0-cp311-cp311-linux_x86_64.whl
```

This approach also supports when you need custom distributions, or packages with native dependencies that are pre-compiled for the correct operating system. For more examples, see Building Python modules from a wheel for Spark ETL workloads using AWS Glue 2.0.

Installing additional Python libraries in AWS Glue 5.0 or above using requirements.txt

In AWS Glue 5.0+, you can provide the defacto-standard `requirements.txt` to manage Python library dependencies. To do that, provide following two job parameters:

- Key: `--python-modules-installer-option`

  Value: `-r`
- Key: `--additional-python-modules`

  Value: `s3://path_to_requirements.txt`

AWS Glue 5.0 nodes initially load python libraries specified in `requirements.txt`.

Here's a sample requirements.txt:

```
awswrangler==3.9.1
elasticsearch==8.15.1
PyAthena==3.9.0
PyMySQL==1.1.1
```

```
PyYAML==6.0.2
pyodbc==5.2.0
pyorc==0.9.0
redshift-connector==2.1.3
scipy==1.14.1
scikit-learn==1.5.2
SQLAlchemy==2.0.36
```

Important

Use this option with caution, especially in production workloads. Pulling dependencies from PyPI at runtime is highly risky because you cannot be sure what artifact pip resolves to. Using unpinned library versions is especially risky since it pulls latest version of the python modules, which can introduce breaking changes or bring in incompatible python module. This could result in job failure due to python installation failure in AWS Glue job environment. While pinning library version increases stability, pip resolution is still not fully deterministic, so similar issues can arise. As a best practice, AWS Glue recommends using frozen artifacts such as zip of wheels or individual wheel files (see the section called "(Recommended) Installing additional Python libraries in AWS Glue 5.0 or above using Zip of Wheels" for more details).

Important

If you do not pin the versions of your transitive dependencies, a primary dependency may pull incompatible transitive dependency versions. As a best practice, all library versions should be pinned for increased consistency in AWS Glue jobs. Even better, AWS Glue recommends packaging your dependencies into a zip of wheels file to ensure maximum consistency and reliability for your production workloads.

Installing additional Python libraries directly configuring as comma separated list

To update or to add a new Python module AWS Glue allows passing `--additional-python-modules` parameter with a list of comma-separated Python modules as values. For example to update/ add scikit-learn module use the following key/value: `"--additional-python-modules", "scikit-learn==0.21.3"`. You have two options to directly configure the python modules.

- **Pinned Python Module**

  ```
  "--additional-python-modules", "scikit-learn==0.21.3,ephem==4.1.6"
  ```

- **Unpinned Python Module: (Not recommended for Production Workloads)**

  ```
  "--additional-python-modules", "scikit-learn>==0.20.0,ephem>=4.0.0"
  ```

  OR

  ```
  "--additional-python-modules", "scikit-learn,ephem"
  ```

> **Important**
>
> Use this option with caution, especially in production workloads. Pulling dependencies from PyPI at runtime is highly risky because you cannot be sure what artifact pip resolves to. Using unpinned library versions is especially risky since it pulls latest version of the python modules, which can introduce breaking changes or bring in incompatible python module. This could result in job failure due to python installation failure in AWS Glue job environment. While pinning library version increases stability, pip resolution is still not fully deterministic, so similar issues can arise. As a best practice, AWS Glue recommends using frozen artifacts such as zip of wheels or individual wheel files (see the section called "(Recommended) Installing additional Python libraries in AWS Glue 5.0 or above using Zip of Wheels" for more details).

> **Important**
>
> If you do not pin the versions of your transitive dependencies, a primary dependency may pull incompatible transitive dependency versions. As a best practice, all library versions should be pinned for increased consistency in AWS Glue jobs. Even better, AWS Glue recommends packaging your dependencies into a zip of wheels file to ensure maximum consistency and reliability for your production workloads.

Including Python files with PySpark native features

AWS Glue uses PySpark to include Python files in AWS Glue ETL jobs. You will want to use `--additional-python-modules` to manage your dependencies when available. You can use the `--`

`extra-py-files` job parameter to include Python files. Dependencies must be hosted in Amazon S3 and the argument value should be a comma delimited list of Amazon S3 paths with no spaces. This functionality behaves like the Python dependency management you would use with Spark. For more information on Python dependency management in Spark, see Using PySpark Native Features page in Apache Spark documentation. `--extra-py-files` is useful in cases where your additional code is not packaged, or when you are migrating a Spark program with an existing toolchain for managing dependencies. For your dependency tooling to be maintainable, you will have to bundle your dependencies before submitting.

Programming scripts that use visual transforms

When you create a AWS Glue job using the AWS Glue Studio visual interface, you can transform your data with managed data transform nodes and custom visual transforms. For more information about managed data transform nodes, see the section called "Transform data with AWS Glue managed transforms". For more information about custom visual transforms, see the section called " Transform data with custom visual transforms ". Scripts using visual transforms can only be generated when your job **Language** is set to use Python.

When generating a AWS Glue job using visual transforms, AWS Glue Studio will include these transforms in the runtime environment using the `--extra-py-files` parameter in the job configuration. For more information about job parameters, see the section called "Job parameters". When making changes to a generated script or runtime environment, you will need to preserve this job configuration for your script to run successfully.

Zipping libraries for inclusion

Unless a library is contained in a single `.py` file, it should be packaged in a `.zip` archive. The package directory should be at the root of the archive, and must contain an `__init__.py` file for the package. Python will then be able to import the package in the normal way.

If your library only consists of a single Python module in one `.py` file, you do not need to place it in a `.zip` file.

Loading Python libraries in AWS Glue Studio notebooks

To specify Python libraries in AWS Glue Studio notebooks, see Installing additional Python modules.

Loading Python libraries in a development endpoint in AWS Glue 0.9/1.0

If you are using different library sets for different ETL scripts, you can either set up a separate development endpoint for each set, or you can overwrite the library `.zip` file(s) that your development endpoint loads every time you switch scripts.

You can use the console to specify one or more library .zip files for a development endpoint when you create it. After assigning a name and an IAM role, choose **Script Libraries and job parameters (optional)** and enter the full Amazon S3 path to your library `.zip` file in the **Python library path** box. For example:

```
s3://bucket/prefix/site-packages.zip
```

If you want, you can specify multiple full paths to files, separating them with commas but no spaces, like this:

```
s3://bucket/prefix/lib_A.zip,s3://bucket_B/prefix/lib_X.zip
```

If you update these `.zip` files later, you can use the console to re-import them into your development endpoint. Navigate to the developer endpoint in question, check the box beside it, and choose **Update ETL libraries** from the **Action** menu.

In a similar way, you can specify library files using the AWS Glue APIs. When you create a development endpoint by calling CreateDevEndpoint action (Python: create_dev_endpoint), you can specify one or more full paths to libraries in the `ExtraPythonLibsS3Path` parameter, in a call that looks this:

```
dep = glue.create_dev_endpoint(
             EndpointName="testDevEndpoint",
             RoleArn="arn:aws:iam::123456789012",
             SecurityGroupIds="sg-7f5ad1ff",
             SubnetId="subnet-c12fdba4",
             PublicKey="ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAABAQCtp04H/y...",
             NumberOfNodes=3,
             ExtraPythonLibsS3Path="s3://bucket/prefix/lib_A.zip,s3://bucket_B/prefix/
lib_X.zip")
```

When you update a development endpoint, you can also update the libraries it loads using a DevEndpointCustomLibraries object and setting the `UpdateEtlLibraries` parameter to `True` when calling UpdateDevEndpoint (update_dev_endpoint).

Using Python libraries in a job or JobRun

When you are creating a new Job on the console, you can specify one or more library .zip files by choosing **Script Libraries and job parameters (optional)** and entering the full Amazon S3 library path(s) in the same way you would when creating a development endpoint:

```
s3://bucket/prefix/lib_A.zip,s3://bucket_B/prefix/lib_X.zip
```

If you are calling CreateJob (create_job), you can specify one or more full paths to default libraries using the `--extra-py-files` default parameter, like this:

```
job = glue.create_job(Name='sampleJob',
                      Role='Glue_DefaultRole',
                      Command={'Name': 'glueetl',
                               'ScriptLocation': 's3://my_script_bucket/scripts/
my_etl_script.py'},
                      DefaultArguments={'--extra-py-files': 's3://bucket/prefix/
lib_A.zip,s3://bucket_B/prefix/lib_X.zip'})
```

Then when you are starting a JobRun, you can override the default library setting with a different one:

```
runId = glue.start_job_run(JobName='sampleJob',
                           Arguments={'--extra-py-files': 's3://bucket/prefix/
lib_B.zip'})
```

Proactively analyze Python dependencies

To proactively identify potential dependency issues before deploying to AWS Glue, you can use the dependency analysis tool to validate your Python packages against your target AWS Glue environment.

AWS provides an open-source Python dependency analyzer tool specifically designed for AWS Glue environments. This tool is available in the AWS Glue samples repository and can be used locally to validate your dependencies before deployment.

This analysis helps ensure your dependencies follow the recommended practice of pinning all library versions for consistent production deployments. For more details, please see the tool's README .

Using the AWS Glue Dependency Analyzer

The AWS Glue Python Dependency Analyzer helps identify unpinned dependencies and version conflicts by simulating pip installation with platform-specific constraints that match your target AWS Glue environment.

```
# Analyze a single Glue job
python glue_dependency_analyzer.py -j my-glue-job

# Analyze multiple jobs with specific AWS configuration
python glue_dependency_analyzer.py -j job1 -j job2 --aws-profile production --aws-
region us-west-2
```

The tool will flag:

- Unpinned dependencies that could install different versions across job runs
- Version conflicts between packages
- Dependencies not available for your target AWS Glue environment

Analyze and fix job failures due to Python dependencies with Amazon Q Developer

Amazon Q Developer is a generative artificial intelligence (AI) powered conversational assistant that can help you understand, build, extend, and operate AWS applications. You can download it by following the instructions in the Getting started guide for Amazon Q.

Amazon Q Developer can be used to analyze and fix job failures due to python dependency. We suggest using the following prompt by replacing the job <Job-Name> placeholder with the name of your glue job.

```
I have an AWS Glue job named <Job-Name> that has failed due to Python module
 installation conflicts. Please assist in diagnosing and resolving this issue using the
 following systematic approach. Proceed once sufficient information is available.

Objective: Implement a fix that addresses the root cause module while minimizing
 disruption to the existing working environment.
```

```
Step 1: Root Cause Analysis
• Retrieve the most recent failed job run ID for the specified Glue job
• Extract error logs from CloudWatch Logs using the job run ID as a log stream prefix
• Analyze the logs to identify:
  • The recently added or modified Python module that triggered the dependency conflict
  • The specific dependency chain causing the installation failure
  • Version compatibility conflicts between required and existing modules

Step 2: Baseline Configuration Identification
• Locate the last successful job run ID prior to the dependency failure
• Document the Python module versions that were functioning correctly in that baseline
 run
• Establish the compatible version constraints for conflicting dependencies

Step 3: Targeted Resolution Implementation
• Apply pinning by updating the job's additional_python_modules parameter
• Pin only the root cause module and its directly conflicting dependencies to
 compatible versions, and do not remove python modules unless necessary
• Preserve flexibility for non-conflicting modules by avoiding unnecessary version
 constraints
• Deploy the configuration changes with minimal changes to the existing configuration
 and execute a validation test run. Do not change the Glue versions.

Implementation Example:
Scenario: Recently added pandas==2.0.0 to additional_python_modules
Error: numpy version conflict (pandas 2.0.0 requires numpy>=1.21, but existing job code
 requires numpy<1.20)
Resolution: Update additional_python_modules to "pandas==1.5.3,numpy==1.19.5"
Rationale: Use pandas 1.5.3 (compatible with numpy 1.19.5) and pin numpy to last known
 working version

Expected Outcome: Restore job functionality with minimal configuration changes while
 maintaining system stability.
```

The prompt instructs Q to:

1. Fetch the latest failed job run ID
2. Find associated logs and details
3. Find successful job runs to detect any changed Python packages
4. Make any configuration fixes and trigger another test run

Python modules already provided in AWS Glue

To change the version of these provided modules, provide new versions with the `--additional-python-modules` job parameter.

AWS Glue version 5.1

AWS Glue version 5.1 includes the following Python modules out of the box:

- aiobotocore==2.25.1
- aiohappyeyeballs==2.6.1
- aiohttp==3.13.2
- aioitertools==0.12.0
- aiosignal==1.4.0
- appdirs==1.4.4
- attrs==25.4.0
- boto3==1.40.61
- botocore==1.40.61
- certifi==2025.10.5
- charset-normalizer==3.4.4
- choreographer==1.2.0
- contourpy==1.3.3
- cycler==0.12.1
- distlib==0.4.0
- filelock==3.20.0
- fonttools==4.60.1
- frozenlist==1.8.0
- fsspec==2025.10.0
- idna==3.11
- iniconfig==2.3.0
- jmespath==1.0.1
- kaleido==1.2.0
- kiwisolver==1.4.9

- logistro==2.0.1
- matplotlib==3.10.7
- multidict==6.7.0
- narwhals==2.10.2
- numpy==2.3.4
- orjson==3.11.4
- packaging==25.0
- pandas==2.3.3
- pillow==12.0.0
- pip==24.0
- platformdirs==4.5.0
- plotly==6.4.0
- pluggy==1.6.0
- propcache==0.4.1
- pyarrow==22.0.0
- Pygments==2.19.2
- pyparsing==3.2.5
- pytest-timeout==2.4.0
- pytest==8.4.2
- python-dateutil==2.9.0.post0
- pytz==2025.2
- requests==2.32.5
- s3fs==2025.10.0
- s3transfer==0.14.0
- seaborn==0.13.2
- setuptools==79.0.1
- simplejson==3.20.2
- six==1.17.0
- tenacity==9.1.2
- typing_extensions==4.15.0

- tzdata==2025.2
- urllib3==2.5.0
- uv==0.9.7
- virtualenv==20.35.4
- wrapt==1.17.3
- yarl==1.22.0

AWS Glue version 5.0

AWS Glue version 5.0 includes the following Python modules out of the box:

- aiobotocore==2.13.1
- aiohappyeyeballs==2.3.5
- aiohttp==3.10.1
- aioitertools==0.11.0
- aiosignal==1.3.1
- appdirs==1.4.4
- attrs==24.2.0
- boto3==1.34.131
- botocore==1.34.131
- certifi==2024.7.4
- charset-normalizer==3.3.2
- contourpy==1.2.1
- cycler==0.12.1
- fonttools==4.53.1
- frozenlist==1.4.1
- fsspec==2024.6.1
- idna==2.10
- jmespath==0.10.0
- kaleido==0.2.1
- kiwisolver==1.4.5

- matplotlib==3.9.0
- multidict==6.0.5
- numpy==1.26.4
- packaging==24.1
- pandas==2.2.2
- pillow==10.4.0
- pip==23.0.1
- plotly==5.23.0
- pyarrow==17.0.0
- pyparsing==3.1.2
- python-dateutil==2.9.0.post0
- pytz==2024.1
- requests==2.32.2
- s3fs==2024.6.1
- s3transfer==0.10.2
- seaborn==0.13.2
- setuptools==59.6.0
- six==1.16.0
- tenacity==9.0.0
- tzdata==2024.1
- urllib3==1.25.10
- virtualenv==20.4.0
- wrapt==1.16.0
- yarl==1.9.4

AWS Glue version 4.0

AWS Glue version 4.0 includes the following Python modules out of the box:

- aiobotocore==2.4.1
- aiohttp==3.8.3

- aioitertools==0.11.0
- aiosignal==1.3.1
- async-timeout==4.0.2
- asynctest==0.13.0
- attrs==22.2.0
- avro-python3==1.10.2
- boto3==1.24.70
- botocore==1.27.59
- certifi==2021.5.30
- chardet==3.0.4
- charset-normalizer==2.1.1
- click==8.1.3
- cycler==0.10.0
- Cython==0.29.32
- fsspec==2021.8.1
- idna==2.10
- importlib-metadata==5.0.0
- jmespath==0.10.0
- joblib==1.0.1
- kaleido==0.2.1
- kiwisolver==1.4.4
- matplotlib==3.4.3
- mpmath==1.2.1
- multidict==6.0.4
- nltk==3.7
- numpy==1.23.5
- packaging==23.0
- pandas==1.5.1
- patsy==0.5.1
- Pillow==9.4.0

- pip==23.0.1
- plotly==5.16.0
- pmdarima==2.0.1
- ptvsd==4.3.2
- pyarrow==10.0.0
- pydevd==2.5.0
- pyhocon==0.3.58
- PyMySQL==1.0.2
- pyparsing==2.4.7
- python-dateutil==2.8.2
- pytz==2021.1
- PyYAML==6.0.1
- regex==2022.10.31
- requests==2.23.0
- s3fs==2022.11.0
- s3transfer==0.6.0
- scikit-learn==1.1.3
- scipy==1.9.3
- setuptools==49.1.3
- six==1.16.0
- statsmodels==0.13.5
- subprocess32==3.5.4
- sympy==1.8
- tbats==1.1.0
- threadpoolctl==3.1.0
- tqdm==4.64.1
- typing_extensions==4.4.0
- urllib3==1.25.11
- wheel==0.37.0
- wrapt==1.14.1

- yarl==1.8.2
- zipp==3.10.0

AWS Glue version 3.0

AWS Glue version 3.0 includes the following Python modules out of the box:,

- aiobotocore==1.4.2
- aiohttp==3.8.3
- aioitertools==0.11.0
- aiosignal==1.3.1
- async-timeout==4.0.2
- asynctest==0.13.0
- attrs==22.2.0
- avro-python3==1.10.2
- boto3==1.18.50
- botocore==1.21.50
- certifi==2021.5.30
- chardet==3.0.4
- charset-normalizer==2.1.1
- click==8.1.3
- cycler==0.10.0
- Cython==0.29.4
- docutils==0.17.1
- enum34==1.1.10
- frozenlist==1.3.3
- fsspec==2021.8.1
- idna==2.10
- importlib-metadata==6.0.0
- jmespath==0.10.0
- joblib==1.0.1

- kiwisolver==1.3.2
- matplotlib==3.4.3
- mpmath==1.2.1
- multidict==6.0.4
- nltk==3.6.3
- numpy==1.19.5
- packaging==23.0
- pandas==1.3.2
- patsy==0.5.1
- Pillow==9.4.0
- pip==23.0
- pmdarima==1.8.2
- ptvsd==4.3.2
- pyarrow==5.0.0
- pydevd==2.5.0
- pyhocon==0.3.58
- PyMySQL==1.0.2
- pyparsing==2.4.7
- python-dateutil==2.8.2
- pytz==2021.1
- PyYAML==5.4.1
- regex==2022.10.31
- requests==2.23.0
- s3fs==2021.8.1
- s3transfer==0.5.0
- scikit-learn==0.24.2
- scipy==1.7.1
- six==1.16.0
- Spark==1.0
- statsmodels==0.12.2

- subprocess32==3.5.4
- sympy==1.8
- tbats==1.1.0
- threadpoolctl==3.1.0
- tqdm==4.64.1
- typing_extensions==4.4.0
- urllib3==1.25.11
- wheel==0.37.0
- wrapt==1.14.1
- yarl==1.8.2
- zipp==3.12.0

AWS Glue version 2.0

AWS Glue version 2.0 includes the following Python modules out of the box:

- avro-python3==1.10.0
- awscli==1.27.60
- boto3==1.12.4
- botocore==1.15.4
- certifi==2019.11.28
- chardet==3.0.4
- click==8.1.3
- colorama==0.4.4
- cycler==0.10.0
- Cython==0.29.15
- docutils==0.15.2
- enum34==1.1.9
- fsspec==0.6.2
- idna==2.9
- importlib-metadata==6.0.0

- jmespath==0.9.4
- joblib==0.14.1
- kiwisolver==1.1.0
- matplotlib==3.1.3
- mpmath==1.1.0
- nltk==3.5
- numpy==1.18.1
- pandas==1.0.1
- patsy==0.5.1
- pmdarima==1.5.3
- ptvsd==4.3.2
- pyarrow==0.16.0
- pyasn1==0.4.8
- pydevd==1.9.0
- pyhocon==0.3.54
- PyMySQL==0.9.3
- pyparsing==2.4.6
- python-dateutil==2.8.1
- pytz==2019.3
- PyYAML==5.3.1
- regex==2022.10.31
- requests==2.23.0
- rsa==4.7.2
- s3fs==0.4.0
- s3transfer==0.3.3
- scikit-learn==0.22.1
- scipy==1.4.1
- setuptools==45.2.0
- six==1.14.0
- Spark==1.0

- statsmodels==0.11.1
- subprocess32==3.5.4
- sympy==1.5.1
- tbats==1.0.9
- tqdm==4.64.1
- typing-extensions==4.4.0
- urllib3==1.25.8
- wheel==0.35.1
- zipp==3.12.0

Appendix A: Creating a Zip of Wheels Artifact

We demonstrate by example how to create a zip of wheels artifact. The example shown downloads the packages `cryptography` and `scipy` into a zip of wheels artifact and copies the zip of wheels to an Amazon S3 location.

1. You must run the commands to create the zip of wheels in an Amazon Linux environment similar to Glue's environment. See Appendix B: AWS Glue environment details. Glue 5.1 uses AL2023 with python version 3.11. Create Dockerfile that will build this environment:

```
FROM --platform=linux/amd64 public.ecr.aws/amazonlinux/amazonlinux:2023-minimal

# Install Python 3.11, pip, and zip utility
RUN dnf install -y python3.11 pip zip && \
    dnf clean all

WORKDIR /build
```

2. Create a requirements.txt file

```
cryptography
scipy
```

3. Build and spin up docker container

```
# Build docker image
docker build --platform linux/amd64 -t glue-wheel-builder .
```

```
# Spin up container
docker run --platform linux/amd64 -v $(pwd)/requirements.txt:/input/
requirements.txt:ro -v $(pwd):/output -it glue-wheel-builder bash
```

4. Run the following commands in the docker image

```
# Create a directory for the wheels
mkdir wheels

# Copy requirements.txt into wheels directory
cp /input/requirements.txt wheels/

# Download the wheels with the correct platform and Python version
pip3 download \
    -r wheels/requirements.txt \
    --dest wheels/ \
    --platform manylinux2014_x86_64 \
    --python-version 311 \
    --only-binary=:all:

# Package the wheels into a zip archive with the .gluewheels.zip suffix
zip -r mylibraries-1.0.0.gluewheels.zip wheels/

# Copy zip to output
cp mylibraries-1.0.0.gluewheels.zip /output/

# Exit the container
exit
```

5. Upload zip of wheels to Amazon S3 location

```
aws s3 cp mylibraries-1.0.0.gluewheels.zip s3://amzn-s3-demo-bucket/example-prefix/
```

6. Optional cleanup

```
rm mylibraries-1.0.0.gluewheels.zip
rm Dockerfile
rm requirements.txt
```

7. Run the Glue job with the following job args:

```
--additional-python-modules s3://amzn-s3-demo-bucket/example-prefix/
mylibraries-1.0.0.gluewheels.zip
```

```
--python-modules-installer-option --no-index
```

Appendix B: AWS Glue environment details

Glue Version Compatibility and Installation Methods

AWS Glue version	Python version	Base image	glibc version	Compatible platform tags
5.1	3.11	Amazon Linux 2023 (AL2023)	2.34	manylinux_2_34_x86_64 manylinux_2_28_x86_64 manylinux2014_x86_64
5.0	3.11	Amazon Linux 2023 (AL2023)	2.34	manylinux_2_34_x86_64 manylinux_2_28_x86_64 manylinux2014_x86_64
4.0	3.10	Amazon Linux 2 (AL2)	2.26	manylinux2014_x86_64
3.0	3.7	Amazon Linux 2 (AL2)	2.26	manylinux2014_x86_64
2.0	3.7	Amazon Linux AMI (AL1)	2.17	manylinux2014_x86_64

Under the AWS shared responsibility model, you are responsible for the management of additional Python modules, libraries, and their dependencies that you use with your AWS Glue ETL jobs. This includes applying updates and security patches.

AWS Glue does not support compiling native code in the job environment. However, AWS Glue jobs run within an Amazon-managed Linux environment. You may be able to provide your native dependencies in a compiled form through a Python wheel file. Please refer to above table for AWS Glue version compatibility details.

> **Important**
>
> Using incompatible dependencies can result in runtime issues, particularly for libraries with native extensions that must match the target environment's architecture and system

libraries. Each AWS Glue version runs on a specific Python version with pre-installed libraries and system configurations.

AWS Glue Python code samples

- Code example: Joining and relationalizing data
- Code example: Data preparation using ResolveChoice, Lambda, and ApplyMapping

Code example: Joining and relationalizing data

This example uses a dataset that was downloaded from http://everypolitician.org/ to the `sample-dataset` bucket in Amazon Simple Storage Service (Amazon S3): `s3://awsglue-datasets/examples/us-legislators/all`. The dataset contains data in JSON format about United States legislators and the seats that they have held in the US House of Representatives and Senate, and has been modified slightly and made available in a public Amazon S3 bucket for purposes of this tutorial.

You can find the source code for this example in the `join_and_relationalize.py` file in the AWS Glue samples repository on the GitHub website.

Using this data, this tutorial shows you how to do the following:

- Use an AWS Glue crawler to classify objects that are stored in a public Amazon S3 bucket and save their schemas into the AWS Glue Data Catalog.
- Examine the table metadata and schemas that result from the crawl.
- Write a Python extract, transfer, and load (ETL) script that uses the metadata in the Data Catalog to do the following:
  - Join the data in the different source files together into a single data table (that is, denormalize the data).
  - Filter the joined table into separate tables by type of legislator.
  - Write out the resulting data to separate Apache Parquet files for later analysis.

The preferred way to debug Python or PySpark scripts while running on AWS is to use Notebooks on AWS Glue Studio.

Step 1: Crawl the data in the Amazon S3 bucket

1. Sign in to the AWS Management Console, and open the AWS Glue console at https://console.aws.amazon.com/glue/.
2. Following the steps in Configuring a crawler, create a new crawler that can crawl the `s3://awsglue-datasets/examples/us-legislators/all` dataset into a database named `legislators` in the AWS Glue Data Catalog. The example data is already in this public Amazon S3 bucket.
3. Run the new crawler, and then check the `legislators` database.

   The crawler creates the following metadata tables:

   - `persons_json`
   - `memberships_json`
   - `organizations_json`
   - `events_json`
   - `areas_json`
   - `countries_r_json`

   This is a semi-normalized collection of tables containing legislators and their histories.

Step 2: Add boilerplate script to the development endpoint notebook

Paste the following boilerplate script into the development endpoint notebook to import the AWS Glue libraries that you need, and set up a single `GlueContext`:

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job

glueContext = GlueContext(SparkContext.getOrCreate())
```

Step 3: Examine the schemas from the data in the Data Catalog

Next, you can easily create examine a DynamicFrame from the AWS Glue Data Catalog, and examine the schemas of the data. For example, to see the schema of the `persons_json` table, add the following in your notebook:

```
persons = glueContext.create_dynamic_frame.from_catalog(
             database="legislators",
             table_name="persons_json")
print "Count: ", persons.count()
persons.printSchema()
```

Here's the output from the print calls:

```
Count:  1961
root
|-- family_name: string
|-- name: string
|-- links: array
|    |-- element: struct
|    |    |-- note: string
|    |    |-- url: string
|-- gender: string
|-- image: string
|-- identifiers: array
|    |-- element: struct
|    |    |-- scheme: string
|    |    |-- identifier: string
|-- other_names: array
|    |-- element: struct
|    |    |-- note: string
|    |    |-- name: string
|    |    |-- lang: string
|-- sort_name: string
|-- images: array
|    |-- element: struct
|    |    |-- url: string
|-- given_name: string
|-- birth_date: string
|-- id: string
|-- contact_details: array
```

```
|    |-- element: struct
|    |    |-- type: string
|    |    |-- value: string
|-- death_date: string
```

Each person in the table is a member of some US congressional body.

To view the schema of the `memberships_json` table, type the following:

```
memberships = glueContext.create_dynamic_frame.from_catalog(
                 database="legislators",
                 table_name="memberships_json")
print "Count: ", memberships.count()
memberships.printSchema()
```

The output is as follows:

```
Count:  10439
root
|-- area_id: string
|-- on_behalf_of_id: string
|-- organization_id: string
|-- role: string
|-- person_id: string
|-- legislative_period_id: string
|-- start_date: string
|-- end_date: string
```

The `organizations` are parties and the two chambers of Congress, the Senate and House of Representatives. To view the schema of the `organizations_json` table, type the following:

```
orgs = glueContext.create_dynamic_frame.from_catalog(
           database="legislators",
           table_name="organizations_json")
print "Count: ", orgs.count()
orgs.printSchema()
```

The output is as follows:

```
Count:  13
root
|-- classification: string
|-- links: array
|    |-- element: struct
|    |    |-- note: string
|    |    |-- url: string
|-- image: string
|-- identifiers: array
|    |-- element: struct
|    |    |-- scheme: string
|    |    |-- identifier: string
|-- other_names: array
|    |-- element: struct
|    |    |-- lang: string
|    |    |-- note: string
|    |    |-- name: string
|-- id: string
|-- name: string
|-- seats: int
|-- type: string
```

Step 4: Filter the data

Next, keep only the fields that you want, and rename `id` to `org_id`. The dataset is small enough that you can view the whole thing.

The `toDF()` converts a `DynamicFrame` to an Apache Spark `DataFrame`, so you can apply the transforms that already exist in Apache Spark SQL:

```
orgs = orgs.drop_fields(['other_names',
                         'identifiers']).rename_field(
                             'id', 'org_id').rename_field(
                                'name', 'org_name')
orgs.toDF().show()
```

The following shows the output:

```
+--------------+--------------------+--------------------+--------------------+-----
+-----------+--------------------+
|classification|              org_id|            org_name|               links|seats|
     type|               image|
+--------------+--------------------+--------------------+--------------------+-----
+-----------+--------------------+
|         party|            party/al|                  AL|                null| null|
     null|                null|
|         party|      party/democrat|            Democrat|[[website,http://...| null|
     null|https://upload.wi...|
|         party|party/democrat-li...|    Democrat-Liberal|[[website,http://...| null|
     null|                null|
|   legislature|d56acebe-8fdc-47b...|House of Represen...|                null|  435|
lower house|                null|
|         party|   party/independent|         Independent|                null| null|
     null|                null|
|         party|party/new_progres...|     New Progressive|[[website,http://...| null|
     null|https://upload.wi...|
|         party|party/popular_dem...|    Popular Democrat|[[website,http://...| null|
     null|                null|
|         party|    party/republican|          Republican|[[website,http://...| null|
     null|https://upload.wi...|
|         party|party/republican-...|Republican-Conser...|[[website,http://...| null|
     null|                null|
|         party|      party/democrat|            Democrat|[[website,http://...| null|
     null|https://upload.wi...|
|         party|   party/independent|         Independent|                null| null|
     null|                null|
|         party|    party/republican|          Republican|[[website,http://...| null|
     null|https://upload.wi...|
|   legislature|8fa6c3d2-71dc-478...|             Senate|                null|  100|
upper house|                null|
+--------------+--------------------+--------------------+--------------------+-----
+-----------+--------------------+
```

Type the following to view the `organizations` that appear in `memberships`:

```
memberships.select_fields(['organization_id']).toDF().distinct().show()
```

The following shows the output:

```
+--------------------+
|     organization_id|
+--------------------+
|d56acebe-8fdc-47b...|
|8fa6c3d2-71dc-478...|
+--------------------+
```

Step 5: Put it all together

Now, use AWS Glue to join these relational tables and create one full history table of legislator `memberships` and their corresponding `organizations`.

1. First, join `persons` and `memberships` on `id` and `person_id`.
2. Next, join the result with `orgs` on `org_id` and `organization_id`.
3. Then, drop the redundant fields, `person_id` and `org_id`.

You can do all these operations in one (extended) line of code:

```
l_history = Join.apply(orgs,
                       Join.apply(persons, memberships, 'id', 'person_id'),
                       'org_id', 'organization_id').drop_fields(['person_id',
 'org_id'])
print "Count: ", l_history.count()
l_history.printSchema()
```

The output is as follows:

```
Count:  10439
root
|-- role: string
|-- seats: int
|-- org_name: string
|-- links: array
|    |-- element: struct
|    |    |-- note: string
|    |    |-- url: string
|-- type: string
|-- sort_name: string
|-- area_id: string
```

```
|-- images: array
|    |-- element: struct
|    |    |-- url: string
|-- on_behalf_of_id: string
|-- other_names: array
|    |-- element: struct
|    |    |-- note: string
|    |    |-- name: string
|    |    |-- lang: string
|-- contact_details: array
|    |-- element: struct
|    |    |-- type: string
|    |    |-- value: string
|-- name: string
|-- birth_date: string
|-- organization_id: string
|-- gender: string
|-- classification: string
|-- death_date: string
|-- legislative_period_id: string
|-- identifiers: array
|    |-- element: struct
|    |    |-- scheme: string
|    |    |-- identifier: string
|-- image: string
|-- given_name: string
|-- family_name: string
|-- id: string
|-- start_date: string
|-- end_date: string
```

You now have the final table that you can use for analysis. You can write it out in a compact, efficient format for analytics—namely Parquet—that you can run SQL over in AWS Glue, Amazon Athena, or Amazon Redshift Spectrum.

The following call writes the table across multiple files to support fast parallel reads when doing analysis later:

```
glueContext.write_dynamic_frame.from_options(frame = l_history,
          connection_type = "s3",
          connection_options = {"path": "s3://glue-sample-target/output-dir/
legislator_history"},
```

```
          format = "parquet")
```

To put all the history data into a single file, you must convert it to a data frame, repartition it, and write it out:

```
s_history = l_history.toDF().repartition(1)
s_history.write.parquet('s3://glue-sample-target/output-dir/legislator_single')
```

Or, if you want to separate it by the Senate and the House:

```
l_history.toDF().write.parquet('s3://glue-sample-target/output-dir/legislator_part',
                               partitionBy=['org_name'])
```

Step 6: Transform the data for relational databases

AWS Glue makes it easy to write the data to relational databases like Amazon Redshift, even with semi-structured data. It offers a transform `relationalize`, which flattens `DynamicFrames` no matter how complex the objects in the frame might be.

Using the `l_history` `DynamicFrame` in this example, pass in the name of a root table (`hist_root`) and a temporary working path to `relationalize`. This returns a `DynamicFrameCollection`. You can then list the names of the `DynamicFrames` in that collection:

```
dfc = l_history.relationalize("hist_root", "s3://glue-sample-target/temp-dir/")
dfc.keys()
```

The following is the output of the `keys` call:

```
[u'hist_root', u'hist_root_contact_details', u'hist_root_links',
 u'hist_root_other_names', u'hist_root_images', u'hist_root_identifiers']
```

`Relationalize` broke the history table out into six new tables: a root table that contains a record for each object in the `DynamicFrame`, and auxiliary tables for the arrays. Array handling in relational databases is often suboptimal, especially as those arrays become large. Separating the arrays into different tables makes the queries go much faster.

Next, look at the separation by examining `contact_details`:

```
l_history.select_fields('contact_details').printSchema()
dfc.select('hist_root_contact_details').toDF().where("id = 10 or id =
 75").orderBy(['id','index']).show()
```

The following is the output of the `show` call:

```
root
|-- contact_details: array
|    |-- element: struct
|    |    |-- type: string
|    |    |-- value: string
+---+-----+-----------------------+-------------------------+
| id|index|contact_details.val.type|contact_details.val.value|
+---+-----+-----------------------+-------------------------+
| 10|    0|                    fax|                         |
| 10|    1|                       |             202-225-1314|
| 10|    2|                  phone|                         |
| 10|    3|                       |             202-225-3772|
| 10|    4|                twitter|                         |
| 10|    5|                       |          MikeRossUpdates|
| 75|    0|                    fax|                         |
| 75|    1|                       |             202-225-7856|
| 75|    2|                  phone|                         |
| 75|    3|                       |             202-225-2711|
| 75|    4|                twitter|                         |
| 75|    5|                       |                SenCapito|
+---+-----+-----------------------+-------------------------+
```

The `contact_details` field was an array of structs in the original `DynamicFrame`. Each element of those arrays is a separate row in the auxiliary table, indexed by `index`. The `id` here is a foreign key into the `hist_root` table with the key `contact_details`:

```
dfc.select('hist_root').toDF().where(
    "contact_details = 10 or contact_details = 75").select(
       ['id', 'given_name', 'family_name', 'contact_details']).show()
```

The following is the output:

```
+--------------------+----------+-----------+---------------+
|                  id|given_name|family_name|contact_details|
+--------------------+----------+-----------+---------------+
|f4fc30ee-7b42-432...|      Mike|       Ross|             10|
|e3c60f34-7d1b-4c0...|   Shelley|     Capito|             75|
+--------------------+----------+-----------+---------------+
```

Notice in these commands that `toDF()` and then a `where` expression are used to filter for the rows that you want to see.

So, joining the `hist_root` table with the auxiliary tables lets you do the following:

- Load data into databases without array support.
- Query each individual item in an array using SQL.

Safely store and access your Amazon Redshift credentials with a AWS Glue connection. For information about how to create your own connection, see Connecting to data.

You are now ready to write your data to a connection by cycling through the `DynamicFrames` one at a time:

```
for df_name in dfc.keys():
  m_df = dfc.select(df_name)
  print "Writing to table: ", df_name
  glueContext.write_dynamic_frame.from_jdbc_conf(frame = m_df, connection settings
 here)
```

Your connection settings will differ based on your type of relational database:

- For instructions on writing to Amazon Redshift consult the section called “Redshift connections”.
- For other databases, consult Connection types and options for ETL in AWS Glue for Spark.

Conclusion

Overall, AWS Glue is very flexible. It lets you accomplish, in a few lines of code, what normally would take days to write. You can find the entire source-to-target ETL scripts in the Python file `join_and_relationalize.py` in the AWS Glue samples on GitHub.

Code example: Data preparation using ResolveChoice, Lambda, and ApplyMapping

The dataset that is used in this example consists of Medicare Provider payment data that was downloaded from two Data.CMS.gov data sets: "Inpatient Prospective Payment System Provider Summary for the Top 100 Diagnosis-Related Groups - FY2011" and "Inpatient Charge Data FY 2011". After downloading the data, we modified the dataset to introduce a couple of erroneous records at the end of the file. This modified file is located in a public Amazon S3 bucket at `s3://awsglue-datasets/examples/medicare/Medicare_Hospital_Provider.csv`.

You can find the source code for this example in the `data_cleaning_and_lambda.py` file in the AWS Glue examples GitHub repository.

The preferred way to debug Python or PySpark scripts while running on AWS is to use Notebooks on AWS Glue Studio.

Step 1: Crawl the data in the Amazon S3 bucket

1. Sign in to the AWS Management Console and open the AWS Glue console at https://console.aws.amazon.com/glue/.
2. Following the process described in Configuring a crawler, create a new crawler that can crawl the `s3://awsglue-datasets/examples/medicare/Medicare_Hospital_Provider.csv` file, and can place the resulting metadata into a database named `payments` in the AWS Glue Data Catalog.
3. Run the new crawler, and then check the `payments` database. You should find that the crawler has created a metadata table named `medicare` in the database after reading the beginning of the file to determine its format and delimiter.

   The schema of the new `medicare` table is as follows:

```
Column  name                                Data type
================================================
drg definition                               string
provider id                                  bigint
provider name                                string
provider street address                      string
provider city                                string
provider state                               string
provider zip code                            bigint
hospital referral region description         string
total discharges                             bigint
```

```
average covered charges                    string
average total payments                     string
average medicare payments                  string
```

Step 2: Add boilerplate script to the development endpoint notebook

Paste the following boilerplate script into the development endpoint notebook to import the AWS Glue libraries that you need, and set up a single `GlueContext`:

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job

glueContext = GlueContext(SparkContext.getOrCreate())
```

Step 3: Compare different schema parsings

Next, you can see if the schema that was recognized by an Apache Spark `DataFrame` is the same as the one that your AWS Glue crawler recorded. Run this code:

```
medicare = spark.read.format(
   "com.databricks.spark.csv").option(
   "header", "true").option(
   "inferSchema", "true").load(
   's3://awsglue-datasets/examples/medicare/Medicare_Hospital_Provider.csv')
medicare.printSchema()
```

Here's the output from the `printSchema` call:

```
root
 |-- DRG Definition: string (nullable = true)
 |-- Provider Id: string (nullable = true)
 |-- Provider Name: string (nullable = true)
 |-- Provider Street Address: string (nullable = true)
 |-- Provider City: string (nullable = true)
 |-- Provider State: string (nullable = true)
```

```
 |-- Provider Zip Code: integer (nullable = true)
 |-- Hospital Referral Region Description: string (nullable = true)
 |--  Total Discharges : integer (nullable = true)
 |--  Average Covered Charges : string (nullable = true)
 |--  Average Total Payments : string (nullable = true)
 |-- Average Medicare Payments: string (nullable = true)
```

Next, look at the schema that an AWS Glue `DynamicFrame` generates:

```
medicare_dynamicframe = glueContext.create_dynamic_frame.from_catalog(
       database = "payments",
       table_name = "medicare")
medicare_dynamicframe.printSchema()
```

The output from `printSchema` is as follows:

```
root
 |-- drg definition: string
 |-- provider id: choice
 |    |-- long
 |    |-- string
 |-- provider name: string
 |-- provider street address: string
 |-- provider city: string
 |-- provider state: string
 |-- provider zip code: long
 |-- hospital referral region description: string
 |-- total discharges: long
 |-- average covered charges: string
 |-- average total payments: string
 |-- average medicare payments: string
```

The `DynamicFrame` generates a schema in which `provider id` could be either a `long` or a `string` type. The `DataFrame` schema lists `Provider Id` as being a `string` type, and the Data Catalog lists `provider id` as being a `bigint` type.

Which one is correct? There are two records at the end of the file (out of 160,000 records) with `string` values in that column. These are the erroneous records that were introduced to illustrate a problem.

To address this kind of problem, the AWS Glue `DynamicFrame` introduces the concept of a *choice* type. In this case, the `DynamicFrame` shows that both `long` and `string` values can appear in that column. The AWS Glue crawler missed the `string` values because it considered only a 2 MB prefix of the data. The Apache Spark `DataFrame` considered the whole dataset, but it was forced to assign the most general type to the column, namely `string`. In fact, Spark often resorts to the most general case when there are complex types or variations with which it is unfamiliar.

To query the `provider id` column, resolve the choice type first. You can use the `resolveChoice` transform method in your `DynamicFrame` to convert those `string` values to `long` values with a `cast:long` option:

```
medicare_res = medicare_dynamicframe.resolveChoice(specs = [('provider
 id','cast:long')])
medicare_res.printSchema()
```

The `printSchema` output is now:

```
root
 |-- drg definition: string
 |-- provider id: long
 |-- provider name: string
 |-- provider street address: string
 |-- provider city: string
 |-- provider state: string
 |-- provider zip code: long
 |-- hospital referral region description: string
 |-- total discharges: long
 |-- average covered charges: string
 |-- average total payments: string
 |-- average medicare payments: string
```

Where the value was a `string` that could not be cast, AWS Glue inserted a `null`.

Another option is to convert the choice type to a `struct`, which keeps values of both types.

Next, look at the rows that were anomalous:

```
medicare_res.toDF().where("'provider id' is NULL").show()
```

You see the following:

```
+--------------------+----------+--------------+----------------------+------------
+-------------+----------------+-------------------------------------+---------------
+-----------------------+---------------------+------------------------+
|      drg definition|provider id|  provider name|provider street address|provider
 city|provider state|provider zip code|hospital referral region description|total
 discharges|average covered charges|average total payments|average medicare payments|
+--------------------+----------+--------------+----------------------+------------
+-------------+----------------+-------------------------------------+---------------
+-----------------------+---------------------+------------------------+
|948 - SIGNS & SYM...|       null|            INC|       1050 DIVISION ST|
 MAUSTON|            WI|            53948|                        WI - Madison|
      12|              $11961.41|              $4619.00|                $3775.33|
|948 - SIGNS & SYM...|       null| INC- ST JOSEPH|     5000 W CHAMBERS ST|
 MILWAUKEE|            WI|            53210|                        WI - Milwaukee|
        14|              $10514.28|              $5562.50|                $4522.78|
+--------------------+----------+--------------+----------------------+------------
+-------------+----------------+-------------------------------------+---------------
+-----------------------+---------------------+------------------------+
```

Now remove the two malformed records, as follows:

```
medicare_dataframe = medicare_res.toDF()
medicare_dataframe = medicare_dataframe.where("'provider id' is NOT NULL")
```

Step 4: Map the data and use Apache Spark Lambda functions

AWS Glue does not yet directly support Lambda functions, also known as user-defined functions. But you can always convert a `DynamicFrame` to and from an Apache Spark `DataFrame` to take advantage of Spark functionality in addition to the special features of `DynamicFrames`.

Next, turn the payment information into numbers, so analytic engines like Amazon Redshift or Amazon Athena can do their number crunching faster:

```
from pyspark.sql.functions import udf
from pyspark.sql.types import StringType

chop_f = udf(lambda x: x[1:], StringType())
medicare_dataframe = medicare_dataframe.withColumn(
```

```
        "ACC", chop_f(
            medicare_dataframe["average covered charges"])).withColumn(
                "ATP", chop_f(
                    medicare_dataframe["average total payments"])).withColumn(
                        "AMP", chop_f(
                            medicare_dataframe["average medicare payments"]))
medicare_dataframe.select(['ACC', 'ATP', 'AMP']).show()
```

The output from the `show` call is as follows:

```
+--------+-------+-------+
|     ACC|    ATP|    AMP|
+--------+-------+-------+
|32963.07|5777.24|4763.73|
|15131.85|5787.57|4976.71|
|37560.37|5434.95|4453.79|
|13998.28|5417.56|4129.16|
|31633.27|5658.33|4851.44|
|16920.79|6653.80|5374.14|
|11977.13|5834.74|4761.41|
|35841.09|8031.12|5858.50|
|28523.39|6113.38|5228.40|
|75233.38|5541.05|4386.94|
|67327.92|5461.57|4493.57|
|39607.28|5356.28|4408.20|
|22862.23|5374.65|4186.02|
|31110.85|5366.23|4376.23|
|25411.33|5282.93|4383.73|
| 9234.51|5676.55|4509.11|
|15895.85|5930.11|3972.85|
|19721.16|6192.54|5179.38|
|10710.88|4968.00|3898.88|
|51343.75|5996.00|4962.45|
+--------+-------+-------+
only showing top 20 rows
```

These are all still strings in the data. We can use the powerful `apply_mapping` transform method to drop, rename, cast, and nest the data so that other data programming languages and systems can easily access it:

```
from awsglue.dynamicframe import DynamicFrame
medicare_tmp_dyf = DynamicFrame.fromDF(medicare_dataframe, glueContext, "nested")
```

```
medicare_nest_dyf = medicare_tmp_dyf.apply_mapping([('drg definition', 'string', 'drg',
 'string'),
                ('provider id', 'long', 'provider.id', 'long'),
                ('provider name', 'string', 'provider.name', 'string'),
                ('provider city', 'string', 'provider.city', 'string'),
                ('provider state', 'string', 'provider.state', 'string'),
                ('provider zip code', 'long', 'provider.zip', 'long'),
                ('hospital referral region description', 'string','rr', 'string'),
                ('ACC', 'string', 'charges.covered', 'double'),
                ('ATP', 'string', 'charges.total_pay', 'double'),
                ('AMP', 'string', 'charges.medicare_pay', 'double')])
medicare_nest_dyf.printSchema()
```

The `printSchema` output is as follows:

```
root
 |-- drg: string
 |-- provider: struct
 |    |-- id: long
 |    |-- name: string
 |    |-- city: string
 |    |-- state: string
 |    |-- zip: long
 |-- rr: string
 |-- charges: struct
 |    |-- covered: double
 |    |-- total_pay: double
 |    |-- medicare_pay: double
```

Turning the data back into a Spark `DataFrame`, you can show what it looks like now:

```
medicare_nest_dyf.toDF().show()
```

The output is as follows:

```
+--------------------+--------------------+--------------+--------------------+
|                 drg|            provider|            rr|             charges|
+--------------------+--------------------+--------------+--------------------+

only showing top 20 rows
```

Step 5: Write the data to Apache Parquet

AWS Glue makes it easy to write the data in a format such as Apache Parquet that relational databases can effectively consume:

```
glueContext.write_dynamic_frame.from_options(
       frame = medicare_nest_dyf,
       connection_type = "s3",
       connection_options = {"path": "s3://glue-sample-target/output-dir/
medicare_parquet"},
       format = "parquet")
```

AWS Glue PySpark extensions reference

AWS Glue has created the following extensions to the PySpark Python dialect.

- Accessing parameters using `getResolvedOptions`
- PySpark extension types
- DynamicFrame class
- DynamicFrameCollection class
- DynamicFrameWriter class
- DynamicFrameReader class

- GlueContext class

Accessing parameters using `getResolvedOptions`

The AWS Glue `getResolvedOptions(args, options)` utility function gives you access to the arguments that are passed to your script when you run a job. To use this function, start by importing it from the AWS Glue `utils` module, along with the `sys` module:

```
import sys
from awsglue.utils import getResolvedOptions
```

`getResolvedOptions(args, options)`

- `args` – The list of arguments contained in `sys.argv`.
- `options` – A Python array of the argument names that you want to retrieve.

Example Retrieving arguments passed to a JobRun

Suppose that you created a JobRun in a script, perhaps within a Lambda function:

```
response = client.start_job_run(
             JobName = 'my_test_Job',
             Arguments = {
               '--day_partition_key':   'partition_0',
               '--hour_partition_key':  'partition_1',
               '--day_partition_value':  day_partition_value,
               '--hour_partition_value': hour_partition_value } )
```

To retrieve the arguments that are passed, you can use the `getResolvedOptions` function as follows:

```
import sys
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv,
                          ['JOB_NAME',
                           'day_partition_key',
                           'hour_partition_key',
                           'day_partition_value',
                           'hour_partition_value'])
```

```
print "The day-partition key is: ", args['day_partition_key']
print "and the day-partition value is: ", args['day_partition_value']
```

Note that each of the arguments are defined as beginning with two hyphens, then referenced in the script without the hyphens. The arguments use only underscores, not hyphens. Your arguments need to follow this convention to be resolved.

PySpark extension types

The types that are used by the AWS Glue PySpark extensions.

DataType

The base class for the other AWS Glue types.

`__init__(properties={})`

- `properties` – Properties of the data type (optional).

`typeName(cls)`

Returns the type of the AWS Glue type class (that is, the class name with "Type" removed from the end).

- `cls` – An AWS Glue class instance derived from `DataType`.

`jsonValue( )`

Returns a JSON object that contains the data type and properties of the class:

```
{
  "dataType": typeName,
  "properties": properties
}
```

AtomicType and simple derivatives

Inherits from and extends the DataType class, and serves as the base class for all the AWS Glue atomic data types.

`fromJsonValue(cls, json_value)`

Initializes a class instance with values from a JSON object.

- `cls` – An AWS Glue type class instance to initialize.
- `json_value` – The JSON object to load key-value pairs from.

The following types are simple derivatives of the AtomicType class:

- `BinaryType` – Binary data.
- `BooleanType` – Boolean values.
- `ByteType` – A byte value.
- `DateType` – A datetime value.
- `DoubleType` – A floating-point double value.
- `IntegerType` – An integer value.
- `LongType` – A long integer value.
- `NullType` – A null value.
- `ShortType` – A short integer value.
- `StringType` – A text string.
- `TimestampType` – A timestamp value (typically in seconds from 1/1/1970).
- `UnknownType` – A value of unidentified type.

DecimalType(AtomicType)

Inherits from and extends the AtomicType class to represent a decimal number (a number expressed in decimal digits, as opposed to binary base-2 numbers).

`__init__(precision=10, scale=2, properties={})`

- `precision` – The number of digits in the decimal number (optional; the default is 10).
- `scale` – The number of digits to the right of the decimal point (optional; the default is 2).
- `properties` – The properties of the decimal number (optional).

EnumType(AtomicType)

Inherits from and extends the AtomicType class to represent an enumeration of valid options.

`__init__(options)`

- `options` – A list of the options being enumerated.

collection types

- ArrayType(DataType)
- ChoiceType(DataType)
- MapType(DataType)
- Field(Object)
- StructType(DataType)
- EntityType(DataType)

ArrayType(DataType)

`__init__(elementType=UnknownType(), properties={})`

- `elementType` – The type of elements in the array (optional; the default is UnknownType).
- `properties` – Properties of the array (optional).

ChoiceType(DataType)

`__init__(choices=[], properties={})`

- `choices` – A list of possible choices (optional).
- `properties` – Properties of these choices (optional).

`add(new_choice)`

Adds a new choice to the list of possible choices.

- `new_choice` – The choice to add to the list of possible choices.

`merge(new_choices)`

Merges a list of new choices with the existing list of choices.

- `new_choices` – A list of new choices to merge with existing choices.

MapType(DataType)

`__init__(valueType=UnknownType, properties={})`

- `valueType` – The type of values in the map (optional; the default is UnknownType).
- `properties` – Properties of the map (optional).

Field(Object)

Creates a field object out of an object that derives from DataType.

`__init__(name, dataType, properties={})`

- `name` – The name to be assigned to the field.
- `dataType` – The object to create a field from.
- `properties` – Properties of the field (optional).

StructType(DataType)

Defines a data structure (`struct`).

`__init__(fields=[], properties={})`

- `fields` – A list of the fields (of type `Field`) to include in the structure (optional).
- `properties` – Properties of the structure (optional).

`add(field)`

- `field` – An object of type `Field` to add to the structure.

`hasField(field)`

Returns `True` if this structure has a field of the same name, or `False` if not.

- `field` – A field name, or an object of type `Field` whose name is used.

`getField(field)`

- `field` – A field name or an object of type `Field` whose name is used. If the structure has a field of the same name, it is returned.

EntityType(DataType)

`__init__(entity, base_type, properties)`

This class is not yet implemented.

other types

- DataSource(object)
- DataSink(object)

DataSource(object)

`__init__(j_source, sql_ctx, name)`

- `j_source` – The data source.
- `sql_ctx` – The SQL context.
- `name` – The data-source name.

`setFormat(format, **options)`

- `format` – The format to set for the data source.
- `options` – A collection of options to set for the data source. For more information about format options, see the section called “Data format options”.

`getFrame()`

Returns a `DynamicFrame` for the data source.

DataSink(object)

`__init__(j_sink, sql_ctx)`

- `j_sink` – The sink to create.
- `sql_ctx` – The SQL context for the data sink.

`setFormat(format, **options)`

- `format` – The format to set for the data sink.
- `options` – A collection of options to set for the data sink. For more information about format options, see the section called “Data format options”.

`setAccumulableSize(size)`

- `size` – The accumulable size to set, in bytes.

`writeFrame(dynamic_frame, info="")`

- `dynamic_frame` – The `DynamicFrame` to write.
- `info` – Information about the `DynamicFrame` (optional).

`write(dynamic_frame_or_dfc, info="")`

Writes a `DynamicFrame` or a `DynamicFrameCollection`.

- `dynamic_frame_or_dfc` – Either a `DynamicFrame` object or a `DynamicFrameCollection` object to be written.
- `info` – Information about the `DynamicFrame` or `DynamicFrames` to be written (optional).

DynamicFrame class

One of the major abstractions in Apache Spark is the SparkSQL `DataFrame`, which is similar to the `DataFrame` construct found in R and Pandas. A `DataFrame` is similar to a table and supports functional-style (map/reduce/filter/etc.) operations and SQL operations (select, project, aggregate).

`DataFrames` are powerful and widely used, but they have limitations with respect to extract, transform, and load (ETL) operations. Most significantly, they require a schema to be specified before any data is loaded. SparkSQL addresses this by making two passes over the data—the first to infer the schema, and the second to load the data. However, this inference is limited and doesn't address the realities of messy data. For example, the same field might be of a different type in different records. Apache Spark often gives up and reports the type as `string` using the original field text. This might not be correct, and you might want finer control over how schema discrepancies are resolved. And for large datasets, an additional pass over the source data might be prohibitively expensive.

To address these limitations, AWS Glue introduces the `DynamicFrame`. A `DynamicFrame` is similar to a `DataFrame`, except that each record is self-describing, so no schema is required initially. Instead, AWS Glue computes a schema on-the-fly when required, and explicitly encodes schema inconsistencies using a choice (or union) type. You can resolve these inconsistencies to make your datasets compatible with data stores that require a fixed schema.

Similarly, a `DynamicRecord` represents a logical record within a `DynamicFrame`. It is like a row in a Spark `DataFrame`, except that it is self-describing and can be used for data that does not conform to a fixed schema. When using AWS Glue with PySpark, you do not typically manipulate independent `DynamicRecords`. Rather, you will transform the dataset together through its `DynamicFrame`.

You can convert `DynamicFrames` to and from `DataFrames` after you resolve any schema inconsistencies.

— construction —

- __init__
- fromDF
- toDF

__init__

__init__(jdf, glue_ctx, name)

- jdf – A reference to the data frame in the Java Virtual Machine (JVM).
- glue_ctx – A GlueContext class object.
- name – An optional name string, empty by default.

fromDF

fromDF(dataframe, glue_ctx, name)

Converts a DataFrame to a DynamicFrame by converting DataFrame fields to DynamicRecord fields. Returns the new DynamicFrame.

A DynamicRecord represents a logical record in a DynamicFrame. It is similar to a row in a Spark DataFrame, except that it is self-describing and can be used for data that does not conform to a fixed schema.

This function expects columns with duplicated names in your DataFrame to have already been resolved.

- dataframe – The Apache Spark SQL DataFrame to convert (required).
- glue_ctx – The GlueContext class object that specifies the context for this transform (required).
- name – The name of the resulting DynamicFrame (optional since AWS Glue 3.0).

toDF

toDF(options)

Converts a DynamicFrame to an Apache Spark DataFrame by converting DynamicRecords into DataFrame fields. Returns the new DataFrame.

A DynamicRecord represents a logical record in a DynamicFrame. It is similar to a row in a Spark DataFrame, except that it is self-describing and can be used for data that does not conform to a fixed schema.

- options – A list of ResolveOption objects that specify how to resolve choice types during the conversion. This parameter is used to handle schema inconsistencies, not for format options like CSV parsing.

For CSV parsing and other format options, specify these in the `from_options` method when creating the DynamicFrame, not in the `toDF` method.

Here's an example of the correct way to handle CSV format options:

```
from awsglue.context import GlueContext
from awsglue.dynamicframe import DynamicFrame
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

# Correct: Specify format options in from_options
csv_dyf = glueContext.create_dynamic_frame.from_options(
    connection_type="s3",
    connection_options={"paths": ["s3://my-bucket/path/to/csv/"]},
    format="csv",
    format_options={
        "withHeader": True,
        "separator": ",",
        "inferSchema": True
    }
)

# Convert to DataFrame (no format options needed here)
csv_df = csv_dyf.toDF()
```

The `options` parameter in `toDF` is specifically for resolving choice types. Specify the target type if you choose the `Project` and `Cast` action type. Examples include the following.

```
>>>toDF([ResolveOption("a.b.c", "KeepAsStruct")])
>>>toDF([ResolveOption("a.b.c", "Project", DoubleType())])
```

— information —

- count
- schema
- printSchema
- show

- repartition
- coalesce

count

`count( )` – Returns the number of rows in the underlying `DataFrame`.

schema

`schema( )` – Returns the schema of this `DynamicFrame`, or if that is not available, the schema of the underlying `DataFrame`.

For more information about the `DynamicFrame` types that make up this schema, see the section called "Types".

printSchema

`printSchema( )` – Prints the schema of the underlying `DataFrame`.

show

`show(num_rows)` – Prints a specified number of rows from the underlying `DataFrame`.

repartition

`repartition(numPartitions)` – Returns a new `DynamicFrame` with `numPartitions` partitions.

coalesce

`coalesce(numPartitions)` – Returns a new `DynamicFrame` with `numPartitions` partitions.

— transforms —

- apply_mapping
- drop_fields
- filter
- join
- map
- mergeDynamicFrame

- relationalize
- rename_field
- resolveChoice
- select_fields
- spigot
- split_fields
- split_rows
- unbox
- the section called “union”
- unnest
- unnest_ddb_json
- write

apply_mapping

`apply_mapping(mappings, transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)`

Applies a declarative mapping to a `DynamicFrame` and returns a new `DynamicFrame` with those mappings applied to the fields that you specify. Unspecified fields are omitted from the new `DynamicFrame`.

- `mappings` – A list of mapping tuples (required). Each consists of: (source column, source type, target column, target type).

  If the source column has a dot `"."` in the name, you must place backticks `"``"` around it. For example, to map `this.old.name` (string) to `thisNewName`, you would use the following tuple:

  ```
  ("`this.old.name`", "string", "thisNewName", "string")
  ```

- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

Example: Use apply_mapping to rename fields and change field types

The following code example shows how to use the `apply_mapping` method to rename selected fields and change field types.

> **Note**
>
> To access the dataset that is used in this example, see Code example: Joining and relationalizing data and follow the instructions in Step 1: Crawl the data in the Amazon S3 bucket.

```
# Example: Use apply_mapping to reshape source data into
# the desired column names and types as a new DynamicFrame

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Create a DynamicFrame and view its schema
persons = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="persons_json"
)
print("Schema for the persons DynamicFrame:")
persons.printSchema()

# Select and rename fields, change field type
print("Schema for the persons_mapped DynamicFrame, created with apply_mapping:")
persons_mapped = persons.apply_mapping(
    [
        ("family_name", "String", "last_name", "String"),
        ("name", "String", "first_name", "String"),
        ("birth_date", "String", "date_of_birth", "Date"),
    ]
```

```
)
persons_mapped.printSchema()
```

Output

```
Schema for the persons DynamicFrame:
root
|-- family_name: string
|-- name: string
|-- links: array
|    |-- element: struct
|    |    |-- note: string
|    |    |-- url: string
|-- gender: string
|-- image: string
|-- identifiers: array
|    |-- element: struct
|    |    |-- scheme: string
|    |    |-- identifier: string
|-- other_names: array
|    |-- element: struct
|    |    |-- lang: string
|    |    |-- note: string
|    |    |-- name: string
|-- sort_name: string
|-- images: array
|    |-- element: struct
|    |    |-- url: string
|-- given_name: string
|-- birth_date: string
|-- id: string
|-- contact_details: array
|    |-- element: struct
|    |    |-- type: string
|    |    |-- value: string
|-- death_date: string

Schema for the persons_mapped DynamicFrame, created with apply_mapping:
root
|-- last_name: string
|-- first_name: string
|-- date_of_birth: date
```

drop_fields

`drop_fields(paths, transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)`

Calls the FlatMap class transform to remove fields from a `DynamicFrame`. Returns a new `DynamicFrame` with the specified fields dropped.

- `paths` – A list of strings. Each contains the full path to a field node that you want to drop. You can use dot notation to specify nested fields. For example, if field `first` is a child of field `name` in the tree, you specify `"name.first"` for the path.

  If a field node has a literal `.` in the name, you must enclose the name in backticks (`` ` ``).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

Example: Use drop_fields to remove fields from a `DynamicFrame`

This code example uses the `drop_fields` method to remove selected top-level and nested fields from a `DynamicFrame`.

Example dataset

The example uses the following dataset that is represented by the `EXAMPLE-FRIENDS-DATA` table in the code:

```
{"name": "Sally", "age": 23, "location": {"state": "WY", "county": "Fremont"},
 "friends": []}
{"name": "Varun", "age": 34, "location": {"state": "NE", "county": "Douglas"},
 "friends": [{"name": "Arjun", "age": 3}]}
```

```
{"name": "George", "age": 52, "location": {"state": "NY"}, "friends": [{"name":
 "Fred"}, {"name": "Amy", "age": 15}]}
{"name": "Haruki", "age": 21, "location": {"state": "AK", "county": "Denali"}}
{"name": "Sheila", "age": 63, "friends": [{"name": "Nancy", "age": 22}]}
```

Example code

```
# Example: Use drop_fields to remove top-level and nested fields from a DynamicFrame.
# Replace MY-EXAMPLE-DATABASE with your Glue Data Catalog database name.
# Replace EXAMPLE-FRIENDS-DATA with your table name.

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Create a DynamicFrame from Glue Data Catalog
glue_source_database = "MY-EXAMPLE-DATABASE"
glue_source_table = "EXAMPLE-FRIENDS-DATA"

friends = glueContext.create_dynamic_frame.from_catalog(
    database=glue_source_database, table_name=glue_source_table
)
print("Schema for friends DynamicFrame before calling drop_fields:")
friends.printSchema()

# Remove location.county, remove friends.age, remove age
friends = friends.drop_fields(paths=["age", "location.county", "friends.age"])
print("Schema for friends DynamicFrame after removing age, county, and friend age:")
friends.printSchema()
```

Output

```
Schema for friends DynamicFrame before calling drop_fields:
root
|-- name: string
|-- age: int
|-- location: struct
|    |-- state: string
|    |-- county: string
|-- friends: array
```

```
|    |-- element: struct
|    |    |-- name: string
|    |    |-- age: int

Schema for friends DynamicFrame after removing age, county, and friend age:
root
|-- name: string
|-- location: struct
|    |-- state: string
|-- friends: array
|    |-- element: struct
|    |    |-- name: string
```

filter

`filter(f, transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)`

Returns a new `DynamicFrame` that contains all `DynamicRecords` within the input `DynamicFrame` that satisfy the specified predicate function `f`.

- `f` – The predicate function to apply to the `DynamicFrame`. The function must take a `DynamicRecord` as an argument and return True if the `DynamicRecord` meets the filter requirements, or False if not (required).

  A `DynamicRecord` represents a logical record in a `DynamicFrame`. It's similar to a row in a Spark `DataFrame`, except that it is self-describing and can be used for data that doesn't conform to a fixed schema.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

Example: Use filter to get a filtered selection of fields

This example uses the `filter` method to create a new `DynamicFrame` that includes a filtered selection of another `DynamicFrame`'s fields.

Like the `map` method, `filter` takes a function as an argument that gets applied to each record in the original `DynamicFrame`. The function takes a record as an input and returns a Boolean value. If the return value is true, the record gets included in the resulting `DynamicFrame`. If it's false, the record is left out.

> **Note**
>
> To access the dataset that is used in this example, see Code example: Data preparation using ResolveChoice, Lambda, and ApplyMapping and follow the instructions in Step 1: Crawl the data in the Amazon S3 bucket.

```
# Example: Use filter to create a new DynamicFrame
# with a filtered selection of records

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Create DynamicFrame from Glue Data Catalog
medicare = glueContext.create_dynamic_frame.from_options(
    "s3",
    {
        "paths": [
            "s3://awsglue-datasets/examples/medicare/Medicare_Hospital_Provider.csv"
        ]
    },
    "csv",
    {"withHeader": True},
)

# Create filtered DynamicFrame with custom lambda
# to filter records by Provider State and Provider City
sac_or_mon = medicare.filter(
```

```
    f=lambda x: x["Provider State"] in ["CA", "AL"]
    and x["Provider City"] in ["SACRAMENTO", "MONTGOMERY"]
)

# Compare record counts
print("Unfiltered record count: ", medicare.count())
print("Filtered record count:  ", sac_or_mon.count())
```

Output

```
Unfiltered record count:  163065
Filtered record count:   564
```

join

`join(paths1, paths2, frame2, transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)`

Performs an equality join with another `DynamicFrame` and returns the resulting `DynamicFrame`.

- `paths1` – A list of the keys in this frame to join.
- `paths2` – A list of the keys in the other frame to join.
- `frame2` – The other `DynamicFrame` to join.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

Example: Use join to combine `DynamicFrames`

This example uses the `join` method to perform a join on three `DynamicFrames`. AWS Glue performs the join based on the field keys that you provide. The resulting `DynamicFrame` contains rows from the two original frames where the specified keys match.

Note that the `join` transform keeps all fields intact. This means that the fields that you specify to match appear in the resulting DynamicFrame, even if they're redundant and contain the same keys. In this example, we use `drop_fields` to remove these redundant keys after the join.

> **Note**
>
> To access the dataset that is used in this example, see Code example: Joining and relationalizing data and follow the instructions in Step 1: Crawl the data in the Amazon S3 bucket.

```
# Example: Use join to combine data from three DynamicFrames

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Load DynamicFrames from Glue Data Catalog
persons = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="persons_json"
)
memberships = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="memberships_json"
)
orgs = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="organizations_json"
)
print("Schema for the persons DynamicFrame:")
persons.printSchema()
print("Schema for the memberships DynamicFrame:")
memberships.printSchema()
print("Schema for the orgs DynamicFrame:")
orgs.printSchema()

# Join persons and memberships by ID
persons_memberships = persons.join(
    paths1=["id"], paths2=["person_id"], frame2=memberships
)
```

```
# Rename and drop fields from orgs
# to prevent field name collisions with persons_memberships
orgs = (
    orgs.drop_fields(["other_names", "identifiers"])
    .rename_field("id", "org_id")
    .rename_field("name", "org_name")
)

# Create final join of all three DynamicFrames
legislators_combined = orgs.join(
    paths1=["org_id"], paths2=["organization_id"], frame2=persons_memberships
).drop_fields(["person_id", "org_id"])

# Inspect the schema for the joined data
print("Schema for the new legislators_combined DynamicFrame:")
legislators_combined.printSchema()
```

Output

```
Schema for the persons DynamicFrame:
root
|-- family_name: string
|-- name: string
|-- links: array
|    |-- element: struct
|    |    |-- note: string
|    |    |-- url: string
|-- gender: string
|-- image: string
|-- identifiers: array
|    |-- element: struct
|    |    |-- scheme: string
|    |    |-- identifier: string
|-- other_names: array
|    |-- element: struct
|    |    |-- lang: string
|    |    |-- note: string
|    |    |-- name: string
|-- sort_name: string

map

`map(f, transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)`

Returns a new `DynamicFrame` that results from applying the specified mapping function to all records in the original `DynamicFrame`.

- `f` – The mapping function to apply to all records in the `DynamicFrame`. The function must take a `DynamicRecord` as an argument and return a new `DynamicRecord` (required).

  A `DynamicRecord` represents a logical record in a `DynamicFrame`. It's similar to a row in an Apache Spark `DataFrame`, except that it is self-describing and can be used for data that doesn't conform to a fixed schema.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string that is associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

Example: Use map to apply a function to every record in a `DynamicFrame`

This example shows how to use the `map` method to apply a function to every record of a `DynamicFrame`. Specifically, this example applies a function called `MergeAddress` to each record in order to merge several address fields into a single `struct` type.

> **Note**
>
> To access the dataset that is used in this example, see Code example: Data preparation using ResolveChoice, Lambda, and ApplyMapping and follow the instructions in Step 1: Crawl the data in the Amazon S3 bucket.

```
# Example: Use map to combine fields in all records
# of a DynamicFrame

from pyspark.context import SparkContext
from awsglue.context import GlueContext
```

```
# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Create a DynamicFrame and view its schema
medicare = glueContext.create_dynamic_frame.from_options(
        "s3",
        {"paths": ["s3://awsglue-datasets/examples/medicare/
Medicare_Hospital_Provider.csv"]},
        "csv",
        {"withHeader": True})
print("Schema for medicare DynamicFrame:")
medicare.printSchema()

# Define a function to supply to the map transform
# that merges address fields into a single field
def MergeAddress(rec):
  rec["Address"] = {}
  rec["Address"]["Street"] = rec["Provider Street Address"]
  rec["Address"]["City"] = rec["Provider City"]
  rec["Address"]["State"] = rec["Provider State"]
  rec["Address"]["Zip.Code"] = rec["Provider Zip Code"]
  rec["Address"]["Array"] = [rec["Provider Street Address"], rec["Provider City"],
 rec["Provider State"], rec["Provider Zip Code"]]
  del rec["Provider Street Address"]
  del rec["Provider City"]
  del rec["Provider State"]
  del rec["Provider Zip Code"]
  return rec

# Use map to apply MergeAddress to every record
mapped_medicare = medicare.map(f = MergeAddress)
print("Schema for mapped_medicare DynamicFrame:")
mapped_medicare.printSchema()
```

Output

```
Schema for medicare DynamicFrame:
root
|-- DRG Definition: string
|-- Provider Id: string
```

```
|-- Provider Name: string
|-- Provider Street Address: string
|-- Provider City: string
|-- Provider State: string
|-- Provider Zip Code: string
|-- Hospital Referral Region Description: string
|-- Total Discharges: string
|-- Average Covered Charges: string
|-- Average Total Payments: string
|-- Average Medicare Payments: string

|-- Provider Name: string
```

mergeDynamicFrame

`mergeDynamicFrame(stage_dynamic_frame, primary_keys, transformation_ctx = "", options = {}, info = "", stageThreshold = 0, totalThreshold = 0)`

Merges this `DynamicFrame` with a staging `DynamicFrame` based on the specified primary keys to identify records. Duplicate records (records with the same primary keys) are not deduplicated. If there is no matching record in the staging frame, all records (including duplicates) are retained from the source. If the staging frame has matching records, the records from the staging frame overwrite the records in the source in AWS Glue.

- `stage_dynamic_frame` – The staging `DynamicFrame` to merge.

- primary_keys – The list of primary key fields to match records from the source and staging dynamic frames.
- transformation_ctx – A unique string that is used to retrieve metadata about the current transformation (optional).
- options – A string of JSON name-value pairs that provide additional information for this transformation. This argument is not currently used.
- info – A String. Any string to be associated with errors in this transformation.
- stageThreshold – A Long. The number of errors in the given transformation for which the processing needs to error out.
- totalThreshold – A Long. The total number of errors up to and including this transformation for which the processing needs to error out.

This method returns a new DynamicFrame that is obtained by merging this DynamicFrame with the staging DynamicFrame.

The returned DynamicFrame contains record A in these cases:

- If A exists in both the source frame and the staging frame, then A in the staging frame is returned.
- If A is in the source table and A.primaryKeys is not in the stagingDynamicFrame, A is not updated in the staging table.

The source frame and staging frame don't need to have the same schema.

Example: Use mergeDynamicFrame to merge two DynamicFrames based on a primary key

The following code example shows how to use the mergeDynamicFrame method to merge a DynamicFrame with a "staging" DynamicFrame, based on the primary key id.

Example dataset

The example uses two DynamicFrames from a DynamicFrameCollection called split_rows_collection. The following is the list of keys in split_rows_collection.

```
dict_keys(['high', 'low'])
```

Example code

```
# Example: Use mergeDynamicFrame to merge DynamicFrames
# based on a set of specified primary keys

from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.transforms import SelectFromCollection

# Inspect the original DynamicFrames
frame_low = SelectFromCollection.apply(dfc=split_rows_collection, key="low")
print("Inspect the DynamicFrame that contains rows where ID < 10")
frame_low.toDF().show()

frame_high = SelectFromCollection.apply(dfc=split_rows_collection, key="high")
print("Inspect the DynamicFrame that contains rows where ID > 10")
frame_high.toDF().show()

# Merge the DynamicFrames based on the "id" primary key
merged_high_low = frame_high.mergeDynamicFrame(
    stage_dynamic_frame=frame_low, primary_keys=["id"]
)

# View the results where the ID is 1 or 20
print("Inspect the merged DynamicFrame that contains the combined rows")
merged_high_low.toDF().where("id = 1 or id= 20").orderBy("id").show()
```

Output

```
Inspect the DynamicFrame that contains rows where ID < 10

relationalize

`relationalize(root_table_name, staging_path, options, transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)`

Converts a `DynamicFrame` into a form that fits within a relational database. Relationalizing a `DynamicFrame` is especially useful when you want to move data from a NoSQL environment like DynamoDB into a relational database like MySQL.

The transform generates a list of frames by unnesting nested columns and pivoting array columns. You can join the pivoted array columns to the root table by using the join key that is generated during the unnest phase.

- `root_table_name` – The name for the root table.
- `staging_path` – The path where the method can store partitions of pivoted tables in CSV format (optional). Pivoted tables are read back from this path.
- `options` – A dictionary of optional parameters.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

Example: Use relationalize to flatten a nested schema in a `DynamicFrame`

This code example uses the `relationalize` method to flatten a nested schema into a form that fits into a relational database.

Example dataset

The example uses a `DynamicFrame` called `legislators_combined` with the following schema. `legislators_combined` has multiple nested fields such as `links`, `images`, and `contact_details`, which will be flattened by the `relationalize` transform.

```
root
|-- role: string
|-- seats: int
|-- org_name: string
|-- links: array
|    |-- element: struct
|    |    |-- note: string
|    |    |-- url: string
|-- type: string
|-- sort_name: string
|-- area_id: string
|-- images: array
|    |-- element: struct
|    |    |-- url: string
|-- on_behalf_of_id: string
|-- other_names: array
|    |-- element: struct
|    |    |-- note: string
|    |    |-- name: string
|    |    |-- lang: string
|-- contact_details: array
|    |-- element: struct
|    |    |-- type: string
|    |    |-- value: string
|-- name: string
|-- birth_date: string
|-- organization_id: string
|-- gender: string
|-- classification: string
|-- legislative_period_id: string
|-- identifiers: array
|    |-- element: struct
|    |    |-- scheme: string
|    |    |-- identifier: string
|-- image: string
|-- given_name: string
|-- start_date: string
|-- family_name: string
|-- id: string
```

```
|-- death_date: string
|-- end_date: string
```

Example code

```
# Example: Use relationalize to flatten
# a nested schema into a format that fits
# into a relational database.
# Replace DOC-EXAMPLE-S3-BUCKET/tmpDir with your own location.

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Apply relationalize and inspect new tables
legislators_relationalized = legislators_combined.relationalize(
    "l_root", "s3://DOC-EXAMPLE-BUCKET/tmpDir"
)
legislators_relationalized.keys()

# Compare the schema of the contact_details
# nested field to the new relationalized table that
# represents it
legislators_combined.select_fields("contact_details").printSchema()
legislators_relationalized.select("l_root_contact_details").toDF().where(
    "id = 10 or id = 75"
).orderBy(["id", "index"]).show()
```

Output

The following output lets you compare the schema of the nested field called `contact_details` to the table that the `relationalize` transform created. Notice that the table records link back to the main table using a foreign key called `id` and an `index` column that represents the positions of the array.

```
dict_keys(['l_root', 'l_root_images', 'l_root_links', 'l_root_other_names',
 'l_root_contact_details', 'l_root_identifiers'])

root
```

```
|-- contact_details: array
|    |-- element: struct
|    |    |-- type: string
|    |    |-- value: string

+---+-----+-----------------------+-----------------------+
| id|index|contact_details.val.type|contact_details.val.value|
+---+-----+-----------------------+-----------------------+
| 10|    0|                    fax|           202-225-4160|
| 10|    1|                  phone|           202-225-3436|
| 75|    0|                    fax|           202-225-6791|
| 75|    1|                  phone|           202-225-2861|
| 75|    2|                twitter|             RepSamFarr|
+---+-----+-----------------------+-----------------------+
```

rename_field

`rename_field(oldName, newName, transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)`

Renames a field in this `DynamicFrame` and returns a new `DynamicFrame` with the field renamed.

- `oldName` – The full path to the node you want to rename.

  If the old name has dots in it, `RenameField` doesn't work unless you place backticks around it (`). For example, to replace `this.old.name` with `thisNewName`, you would call rename_field as follows.

  ```
  newDyF = oldDyF.rename_field("`this.old.name`", "thisNewName")
  ```

- `newName` – The new name, as a full path.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

Example: Use rename_field to rename fields in a `DynamicFrame`

This code example uses the `rename_field` method to rename fields in a `DynamicFrame`. Notice that the example uses method chaining to rename multiple fields at the same time.

> **Note**
>
> To access the dataset that is used in this example, see Code example: Joining and relationalizing data and follow the instructions in Step 1: Crawl the data in the Amazon S3 bucket.

Example code

```
# Example: Use rename_field to rename fields
# in a DynamicFrame

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Inspect the original orgs schema
orgs = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="organizations_json"
)
print("Original orgs schema: ")
orgs.printSchema()

# Rename fields and view the new schema
orgs = orgs.rename_field("id", "org_id").rename_field("name", "org_name")
print("New orgs schema with renamed fields: ")
orgs.printSchema()
```

Output

```
Original orgs schema:
root
|-- identifiers: array
|    |-- element: struct
```

```
|    |    |-- scheme: string
|    |    |-- identifier: string
|-- other_names: array
|    |-- element: struct
|    |    |-- lang: string
|    |    |-- note: string
|    |    |-- name: string

```

resolveChoice

`resolveChoice(specs = None, choice = "" , database = None , table_name = None , transformation_ctx="", info="", stageThreshold=0, totalThreshold=0, catalog_id = None)`

Resolves a choice type within this `DynamicFrame` and returns the new `DynamicFrame`.

- `specs` – A list of specific ambiguities to resolve, each in the form of a tuple: `(field_path, action)`.

  There are two ways to use `resolveChoice`. The first is to use the `specs` argument to specify a sequence of specific fields and how to resolve them. The other mode for `resolveChoice` is to use the `choice` argument to specify a single resolution for all `ChoiceTypes`.

  Values for `specs` are specified as tuples made up of `(field_path, action)` pairs. The `field_path` value identifies a specific ambiguous element, and the `action` value identifies the corresponding resolution. The following are the possible actions:

  - `cast:`*`type`* – Attempts to cast all values to the specified type. For example: `cast:int`.
  - `make_cols` – Converts each distinct type to a column with the name *`columnName`*`_`*`type`*. It resolves a potential ambiguity by flattening the data. For example, if `columnA` could be an `int` or a `string`, the resolution would be to produce two columns named `columnA_int` and `columnA_string` in the resulting `DynamicFrame`.
  - `make_struct` – Resolves a potential ambiguity by using a `struct` to represent the data. For example, if data in a column could be an `int` or a `string`, the `make_struct` action produces a column of structures in the resulting `DynamicFrame`. Each structure contains both an `int` and a `string`.
  - `project:`*`type`* – Resolves a potential ambiguity by projecting all the data to one of the possible data types. For example, if data in a column could be an `int` or a `string`, using a `project:string` action produces a column in the resulting `DynamicFrame` where all the `int` values have been converted to strings.

  If the `field_path` identifies an array, place empty square brackets after the name of the array to avoid ambiguity. For example, suppose you are working with data structured as follows:

```
"myList": [
  { "price": 100.00 },
  { "price": "$100.00" }
```

```
]
```

You can select the numeric rather than the string version of the price by setting the `field_path` to `"myList[].price"`, and setting the `action` to `"cast:double"`.

> **Note**
>
> You can only use one of the `specs` and `choice` parameters. If the `specs` parameter is not None, then the `choice` parameter must be an empty string. Conversely, if the `choice` is not an empty string, then the `specs` parameter must be None.

- `choice` – Specifies a single resolution for all `ChoiceTypes`. You can use this in cases where the complete list of `ChoiceTypes` is unknown before runtime. In addition to the actions listed previously for `specs`, this argument also supports the following action:
  - `match_catalog` – Attempts to cast each `ChoiceType` to the corresponding type in the specified Data Catalog table.
- `database` – The Data Catalog database to use with the `match_catalog` action.
- `table_name` – The Data Catalog table to use with the `match_catalog` action.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional).The default is zero, which indicates that the process should not error out.
- `catalog_id` – The catalog ID of the Data Catalog being accessed (the account ID of the Data Catalog). When set to None (default value), it uses the catalog ID of the calling account.

Example: Use resolveChoice to handle a column that contains multiple types

This code example uses the `resolveChoice` method to specify how to handle a `DynamicFrame` column that contains values of multiple types. The example demonstrates two common ways to handle a column with different types:

- Cast the column to a single data type.

- Retain all types in separate columns.

Example dataset

> **Note**
>
> To access the dataset that is used in this example, see Code example: Data preparation using ResolveChoice, Lambda, and ApplyMapping and follow the instructions in Step 1: Crawl the data in the Amazon S3 bucket.

The example uses a `DynamicFrame` called `medicare` with the following schema:

```
root
|-- drg definition: string
|-- provider id: choice
|    |-- long
|    |-- string
|-- provider name: string
|-- provider street address: string
|-- provider city: string
|-- provider state: string
|-- provider zip code: long
|-- hospital referral region description: string
|-- total discharges: long
|-- average covered charges: string
|-- average total payments: string
|-- average medicare payments: string
```

Example code

```
# Example: Use resolveChoice to handle
# a column that contains multiple types

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)
```

```
# Load the input data and inspect the "provider id" column
medicare = glueContext.create_dynamic_frame.from_catalog(
    database="payments", table_name="medicare_hospital_provider_csv"
)
print("Inspect the provider id column:")
medicare.toDF().select("provider id").show()

# Cast provider id to type long
medicare_resolved_long = medicare.resolveChoice(specs=[("provider id", "cast:long")])
print("Schema after casting provider id to type long:")
medicare_resolved_long.printSchema()
medicare_resolved_long.toDF().select("provider id").show()

# Create separate columns
# for each provider id type
medicare_resolved_cols = medicare.resolveChoice(choice="make_cols")
print("Schema after creating separate columns for each type:")
medicare_resolved_cols.printSchema()
medicare_resolved_cols.toDF().select("provider id_long", "provider id_string").show()
```

Output

```
Inspect the 'provider id' column:

select_fields

`select_fields(paths, transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)`

Returns a new `DynamicFrame` that contains the selected fields.

- `paths` – A list of strings. Each string is a path to a top-level node that you want to select.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

Example: Use select_fields to create a new `DynamicFrame` with chosen fields

The following code example shows how to use the `select_fields` method to create a new `DynamicFrame` with a chosen list of fields from an existing `DynamicFrame`.

> **Note**
>
> To access the dataset that is used in this example, see Code example: Joining and relationalizing data and follow the instructions in Step 1: Crawl the data in the Amazon S3 bucket.

```
# Example: Use select_fields to select specific fields from a DynamicFrame

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
```

```
glueContext = GlueContext(sc)

# Create a DynamicFrame and view its schema
persons = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="persons_json"
)
print("Schema for the persons DynamicFrame:")
persons.printSchema()

# Create a new DynamicFrame with chosen fields
names = persons.select_fields(paths=["family_name", "given_name"])
print("Schema for the names DynamicFrame, created with select_fields:")
names.printSchema()
names.toDF().show()
```

Output

```
Schema for the persons DynamicFrame:
root
|-- family_name: string
|-- name: string
|-- links: array
|    |-- element: struct
|    |    |-- note: string

simplify_ddb_json

`simplify_ddb_json(): DynamicFrame`

Simplifies nested columns in a `DynamicFrame` that are specifically in the DynamoDB JSON structure, and returns a new simplified `DynamicFrame`. If there're multiple types or Map type

in a List type, the elements in the List will not be simplified. Note that this is a specific type of transform that behaves differently from the regular `unnest` transform and requires the data to already be in the DynamoDB JSON structure. For more information, see DynamoDB JSON.

For example, the schema of a reading an export with the DynamoDB JSON structure might look like the following:

```
root
|-- Item: struct
|    |-- parentMap: struct
|    |    |-- M: struct
|    |    |    |-- childMap: struct
|    |    |    |    |-- M: struct
|    |    |    |    |    |-- appName: struct
|    |    |    |    |    |    |-- S: string
|    |    |    |    |    |-- packageName: struct
|    |    |    |    |    |    |-- S: string
|    |    |    |    |    |-- updatedAt: struct
|    |    |    |    |    |    |-- N: string
|    |-- strings: struct
|    |    |-- SS: array
|    |    |    |-- element: string
|    |-- numbers: struct
|    |    |-- NS: array
|    |    |    |-- element: string
|    |-- binaries: struct
|    |    |-- BS: array
|    |    |    |-- element: string
|    |-- isDDBJson: struct
|    |    |-- BOOL: boolean
|    |-- nullValue: struct
|    |    |-- NULL: boolean
```

The `simplify_ddb_json()` transform would convert this to:

```
root
|-- parentMap: struct
|    |-- childMap: struct
|    |    |-- appName: string
|    |    |-- packageName: string
|    |    |-- updatedAt: string
|-- strings: array
```

```
|    |-- element: string
|-- numbers: array
|    |-- element: string
|-- binaries: array
|    |-- element: string
|-- isDDBJson: boolean
|-- nullValue: null
```

Example: Use simplify_ddb_json to invoke a DynamoDB JSON simplify

This code example uses the `simplify_ddb_json` method to use the AWS Glue DynamoDB export connector, invoke a DynamoDB JSON simplify, and print the number of partitions.

Example code

```
from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext()
glueContext = GlueContext(sc)

dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type = "dynamodb",
    connection_options = {
        'dynamodb.export': 'ddb',
        'dynamodb.tableArn': '<table arn>',
        'dynamodb.s3.bucket': '<bucket name>',
        'dynamodb.s3.prefix': '<bucket prefix>',
        'dynamodb.s3.bucketOwner': '<account_id of bucket>'
    }
)
simplified = dynamicFrame.simplify_ddb_json()
print(simplified.getNumPartitions())
```

spigot

`spigot(path, options={})`

Writes sample records to a specified destination to help you verify the transformations performed by your job.

- `path` – The path of the destination to write to (required).

- `options` – Key-value pairs that specify options (optional). The `"topk"` option specifies that the first k records should be written. The `"prob"` option specifies the probability (as a decimal) of choosing any given record. You can use it in selecting records to write.
- `transformation_ctx` – A unique string that is used to identify state information (optional).

Example: Use spigot to write sample fields from a `DynamicFrame` to Amazon S3

This code example uses the `spigot` method to write sample records to an Amazon S3 bucket after applying the `select_fields` transform.

Example dataset

> **Note**
>
> To access the dataset that is used in this example, see Code example: Joining and relationalizing data and follow the instructions in Step 1: Crawl the data in the Amazon S3 bucket.

The example uses a `DynamicFrame` called `persons` with the following schema:

```
root
|-- family_name: string
|-- name: string
|-- links: array
|    |-- element: struct
|    |    |-- note: string
|    |    |-- url: string
|-- gender: string
|-- image: string
|-- identifiers: array
|    |-- element: struct
|    |    |-- scheme: string
|    |    |-- identifier: string
|-- other_names: array
|    |-- element: struct
|    |    |-- lang: string
|    |    |-- note: string
|    |    |-- name: string
|-- sort_name: string
|-- images: array
```

```
|    |-- element: struct
|    |    |-- url: string
|-- given_name: string
|-- birth_date: string
|-- id: string
|-- contact_details: array
|    |-- element: struct
|    |    |-- type: string
|    |    |-- value: string
|-- death_date: string
```

Example code

```
# Example: Use spigot to write sample records
# to a destination during a transformation
# from pyspark.context import SparkContext.
# Replace DOC-EXAMPLE-BUCKET with your own location.

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Load table data into a DynamicFrame
persons = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="persons_json"
)

# Perform the select_fields on the DynamicFrame
persons = persons.select_fields(paths=["family_name", "given_name", "birth_date"])

# Use spigot to write a sample of the transformed data
# (the first 10 records)
spigot_output = persons.spigot(
    path="s3://DOC-EXAMPLE-BUCKET", options={"topk": 10}
)
# Example: Use spigot to write sample records
# to a destination during a transformation
# from pyspark.context import SparkContext.
# Replace DOC-EXAMPLE-BUCKET with your own location.
```

```
from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Load table data into a DynamicFrame
persons = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="persons_json"
)

# Perform the select_fields on the DynamicFrame
persons = persons.select_fields(paths=["family_name", "given_name", "birth_date"])

# Use spigot to write a sample of the transformed data
# (the first 10 records)
spigot_output = persons.spigot(
    path="s3://DOC-EXAMPLE-BUCKET", options={"topk": 10}
)
```

Output

The following is an example of the data that `spigot` writes to Amazon S3. Because the example code specified `options={"topk": 10}`, the sample data contains the first 10 records.

```
{"family_name":"Collins","given_name":"Michael","birth_date":"1944-10-15"}
{"family_name":"Huizenga","given_name":"Bill","birth_date":"1969-01-31"}
{"family_name":"Clawson","given_name":"Curtis","birth_date":"1959-09-28"}
{"family_name":"Solomon","given_name":"Gerald","birth_date":"1930-08-14"}
{"family_name":"Rigell","given_name":"Edward","birth_date":"1960-05-28"}
{"family_name":"Crapo","given_name":"Michael","birth_date":"1951-05-20"}
{"family_name":"Hutto","given_name":"Earl","birth_date":"1926-05-12"}
{"family_name":"Ertel","given_name":"Allen","birth_date":"1937-11-07"}
{"family_name":"Minish","given_name":"Joseph","birth_date":"1916-09-01"}
{"family_name":"Andrews","given_name":"Robert","birth_date":"1957-08-04"}
```

split_fields

`split_fields(paths, name1, name2, transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)`

Returns a new `DynamicFrameCollection` that contains two `DynamicFrames`. The first `DynamicFrame` contains all the nodes that have been split off, and the second contains the nodes that remain.

- `paths` – A list of strings, each of which is a full path to a node that you want to split into a new `DynamicFrame`.
- `name1` – A name string for the `DynamicFrame` that is split off.
- `name2` – A name string for the `DynamicFrame` that remains after the specified nodes have been split off.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

Example: Use split_fields to split selected fields into a separate `DynamicFrame`

This code example uses the `split_fields` method to split a list of specified fields into a separate `DynamicFrame`.

Example dataset

The example uses a `DynamicFrame` called `l_root_contact_details` that is from a collection named `legislators_relationalized`.

`l_root_contact_details` has the following schema and entries.

```
root
|-- id: long
```

```
|-- index: int
|-- contact_details.val.type: string
|-- contact_details.val.value: string

+---+-----+-----------------------+-----------------------+
| id|index|contact_details.val.type|contact_details.val.value|
+---+-----+-----------------------+-----------------------+
|  1|    0|                  phone|             202-225-5265|
|  1|    1|                twitter|              kathyhochul|
|  2|    0|                  phone|             202-225-3252|
|  2|    1|                twitter|            repjackyrosen|
|  3|    0|                    fax|             202-225-1314|
|  3|    1|                  phone|             202-225-3772|
...
```

Example code

```
# Example: Use split_fields to split selected
# fields into a separate DynamicFrame

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Load the input DynamicFrame and inspect its schema
frame_to_split = legislators_relationalized.select("l_root_contact_details")
print("Inspect the input DynamicFrame schema:")
frame_to_split.printSchema()

# Split id and index fields into a separate DynamicFrame
split_fields_collection = frame_to_split.split_fields(["id", "index"], "left", "right")

# Inspect the resulting DynamicFrames
print("Inspect the schemas of the DynamicFrames created with split_fields:")
split_fields_collection.select("left").printSchema()
split_fields_collection.select("right").printSchema()
```

Output

```
Inspect the input DynamicFrame's schema:
```

```
root
|-- id: long
|-- index: int
|-- contact_details.val.type: string
|-- contact_details.val.value: string

Inspect the schemas of the DynamicFrames created with split_fields:
root
|-- id: long
|-- index: int

root
|-- contact_details.val.type: string
|-- contact_details.val.value: string
```

split_rows

`split_rows(comparison_dict, name1, name2, transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)`

Splits one or more rows in a `DynamicFrame` off into a new `DynamicFrame`.

The method returns a new `DynamicFrameCollection` that contains two `DynamicFrames`. The first `DynamicFrame` contains all the rows that have been split off, and the second contains the rows that remain.

- `comparison_dict` – A dictionary where the key is a path to a column, and the value is another dictionary for mapping comparators to values that the column values are compared to. For example, `{"age": {">": 10, "<": 20}}` splits off all rows whose value in the age column is greater than 10 and less than 20.
- `name1` – A name string for the `DynamicFrame` that is split off.
- `name2` – A name string for the `DynamicFrame` that remains after the specified nodes have been split off.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

Example: Use split_rows to split rows in a `DynamicFrame`

This code example uses the `split_rows` method to split rows in a `DynamicFrame` based on the `id` field value.

Example dataset

The example uses a `DynamicFrame` called `l_root_contact_details` that is selected from a collection named `legislators_relationalized`.

`l_root_contact_details` has the following schema and entries.

```
root
|-- id: long
|-- index: int
|-- contact_details.val.type: string
|-- contact_details.val.value: string

```

Example code

```
# Example: Use split_rows to split up
# rows in a DynamicFrame based on value

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Retrieve the DynamicFrame to split
frame_to_split = legislators_relationalized.select("l_root_contact_details")

# Split up rows by ID
split_rows_collection = frame_to_split.split_rows({"id": {">": 10}}, "high", "low")

# Inspect the resulting DynamicFrames
print("Inspect the DynamicFrame that contains IDs < 10")
split_rows_collection.select("low").toDF().show()
print("Inspect the DynamicFrame that contains IDs > 10")
split_rows_collection.select("high").toDF().show()
```

Output

```
Inspect the DynamicFrame that contains IDs < 10
+---+-----+-----------------------+-------------------------+

unbox

`unbox(path, format, transformation_ctx="", info="", stageThreshold=0, totalThreshold=0, **options)`

Unboxes (reformats) a string field in a `DynamicFrame` and returns a new `DynamicFrame` that contains the unboxed `DynamicRecords`.

A `DynamicRecord` represents a logical record in a `DynamicFrame`. It's similar to a row in an Apache Spark `DataFrame`, except that it is self-describing and can be used for data that doesn't conform to a fixed schema.

- `path` – A full path to the string node you want to unbox.
- `format` – A format specification (optional). You use this for an Amazon S3 or AWS Glue connection that supports multiple formats. For the formats that are supported, see Data format options for inputs and outputs in AWS Glue for Spark.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `options` – One or more of the following:
  - `separator` – A string that contains the separator character.
  - `escaper` – A string that contains the escape character.
  - `skipFirst` – A Boolean value that indicates whether to skip the first instance.
  - `withSchema` – A string containing a JSON representation of the node's schema. The format of a schema's JSON representation is defined by the output of `StructType.json()`.
  - `withHeader` – A Boolean value that indicates whether a header is included.

Example: Use unbox to unbox a string field into a struct

This code example uses the unbox method to *unbox*, or reformat, a string field in a `DynamicFrame` into a field of type struct.

Example dataset

The example uses a `DynamicFrame` called `mapped_with_string` with the following schema and entries.

Notice the field named `AddressString`. This is the field that the example unboxes into a struct.

```
root
|-- Average Total Payments: string
|-- AddressString: string
|-- Average Covered Charges: string
|-- DRG Definition: string
|-- Average Medicare Payments: string

```

union

union(frame1, frame2, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)

Union two DynamicFrames. Returns DynamicFrame containing all records from both input DynamicFrames. This transform may return different results from the union of two DataFrames with equivalent data. If you need the Spark DataFrame union behavior, consider using `toDF`.

- `frame1` – First DynamicFrame to union.
- `frame2` – Second DynamicFrame to union.
- `transformation_ctx` – (optional) A unique string that is used to identify stats / state information
- `info` – (optional) Any string to be associated with errors in the transformation
- `stageThreshold` – (optional) Max number of errors in the transformation until processing will error out
- `totalThreshold` – (optional) Max number of errors total until processing will error out.

unnest

unnest(transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)

Unnests nested objects in a `DynamicFrame`, which makes them top-level objects, and returns a new unnested `DynamicFrame`.

- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

Example: Use unnest to turn nested fields into top-level fields

This code example uses the `unnest` method to flatten all of the nested fields in a `DynamicFrame` into top-level fields.

Example dataset

The example uses a `DynamicFrame` called `mapped_medicare` with the following schema. Notice that the `Address` field is the only field that contains nested data.

```
root
|-- Average Total Payments: string
|-- Average Covered Charges: string
|-- DRG Definition: string
|-- Average Medicare Payments: string
|-- Hospital Referral Region Description: string
|-- Address: struct
|    |-- Zip.Code: string
|    |-- City: string
|    |-- Array: array
|    |    |-- element: string
|    |-- State: string
|    |-- Street: string
|-- Provider Id: string
|-- Total Discharges: string
|-- Provider Name: string
```

Example code

```
# Example: Use unnest to unnest nested
# objects in a DynamicFrame

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Unnest all nested fields
unnested = mapped_medicare.unnest()
unnested.printSchema()
```

Output

```
root
|-- Average Total Payments: string
|-- Average Covered Charges: string
|-- DRG Definition: string
|-- Average Medicare Payments: string
|-- Hospital Referral Region Description: string
|-- Address.Zip.Code: string
|-- Address.City: string
|-- Address.Array: array
|    |-- element: string
|-- Address.State: string
|-- Address.Street: string
|-- Provider Id: string
|-- Total Discharges: string
|-- Provider Name: string
```

unnest_ddb_json

Unnests nested columns in a `DynamicFrame` that are specifically in the DynamoDB JSON structure, and returns a new unnested `DynamicFrame`. Columns that are of an array of struct types will not be unnested. Note that this is a specific type of unnesting transform that behaves differently from the regular `unnest` transform and requires the data to already be in the DynamoDB JSON structure. For more information, see DynamoDB JSON.

`unnest_ddb_json(transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)`

- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional: zero by default, indicating that the process should not error out).
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional: zero by default, indicating that the process should not error out).

For example, the schema of a reading an export with the DynamoDB JSON structure might look like the following:

```
root
|-- Item: struct
|    |-- ColA: struct
|    |    |-- S: string
|    |-- ColB: struct
|    |    |-- S: string
|    |-- ColC: struct
|    |    |-- N: string
|    |-- ColD: struct
|    |    |-- L: array
|    |    |    |-- element: null
```

The `unnest_ddb_json()` transform would convert this to:

```
root
|-- ColA: string
|-- ColB: string
|-- ColC: string
|-- ColD: array
|    |-- element: null
```

The following code example shows how to use the AWS Glue DynamoDB export connector, invoke a DynamoDB JSON unnest, and print the number of partitions:

```
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
glue_context= GlueContext(SparkContext.getOrCreate())
job = Job(glue_context)
job.init(args["JOB_NAME"], args)

dynamicFrame = glue_context.create_dynamic_frame.from_options(
    connection_type="dynamodb",
    connection_options={
        "dynamodb.export": "ddb",
```

```
        "dynamodb.tableArn": "<test_source>",
        "dynamodb.s3.bucket": "<bucket name>",
        "dynamodb.s3.prefix": "<bucket prefix>",
        "dynamodb.s3.bucketOwner": "<account_id>",
    }
)
unnested = dynamicFrame.unnest_ddb_json()
print(unnested.getNumPartitions())

job.commit()
```

write

`write(connection_type, connection_options, format, format_options, accumulator_size)`

Gets a DataSink(object) of the specified connection type from the GlueContext class of this `DynamicFrame`, and uses it to format and write the contents of this `DynamicFrame`. Returns the new `DynamicFrame` formatted and written as specified.

- `connection_type` – The connection type to use. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, and `oracle`.
- `connection_options` – The connection option to use (optional). For a `connection_type` of `s3`, an Amazon S3 path is defined.

```
connection_options = {"path": "s3://aws-glue-target/temp"}
```

For JDBC connections, several properties must be defined. Note that the database name must be part of the URL. It can optionally be included in the connection options.

> **Warning**
>
> Storing passwords in your script is not recommended. Consider using `boto3` to retrieve them from AWS Secrets Manager or the AWS Glue Data Catalog.

```
connection_options = {"url": "jdbc-url/database", "user": "username",
 "password": passwordVariable,"dbtable": "table-name", "redshiftTmpDir": "s3-tempdir-
path"}
```

- `format` – A format specification (optional). This is used for an Amazon Simple Storage Service (Amazon S3) or an AWS Glue connection that supports multiple formats. See Data format options for inputs and outputs in AWS Glue for Spark for the formats that are supported.
- `format_options` – Format options for the specified format. See Data format options for inputs and outputs in AWS Glue for Spark for the formats that are supported.
- `accumulator_size` – The accumulable size to use, in bytes (optional).

— errors —

- assertErrorThreshold
- errorsAsDynamicFrame
- errorsCount
- stageErrorsCount

assertErrorThreshold

`assertErrorThreshold( )` – An assert for errors in the transformations that created this `DynamicFrame`. Returns an `Exception` from the underlying `DataFrame`.

errorsAsDynamicFrame

`errorsAsDynamicFrame( )` – Returns a `DynamicFrame` that has error records nested inside.

Example: Use errorsAsDynamicFrame to view error records

The following code example shows how to use the `errorsAsDynamicFrame` method to view an error record for a `DynamicFrame`.

Example dataset

The example uses the following dataset that you can upload to Amazon S3 as JSON. Notice that the second record is malformed. Malformed data typically breaks file parsing when you use SparkSQL. However, `DynamicFrame` recognizes malformation issues and turns malformed lines into error records that you can handle individually.

```
{"id": 1, "name": "george", "surname": "washington", "height": 178}
{"id": 2, "name": "benjamin", "surname": "franklin",
{"id": 3, "name": "alexander", "surname": "hamilton", "height": 171}
{"id": 4, "name": "john", "surname": "jay", "height": 190}
```

Example code

```
# Example: Use errorsAsDynamicFrame to view error records.
# Replace s3://DOC-EXAMPLE-S3-BUCKET/error_data.json with your location.

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Create errors DynamicFrame, view schema
errors = glueContext.create_dynamic_frame.from_options(
    "s3", {"paths": ["s3://DOC-EXAMPLE-S3-BUCKET/error_data.json"]}, "json"
)
print("Schema of errors DynamicFrame:")
errors.printSchema()

# Show that errors only contains valid entries from the dataset
print("errors contains only valid records from the input dataset (2 of 4 records)")
errors.toDF().show()

# View errors
print("Errors count:", str(errors.errorsCount()))
print("Errors:")
errors.errorsAsDynamicFrame().toDF().show()

# View error fields and error data
error_record = errors.errorsAsDynamicFrame().toDF().head()

error_fields = error_record["error"]
print("Error fields: ")
print(error_fields.asDict().keys())

print("\nError record data:")
for key in error_fields.asDict().keys():
    print("\n", key, ": ", str(error_fields[key]))
```

Output

```
Schema of errors DynamicFrame:
root
```

```
|-- id: int
|-- name: string
|-- surname: string
|-- height: int

Comprehensive DynamicFrame examples

The following examples demonstrate various ways to create and work with DynamicFrames beyond basic Glue catalog scenarios.

Loading from PostgreSQL with SQL SELECT query

This example shows how to load data from a PostgreSQL database using a custom SQL SELECT query:

```
from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

# Load specific data from PostgreSQL with custom query
postgres_dyf = glueContext.create_dynamic_frame.from_options(
    connection_type="postgresql",
    connection_options={
        "url": "jdbc:postgresql://your-postgres-host:5432/your-database",
        "user": "your-username",
        "password": "your-password",
        "dbtable": "(SELECT customer_id, customer_name, email FROM customers WHERE
 active = true) AS filtered_customers"
    }
)
```

Loading specific columns to avoid full table scans

This example demonstrates how to load only specific columns from a large database table:

```
from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

# Load only specific columns from a large table
selected_columns_dyf = glueContext.create_dynamic_frame.from_options(
    connection_type="mysql",
    connection_options={
        "url": "jdbc:mysql://your-mysql-host:3306/your-database",
        "user": "your-username",
        "password": "your-password",
        "dbtable": "(SELECT order_id, customer_id FROM large_orders_table) AS
 selected_data"
    }
)

# Alternative approach using column selection in query
efficient_load_dyf = glueContext.create_dynamic_frame.from_options(
    connection_type="postgresql",
```

```
    connection_options={
        "url": "jdbc:postgresql://your-postgres-host:5432/your-database",
        "user": "your-username",
        "password": "your-password",
        "query": "SELECT product_id, product_name FROM products WHERE category =
 'electronics'"
    }
)
```

Row-level filtering via JDBC connections

This example shows how to use row-level filtering to load only specific rows from a database table:

```
from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

# Load filtered rows using WHERE clause
filtered_rows_dyf = glueContext.create_dynamic_frame.from_options(
    connection_type="postgresql",
    connection_options={
        "url": "jdbc:postgresql://your-postgres-host:5432/your-database",
        "user": "your-username",
        "password": "your-password",
        "dbtable": "(SELECT * FROM transactions WHERE transaction_date >= '2024-01-01'
 AND amount > 100) AS recent_large_transactions"
    }
)

# Using partitionColumn for parallel loading with filtering
partitioned_load_dyf = glueContext.create_dynamic_frame.from_options(
    connection_type="mysql",
    connection_options={
        "url": "jdbc:mysql://your-mysql-host:3306/your-database",
        "user": "your-username",
        "password": "your-password",
        "dbtable": "sales_data",
        "partitionColumn": "sale_date",
        "lowerBound": "2024-01-01",
        "upperBound": "2024-12-31",
        "numPartitions": "10"
    }
```

```
)
```

Creating DynamicFrame from in-memory Python data

This example demonstrates how to create a DynamicFrame from Python lists, tuples, or dictionaries:

```
from awsglue.context import GlueContext
from awsglue.dynamicframe import DynamicFrame
from pyspark.context import SparkContext
from pyspark.sql import Row

sc = SparkContext()
glueContext = GlueContext(sc)

# Method 1: From list of tuples
data_tuples = [
    ("John", "Doe", 30, "Engineer"),
    ("Jane", "Smith", 25, "Designer"),
    ("Bob", "Johnson", 35, "Manager")
]

# Convert to RDD of Rows
rdd = sc.parallelize([Row(first_name=row[0], last_name=row[1], age=row[2], job=row[3])
 for row in data_tuples])
df = glueContext.spark_session.createDataFrame(rdd)
dyf_from_tuples = DynamicFrame.fromDF(df, glueContext, "employees_from_tuples")

# Method 2: From list of dictionaries
data_dicts = [
    {"product_id": 1, "product_name": "Laptop", "price": 999.99, "category":
 "Electronics"},
    {"product_id": 2, "product_name": "Book", "price": 19.99, "category": "Education"},
    {"product_id": 3, "product_name": "Chair", "price": 149.99, "category":
 "Furniture"}
]

df_from_dicts = glueContext.spark_session.createDataFrame(data_dicts)
dyf_from_dicts = DynamicFrame.fromDF(df_from_dicts, glueContext, "products_from_dicts")

# Method 3: From nested data structures
nested_data = [
    {
```

```
        "customer_id": 1,
        "customer_info": {
            "name": "Alice Brown",
            "email": "alice@example.com"
        },
        "orders": [
            {"order_id": 101, "amount": 250.00},
            {"order_id": 102, "amount": 175.50}
        ]
    }
]

df_nested = glueContext.spark_session.createDataFrame(nested_data)
dyf_nested = DynamicFrame.fromDF(df_nested, glueContext, "customers_with_orders")
```

Performance optimization for large datasets

When working with large datasets, consider these performance optimization techniques:

```
# Use partitioning for parallel reads
large_table_dyf = glueContext.create_dynamic_frame.from_options(
    connection_type="postgresql",
    connection_options={
        "url": "jdbc:postgresql://your-postgres-host:5432/your-database",
        "user": "your-username",
        "password": "your-password",
        "dbtable": "large_table",
        "partitionColumn": "id",
        "lowerBound": "1",
        "upperBound": "1000000",
        "numPartitions": "20"
    }
)

# Use pushdown predicates to filter at source
filtered_dyf = glueContext.create_dynamic_frame.from_options(
    connection_type="mysql",
    connection_options={
        "url": "jdbc:mysql://your-mysql-host:3306/your-database",
        "user": "your-username",
        "password": "your-password",
        "dbtable": "transactions"
    },
    push_down_predicate="transaction_date >= '2024-01-01'"
```

```
)
```

errorsCount

`errorsCount( )` – Returns the total number of errors in a `DynamicFrame`.

stageErrorsCount

`stageErrorsCount` – Returns the number of errors that occurred in the process of generating this `DynamicFrame`.

DynamicFrameCollection class

A `DynamicFrameCollection` is a dictionary of DynamicFrame class objects, in which the keys are the names of the `DynamicFrames` and the values are the `DynamicFrame` objects.

__init__

`__init__(dynamic_frames, glue_ctx)`

- `dynamic_frames` – A dictionary of DynamicFrame class objects.
- `glue_ctx` – A GlueContext class object.

Keys

`keys( )` – Returns a list of the keys in this collection, which generally consists of the names of the corresponding `DynamicFrame` values.

Values

`values(key)` – Returns a list of the `DynamicFrame` values in this collection.

Select

`select(key)`

Returns the `DynamicFrame` that corresponds to the specfied key (which is generally the name of the `DynamicFrame`).

- `key` – A key in the `DynamicFrameCollection`, which usually represents the name of a `DynamicFrame`.

Map

`map(callable, transformation_ctx="")`

Uses a passed-in function to create and return a new `DynamicFrameCollection` based on the `DynamicFrames` in this collection.

- `callable` – A function that takes a `DynamicFrame` and the specified transformation context as parameters and returns a `DynamicFrame`.
- `transformation_ctx` – A transformation context to be used by the callable (optional).

Flatmap

`flatmap(f, transformation_ctx="")`

Uses a passed-in function to create and return a new `DynamicFrameCollection` based on the `DynamicFrames` in this collection.

- `f` – A function that takes a `DynamicFrame` as a parameter and returns a `DynamicFrame` or `DynamicFrameCollection`.
- `transformation_ctx` – A transformation context to be used by the function (optional).

DynamicFrameWriter class

methods

- __init__
- from_options
- from_catalog
- from_jdbc_conf

__init__

`__init__(glue_context)`

- `glue_context` – The GlueContext class to use.

from_options

`from_options(frame, connection_type, connection_options={}, format=None, format_options={}, transformation_ctx="")`

Writes a `DynamicFrame` using the specified connection and format.

- `frame` – The `DynamicFrame` to write.
- `connection_type` – The connection type. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, and `oracle`.
- `connection_options` – Connection options, such as path and database table (optional). For a `connection_type` of `s3`, an Amazon S3 path is defined.

```
connection_options = {"path": "s3://aws-glue-target/temp"}
```

For JDBC connections, several properties must be defined. Note that the database name must be part of the URL. It can optionally be included in the connection options.

> **Warning**
>
> Storing passwords in your script is not recommended. Consider using `boto3` to retrieve them from AWS Secrets Manager or the AWS Glue Data Catalog.

```
connection_options = {"url": "jdbc-url/database", "user": "username",
 "password": passwordVariable,"dbtable": "table-name", "redshiftTmpDir": "s3-tempdir-
path"}
```

The `dbtable` property is the name of the JDBC table. For JDBC data stores that support schemas within a database, specify `schema.table-name`. If a schema is not provided, then the default "public" schema is used.

For more information, see Connection types and options for ETL in AWS Glue for Spark.

- `format` – A format specification (optional). This is used for an Amazon Simple Storage Service (Amazon S3) or an AWS Glue connection that supports multiple formats. See Data format options for inputs and outputs in AWS Glue for Spark for the formats that are supported.

- `format_options` – Format options for the specified format. See Data format options for inputs and outputs in AWS Glue for Spark for the formats that are supported.
- `transformation_ctx` – A transformation context to use (optional).

from_catalog

`from_catalog(frame, name_space, table_name, redshift_tmp_dir="", transformation_ctx="")`

Writes a `DynamicFrame` using the specified catalog database and table name.

- `frame` – The `DynamicFrame` to write.
- `name_space` – The database to use.
- `table_name` – The `table_name` to use.
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional).
- `transformation_ctx` – A transformation context to use (optional).
- `additional_options` – Additional options provided to AWS Glue.

  To write to Lake Formation governed tables, you can use these additional options:

  - `transactionId` – (String) The transaction ID at which to do the write to the Governed table. This transaction can not be already committed or aborted, or the write will fail.
  - `callDeleteObjectsOnCancel` – (Boolean, optional) If set to `true` (default), AWS Glue automatically calls the `DeleteObjectsOnCancel` API after the object is written to Amazon S3. For more information, see DeleteObjectsOnCancel in the *AWS Lake Formation Developer Guide*.

  Example: Writing to a governed table in Lake Formation

```
txId = glueContext.start_transaction(read_only=False)
glueContext.write_dynamic_frame.from_catalog(
    frame=dyf,
    database = db,
    table_name = tbl,
    transformation_ctx = "datasource0",
    additional_options={"transactionId":txId})
...
glueContext.commit_transaction(txId)
```

from_jdbc_conf

`from_jdbc_conf(frame, catalog_connection, connection_options={}, redshift_tmp_dir = "", transformation_ctx="")`

Writes a `DynamicFrame` using the specified JDBC connection information.

- `frame` – The `DynamicFrame` to write.
- `catalog_connection` – A catalog connection to use.
- `connection_options` – Connection options, such as path and database table (optional).
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional).
- `transformation_ctx` – A transformation context to use (optional).

Example for write_dynamic_frame

This example writes the output locally using a `connection_type` of S3 with a POSIX path argument in `connection_options`, which allows writing to local storage.

```
glueContext.write_dynamic_frame.from_options(\
frame = dyf_splitFields,\
connection_options = {'path': '/home/glue/GlueLocalOutput/'},\
connection_type = 's3',\
format = 'json')
```

DynamicFrameReader class

— methods —

- __init__
- from_rdd
- from_options
- from_catalog

__init__

`__init__(glue_context)`

- `glue_context` – The GlueContext class to use.

from_rdd

`from_rdd(data, name, schema=None, sampleRatio=None)`

Reads a `DynamicFrame` from a Resilient Distributed Dataset (RDD).

- `data` – The dataset to read from.
- `name` – The name to read from.
- `schema` – The schema to read (optional).
- `sampleRatio` – The sample ratio (optional).

from_options

`from_options(connection_type, connection_options={}, format=None, format_options={}, transformation_ctx="")`

Reads a `DynamicFrame` using the specified connection and format.

- `connection_type` – The connection type. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, `oracle`, dynamodb, and `snowflake`.
- `connection_options` – Connection options, such as path and database table (optional). For more information, see Connection types and options for ETL in AWS Glue for Spark . For a `connection_type` of `s3`, Amazon S3 paths are defined in an array.

```
connection_options = {"paths": [ "s3://amzn-s3-demo-bucket/object_a", "s3://amzn-s3-demo-bucket/object_b"]}
```

  For JDBC connections, several properties must be defined. Note that the database name must be part of the URL. It can optionally be included in the connection options.

> **Warning**
>
> Storing passwords in your script is not recommended. Consider using `boto3` to retrieve them from AWS Secrets Manager or the AWS Glue Data Catalog.

```
connection_options = {"url": "jdbc-url/database", "user": "username",
 "password": passwordVariable,"dbtable": "table-name", "redshiftTmpDir": "s3-tempdir-
path"}
```

For a JDBC connection that performs parallel reads, you can set the hashfield option. For example:

```
connection_options = {"url": "jdbc-url/database", "user": "username",
 "password": passwordVariable,"dbtable": "table-name", "redshiftTmpDir": "s3-tempdir-
path" , "hashfield": "month"}
```

For more information, see Reading from JDBC tables in parallel.

- `format` – A format specification (optional). This is used for an Amazon Simple Storage Service (Amazon S3) or an AWS Glue connection that supports multiple formats. See Data format options for inputs and outputs in AWS Glue for Spark for the formats that are supported.
- `format_options` – Format options for the specified format. See Data format options for inputs and outputs in AWS Glue for Spark for the formats that are supported.
- `transformation_ctx` – The transformation context to use (optional).
- `push_down_predicate` – Filters partitions without having to list and read all the files in your dataset. For more information, see Pre-Filtering Using Pushdown Predicates.

from_catalog

`from_catalog(database, table_name, redshift_tmp_dir="", transformation_ctx="", push_down_predicate="", additional_options={})`

Reads a `DynamicFrame` using the specified catalog namespace and table name.

- `database` – The database to read from.
- `table_name` – The name of the table to read from.
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional if not reading data from Redshift).
- `transformation_ctx` – The transformation context to use (optional).
- `push_down_predicate` – Filters partitions without having to list and read all the files in your dataset. For more information, see Pre-filtering using pushdown predicates.

- `additional_options` – Additional options provided to AWS Glue.
  - To use a JDBC connection that performs parallel reads, you can set the `hashfield`, `hashexpression`, or `hashpartitions` options. For example:

    ```
    additional_options = {"hashfield": "month"}
    ```

    For more information, see Reading from JDBC tables in parallel.
  - To pass a catalog expression to filter based on the index columns, you can see the `catalogPartitionPredicate` option.

    `catalogPartitionPredicate` — You can pass a catalog expression to filter based on the index columns. This pushes down the filtering to the server side. For more information, see AWS Glue Partition Indexes. Note that `push_down_predicate` and `catalogPartitionPredicate` use different syntaxes. The former one uses Spark SQL standard syntax and the later one uses JSQL parser.

    For more information, see Managing partitions for ETL output in AWS Glue.

GlueContext class

Wraps the Apache Spark SparkContext object, and thereby provides mechanisms for interacting with the Apache Spark platform.

__init__

`__init__(sparkContext)`

- `sparkContext` – The Apache Spark context to use.

Creating

- __init__
- getSource
- create_dynamic_frame_from_rdd
- create_dynamic_frame_from_catalog
- create_dynamic_frame_from_options
- create_sample_dynamic_frame_from_catalog

- create_sample_dynamic_frame_from_options
- add_ingestion_time_columns
- create_data_frame_from_catalog
- create_data_frame_from_options
- forEachBatch

getSource

`getSource(connection_type, transformation_ctx = "", **options)`

Creates a `DataSource` object that can be used to read `DynamicFrames` from external sources.

- `connection_type` – The connection type to use, such as Amazon Simple Storage Service (Amazon S3), Amazon Redshift, and JDBC. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, `oracle`, and dynamodb.
- `transformation_ctx` – The transformation context to use (optional).
- `options` – A collection of optional name-value pairs. For more information, see Connection types and options for ETL in AWS Glue for Spark.

The following is an example of using `getSource`.

```
>>> data_source = context.getSource("file", paths=["/in/path"])
>>> data_source.setFormat("json")
>>> myFrame = data_source.getFrame()
```

create_dynamic_frame_from_rdd

`create_dynamic_frame_from_rdd(data, name, schema=None, sample_ratio=None, transformation_ctx="")`

Returns a `DynamicFrame` that is created from an Apache Spark Resilient Distributed Dataset (RDD).

- `data` – The data source to use.
- `name` – The name of the data to use.
- `schema` – The schema to use (optional).

- `sample_ratio` – The sample ratio to use (optional).
- `transformation_ctx` – The transformation context to use (optional).

create_dynamic_frame_from_catalog

`create_dynamic_frame_from_catalog(database, table_name, redshift_tmp_dir, transformation_ctx = "", push_down_predicate= "", additional_options = {}, catalog_id = None)`

Returns a `DynamicFrame` that is created using a Data Catalog database and table name. When using this method, you provide `format_options` through table properties on the specified AWS Glue Data Catalog table and other options through the `additional_options` argument.

- `Database` – The database to read from.
- `table_name` – The name of the table to read from.
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional).
- `transformation_ctx` – The transformation context to use (optional).
- `push_down_predicate` – Filters partitions without having to list and read all the files in your dataset. For supported sources and limitations, see Optimizing reads with pushdown in AWS Glue ETL. For more information, see Pre-filtering using pushdown predicates.
- `additional_options` – A collection of optional name-value pairs. The possible options include those listed in Connection types and options for ETL in AWS Glue for Spark except for `endpointUrl`, `streamName`, `bootstrap.servers`, `security.protocol`, `topicName`, `classification`, and `delimiter`. Another supported option is `catalogPartitionPredicate`:

  `catalogPartitionPredicate` — You can pass a catalog expression to filter based on the index columns. This pushes down the filtering to the server side. For more information, see AWS Glue Partition Indexes. Note that `push_down_predicate` and `catalogPartitionPredicate` use different syntaxes. The former one uses Spark SQL standard syntax and the later one uses JSQL parser.
- `catalog_id` — The catalog ID (account ID) of the Data Catalog being accessed. When None, the default account ID of the caller is used.

create_dynamic_frame_from_options

`create_dynamic_frame_from_options(connection_type, connection_options={}, format=None, format_options={}, transformation_ctx = "")`

Returns a `DynamicFrame` created with the specified connection and format.

- `connection_type` – The connection type, such as Amazon S3, Amazon Redshift, and JDBC. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, `oracle`, and `dynamodb`.
- `connection_options` – Connection options, such as paths and database table (optional). For a `connection_type` of `s3`, a list of Amazon S3 paths is defined.

```
connection_options = {"paths": ["s3://aws-glue-target/temp"]}
```

For JDBC connections, several properties must be defined. Note that the database name must be part of the URL. It can optionally be included in the connection options.

> **Warning**
>
> Storing passwords in your script is not recommended. Consider using `boto3` to retrieve them from AWS Secrets Manager or the AWS Glue Data Catalog.

```
connection_options = {"url": "jdbc-url/database", "user": "username",
 "password": passwordVariable,"dbtable": "table-name", "redshiftTmpDir": "s3-tempdir-path"}
```

The `dbtable` property is the name of the JDBC table. For JDBC data stores that support schemas within a database, specify `schema.table-name`. If a schema is not provided, then the default "public" schema is used.

For more information, see Connection types and options for ETL in AWS Glue for Spark.

- `format` – A format specification. This is used for an Amazon S3 or an AWS Glue connection that supports multiple formats. See Data format options for inputs and outputs in AWS Glue for Spark for the formats that are supported.
- `format_options` – Format options for the specified format. See Data format options for inputs and outputs in AWS Glue for Spark for the formats that are supported.

- `transformation_ctx` – The transformation context to use (optional).
- `push_down_predicate` – Filters partitions without having to list and read all the files in your dataset. For supported sources and limitations, see Optimizing reads with pushdown in AWS Glue ETL. For more information, see Pre-Filtering Using Pushdown Predicates.

create_sample_dynamic_frame_from_catalog

`create_sample_dynamic_frame_from_catalog(database, table_name, num, redshift_tmp_dir, transformation_ctx = "", push_down_predicate= "", additional_options = {}, sample_options = {}, catalog_id = None)`

Returns a sample `DynamicFrame` that is created using a Data Catalog database and table name. The `DynamicFrame` only contains first `num` records from a datasource.

- `database` – The database to read from.
- `table_name` – The name of the table to read from.
- `num` – The maximum number of records in the returned sample dynamic frame.
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional).
- `transformation_ctx` – The transformation context to use (optional).
- `push_down_predicate` – Filters partitions without having to list and read all the files in your dataset. For more information, see Pre-filtering using pushdown predicates.
- `additional_options` – A collection of optional name-value pairs. The possible options include those listed in Connection types and options for ETL in AWS Glue for Spark except for `endpointUrl`, `streamName`, `bootstrap.servers`, `security.protocol`, `topicName`, `classification`, and `delimiter`.
- `sample_options` – Parameters to control sampling behavior (optional). Current available parameters for Amazon S3 sources:
  - `maxSamplePartitions` – The maximum number of partitions the sampling will read. Default value is 10
  - `maxSampleFilesPerPartition` – The maximum number of files the sampling will read in one partition. Default value is 10.

    These parameters help to reduce the time consumed by file listing. For example, suppose the dataset has 1000 partitions, and each partition has 10 files. If you set `maxSamplePartitions` = 10, and `maxSampleFilesPerPartition` = 10, instead of listing all 10,000 files, the

sampling will only list and read the first 10 partitions with the first 10 files in each: 10*10 = 100 files in total.

- `catalog_id` – The catalog ID of the Data Catalog being accessed (the account ID of the Data Catalog). Set to `None` by default. `None` defaults to the catalog ID of the calling account in the service.

create_sample_dynamic_frame_from_options

`create_sample_dynamic_frame_from_options(connection_type, connection_options={}, num, sample_options={}, format=None, format_options={}, transformation_ctx = "")`

Returns a sample `DynamicFrame` created with the specified connection and format. The `DynamicFrame` only contains first `num` records from a datasource.

- `connection_type` – The connection type, such as Amazon S3, Amazon Redshift, and JDBC. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, `oracle`, and `dynamodb`.
- `connection_options` – Connection options, such as paths and database table (optional). For more information, see Connection types and options for ETL in AWS Glue for Spark.
- `num` – The maximum number of records in the returned sample dynamic frame.
- `sample_options` – Parameters to control sampling behavior (optional). Current available parameters for Amazon S3 sources:
  - `maxSamplePartitions` – The maximum number of partitions the sampling will read. Default value is 10
  - `maxSampleFilesPerPartition` – The maximum number of files the sampling will read in one partition. Default value is 10.

    These parameters help to reduce the time consumed by file listing. For example, suppose the dataset has 1000 partitions, and each partition has 10 files. If you set `maxSamplePartitions` = 10, and `maxSampleFilesPerPartition` = 10, instead of listing all 10,000 files, the sampling will only list and read the first 10 partitions with the first 10 files in each: 10*10 = 100 files in total.
- `format` – A format specification. This is used for an Amazon S3 or an AWS Glue connection that supports multiple formats. See Data format options for inputs and outputs in AWS Glue for Spark for the formats that are supported.

- `format_options` – Format options for the specified format. See Data format options for inputs and outputs in AWS Glue for Spark for the formats that are supported.
- `transformation_ctx` – The transformation context to use (optional).
- `push_down_predicate` – Filters partitions without having to list and read all the files in your dataset. For more information, see Pre-filtering using pushdown predicates.

add_ingestion_time_columns

`add_ingestion_time_columns(dataFrame, timeGranularity = "")`

Appends ingestion time columns like `ingest_year`, `ingest_month`, `ingest_day`, `ingest_hour`, `ingest_minute` to the input `DataFrame`. This function is automatically generated in the script generated by the AWS Glue when you specify a Data Catalog table with Amazon S3 as the target. This function automatically updates the partition with ingestion time columns on the output table. This allows the output data to be automatically partitioned on ingestion time without requiring explicit ingestion time columns in the input data.

- `dataFrame` – The `dataFrame` to append the ingestion time columns to.
- `timeGranularity` – The granularity of the time columns. Valid values are "`day`", "`hour`" and "`minute`". For example, if "`hour`" is passed in to the function, the original `dataFrame` will have "`ingest_year`", "`ingest_month`", "`ingest_day`", and "`ingest_hour`" time columns appended.

Returns the data frame after appending the time granularity columns.

Example:

```
dynamic_frame = DynamicFrame.fromDF(glueContext.add_ingestion_time_columns(dataFrame,
 "hour"))
```

create_data_frame_from_catalog

`create_data_frame_from_catalog(database, table_name, transformation_ctx = "", additional_options = {})`

Returns a `DataFrame` that is created using information from a Data Catalog table.

- `database` – The Data Catalog database to read from.

- `table_name` – The name of the Data Catalog table to read from.
- `transformation_ctx` – The transformation context to use (optional).
- `additional_options` – A collection of optional name-value pairs. The possible options include those listed in Connection types and options for ETL in AWS Glue for Spark for streaming sources, such as `startingPosition`, `maxFetchTimeInMs`, and `startingOffsets`.
  - `useSparkDataSource` – When set to true, forces AWS Glue to use the native Spark Data Source API to read the table. The Spark Data Source API supports the following formats: AVRO, binary, CSV, JSON, ORC, Parquet, and text. In a Data Catalog table, you specify the format using the `classification` property. To learn more about the Spark Data Source API, see the official Apache Spark documentation.

    Using `create_data_frame_from_catalog` with `useSparkDataSource` has the following benefits:

    - Directly returns a `DataFrame` and provides an alternative to `create_dynamic_frame.from_catalog().toDF()`.
    - Supports AWS Lake Formation table-level permission control for native formats.
    - Supports reading data lake formats without AWS Lake Formation table-level permission control. For more information, see Using data lake frameworks with AWS Glue ETL jobs.

    When you enable `useSparkDataSource`, you can also add any of the Spark Data Source options in `additional_options` as needed. AWS Glue passes these options directly to the Spark reader.
  - `useCatalogSchema` – When set to true, AWS Glue applies the Data Catalog schema to the resulting `DataFrame`. Otherwise, the reader infers the schema from the data. When you enable `useCatalogSchema`, you must also set `useSparkDataSource` to true.

Limitations

Consider the following limitations when you use the `useSparkDataSource` option:

- When you use `useSparkDataSource`, AWS Glue creates a new `DataFrame` in a separate Spark session that is different from the original Spark session.
- Spark DataFrame partition filtering doesn't work with the following AWS Glue features.
  - Job bookmarks
  - Excluding Amazon S3 storage classes

- Catalog partition predicates

To use partition filtering with these features, you can use the AWS Glue pushdown predicate. For more information, see Pre-filtering using pushdown predicates. Filtering on non-partitioned columns is not affected.

The following example script demonstrates the incorrect way to perform partition filtering with the `excludeStorageClasses` option.

```
// Incorrect partition filtering using Spark filter with excludeStorageClasses
read_df = glueContext.create_data_frame.from_catalog(
    database=database_name,
    table_name=table_name,
    additional_options = {
      "useSparkDataSource": True,
      "excludeStorageClasses" : ["GLACIER", "DEEP_ARCHIVE"]
    }
)

//  Suppose year and month are partition keys.
//  Filtering on year and month won't work, the filtered_df will still
//  contain data with other year/month values.
filtered_df = read_df.filter("year == '2017 and month == '04' and 'state == 'CA'")
```

The following example script demonstrates the correct way to use a pushdown predicate in order to perform partition filtering with the `excludeStorageClasses` option.

```
// Correct partition filtering using the AWS Glue pushdown predicate
// with excludeStorageClasses
read_df = glueContext.create_data_frame.from_catalog(
    database=database_name,
    table_name=table_name,
    //  Use AWS Glue pushdown predicate to perform partition filtering
    push_down_predicate = "(year=='2017' and month=='04')"
    additional_options = {
      "useSparkDataSource": True,
      "excludeStorageClasses" : ["GLACIER", "DEEP_ARCHIVE"]
    }
)

//  Use Spark filter only on non-partitioned columns
```

```
filtered_df = read_df.filter("state == 'CA'")
```

Example: Creating a CSV table using the Spark data source reader

```
//  Read a CSV table with '\t' as separator
read_df = glueContext.create_data_frame.from_catalog(
    database=<database_name>,
    table_name=<table_name>,
    additional_options = {"useSparkDataSource": True,  "sep": '\t'}
)
```

create_data_frame_from_options

`create_data_frame_from_options(connection_type, connection_options={}, format=None, format_options={}, transformation_ctx = "")`

This API is now deprecated. Instead use the `getSource()` API. Returns a `DataFrame` created with the specified connection and format. Use this function only with AWS Glue streaming sources.

- `connection_type` – The streaming connection type. Valid values include `kinesis` and `kafka`.
- `connection_options` – Connection options, which are different for Kinesis and Kafka. You can find the list of all connection options for each streaming data source at Connection types and options for ETL in AWS Glue for Spark. Note the following differences in streaming connection options:
  - Kinesis streaming sources require `streamARN`, `startingPosition`, `inferSchema`, and `classification`.
  - Kafka streaming sources require `connectionName`, `topicName`, `startingOffsets`, `inferSchema`, and `classification`.
- `format` – A format specification. This is used for an Amazon S3 or an AWS Glue connection that supports multiple formats. For information about the supported formats, see Data format options for inputs and outputs in AWS Glue for Spark.
- `format_options` – Format options for the specified format. For information about the supported format options, see Data format options for inputs and outputs in AWS Glue for Spark.
- `transformation_ctx` – The transformation context to use (optional).

Example for Amazon Kinesis streaming source:

```
kinesis_options =
   { "streamARN": "arn:aws:kinesis:us-east-2:777788889999:stream/fromOptionsStream",
     "startingPosition": "TRIM_HORIZON",
     "inferSchema": "true",
     "classification": "json"
   }
data_frame_datasource0 =
 glueContext.create_data_frame.from_options(connection_type="kinesis",
 connection_options=kinesis_options)
```

Example for Kafka streaming source:

```
kafka_options =
    { "connectionName": "ConfluentKafka",
      "topicName": "kafka-auth-topic",
      "startingOffsets": "earliest",
      "inferSchema": "true",
      "classification": "json"
    }
data_frame_datasource0 =
 glueContext.create_data_frame.from_options(connection_type="kafka",
 connection_options=kafka_options)
```

forEachBatch

`forEachBatch(frame, batch_function, options)`

Applies the `batch_function` passed in to every micro batch that is read from the Streaming source.

- `frame` – The DataFrame containing the current micro batch.
- `batch_function` – A function that will be applied for every micro batch.
- `options` – A collection of key-value pairs that holds information about how to process micro batches. The following options are required:
  - `windowSize` – The amount of time to spend processing each batch.
  - `checkpointLocation` – The location where checkpoints are stored for the streaming ETL job.
  - `batchMaxRetries` – The maximum number of times to retry the batch if it fails. The default value is 3. This option is only configurable for Glue version 2.0 and above.

Example:

```
glueContext.forEachBatch(
    frame = data_frame_datasource0,
    batch_function = processBatch,
    options = {
        "windowSize": "100 seconds",
        "checkpointLocation": "s3://kafka-auth-dataplane/confluent-test/output/
checkpoint/"
    }
)

def processBatch(data_frame, batchId):
    if (data_frame.count() > 0):
        datasource0 = DynamicFrame.fromDF(
          glueContext.add_ingestion_time_columns(data_frame, "hour"),
          glueContext, "from_data_frame"
        )
        additionalOptions_datasink1 = {"enableUpdateCatalog": True}
        additionalOptions_datasink1["partitionKeys"] = ["ingest_yr", "ingest_mo",
 "ingest_day"]
        datasink1 = glueContext.write_dynamic_frame.from_catalog(
          frame = datasource0,
          database = "tempdb",
          table_name = "kafka-auth-table-output",
          transformation_ctx = "datasink1",
          additional_options = additionalOptions_datasink1
        )
```

Working with datasets in Amazon S3

- purge_table
- purge_s3_path
- transition_table
- transition_s3_path

purge_table

`purge_table(catalog_id=None, database="", table_name="", options={}, transformation_ctx="")`

Deletes files from Amazon S3 for the specified catalog's database and table. If all files in a partition are deleted, that partition is also deleted from the catalog. We don't support purge_table action on tables registered with Lake Formation.

If you want to be able to recover deleted objects, you can turn on object versioning on the Amazon S3 bucket. When an object is deleted from a bucket that doesn't have object versioning enabled, the object can't be recovered. For more information about how to recover deleted objects in a version-enabled bucket, see How can I retrieve an Amazon S3 object that was deleted? in the AWS Support Knowledge Center.

- `catalog_id` – The catalog ID of the Data Catalog being accessed (the account ID of the Data Catalog). Set to `None` by default. `None` defaults to the catalog ID of the calling account in the service.
- `database` – The database to use.
- `table_name` – The name of the table to use.
- `options` – Options to filter files to be deleted and for manifest file generation.
  - `retentionPeriod` – Specifies a period in number of hours to retain files. Files newer than the retention period are retained. Set to 168 hours (7 days) by default.
  - `partitionPredicate` – Partitions satisfying this predicate are deleted. Files within the retention period in these partitions are not deleted. Set to `""` – empty by default.
  - `excludeStorageClasses` – Files with storage class in the `excludeStorageClasses` set are not deleted. The default is `Set()` – an empty set.
  - `manifestFilePath` – An optional path for manifest file generation. All files that were successfully purged are recorded in `Success.csv`, and those that failed in `Failed.csv`
- `transformation_ctx` – The transformation context to use (optional). Used in the manifest file path.

Example

```
glueContext.purge_table("database", "table", {"partitionPredicate": "(month=='march')",
 "retentionPeriod": 1, "excludeStorageClasses": ["STANDARD_IA"], "manifestFilePath":
 "s3://bucketmanifest/"})
```

purge_s3_path

`purge_s3_path(s3_path, options={}, transformation_ctx="")`

Deletes files from the specified Amazon S3 path recursively.

If you want to be able to recover deleted objects, you can turn on object versioning on the Amazon S3 bucket. When an object is deleted from a bucket that doesn't have object versioning turned on, the object can't be recovered. For more information about how to recover deleted objects in a bucket with versioning, see How can I retrieve an Amazon S3 object that was deleted? in the Support Knowledge Center.

- `s3_path` – The path in Amazon S3 of the files to be deleted in the format `s3://<bucket>/<prefix>/`
- `options` – Options to filter files to be deleted and for manifest file generation.
  - `retentionPeriod` – Specifies a period in number of hours to retain files. Files newer than the retention period are retained. Set to 168 hours (7 days) by default.
  - `excludeStorageClasses` – Files with storage class in the `excludeStorageClasses` set are not deleted. The default is `Set()` – an empty set.
  - `manifestFilePath` – An optional path for manifest file generation. All files that were successfully purged are recorded in `Success.csv`, and those that failed in `Failed.csv`
- `transformation_ctx` – The transformation context to use (optional). Used in the manifest file path.

Example

```
glueContext.purge_s3_path("s3://bucket/path/", {"retentionPeriod": 1,
 "excludeStorageClasses": ["STANDARD_IA"], "manifestFilePath": "s3://bucketmanifest/"})
```

transition_table

`transition_table(database, table_name, transition_to, options={}, transformation_ctx="", catalog_id=None)`

Transitions the storage class of the files stored on Amazon S3 for the specified catalog's database and table.

You can transition between any two storage classes. For the `GLACIER` and `DEEP_ARCHIVE` storage classes, you can transition to these classes. However, you would use an `S3 RESTORE` to transition from `GLACIER` and `DEEP_ARCHIVE` storage classes.

If you're running AWS Glue ETL jobs that read files or partitions from Amazon S3, you can exclude some Amazon S3 storage class types. For more information, see Excluding Amazon S3 Storage Classes.

- `database` – The database to use.
- `table_name` – The name of the table to use.
- `transition_to` – The Amazon S3 storage class to transition to.
- `options` – Options to filter files to be deleted and for manifest file generation.
  - `retentionPeriod` – Specifies a period in number of hours to retain files. Files newer than the retention period are retained. Set to 168 hours (7 days) by default.
  - `partitionPredicate` – Partitions satisfying this predicate are transitioned. Files within the retention period in these partitions are not transitioned. Set to `""` – empty by default.
  - `excludeStorageClasses` – Files with storage class in the `excludeStorageClasses` set are not transitioned. The default is `Set()` – an empty set.
  - `manifestFilePath` – An optional path for manifest file generation. All files that were successfully transitioned are recorded in `Success.csv`, and those that failed in `Failed.csv`
  - `accountId` – The Amazon Web Services account ID to run the transition transform. Mandatory for this transform.
  - `roleArn` – The AWS role to run the transition transform. Mandatory for this transform.
- `transformation_ctx` – The transformation context to use (optional). Used in the manifest file path.
- `catalog_id` – The catalog ID of the Data Catalog being accessed (the account ID of the Data Catalog). Set to `None` by default. `None` defaults to the catalog ID of the calling account in the service.

Example

```
glueContext.transition_table("database", "table", "STANDARD_IA", {"retentionPeriod": 1,
 "excludeStorageClasses": ["STANDARD_IA"], "manifestFilePath": "s3://bucketmanifest/",
 "accountId": "12345678901", "roleArn": "arn:aws:iam::123456789012:user/example-
username"})
```

transition_s3_path

`transition_s3_path(s3_path, transition_to, options={}, transformation_ctx="")`

Transitions the storage class of the files in the specified Amazon S3 path recursively.

You can transition between any two storage classes. For the `GLACIER` and `DEEP_ARCHIVE` storage classes, you can transition to these classes. However, you would use an `S3 RESTORE` to transition from `GLACIER` and `DEEP_ARCHIVE` storage classes.

If you're running AWS Glue ETL jobs that read files or partitions from Amazon S3, you can exclude some Amazon S3 storage class types. For more information, see Excluding Amazon S3 Storage Classes.

- `s3_path` – The path in Amazon S3 of the files to be transitioned in the format `s3://<bucket>/<prefix>/`
- `transition_to` – The Amazon S3 storage class to transition to.
- `options` – Options to filter files to be deleted and for manifest file generation.
  - `retentionPeriod` – Specifies a period in number of hours to retain files. Files newer than the retention period are retained. Set to 168 hours (7 days) by default.
  - `partitionPredicate` – Partitions satisfying this predicate are transitioned. Files within the retention period in these partitions are not transitioned. Set to `""` – empty by default.
  - `excludeStorageClasses` – Files with storage class in the `excludeStorageClasses` set are not transitioned. The default is `Set()` – an empty set.
  - `manifestFilePath` – An optional path for manifest file generation. All files that were successfully transitioned are recorded in `Success.csv`, and those that failed in `Failed.csv`
  - `accountId` – The Amazon Web Services account ID to run the transition transform. Mandatory for this transform.
  - `roleArn` – The AWS role to run the transition transform. Mandatory for this transform.

- `transformation_ctx` – The transformation context to use (optional). Used in the manifest file path.

Example

```
glueContext.transition_s3_path("s3://bucket/prefix/", "STANDARD_IA",
 {"retentionPeriod": 1, "excludeStorageClasses": ["STANDARD_IA"],
 "manifestFilePath": "s3://bucketmanifest/", "accountId": "12345678901", "roleArn":
 "arn:aws:iam::123456789012:user/example-username"})
```

Extracting

- extract_jdbc_conf

extract_jdbc_conf

`extract_jdbc_conf(connection_name, catalog_id = None)`

Returns a `dict` with keys with the configuration properties from the AWS Glue connection object in the Data Catalog.

- `user` – The database user name.
- `password` – The database password.
- `vendor` – Specifies a vendor (`mysql`, `postgresql`, `oracle`, `sqlserver`, etc.).
- `enforceSSL` – A boolean string indicating if a secure connection is required.
- `customJDBCCert` – Use a specific client certificate from the Amazon S3 path indicated.
- `skipCustomJDBCCertValidation` – A boolean string indicating if the `customJDBCCert` must be validated by a CA.
- `customJDBCCertString` – Additional information about the custom certificate, specific for the driver type.
- `url` – (Deprecated) JDBC URL with only protocol, server and port.
- `fullUrl` – JDBC URL as entered when the connection was created (Available in AWS Glue version 3.0 or later).

Example retrieving JDBC configurations:

```
jdbc_conf = glueContext.extract_jdbc_conf(connection_name="your_glue_connection_name")
print(jdbc_conf)
>>> {'enforceSSL': 'false', 'skipCustomJDBCCertValidation': 'false', 'url':
 'jdbc:mysql://myserver:3306', 'fullUrl': 'jdbc:mysql://myserver:3306/mydb',
 'customJDBCCertString': '', 'user': 'admin', 'customJDBCCert': '', 'password': '1234',
 'vendor': 'mysql'}
```

Transactions

- start_transaction
- commit_transaction
- cancel_transaction

start_transaction

`start_transaction(read_only)`

Start a new transaction. Internally calls the Lake Formation startTransaction API.

- `read_only` – (Boolean) Indicates whether this transaction should be read only or read and write. Writes made using a read-only transaction ID will be rejected. Read-only transactions do not need to be committed.

Returns the transaction ID.

commit_transaction

`commit_transaction(transaction_id, wait_for_commit = True)`

Attempts to commit the specified transaction. `commit_transaction` may return before the transaction has finished committing. Internally calls the Lake Formation commitTransaction API.

- `transaction_id` – (String) The transaction to commit.
- `wait_for_commit` – (Boolean) Determines whether the `commit_transaction` returns immediately. The default value is true. If false, `commit_transaction` polls and waits until the transaction is committed. The amount of wait time is restricted to 1 minute using exponential backoff with a maximum of 6 retry attempts.

Returns a Boolean to indicate whether the commit is done or not.

cancel_transaction

`cancel_transaction(transaction_id)`

Attempts to cancel the specified transaction. Returns a `TransactionCommittedException` exception if the transaction was previously committed. Internally calls the Lake Formation CancelTransaction API.

- `transaction_id` – (String) The transaction to cancel.

Writing

- getSink
- write_dynamic_frame_from_options
- write_from_options
- write_dynamic_frame_from_catalog
- write_data_frame_from_catalog
- write_dynamic_frame_from_jdbc_conf
- write_from_jdbc_conf

getSink

`getSink(connection_type, format = None, transformation_ctx = "", **options)`

Gets a `DataSink` object that can be used to write `DynamicFrames` to external sources. Check the SparkSQL `format` first to be sure to get the expected sink.

- `connection_type` – The connection type to use, such as Amazon S3, Amazon Redshift, and JDBC. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, `oracle`, `kinesis`, and `kafka`.
- `format` – The SparkSQL format to use (optional).
- `transformation_ctx` – The transformation context to use (optional).
- `options` – A collection of name-value pairs used to specify the connection options. Some of the possible values are:
  - `user` and `password`: For authorization
  - `url`: The endpoint for the data store

- `dbtable`: The name of the target table
- `bulkSize`: Degree of parallelism for insert operations

The options that you can specify depends on the connection type. See Connection types and options for ETL in AWS Glue for Spark for additional values and examples.

Example:

```
>>> data_sink = context.getSink("s3")
>>> data_sink.setFormat("json"),
>>> data_sink.writeFrame(myFrame)
```

write_dynamic_frame_from_options

`write_dynamic_frame_from_options(frame, connection_type, connection_options={}, format=None, format_options={}, transformation_ctx = "")`

Writes and returns a `DynamicFrame` using the specified connection and format.

- `frame` – The `DynamicFrame` to write.
- `connection_type` – The connection type, such as Amazon S3, Amazon Redshift, and JDBC. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, `oracle`, `kinesis`, and `kafka`.
- `connection_options` – Connection options, such as path and database table (optional). For a `connection_type` of `s3`, an Amazon S3 path is defined.

  ```
  connection_options = {"path": "s3://aws-glue-target/temp"}
  ```

  For JDBC connections, several properties must be defined. Note that the database name must be part of the URL. It can optionally be included in the connection options.

  > **Warning**
  >
  > Storing passwords in your script is not recommended. Consider using `boto3` to retrieve them from AWS Secrets Manager or the AWS Glue Data Catalog.

```
connection_options = {"url": "jdbc-url/database", "user": "username",
 "password": passwordVariable,"dbtable": "table-name", "redshiftTmpDir": "s3-tempdir-
path"}
```

The `dbtable` property is the name of the JDBC table. For JDBC data stores that support schemas within a database, specify `schema.table-name`. If a schema is not provided, then the default "public" schema is used.

For more information, see Connection types and options for ETL in AWS Glue for Spark.

- `format` – A format specification. This is used for an Amazon S3 or an AWS Glue connection that supports multiple formats. See Data format options for inputs and outputs in AWS Glue for Spark for the formats that are supported.
- `format_options` – Format options for the specified format. See Data format options for inputs and outputs in AWS Glue for Spark for the formats that are supported.
- `transformation_ctx` – A transformation context to use (optional).

write_from_options

`write_from_options(frame_or_dfc, connection_type, connection_options={}, format={}, format_options={}, transformation_ctx = "")`

Writes and returns a `DynamicFrame` or `DynamicFrameCollection` that is created with the specified connection and format information.

- `frame_or_dfc` – The `DynamicFrame` or `DynamicFrameCollection` to write.
- `connection_type` – The connection type, such as Amazon S3, Amazon Redshift, and JDBC. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, and `oracle`.
- `connection_options` – Connection options, such as path and database table (optional). For a `connection_type` of `s3`, an Amazon S3 path is defined.

```
connection_options = {"path": "s3://aws-glue-target/temp"}
```

For JDBC connections, several properties must be defined. Note that the database name must be part of the URL. It can optionally be included in the connection options.

> **Warning**
>
> Storing passwords in your script is not recommended. Consider using `boto3` to retrieve them from AWS Secrets Manager or the AWS Glue Data Catalog.

```
connection_options = {"url": "jdbc-url/database", "user": "username",
 "password": passwordVariable,"dbtable": "table-name", "redshiftTmpDir": "s3-tempdir-
path"}
```

The `dbtable` property is the name of the JDBC table. For JDBC data stores that support schemas within a database, specify `schema.table-name`. If a schema is not provided, then the default "public" schema is used.

For more information, see Connection types and options for ETL in AWS Glue for Spark.

- `format` – A format specification. This is used for an Amazon S3 or an AWS Glue connection that supports multiple formats. See Data format options for inputs and outputs in AWS Glue for Spark for the formats that are supported.
- `format_options` – Format options for the specified format. See Data format options for inputs and outputs in AWS Glue for Spark for the formats that are supported.
- `transformation_ctx` – A transformation context to use (optional).

write_dynamic_frame_from_catalog

`write_dynamic_frame_from_catalog(frame, database, table_name, redshift_tmp_dir, transformation_ctx = "", additional_options = {}, catalog_id = None)`

Writes and returns a `DynamicFrame` using information from a Data Catalog database and table.

- `frame` – The `DynamicFrame` to write.
- `Database` – The Data Catalog database that contains the table.
- `table_name` – The name of the Data Catalog table associated with the target.
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional).
- `transformation_ctx` – The transformation context to use (optional).

- `additional_options` – A collection of optional name-value pairs.
- `catalog_id` — The catalog ID (account ID) of the Data Catalog being accessed. When None, the default account ID of the caller is used.

write_data_frame_from_catalog

`write_data_frame_from_catalog(frame, database, table_name, redshift_tmp_dir, transformation_ctx = "", additional_options = {}, catalog_id = None)`

Writes and returns a `DataFrame` using information from a Data Catalog database and table. This method supports writing to data lake formats (Hudi, Iceberg, and Delta Lake). For more information, see Using data lake frameworks with AWS Glue ETL jobs.

- `frame` – The `DataFrame` to write.
- `Database` – The Data Catalog database that contains the table.
- `table_name` – The name of the Data Catalog table that is associated with the target.
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional).
- `transformation_ctx` – The transformation context to use (optional).
- `additional_options` – A collection of optional name-value pairs.
  - `useSparkDataSink` – When set to true, forces AWS Glue to use the native Spark Data Sink API to write to the table. When you enable this option, you can add any Spark Data Source options to `additional_options` as needed. AWS Glue passes these options directly to the Spark writer.
- `catalog_id` – The catalog ID (account ID) of the Data Catalog being accessed. When you don't specify a value, the default account ID of the caller is used.

Limitations

Consider the following limitations when you use the `useSparkDataSink` option:

- The `enableUpdateCatalog` option isn't supported when you use the `useSparkDataSink` option.

Example: Writing to a Hudi table using the Spark Data Source writer

```
hudi_options = {
    'useSparkDataSink': True,
    'hoodie.table.name': <table_name>,
    'hoodie.datasource.write.storage.type': 'COPY_ON_WRITE',
    'hoodie.datasource.write.recordkey.field': 'product_id',
    'hoodie.datasource.write.table.name': <table_name>,
    'hoodie.datasource.write.operation': 'upsert',
    'hoodie.datasource.write.precombine.field': 'updated_at',
    'hoodie.datasource.write.hive_style_partitioning': 'true',
    'hoodie.upsert.shuffle.parallelism': 2,
    'hoodie.insert.shuffle.parallelism': 2,
    'hoodie.datasource.hive_sync.enable': 'true',
    'hoodie.datasource.hive_sync.database': <database_name>,
    'hoodie.datasource.hive_sync.table': <table_name>,
    'hoodie.datasource.hive_sync.use_jdbc': 'false',
    'hoodie.datasource.hive_sync.mode': 'hms'}

glueContext.write_data_frame.from_catalog(
    frame = <df_product_inserts>,
    database = <database_name>,
    table_name = <table_name>,
    additional_options = hudi_options
)
```

write_dynamic_frame_from_jdbc_conf

`write_dynamic_frame_from_jdbc_conf(frame, catalog_connection, connection_options={}, redshift_tmp_dir = "", transformation_ctx = "", catalog_id = None)`

Writes and returns a `DynamicFrame` using the specified JDBC connection information.

- `frame` – The `DynamicFrame` to write.
- `catalog_connection` – A catalog connection to use.
- `connection_options` – Connection options, such as path and database table (optional). For more information, see Connection types and options for ETL in AWS Glue for Spark.
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional).
- `transformation_ctx` – A transformation context to use (optional).
- `catalog_id` — The catalog ID (account ID) of the Data Catalog being accessed. When None, the default account ID of the caller is used.

write_from_jdbc_conf

`write_from_jdbc_conf(frame_or_dfc, catalog_connection, connection_options={}, redshift_tmp_dir = "", transformation_ctx = "", catalog_id = None)`

Writes and returns a `DynamicFrame` or `DynamicFrameCollection` using the specified JDBC connection information.

- `frame_or_dfc` – The `DynamicFrame` or `DynamicFrameCollection` to write.
- `catalog_connection` – A catalog connection to use.
- `connection_options` – Connection options, such as path and database table (optional). For more information, see Connection types and options for ETL in AWS Glue for Spark.
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional).
- `transformation_ctx` – A transformation context to use (optional).
- `catalog_id` — The catalog ID (account ID) of the Data Catalog being accessed. When None, the default account ID of the caller is used.

AWS Glue PySpark transforms reference

AWS Glue provides the following built-in transforms that you can use in PySpark ETL operations. Your data passes from transform to transform in a data structure called a *DynamicFrame*, which is an extension to an Apache Spark SQL `DataFrame`. The `DynamicFrame` contains your data, and you reference its schema to process your data.

Most of these transforms also exist as methods of the `DynamicFrame` class. For more information, see DynamicFrame transforms .

- GlueTransform base class
- ApplyMapping class
- DropFields class
- DropNullFields class
- ErrorsAsDynamicFrame class
- EvaluateDataQuality class
- FillMissingValues class
- Filter class

- FindIncrementalMatches class
- FindMatches class
- FlatMap class
- Join class
- Map class
- MapToCollection class
- mergeDynamicFrame
- Relationalize class
- RenameField class
- ResolveChoice class
- SelectFields class
- SelectFromCollection class
- Simplify_ddb_json class
- Spigot class
- SplitFields class
- SplitRows class
- Unbox class
- UnnestFrame class

GlueTransform base class

The base class that all the `awsglue.transforms` classes inherit from.

The classes all define a `__call__` method. They either override the `GlueTransform` class methods listed in the following sections, or they are called using the class name by default.

Methods

- apply(cls, *args, **kwargs)
- name(cls)
- describeArgs(cls)
- describeReturn(cls)
- describeTransform(cls)

- describeErrors(cls)
- describe(cls)

apply(cls, *args, **kwargs)

Applies the transform by calling the transform class, and returns the result.

- `cls` – The `self` class object.

name(cls)

Returns the name of the derived transform class.

- `cls` – The `self` class object.

describeArgs(cls)

- `cls` – The `self` class object.

Returns a list of dictionaries, each corresponding to a named argument, in the following format:

```
[
  {
    "name": "(name of argument)",
    "type": "(type of argument)",
    "description": "(description of argument)",
    "optional": "(Boolean, True if the argument is optional)",
    "defaultValue": "(Default value string, or None)(String; the default value, or
 None)"
  },
...
]
```

Raises a `NotImplementedError` exception when called in a derived transform where it is not implemented.

describeReturn(cls)

- `cls` – The `self` class object.

Returns a dictionary with information about the return type, in the following format:

```
{
  "type": "(return type)",
  "description": "(description of output)"
}
```

Raises a `NotImplementedError` exception when called in a derived transform where it is not implemented.

describeTransform(cls)

Returns a string describing the transform.

- `cls` – The `self` class object.

Raises a `NotImplementedError` exception when called in a derived transform where it is not implemented.

describeErrors(cls)

- `cls` – The `self` class object.

Returns a list of dictionaries, each describing a possible exception thrown by this transform, in the following format:

```
[
  {
    "type": "(type of error)",
    "description": "(description of error)"
  },
...
]
```

describe(cls)

- `cls` – The `self` class object.

Returns an object with the following format:

```
{
  "transform" : {
    "name" : cls.name( ),
    "args" : cls.describeArgs( ),
    "returns" : cls.describeReturn( ),
    "raises" : cls.describeErrors( ),
    "location" : "internal"
  }
}
```

ApplyMapping class

Applies a mapping in a `DynamicFrame`.

Example

We recommend that you use the `DynamicFrame.apply_mapping()` method to apply a mapping in a `DynamicFrame`. To view a code example, see Example: Use apply_mapping to rename fields and change field types.

Methods

- __call__
- apply
- name
- describeArgs
- describeReturn
- describeTransform
- describeErrors
- Describe

__call__(frame, mappings, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)

Applies a declarative mapping to a specified `DynamicFrame`.

- `frame` – The `DynamicFrame` to apply the mapping to (required).
- `mappings` – A list of mapping tuples (required). Each consists of: (source column, source type, target column, target type).

If the source column has a dot "." in the name, you must place back-ticks "``" around it. For example, to map `this.old.name` (string) to `thisNewName`, you would use the following tuple:

```
("`this.old.name`", "string", "thisNewName", "string")
```

- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string that is associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

Returns only the fields of the `DynamicFrame` that are specified in the "mapping" tuples.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply.

name(cls)

Inherited from `GlueTransform` name.

describeArgs(cls)

Inherited from `GlueTransform` describeArgs.

describeReturn(cls)

Inherited from `GlueTransform` describeReturn.

describeTransform(cls)

Inherited from `GlueTransform` describeTransform.

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

DropFields class

Drops fields within a `DynamicFrame`.

Example

We recommend that you use the `DynamicFrame.drop_fields()` method to drop fields from a `DynamicFrame`. To view a code example, see Example: Use drop_fields to remove fields from a `DynamicFrame`.

Methods

- __call__
- apply
- name
- describeArgs
- describeReturn
- describeTransform
- describeErrors
- Describe

__call__(frame, paths, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)

Drops nodes within a `DynamicFrame`.

- `frame` – The `DynamicFrame` to drop the nodes in (required).
- `paths` – A list of full paths to the nodes to drop (required).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

Returns a new `DynamicFrame` without the specified fields.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply.

name(cls)

Inherited from `GlueTransform` name.

describeArgs(cls)

Inherited from `GlueTransform` describeArgs.

describeReturn(cls)

Inherited from `GlueTransform` describeReturn.

describeTransform(cls)

Inherited from `GlueTransform` describeTransform.

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

DropNullFields class

Drops all null fields in a `DynamicFrame` whose type is `NullType`. These are fields with missing or null values in every record in the `DynamicFrame` dataset.

Example

This example uses `DropNullFields` to create a new `DynamicFrame` where fields of type `NullType` have been dropped. In order to demonstrate `DropNullFields`, we add a new column named `empty_column` with type null to the already-loaded `persons` dataset.

> **Note**
>
> To access the dataset that is used in this example, see Code example: Joining and relationalizing data and follow the instructions in Step 1: Crawl the data in the Amazon S3 bucket.

```
# Example: Use DropNullFields to create a new DynamicFrame without NullType fields

from pyspark.context import SparkContext
from awsglue.context import GlueContext
from pyspark.sql.functions import lit
from pyspark.sql.types import NullType
from awsglue.dynamicframe import DynamicFrame
from awsglue.transforms import DropNullFields

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Create DynamicFrame
persons = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="persons_json"
)
print("Schema for the persons DynamicFrame:")
persons.printSchema()

# Add new column "empty_column" with NullType
persons_with_nulls = persons.toDF().withColumn("empty_column",
 lit(None).cast(NullType()))
persons_with_nulls_dyf = DynamicFrame.fromDF(persons_with_nulls, glueContext,
 "persons_with_nulls")
print("Schema for the persons_with_nulls_dyf DynamicFrame:")
persons_with_nulls_dyf.printSchema()

# Remove the NullType field
persons_no_nulls = DropNullFields.apply(persons_with_nulls_dyf)
print("Schema for the persons_no_nulls DynamicFrame:")
persons_no_nulls.printSchema()
```

Output

```
Schema for the persons DynamicFrame:
root
|-- family_name: string
|-- name: string
|-- links: array
|    |-- element: struct
|    |    |-- note: string
|    |    |-- url: string

Methods

- __call__
- apply
- name
- describeArgs
- describeReturn
- describeTransform
- describeErrors
- Describe

__call__(frame, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)

Drops all null fields in a `DynamicFrame` whose type is `NullType`. These are fields with missing or null values in every record in the `DynamicFrame` dataset.

- `frame` – The `DynamicFrame` to drop null fields in (required).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

Returns a new `DynamicFrame` with no null fields.

apply(cls, *args, **kwargs)

- `cls` – cls

ErrorsAsDynamicFrame class

Returns a `DynamicFrame` that contains nested records for errors that occurred while the source `DynamicFrame` was created.

Example

We recommend that you use the `DynamicFrame.errorsAsDynamicFrame()` method to retrieve and view error records. To view a code example, see Example: Use errorsAsDynamicFrame to view error records.

Methods

- __call__
- apply
- name
- describeArgs
- describeReturn

- describeTransform
- describeErrors
- Describe

__call__(frame)

Returns a `DynamicFrame` that contains nested error records that relate to the source `DynamicFrame`.

- `frame` – The source `DynamicFrame` (required).

apply(cls, *args, **kwargs)

- `cls` – cls

name(cls)

- `cls` – cls

describeArgs(cls)

- `cls` – cls

describeReturn(cls)

- `cls` – cls

describeTransform(cls)

- `cls` – cls

describeErrors(cls)

- `cls` – cls

describe(cls)

- `cls` – cls

EvaluateDataQuality class

Evaluates a data quality ruleset against a `DynamicFrame` and returns a new `DynamicFrame` with results of the evaluation.

Example

The following example code demonstrates how to evaluate data quality for a `DynamicFrame` and then view the data quality results.

```
from awsglue.transforms import *
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsgluedq.transforms import EvaluateDataQuality

#Create Glue context
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Define DynamicFrame
legislatorsAreas = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="areas_json")

# Create data quality ruleset
ruleset = """Rules = [ColumnExists "id", IsComplete "id"]"""

# Evaluate data quality
dqResults = EvaluateDataQuality.apply(
    frame=legislatorsAreas,
    ruleset=ruleset,
    publishing_options={
        "dataQualityEvaluationContext": "legislatorsAreas",
        "enableDataQualityCloudWatchMetrics": True,
        "enableDataQualityResultsPublishing": True,
        "resultsS3Prefix": "amzn-s3-demo-bucket1",
    },
)
```

```
# Inspect data quality results
dqResults.printSchema()
dqResults.toDF().show()
```

Output

```
root
|-- Rule: string
|-- Outcome: string
|-- FailureReason: string
|-- EvaluatedMetrics: map
|    |-- keyType: string
|    |-- valueType: double

+----------------------+-------+-------------+--------------------------------------+
|Rule                  |Outcome|FailureReason|EvaluatedMetrics                      |
+----------------------+-------+-------------+--------------------------------------+
|ColumnExists "id"     |Passed |null         |{}                                    |
|IsComplete "id"       |Passed |null         |{Column.first_name.Completeness -> 1.0}|
+----------------------+-------+-------------+--------------------------------------+
```

Methods

- __call__
- apply
- name
- describeArgs
- describeReturn
- describeTransform
- describeErrors
- describe

__call__(frame, ruleset, publishing_options = {})

- `frame` – The `DynamicFrame` that you want evaluate the data quality of.
- `ruleset` – A Data Quality Definition Language (DQDL) ruleset in string format. To learn more about DQDL, see the Data Quality Definition Language (DQDL) reference guide.

- `publishing_options` – A dictionary that specifies the following options for publishing evaluation results and metrics:
  - `dataQualityEvaluationContext` – A string that specifies the namespace under which AWS Glue should publish Amazon CloudWatch metrics and the data quality results. The aggregated metrics appear in CloudWatch, while the full results appear in the AWS Glue Studio interface.
    - Required: No
    - Default value: `default_context`
  - `enableDataQualityCloudWatchMetrics` – Specifies whether the results of the data quality evaluation should be published to CloudWatch. You specify a namespace for the metrics using the `dataQualityEvaluationContext` option.
    - Required: No
    - Default value: False
  - `enableDataQualityResultsPublishing` – Specifies whether the data quality results should be visible on the **Data Quality** tab in the AWS Glue Studio interface.
    - Required: No
    - Default value: True
  - `resultsS3Prefix` – Specifies the Amazon S3 location where AWS Glue can write the data quality evaluation results.
    - Required: No
    - Default value: "" (empty string)

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply.

name(cls)

Inherited from `GlueTransform` name.

describeArgs(cls)

Inherited from `GlueTransform` describeArgs.

describeReturn(cls)

Inherited from `GlueTransform` describeReturn.

describeTransform(cls)

Inherited from `GlueTransform` describeTransform.

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

FillMissingValues class

The `FillMissingValues` class locates null values and empty strings in a specified `DynamicFrame` and uses machine learning methods, such as linear regression and random forest, to predict the missing values. The ETL job uses the values in the input dataset to train the machine learning model, which then predicts what the missing values should be.

> **Tip**
>
> If you use incremental data sets, then each incremental set is used as the training data for the machine learning model, so the results might not be as accurate.

To import:

```
from awsglueml.transforms import FillMissingValues
```

Methods

- Apply

apply(frame, missing_values_column, output_column ="", transformation_ctx ="", info ="", stageThreshold = 0, totalThreshold = 0)

Fills a dynamic frame's missing values in a specified column and returns a new frame with estimates in a new column. For rows without missing values, the specified column's value is duplicated to the new column.

- `frame` – The `DynamicFrame` in which to fill missing values. Required.

- `missing_values_column` – The column containing missing values (`null` values and empty strings). Required.
- `output_column` – The name of the new column that will contain estimated values for all rows whose value was missing. Optional; the default is the name of `missing_values_column` suffixed by `"_filled"`.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional; the default is zero).
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional; the default is zero).

Returns a new `DynamicFrame` with one additional column that contains estimations for rows with missing values and the present value for other rows.

Filter class

Builds a new `DynamicFrame` that contains records from the input `DynamicFrame` that satisfy a specified predicate function.

Example

We recommend that you use the `DynamicFrame.filter()` method to filter records in a `DynamicFrame`. To view a code example, see Example: Use filter to get a filtered selection of fields.

Methods

- __call__
- apply
- name
- describeArgs
- describeReturn
- describeTransform
- describeErrors
- describe

__call__(frame, f, transformation_ctx="", info="", stageThreshold=0, totalThreshold=0))

Returns a new `DynamicFrame` that is built by selecting records from the input `DynamicFrame` that satisfy a specified predicate function.

- `frame` – The source `DynamicFrame` to apply the specified filter function to (required).
- `f` – The predicate function to apply to each `DynamicRecord` in the `DynamicFrame`. The function must take a `DynamicRecord` as its argument and return True if the `DynamicRecord` meets the filter requirements, or False if it doesn't (required).

  A `DynamicRecord` represents a logical record in a `DynamicFrame`. It's similar to a row in a Spark `DataFrame`, except that it is self-describing and can be used for data that doesn't conform to a fixed schema.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string that is associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply.

name(cls)

Inherited from `GlueTransform` name.

describeArgs(cls)

Inherited from `GlueTransform` describeArgs.

describeReturn(cls)

Inherited from `GlueTransform` describeReturn.

describeTransform(cls)

Inherited from `GlueTransform` describeTransform.

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

FindIncrementalMatches class

Identifies matching records in the existing and incremental `DynamicFrame` and creates a new `DynamicFrame` with a unique identifier assigned to each group of matching records.

To import:

```
from awsglueml.transforms import FindIncrementalMatches
```

Methods

- Apply

apply(existingFrame, incrementalFrame, transformId, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0, enforcedMatches = none, computeMatchConfidenceScores = 0)

Identifies matching records in the input `DynamicFrame` and creates a new `DynamicFrame` with a unique identifier assigned to each group of matching records.

- `existingFrame` – The existing and pre-matched `DynamicFrame` to apply the FindIncrementalMatches transform. Required.
- `incrementalFrame` – The incremental `DynamicFrame` to apply the FindIncrementalMatches transform to match against the `existingFrame`. Required.
- `transformId` – The unique ID associated with the FindIncrementalMatches transform to apply on records in the `DynamicFrames`. Required.
- `transformation_ctx` – A unique string that is used to identify stats/state information. Optional.
- `info` – A string to be associated with errors in the transformation. Optional.
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out. Optional. The default is zero.

- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out. Optional. The default is zero.
- `enforcedMatches` – The `DynamicFrame` used to enforce matches. Optional. The default is None.
- `computeMatchConfidenceScores` – A Boolean value indicating whether to compute a confidence score for each group of matching records. Optional. The default is false.

Returns a new `DynamicFrame` with a unique identifier assigned to each group of matching records.

FindMatches class

Identifies matching records in the input `DynamicFrame` and creates a new `DynamicFrame` with a unique identifier assigned to each group of matching records.

To import:

```
from awsglueml.transforms import FindMatches
```

Methods

- Apply

apply(frame, transformId, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0, enforcedMatches = none, computeMatchConfidenceScores = 0)

Identifies matching records in the input `DynamicFrame` and creates a new `DynamicFrame` with a unique identifier assigned to each group of matching records.

- `frame` – The `DynamicFrame` to apply the FindMatches transform. Required.
- `transformId` – The unique ID associated with the FindMatches transform to apply on records in the `DynamicFrame`. Required.
- `transformation_ctx` – A unique string that is used to identify stats/state information. Optional.
- `info` – A string to be associated with errors in the transformation. Optional.
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out. Optional. The default is zero.

- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out. Optional. The default is zero.
- `enforcedMatches` – The `DynamicFrame` used to enforce matches. Optional. The default is None.
- `computeMatchConfidenceScores` – A Boolean value indicating whether to compute a confidence score for each group of matching records. Optional. The default is false.

Returns a new `DynamicFrame` with a unique identifier assigned to each group of matching records.

FlatMap class

Applies a transform to each `DynamicFrame` in a collection. Results are not flattened into a single `DynamicFrame`, but preserved as a collection.

Examples for FlatMap

The following example snippet demonstrates how to use the `ResolveChoice` transform on a collection of dynamic frames when applied to a `FlatMap`. The data used for input is in the JSON located at the placeholder Amazon S3 address `s3://bucket/path-for-data/sample.json` and contains the following data.

Example JSON data

```
[{
    "firstname": "Arnav",
    "lastname": "Desai",
    "address": {
        "street": "6 Anyroad Avenue",
        "city": "London",
        "state": "England",
        "country": "UK"
    },
    "phone": 17235550101,
    "affiliations": [
        "General Anonymous Example Products",
        "Example Independent Research",
        "Government Department of Examples"
    ]
},
{
    "firstname": "Mary",
```

```
    "lastname": "Major",
    "address": {
        "street": "7821 Spot Place",
        "city": "Centerville",
        "state": "OK",
        "country": "US"
    },
    "phone": 19185550023,
    "affiliations": [
        "Example Dot Com",
        "Example Independent Research",
        "Example.io"
    ]
},
{
    "firstname": "Paulo",
    "lastname": "Santos",
    "address": {
        "street": "123 Maple Street",
        "city": "London",
        "state": "Ontario",
        "country": "CA"
    },
    "phone": 12175550181,
    "affiliations": [
        "General Anonymous Example Products",
        "Example Dot Com"
    ]
}]
```

Example Apply ResolveChoice to a DynamicFrameCollection and show output.

```
#Read DynamicFrame
datasource = glueContext.create_dynamic_frame_from_options("s3", connection_options =
 {"paths":["s3://bucket/path/to/file/mysamplejson.json"]}, format="json")
datasource.printSchema()
datasource.show()

## Split to create a DynamicFrameCollection
split_frame=datasource.split_fields(["firstname","lastname","address"],"personal_info","busines
split_frame.keys()
print("---")
```

```
## Use FlatMap to run ResolveChoice
kwargs = {"choice": "cast:string"}
flat = FlatMap.apply(split_frame, ResolveChoice, frame_name="frame",
 transformation_ctx='tcx', **kwargs)
flat.keys()

##Select one of the DynamicFrames
personal_info = flat.select("personal_info")
personal_info.printSchema()
personal_info.show()
print("---")

business_info = flat.select("business_info")
business_info.printSchema()
business_info.show()
```

> **Important**
>
> When calling `FlatMap.apply`, the `frame_name` parameter **must** be `"frame"`. No other value is currently accepted.

Example output

```
root
|-- firstname: string
|-- lastname: string
|-- address: struct
|    |-- street: string
|    |-- city: string
|    |-- state: string
|    |-- country: string
|-- phone: long
|-- affiliations: array
|    |-- element: string
---

}
```

Methods

- __call__
- Apply
- Name
- describeArgs

- describeReturn
- describeTransform
- describeErrors
- Describe

__call__(dfc, BaseTransform, frame_name, transformation_ctx = "", **base_kwargs)

Applies a transform to each `DynamicFrame` in a collection and flattens the results.

- `dfc` – The `DynamicFrameCollection` over which to flatmap (required).
- `BaseTransform` – A transform derived from `GlueTransform` to apply to each member of the collection (required).
- `frame_name` – The argument name to pass the elements of the collection to (required).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `base_kwargs` – Arguments to pass to the base transform (required).

Returns a new `DynamicFrameCollection` created by applying the transform to each `DynamicFrame` in the source `DynamicFrameCollection`.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply.

name(cls)

Inherited from `GlueTransform` name.

describeArgs(cls)

Inherited from `GlueTransform` describeArgs.

describeReturn(cls)

Inherited from `GlueTransform` describeReturn.

describeTransform(cls)

Inherited from `GlueTransform` describeTransform.

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

Join class

Performs an equality join on two `DynamicFrames`.

Example

We recommend that you use the `DynamicFrame.join()` method to join `DynamicFrames`. To view a code example, see Example: Use join to combine `DynamicFrames`.

Methods

- __call__
- apply
- name
- describeArgs
- describeReturn
- describeTransform
- describeErrors
- Describe

__call__(frame1, frame2, keys1, keys2, transformation_ctx = "")

Performs an equality join on two `DynamicFrames`.

- `frame1` – The first `DynamicFrame` to join (required).
- `frame2` – The second `DynamicFrame` to join (required).
- `keys1` – The keys to join on for the first frame (required).
- `keys2` – The keys to join on for the second frame (required).
- `transformation_ctx` – A unique string that is used to identify state information (optional).

Returns a new `DynamicFrame` that is created by joining the two `DynamicFrames`.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply.

name(cls)

Inherited from `GlueTransform` name.

describeArgs(cls)

Inherited from `GlueTransform` describeArgs.

describeReturn(cls)

Inherited from `GlueTransform` describeReturn.

describeTransform(cls)

Inherited from `GlueTransform` describeTransform.

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

Map class

Builds a new `DynamicFrame` by applying a function to all records in the input `DynamicFrame`.

Example

We recommend that you use the `DynamicFrame.map()` method to apply a function to all records in a `DynamicFrame`. To view a code example, see Example: Use map to apply a function to every record in a `DynamicFrame`.

Methods

- __call__
- apply
- name

- describeArgs
- describeReturn
- describeTransform
- describeErrors
- Describe

__call__(frame, f, transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)

Returns a new `DynamicFrame` that results from applying the specified function to all `DynamicRecords` in the original `DynamicFrame`.

- `frame` – The original `DynamicFrame` to apply the mapping function to (required).
- `f` – The function to apply to all `DynamicRecords` in the `DynamicFrame`. The function must take a `DynamicRecord` as an argument and return a new `DynamicRecord` that is produced by the mapping (required).

  A `DynamicRecord` represents a logical record in a `DynamicFrame`. It's similar to a row in an Apache Spark `DataFrame`, except that it is self-describing and can be used for data that doesn't conform to a fixed schema.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

Returns a new `DynamicFrame` that results from applying the specified function to all `DynamicRecords` in the original `DynamicFrame`.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply.

name(cls)

Inherited from `GlueTransform` name.

describeArgs(cls)

Inherited from `GlueTransform` describeArgs.

describeReturn(cls)

Inherited from `GlueTransform` describeReturn.

describeTransform(cls)

Inherited from `GlueTransform` describeTransform.

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

MapToCollection class

Applies a transform to each `DynamicFrame` in the specified `DynamicFrameCollection`.

Methods

- __call__
- Apply
- Name
- describeArgs
- describeReturn
- describeTransform
- describeErrors
- Describe

__call__(dfc, BaseTransform, frame_name, transformation_ctx = "", **base_kwargs)

Applies a transform function to each `DynamicFrame` in the specified `DynamicFrameCollection`.

- `dfc` – The `DynamicFrameCollection` over which to apply the transform function (required).
- `callable` – A callable transform function to apply to each member of the collection (required).

- `transformation_ctx` – A unique string that is used to identify state information (optional).

Returns a new `DynamicFrameCollection` created by applying the transform to each `DynamicFrame` in the source `DynamicFrameCollection`.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply

name(cls)

Inherited from `GlueTransform` name.

describeArgs(cls)

Inherited from `GlueTransform` describeArgs.

describeReturn(cls)

Inherited from `GlueTransform` describeReturn.

describeTransform(cls)

Inherited from `GlueTransform` describeTransform.

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

Relationalize class

Flattens a nested schema in a `DynamicFrame` and pivots out array columns from the flattened frame.

Example

We recommend that you use the `DynamicFrame.relationalize()` method to relationalize a `DynamicFrame`. To view a code example, see Example: Use relationalize to flatten a nested schema in a `DynamicFrame`.

Methods

- __call__
- apply
- name
- describeArgs
- describeReturn
- describeTransform
- describeErrors
- describe

__call__(frame, staging_path=None, name='roottable', options=None, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)

Relationalizes a `DynamicFrame` and produces a list of frames that are generated by unnesting nested columns and pivoting array columns. You can join a pivoted array column to the root table by using the join key that is generated in the unnest phase.

- `frame` – The `DynamicFrame` to relationalize (required).
- `staging_path` – The path where the method can store partitions of pivoted tables in CSV format (optional). Pivoted tables are read back from this path.
- `name` – The name of the root table (optional).
- `options` – A dictionary of optional parameters. Currently unused.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply.

name(cls)

Inherited from `GlueTransform` name.

describeArgs(cls)

Inherited from `GlueTransform` describeArgs.

describeReturn(cls)

Inherited from `GlueTransform` describeReturn.

describeTransform(cls)

Inherited from `GlueTransform` describeTransform.

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

RenameField class

Renames a node within a `DynamicFrame`.

Example

We recommend that you use the `DynamicFrame.rename_field()` method to rename a field in a `DynamicFrame`. To view a code example, see Example: Use rename_field to rename fields in a `DynamicFrame`.

Methods

- __call__
- apply
- name
- describeArgs
- describeReturn
- describeTransform
- describeErrors

- describe

__call__(frame, old_name, new_name, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)

Renames a node within a `DynamicFrame`.

- `frame` – The `DynamicFrame` in which to rename a node (required).
- `old_name` – The full path to the node to rename (required).

  If the old name has dots in it, RenameField will not work unless you place backticks around it (``). For example, to replace `this.old.name` with `thisNewName`, you would call RenameField as follows:

  ```
  newDyF = RenameField(oldDyF, "`this.old.name`", "thisNewName")
  ```

- `new_name` – The new name, including full path (required).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply.

name(cls)

Inherited from `GlueTransform` name.

describeArgs(cls)

Inherited from `GlueTransform` describeArgs.

describeReturn(cls)

Inherited from `GlueTransform` describeReturn.

describeTransform(cls)

Inherited from `GlueTransform` describeTransform.

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

ResolveChoice class

Resolves a choice type within a `DynamicFrame`.

Example

We recommend that you use the `DynamicFrame.resolveChoice()` method to handle fields that contain multiple types in a `DynamicFrame`. To view a code example, see Example: Use resolveChoice to handle a column that contains multiple types.

Methods

- __call__
- apply
- name
- describeArgs
- describeReturn
- describeTransform
- describeErrors
- describe

__call__(frame, specs = none, choice = "", transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)

Provides information for resolving ambiguous types within a `DynamicFrame`. It returns the resulting `DynamicFrame`.

- `frame` – The `DynamicFrame` in which to resolve the choice type (required).
- `specs` – A list of specific ambiguities to resolve, each in the form of a tuple: `(path, action)`. The `path` value identifies a specific ambiguous element, and the `action` value identifies the corresponding resolution.

  You can only use one of the `spec` and `choice` parameters. If the `spec` parameter is not `None`, then the `choice` parameter must be an empty string. Conversely, if the `choice` is not an empty string, then the `spec` parameter must be `None`. If neither parameter is provided, AWS Glue tries to parse the schema and use it to resolve ambiguities.

  You can specify one of the following resolution strategies in the `action` portion of a `specs` tuple:

  - `cast` – Allows you to specify a type to cast to (for example, `cast:int`).
  - `make_cols` – Resolves a potential ambiguity by flattening the data. For example, if `columnA` could be an `int` or a `string`, the resolution is to produce two columns named `columnA_int` and `columnA_string` in the resulting `DynamicFrame`.
  - `make_struct` – Resolves a potential ambiguity by using a struct to represent the data. For example, if data in a column could be an `int` or a `string`, using the `make_struct` action produces a column of structures in the resulting `DynamicFrame` with each containing both an `int` and a `string`.
  - `project` – Resolves a potential ambiguity by retaining only values of a specified type in the resulting `DynamicFrame`. For example, if data in a `ChoiceType` column could be an `int` or a `string`, specifying a `project:string` action drops values from the resulting `DynamicFrame` that are not type `string`.

  If the `path` identifies an array, place empty square brackets after the name of the array to avoid ambiguity. For example, suppose you are working with data structured as follows:

  ```
  "myList": [
    { "price": 100.00 },
    { "price": "$100.00" }
  ]
  ```

  You can select the numeric rather than the string version of the price by setting the `path` to `"myList[].price"`, and setting the `action` to `"cast:double"`.
- `choice` – The default resolution action if the `specs` parameter is `None`. If the `specs` parameter is not `None`, then this must not be set to anything but an empty string.

In addition to the `specs` actions previously described, this argument also supports the following action:

- `MATCH_CATALOG` – Attempts to cast each `ChoiceType` to the corresponding type in the specified Data Catalog table.

- `database` – The AWS Glue Data Catalog database to use with the `MATCH_CATALOG` choice (required for `MATCH_CATALOG`).
- `table_name` – The AWS Glue Data Catalog table name to use with the `MATCH_CATALOG` action (required for `MATCH_CATALOG`).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply.

name(cls)

Inherited from `GlueTransform` name.

describeArgs(cls)

Inherited from `GlueTransform` describeArgs.

describeReturn(cls)

Inherited from `GlueTransform` describeReturn.

describeTransform(cls)

Inherited from `GlueTransform` describeTransform.

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

SelectFields class

The `SelectFields` class creates a new `DynamicFrame` from an existing `DynamicFrame`, and keeps only the fields that you specify. `SelectFields` provides similar functionality to a SQL `SELECT` statement.

Example

We recommend that you use the `DynamicFrame.select_fields()` method to select fields from a `DynamicFrame`. To view a code example, see Example: Use select_fields to create a new `DynamicFrame` with chosen fields.

Methods

- __call__
- apply
- name
- describeArgs
- describeReturn
- describeTransform
- describeErrors
- Describe

__call__(frame, paths, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)

Gets fields (nodes) in a `DynamicFrame`.

- `frame` – The `DynamicFrame` to select fields in (required).
- `paths` – A list of full paths to the fields to select (required).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string that is associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.

- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

Returns a new `DynamicFrame` that contains only the specified fields.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply.

name(cls)

Inherited from `GlueTransform` name.

describeArgs(cls)

Inherited from `GlueTransform` describeArgs.

describeReturn(cls)

Inherited from `GlueTransform` describeReturn.

describeTransform(cls)

Inherited from `GlueTransform` describeTransform.

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

SelectFromCollection class

Selects one `DynamicFrame` in a `DynamicFrameCollection`.

Example

This example uses `SelectFromCollection` to select a `DynamicFrame` from a `DynamicFrameCollection`.

Example dataset

The example selects two `DynamicFrames` from a `DynamicFrameCollection` called `split_rows_collection`. The following is the list of keys in `split_rows_collection`.

```
dict_keys(['high', 'low'])
```

Example code

```
# Example: Use SelectFromCollection to select
# DynamicFrames from a DynamicFrameCollection

from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.transforms import SelectFromCollection

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Select frames and inspect entries
frame_low = SelectFromCollection.apply(dfc=split_rows_collection, key="low")
frame_low.toDF().show()

frame_high = SelectFromCollection.apply(dfc=split_rows_collection, key="high")
frame_high.toDF().show()
```

Output

```

```

Methods

- __call__
- apply
- name

- describeArgs
- describeReturn
- describeTransform
- describeErrors
- describe

__call__(dfc, key, transformation_ctx = "")

Gets one `DynamicFrame` from a `DynamicFrameCollection`.

- `dfc` – The `DynamicFrameCollection` that the `DynamicFrame` should be selected from (required).
- `key` – The key of the `DynamicFrame` to select (required).
- `transformation_ctx` – A unique string that is used to identify state information (optional).

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply.

name(cls)

Inherited from `GlueTransform` name.

describeArgs(cls)

Inherited from `GlueTransform` describeArgs.

describeReturn(cls)

describe(cls)

Inherited from `GlueTransform` describe.

Simplify_ddb_json class

Simplifies nested columns in a `DynamicFrame` that are specifically in the DynamoDB JSON structure, and returns a new simplified `DynamicFrame`.

Example

We recommend that you use the `DynamicFrame.simplify_ddb_json()` method to simplify nested columns in a `DynamicFrame` that are specifically in the DynamoDB JSON structure. To view a code example, see Example: Use simplify_ddb_json to invoke a DynamoDB JSON simplify.

Spigot class

Writes sample records to a specified destination to help you verify the transformations performed by your AWS Glue job.

Example

We recommend that you use the `DynamicFrame.spigot()` method to write a subset of records from a `DynamicFrame` to a specified destination. To view a code example, see Example: Use spigot to write sample fields from a `DynamicFrame` to Amazon S3.

Methods

- __call__
- apply
- name
- describeArgs
- describeReturn
- describeTransform
- describeErrors
- describe

__call__(frame, path, options, transformation_ctx = "")

Writes sample records to a specified destination during a transformation.

- `frame` – The `DynamicFrame` to spigot (required).
- `path` – The path of the destination to write to (required).
- `options` – JSON key-value pairs that specify options (optional). The `"topk"` option specifies that the first *k* records should be written. The `"prob"` option specifies the probability (as a decimal) of picking any given record. You use this in selecting records to write.
- `transformation_ctx` – A unique string that is used to identify state information (optional).

SplitFields class

Splits a `DynamicFrame` into two new ones, by specified fields.

Example

We recommend that you use the `DynamicFrame.split_fields()` method to split fields in a `DynamicFrame`. To view a code example, see Example: Use split_fields to split selected fields into a separate `DynamicFrame`.

Methods

- __call__
- apply
- name
- describeArgs
- describeReturn
- describeTransform
- describeErrors
- describe

__call__(frame, paths, name1 = none, name2 = none, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)

Splits one or more fields in a `DynamicFrame` off into a new `DynamicFrame`, and creates another new `DynamicFrame` that contains the fields that remain.

- `frame` – The source `DynamicFrame` to split into two new ones (required).
- `paths` – A list of full paths to the fields to be split (required).
- `name1` – The name to assign to the `DynamicFrame` that will contain the fields to be split off (optional). If no name is supplied, the name of the source frame is used with "1" appended.
- `name2` – The name to assign to the `DynamicFrame` that will contain the fields that remain after the specified fields are split off (optional). If no name is provided, the name of the source frame is used with "2" appended.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.

- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply.

name(cls)

Inherited from `GlueTransform` name.

describeArgs(cls)

Inherited from `GlueTransform` describeArgs.

describeReturn(cls)

SplitRows class

Creates a `DynamicFrameCollection` that contains two `DynamicFrames`. One `DynamicFrame` contains only the specified rows to be split, and the other contains all remaining rows.

Example

We recommend that you use the `DynamicFrame.split_rows()` method to split rows in a `DynamicFrame`. To view a code example, see Example: Use split_rows to split rows in a `DynamicFrame`.

Methods

- __call__

- apply
- name
- describeArgs
- describeReturn
- describeTransform
- describeErrors
- describe

__call__(frame, comparison_dict, name1="frame1", name2="frame2", transformation_ctx = "", info = none, stageThreshold = 0, totalThreshold = 0)

Splits one or more rows in a `DynamicFrame` off into a new `DynamicFrame`.

- `frame` – The source `DynamicFrame` to split into two new ones (required).
- `comparison_dict` – A dictionary where the key is the full path to a column, and the value is another dictionary for mapping comparators to values that the column values are compared to. For example, `{"age": {">": 10, "<": 20}}` splits rows where the value of "age" is between 10 and 20, exclusive, from rows where "age" is outside that range (required).
- `name1` – The name to assign to the `DynamicFrame` that will contain the rows to be split off (optional).
- `name2` – The name to assign to the `DynamicFrame` that will contain the rows that remain after the specified rows are split off (optional).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply.

name(cls)

Inherited from `GlueTransform` name.

describeArgs(cls)

Inherited from `GlueTransform` describeArgs.

describeReturn(cls)

Inherited from `GlueTransform` describeReturn.

describeTransform(cls)

Inherited from `GlueTransform` describeTransform.

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

Unbox class

Unboxes (reformats) a string field in a `DynamicFrame`.

Example

We recommend that you use the `DynamicFrame.unbox()` method to unbox a field in a `DynamicFrame`. To view a code example, see Example: Use unbox to unbox a string field into a struct.

Methods

- __call__
- apply
- name
- describeArgs
- describeReturn

- describeTransform
- describeErrors
- describe

__call__(frame, path, format, transformation_ctx = "", info="", stageThreshold=0, totalThreshold=0, **options)

Unboxes a string field in a `DynamicFrame`.

- `frame` – The `DynamicFrame` in which to unbox a field. (required).
- `path` – The full path to the `StringNode` to unbox (required).
- `format` – A format specification (optional). This is used for an Amazon S3 or AWS Glue connection that supports multiple formats. For the formats that are supported, see Data format options for inputs and outputs in AWS Glue for Spark.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.
- `separator` – A separator token (optional).
- `escaper` – An escape token (optional).
- `skipFirst` – `True` if the first line of data should be skipped, or `False` if it should not be skipped (optional).
- withSchema – A string that contains a schema for the data to be unboxed (optional). This should always be created using `StructType.json`.
- `withHeader` – `True` if the data being unpacked includes a header, or `False` if not (optional).

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply.

name(cls)

Inherited from `GlueTransform` name.

describeArgs(cls)

Inherited from `GlueTransform` describeArgs.

describeReturn(cls)

Inherited from `GlueTransform` describeReturn.

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

UnnestFrame class

Unnests a `DynamicFrame`, flattens nested objects to top-level elements, and generates join keys for array objects.

Example

We recommend that you use the `DynamicFrame.unnest()` method to flatten nested structures in a `DynamicFrame`. To view a code example, see Example: Use unnest to turn nested fields into top-level fields.

Methods

- __call__
- apply
- name
- describeArgs
- describeReturn
- describeTransform

- describeErrors
- describe

__call__(frame, transformation_ctx = "", info="", stageThreshold=0, totalThreshold=0)

Unnests a `DynamicFrame`, flattens nested objects to top-level elements, and generates join keys for array objects.

- `frame` – The `DynamicFrame` to unnest (required).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply.

name(cls)

Inherited from `GlueTransform` name.

describeArgs(cls)

Inherited from `GlueTransform` describeArgs.

describeReturn(cls)

Inherited from `GlueTransform` describeReturn.

describeTransform(cls)

Inherited from `GlueTransform` describeTransform.

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

FlagDuplicatesInColumn class

The `FlagDuplicatesInColumn` transform returns a new column with a specified value in each row that indicates whether the value in the row's source column matches a value in an earlier row of the source column. When matches are found, they are flagged as duplicates. The initial occurrence is not flagged, because it doesn't match an earlier row.

Example

```
from pyspark.context import SparkContext
from pyspark.sql import SparkSession
from awsgluedi.transforms import *

sc = SparkContext()
spark = SparkSession(sc)

datasource1 = spark.read.json("s3://${BUCKET}/json/zips/raw/data")

try:
    df_output = column.FlagDuplicatesInColumn.apply(
        data_frame=datasource1,
        spark_context=sc,
        source_column="city",
        target_column="flag_col",
        true_string="True",
        false_string="False"
    )
except:
    print("Unexpected Error happened ")
    raise
```

Output

The `FlagDuplicatesInColumn` transformation will add a new column `flag_col` to the `df_output` DataFrame. This column will contain a string value indicating whether the corresponding row has a duplicate value in the `city` column or not. If a row has a duplicate `city` value, the `flag_col` will contain the `true_string` value "True". If a row has a unique `city` value, the `flag_col` will contain the `false_string` value "False".

The resulting `df_output` DataFrame will contain all columns from the original `datasource1` DataFrame, plus the additional `flag_col` column indicating duplicate `city` values.

Methods

- __call__
- apply
- name
- describeArgs
- describeReturn
- describeTransform
- describeErrors
- describe

__call__(spark_context, data_frame, source_column, target_column, true_string=DEFAULT_TRUE_STRING, false_string=DEFAULT_FALSE_STRING)

The `FlagDuplicatesInColumn` transform returns a new column with a specified value in each row that indicates whether the value in the row's source column matches a value in an earlier row of the source column. When matches are found, they are flagged as duplicates. The initial occurrence is not flagged, because it doesn't match an earlier row.

- `source_column` – Name of the source column.
- `target_column` – Name of the target column.
- `true_string` – String to be inserted in the target column when a source column value duplicates an earlier value in that column.
- `false_string` – String to be inserted in the target column when a source column value is distinct from earlier values in that column.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply.

name(cls)

Inherited from `GlueTransform` name.

describeArgs(cls)

Inherited from `GlueTransform` describeArgs.

describeReturn(cls)

Inherited from `GlueTransform` describeReturn.

describeTransform(cls)

Inherited from `GlueTransform` describeTransform.

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

FormatPhoneNumber class

The `FormatPhoneNumber` transform returns a column in which a phone number string is converted into a formatted value.

Example

```
from pyspark.context import SparkContext
from pyspark.sql import SparkSession
from awsgluedi.transforms import *

sc = SparkContext()
spark = SparkSession(sc)

input_df = spark.createDataFrame(
    [
        ("408-341-5669",),
        ("4083415669",)
    ],
    ["phone"],
)
```

```
try:
    df_output = column_formatting.FormatPhoneNumber.apply(
        data_frame=input_df,
        spark_context=sc,
        source_column="phone",
        default_region="US"
    )
    df_output.show()
except:
    print("Unexpected Error happened ")
    raise
```

Output

The output will be:

```
```
+---------------+
| phone|
+---------------+
|(408) 341-5669|
|(408) 341-5669|
+---------------+
```
```

The `FormatPhoneNumber` transformation takes the `source_column` as `"phone"` and the `default_region` as `"US"`.

The transformation successfully formats both phone numbers, regardless of their initial format, to the standard US format `(408) 341-5669`.

Methods

- __call__
- apply
- name
- describeArgs
- describeReturn
- describeTransform

- describeErrors
- describe

__call__(spark_context, data_frame, source_column, phone_number_format=None, default_region=None, default_region_column=None)

The `FormatPhoneNumber` transform returns a column in which a phone number string is converted into a formatted value.

- `source_column` – The name of an existing column.
- `phone_number_format` – The format to convert the phone number to. If no format is specified, the default is `E.164`, an internationally-recognized standard phone number format. Valid values include the following:
  - E164 (omit the period after E)
- `default_region` – A valid region code consisting of two or three uppercase letters that specifies the region for the phone number when no country code is present in the number itself. At most, one of `defaultRegion` or `defaultRegionColumn` can be provided.
- `default_region_column` – The name of a column of the advanced data type `Country`. The region code from the specified column is used to determine the country code for the phone number when no country code is present in the number itself. At most, one of `defaultRegion` or `defaultRegionColumn` can be provided.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply.

name(cls)

Inherited from `GlueTransform` name.

describeArgs(cls)

Inherited from `GlueTransform` describeArgs.

describeReturn(cls)

Inherited from `GlueTransform` describeReturn.

describeTransform(cls)

Inherited from `GlueTransform` describeTransform.

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

FormatCase class

The `FormatCase` transform changes each string in a column to the specified case type.

Example

```
from pyspark.context import SparkContext
from pyspark.sql import SparkSession
from awsgluedi.transforms import *

sc = SparkContext()
spark = SparkSession(sc)

datasource1 = spark.read.json("s3://${BUCKET}/json/zips/raw/data")

try:
    df_output = data_cleaning.FormatCase.apply(
        data_frame=datasource1,
        spark_context=sc,
        source_column="city",
        case_type="LOWER"
    )
except:
    print("Unexpected Error happened ")
    raise
```

Output

The `FormatCase` transformation will convert the values in the `city` column to lowercase based on the `case_type="LOWER"` parameter. The resulting `df_output` DataFrame will contain

all columns from the original `datasource1` DataFrame, but with the `city` column values in lowercase.

Methods

- __call__
- apply
- name
- describeArgs
- describeReturn
- describeTransform
- describeErrors
- describe

__call__(spark_context, data_frame, source_column, case_type)

The `FormatCase` transform changes each string in a column to the specified case type.

- `source_column` – The name of an existing column.
- `case_type` – Supported case types are `CAPITAL`,`LOWER`, `UPPER`, `SENTENCE`.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply.

name(cls)

Inherited from `GlueTransform` name.

describeArgs(cls)

Inherited from `GlueTransform` describeArgs.

describeReturn(cls)

Inherited from `GlueTransform` describeReturn.

describeTransform(cls)

Inherited from `GlueTransform` describeTransform.

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

FillWithMode class

The `FillWithMode` transform formats a column according to the phone numberformat you specify. You can also specify tie-breaker logic, where some of the values are identical. For example, consider the following values: `1 2 2 3 3 4`

A modeType of `MINIMUM` causes `FillWithMode` to return 2 as the mode value. If modeType is `MAXIMUM`, the mode is 3. For `AVERAGE`, the mode is 2.5.

Example

```
from awsglue.context import *
from pyspark.sql import SparkSession
from awsgluedi.transforms import *

sc = SparkContext()
spark = SparkSession(sc)

input_df = spark.createDataFrame(
    [
        (105.111, 13.12),
        (1055.123, 13.12),
        (None, 13.12),
        (13.12, 13.12),
        (None, 13.12),
    ],
    ["source_column_1", "source_column_2"],
)

try:
    df_output = data_quality.FillWithMode.apply(
        data_frame=input_df,
        spark_context=sc,
        source_column="source_column_1",
        mode_type="MAXIMUM"
    )
```

```
    df_output.show()
except:
    print("Unexpected Error happened ")
    raise
```

Output

The output of the given code will be:

```
```
+---------------+---------------+
|source_column_1|source_column_2|
+---------------+---------------+
105.111	13.12
1055.123	13.12
1055.123	13.12
13.12	13.12
1055.123	13.12
+---------------+---------------+
```
```

The `FillWithMode` transformation from the `awsglue.data_quality` module is applied to the `input_df` DataFrame. It replaces the `null` values in the `source_column_1` column with the maximum value (`mode_type="MAXIMUM"`) from the non-null values in that column.

In this case, the maximum value in the `source_column_1` column is `1055.123`. Therefore, the `null` values in `source_column_1` are replaced by `1055.123` in the output DataFrame `df_output`.

Methods

- __call__
- apply
- name
- describeArgs
- describeReturn
- describeTransform
- describeErrors
- describe

__call__(spark_context, data_frame, source_column, mode_type)

The `FillWithMode` transform formats the case of strings in a column.

- `source_column` – The name of an existing column.
- `mode_type` – How to resolve tie values in the data. This value must be one of `MINIMUM`, `NONE`, `AVERAGE`, or `MAXIMUM`.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply.

name(cls)

Inherited from `GlueTransform` name.

describeArgs(cls)

Inherited from `GlueTransform` describeArgs.

describeReturn(cls)

Inherited from `GlueTransform` describeReturn.

describeTransform(cls)

Inherited from `GlueTransform` describeTransform.

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

FlagDuplicateRows class

The `FlagDuplicateRows` transform returns a new column with a specified value in each row that indicates whether that row is an exact match of an earlier row in the dataset. When matches are found, they are flagged as duplicates. The initial occurrence is not flagged, because it doesn't match an earlier row.

Example

```
from pyspark.context import SparkContext
from pyspark.sql import SparkSession
from awsgluedi.transforms import *

sc = SparkContext()
spark = SparkSession(sc)

input_df = spark.createDataFrame(
    [
        (105.111, 13.12),
        (13.12, 13.12),
        (None, 13.12),
        (13.12, 13.12),
        (None, 13.12),
    ],
    ["source_column_1", "source_column_2"],
)

try:
    df_output = data_quality.FlagDuplicateRows.apply(
        data_frame=input_df,
        spark_context=sc,
        target_column="flag_row",
        true_string="True",
        false_string="False",
        target_index=1
    )
except:
    print("Unexpected Error happened ")
    raise
```

Output

The output will be a PySpark DataFrame with an additional column `flag_row` that indicates whether a row is a duplicate or not, based on the `source_column_1` column. The resulting `df_output` DataFrame will contain the following rows:

```
```
+---------------+---------------+--------+
|source_column_1|source_column_2|flag_row|
```
```

```
+---------------+---------------+--------+
| 105.111| 13.12| False|
| 13.12| 13.12| True|
| null| 13.12| True|
| 13.12| 13.12| True|
| null| 13.12| True|
+---------------+---------------+--------+
```

The `flag_row` column indicates whether a row is a duplicate or not. The `true_string` is set to "True", and the `false_string` is set to "False". The `target_index` is set to 1, which means that the `flag_row` column will be inserted at the second position (index 1) in the output DataFrame.

Methods

- __call__
- apply
- name
- describeArgs
- describeReturn
- describeTransform
- describeErrors
- describe

__call__(spark_context, data_frame, target_column, true_string=DEFAULT_TRUE_STRING, false_string=DEFAULT_FALSE_STRING, target_index=None)

The `FlagDuplicateRows` transform returns a new column with a specified value in each row that indicates whether that row is an exact match of an earlier row in the dataset. When matches are found, they are flagged as duplicates. The initial occurrence is not flagged, because it doesn't match an earlier row.

- `true_string` – Value to be inserted if the row matches an earlier row.
- `false_string` – Value to be inserted if the row is unique.
- `target_column` – Name of the new column that is inserted in the dataset.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply.

name(cls)

Inherited from `GlueTransform` name.

describeArgs(cls)

Inherited from `GlueTransform` describeArgs.

describeReturn(cls)

Inherited from `GlueTransform` describeReturn.

describeTransform(cls)

Inherited from `GlueTransform` describeTransform.

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

RemoveDuplicates class

The `RemoveDuplicates` transform deletes an entire row, if a duplicate value is encountered in a selected source column.

Example

```
from pyspark.context import SparkContext
from pyspark.sql import SparkSession
from awsgluedi.transforms import *

sc = SparkContext()
spark = SparkSession(sc)
```

```
input_df = spark.createDataFrame(
    [
        (105.111, 13.12),
        (13.12, 13.12),
        (None, 13.12),
        (13.12, 13.12),
        (None, 13.12),
    ],
    ["source_column_1", "source_column_2"],
)

try:
    df_output = data_quality.RemoveDuplicates.apply(
        data_frame=input_df,
        spark_context=sc,
        source_column="source_column_1"
    )
except:
    print("Unexpected Error happened ")
    raise
```

Output

The output will be a PySpark DataFrame with duplicates removed based on the `source_column_1` column. The resulting `df_output` DataFrame will contain the following rows:

```
```
+---------------+---------------+
|source_column_1|source_column_2|
+---------------+---------------+
105.111	13.12
13.12	13.12
null	13.12
+---------------+---------------+
```
```

Note that the rows with `source_column_1` values of `13.12` and `null` appear only once in the output DataFrame, as the duplicates have been removed based on the `source_column_1` column.

Methods

- __call__

- apply
- name
- describeArgs
- describeReturn
- describeTransform
- describeErrors
- describe

__call__(spark_context, data_frame, source_column)

The `RemoveDuplicates` transform deletes an entire row, if a duplicate value is encountered in a selected source column.

- `source_column` – The name of an existing column.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply.

name(cls)

Inherited from `GlueTransform` name.

describeArgs(cls)

Inherited from `GlueTransform` describeArgs.

describeReturn(cls)

Inherited from `GlueTransform` describeReturn.

describeTransform(cls)

Inherited from `GlueTransform` describeTransform.

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

MonthName class

The `MonthName` transform creates a new column containing the name of the month, from a string that represents a date.

Example

```
from pyspark.context import SparkContext
from pyspark.sql import SparkSession
from awsgluedi.transforms import *

sc = SparkContext()
spark = SparkSession(sc)

spark.conf.set("spark.sql.legacy.timeParserPolicy", "LEGACY")

input_df = spark.createDataFrame(
    [
        ("20-2018-12",),
        ("2018-20-12",),
        ("20182012",),
        ("12202018",),
        ("20122018",),
        ("20-12-2018",),
        ("12/20/2018",),
        ("02/02/02",),
        ("02 02 2009",),
        ("02/02/2009",),
        ("August/02/2009",),
        ("02/june/2009",),
        ("02/2020/june",),
        ("2013-02-21 06:35:45.658505",),
        ("August 02 2009",),
        ("2013/02/21",),
        (None,),
    ],
    ["column_1"],
)

try:
```

```
    df_output = datetime_functions.MonthName.apply(
        data_frame=input_df,
        spark_context=sc,
        source_column="column_1",
        target_column="target_column"
    )
    df_output.show()
except:
    print("Unexpected Error happened ")
    raise
```

Output

The output will be:

```
```
+------------+------------+
| column_1|target_column|
+------------+------------+
20-2018-12	December
2018-20-12	null
20182012	null
12202018	null
20122018	null
20-12-2018	December
12/20/2018	December
02/02/02	February
02 02 2009	February
02/02/2009	February
August/02/2009	August
02/june/2009	null
02/2020/june	null
2013-02-21 06:35:45.658505	February
August 02 2009	August
2013/02/21	February
null	null
+------------+------------+
```
```

The `MonthName` transformation takes the `source_column` as `"column_1"` and the `target_column` as `"target_column"`. It attempts to extract the month name from the date/time strings in the `"column_1"` column and places it in the `"target_column"` column. If the date/

time string is in an unrecognized format or cannot be parsed, the `"target_column"` value is set to `null`.

The transformation successfully extracts the month name from various date/time formats, such as "20-12-2018", "12/20/2018", "02/02/2009", "2013-02-21 06:35:45.658505", and "August 02 2009".

Methods

- __call__
- apply
- name
- describeArgs
- describeReturn
- describeTransform
- describeErrors
- describe

__call__(spark_context, data_frame, target_column, source_column=None, value=None)

The `MonthName` transform creates a new column containing the name of the month, from a string that represents a date.

- `source_column` – The name of an existing column.
- `value` – A character string to evaluate..
- `target_column` – A name for the newly created column.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply.

name(cls)

Inherited from `GlueTransform` name.

describeArgs(cls)

Inherited from `GlueTransform` describeArgs.

describeReturn(cls)

Inherited from `GlueTransform` describeReturn.

describeTransform(cls)

Inherited from `GlueTransform` describeTransform.

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

IsEven class

The `IsEven` transform returns a Boolean value in a new column that indicates whether the source column or value is even. If the source column or value is a decimal, the result is false.

Example

```
from pyspark.context import SparkContext
from pyspark.sql import SparkSession
from awsgluedi.transforms import *

sc = SparkContext()
spark = SparkSession(sc)

input_df = spark.createDataFrame(
    [(5,), (0,), (-1,), (2,), (None,)],
    ["source_column"],
)

try:
    df_output = math_functions.IsEven.apply(
        data_frame=input_df,
        spark_context=sc,
        source_column="source_column",
        target_column="target_column",
        value=None,
        true_string="Even",
```

```
        false_string="Not even",
    )
    df_output.show()
except:
    print("Unexpected Error happened ")
    raise
```

Output

The output will be:

```
```
+------------+------------+
|source_column|target_column|
+------------+------------+
5	Not even
0	Even
-1	Not even
2	Even
null	null
+------------+------------+
```
```

The `IsEven` transformation takes the `source_column` as "source_column" and the `target_column` as "target_column". It checks if the value in the `"source_column"` is even or not. If the value is even, it sets the `"target_column"` value to the `true_string` "Even". If the value is odd, it sets the `"target_column"` value to the `false_string` "Not even". If the `"source_column"` value is `null`, the `"target_column"` value is set to `null`.

The transformation correctly identifies the even numbers (0 and 2) and sets the `"target_column"` value to "Even". For odd numbers (5 and -1), it sets the `"target_column"` value to "Not even". For the `null` value in `"source_column"`, the `"target_column"` value is set to `null`.

Methods

- apply
- name
- describeArgs

- describeReturn
- describeTransform
- describeErrors
- describe

__call__(spark_context, data_frame, target_column, source_column=None, true_string=DEFAULT_TRUE_STRING, false_string=DEFAULT_FALSE_STRING, value=None)

The `IsEven` transform returns a Boolean value in a new column that indicates whether the source column or value is even. If the source column or value is a decimal, the result is false.

- `source_column` – The name of an existing column.
- `target_column` – The name of the new column to be created.
- `true_string` – A string that indicates whether the value is even.
- `false_string` – A string that indicates whether the value is not even.

CryptographicHash class

The `CryptographicHash` transform applies an algorithm to hash values in the column.

Example

```
from pyspark.context import SparkContext
from pyspark.sql import SparkSession
from awsgluedi.transforms import *

secret = "${SECRET}"
sc = SparkContext()
spark = SparkSession(sc)

input_df = spark.createDataFrame(
    [
        (1, "1234560000"),
        (2, "1234560001"),
        (3, "1234560002"),
        (4, "1234560003"),
        (5, "1234560004"),
        (6, "1234560005"),
        (7, "1234560006"),
        (8, "1234560007"),
        (9, "1234560008"),
        (10, "1234560009"),
    ],
    ["id", "phone"],
)

try:
    df_output = pii.CryptographicHash.apply(
        data_frame=input_df,
        spark_context=sc,
        source_columns=["id", "phone"],
        secret_id=secret,
        algorithm="HMAC_SHA256",
        output_format="BASE64",
    )
    df_output.show()
```

```
except:
    print("Unexpected Error happened ")
    raise
```

Output

The output will be:

```
```
+---+------------+------------------+------------------+
| id| phone | id_hashed | phone_hashed |

10	1234560009	GRN6nFXkxk349...	VJdsKt8VbxBbt...
+---+------------+------------------+------------------+
```
```

The transformation computes the cryptographic hashes of the values in the `id` and `phone` columns using the specified algorithm and secret key, and encodes the hashes in Base64 format. The resulting `df_output` DataFrame contains all columns from the original `input_df` DataFrame, plus the additional `id_hashed` and `phone_hashed` columns with the computed hashes.

Methods

- __call__
- apply
- name
- describeArgs
- describeReturn
- describeTransform

- describeErrors
- describe

__call__(spark_context, data_frame, source_columns, secret_id, algorithm=None, secret_version=None, create_secret_if_missing=False, output_format=None, entity_type_filter=None)

The `CryptographicHash` transform applies an algorithm to hash values in the column.

- `source_columns` – An array of existing columns.
- `secret_id` – The ARN of the Secrets Manager secret key. The key used in the hash-based message authentication code (HMAC) prefix algorithm to hash the source columns.
- `secret_version` – Optional. Defaults to the latest secret version.
- `entity_type_filter` – Optional array of entity types. Can be used to encrypt only detected PII in free-text column.
- `create_secret_if_missing` – Optional boolean. If true will attempt to create the secret on behalf of the caller.
- `algorithm` – The algorithm used to hash your data. Valid enum values: MD5, SHA1, SHA256, SHA512, HMAC_MD5, HMAC_SHA1, HMAC_SHA256, HMAC_SHA512.

apply(cls, *args, **kwargs)

Inherited from `GlueTransform` apply.

describeReturn(cls)

Inherited from `GlueTransform` describeReturn.

describeTransform(cls)

Inherited from `GlueTransform` describeTransform.

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

Decrypt class

The `Decrypt` transform decrypts inside of AWS Glue. Your data can also be decrypted outside of AWS Glue with the AWS Encryption SDK. If the provided KMS key ARN does not match what was used to encrypt the column, the decrypt operation fails.

Example

```
from pyspark.context import SparkContext
from pyspark.sql import SparkSession
from awsgluedi.transforms import *

kms = "${KMS}"
sc = SparkContext()
spark = SparkSession(sc)

input_df = spark.createDataFrame(
    [
        (1, "1234560000"),
        (2, "1234560001"),
        (3, "1234560002"),
        (4, "1234560003"),
        (5, "1234560004"),
        (6, "1234560005"),
        (7, "1234560006"),
        (8, "1234560007"),
        (9, "1234560008"),
        (10, "1234560009"),
    ],
    ["id", "phone"],
)

try:
    df_encrypt = pii.Encrypt.apply(
        data_frame=input_df,
```

```
        spark_context=sc,
        source_columns=["phone"],
        kms_key_arn=kms
    )
    df_decrypt = pii.Decrypt.apply(
        data_frame=df_encrypt,
        spark_context=sc,
        source_columns=["phone"],
        kms_key_arn=kms
    )
    df_decrypt.show()
except:
    print("Unexpected Error happened ")
    raise
```

Output

The output will be a PySpark DataFrame with the original `id` column and the decrypted `phone` column:

```
```
+---+------------+
| id| phone|
+---+------------+
1	1234560000
2	1234560001
3	1234560002
4	1234560003
5	1234560004
6	1234560005
7	1234560006
8	1234560007
9	1234560008
10	1234560009
+---+------------+
```
```

The `Encrypt` transform takes the `source_columns` as `["phone"]` and the `kms_key_arn` as the value of the `${KMS}` environment variable. The transformation encrypts the values in the `phone` column using the specified KMS key. The encrypted DataFrame `df_encrypt` is then passed to the `Decrypt` transform from the `awsglue.pii` module. It takes the `source_columns`

as `["phone"]` and the `kms_key_arn` as the value of the `${KMS}` environment variable. The transformation decrypts the encrypted values in the `phone` column using the same KMS key. The resulting `df_decrypt` DataFrame contains the original `id` column and the decrypted `phone` column.

Methods

- __call__
- apply
- name
- describeArgs
- describeReturn
- describeTransform
- describeErrors
- describe

__call__(spark_context, data_frame, source_columns, kms_key_arn)

The `Decrypt` transform decrypts inside of AWS Glue. Your data can also be decrypted outside of AWS Glue with the AWS Encryption SDK. If the provided KMS key ARN does not match what was used to encrypt the column, the decrypt operation fails.

- `source_columns` – An array of existing columns.
- `kms_key_arn` – The key ARN of the AWS Key Management Service key to use to decrypt the source columns.

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

Encrypt class

The `Encrypt` transform encrypts source columns using the AWS Key Management Service key. The `Encrypt` transform can encrypt up to 128 MiB per cell. It will attempt to preserve the format on decryption. To preserve the data type, the data type metadata must serialize to less than 1KB. Otherwise, you must set the `preserve_data_type` parameter to false. The data type metadata will be stored in plaintext in the encryption context.

Example

```
from pyspark.context import SparkContext
from pyspark.sql import SparkSession
from awsgluedi.transforms import *

kms = "${KMS}"
sc = SparkContext()
spark = SparkSession(sc)

input_df = spark.createDataFrame(
    [
        (1, "1234560000"),
        (2, "1234560001"),
        (3, "1234560002"),
        (4, "1234560003"),
        (5, "1234560004"),
        (6, "1234560005"),
        (7, "1234560006"),
```

```
        (8, "1234560007"),
        (9, "1234560008"),
        (10, "1234560009"),
    ],
    ["id", "phone"],
)

try:
    df_encrypt = pii.Encrypt.apply(
        data_frame=input_df,
        spark_context=sc,
        source_columns=["phone"],
        kms_key_arn=kms
    )
except:
    print("Unexpected Error happened ")
    raise
```

Output

The output will be a PySpark DataFrame with the original `id` column and an additional column containing the encrypted values of the `phone` column.

```
```
+---+------------+-------------------------+
| id| phone | phone_encrypted |
+---+------------+-------------------------+
1	1234560000	EncryptedData1234...abc
2	1234560001	EncryptedData5678...def
3	1234560002	EncryptedData9012...ghi
4	1234560003	EncryptedData3456...jkl
5	1234560004	EncryptedData7890...mno
6	1234560005	EncryptedData1234...pqr
7	1234560006	EncryptedData5678...stu
8	1234560007	EncryptedData9012...vwx
9	1234560008	EncryptedData3456...yz0
10	1234560009	EncryptedData7890...123
+---+------------+-------------------------+
```
```

The `Encrypt` transform takes the `source_columns` as `["phone"]` and the `kms_key_arn` as the value of the `${KMS}` environment variable. The transformation encrypts the values

in the `phone` column using the specified KMS key. The resulting `df_encrypt` DataFrame contains the original `id` column, the original `phone` column, and an additional column named `phone_encrypted` containing the encrypted values of the `phone` column.

Methods

describeErrors(cls)

Inherited from `GlueTransform` describeErrors.

describe(cls)

Inherited from `GlueTransform` describe.

IntToIp class

The `IntToIp` transform converts the integer value of source column or other value to the corresponding IPv4 value in then target column, and returns the result in a new column.

Example

```
from pyspark.context import SparkContext
from pyspark.sql import SparkSession
from awsgluedi.transforms import *

sc = SparkContext()
spark = SparkSession(sc)

input_df = spark.createDataFrame(
    [
        (3221225473,),
        (0,),
        (1,),
        (100,),
        (168430090,),
        (4294967295,),
        (4294967294,),
        (4294967296,),
```

```
        (-1,),
        (None,),
    ],
    ["source_column_int"],
)

try:
    df_output = web_functions.IntToIp.apply(
        data_frame=input_df,
        spark_context=sc,
        source_column="source_column_int",
        target_column="target_column",
        value=None
    )
    df_output.show()
except:
    print("Unexpected Error happened ")
    raise
```

Output

The output will be:

```
```
+---------------+---------------+
|source_column_int|target_column|
+---------------+---------------+
3221225473	192.0.0.1
0	0.0.0.0
1	0.0.0.1
100	0.0.0.100
168430090	10.0.0.10
4294967295	255.255.255.255
4294967294	255.255.255.254
4294967296	null
-1	null
null	null
+---------------+---------------+
```
```

The `IntToIp.apply` transformation takes the `source_column` as `"source_column_int"` and the `target_column` as `"target_column"` and converts the integer values in the

`source_column_int` column to their corresponding IPv4 address representation and stores the result in the `target_column` column.

For valid integer values within the range of IPv4 addresses (0 to 4294967295), the transformation successfully converts them to their IPv4 address representation (e.g., 192.0.0.1, 0.0.0.0, 10.0.0.10, 255.255.255.255).

For integer values outside the valid range (e.g., 4294967296, -1), the `target_column` value is set to `null`. For `null` values in the `source_column_int` column, the `target_column` value is also set to `null`.

Methods

IpToInt class

The `IpToInt` transform converts the Internet Protocol version 4 (IPv4) value of the source column or other value to the corresponding integer value in the target column, and returns the result in a new column.

Example

For AWS Glue 4.0 and above, create or update job arguments with `key: --enable-glue-di-transforms, value: true`

```
from pyspark.context import SparkContext
from awsgluedi.transforms import *

sc = SparkContext()

input_df = spark.createDataFrame(
    [
        ("192.0.0.1",),
        ("10.10.10.10",),
        ("1.2.3.4",),
        ("1.2.3.6",),
        ("http://12.13.14.15",),
        ("https://16.17.18.19",),
        ("1.2.3.4",),
```

```
        (None,),
        ("abc",),
        ("abc.abc.abc.abc",),
        ("321.123.123.123",),
        ("244.4.4.4",),
        ("255.255.255.255",),
    ],
    ["source_column_ip"],
)

    df_output = web_functions.IpToInt.apply(
        data_frame=input_df,
        spark_context=sc,
        source_column="source_column_ip",
        target_column="target_column",
        value=None
    )
    df_output.show()
```

Output

The output will be:

```
```
+----------------+---------------+
|source_column_ip| target_column|
+----------------+---------------+
192.0.0.1	3221225473
10.10.10.10	168427722
1.2.3.4	16909060
1.2.3.6	16909062
http://12.13.14.15	null
https://16.17.18.19	null
1.2.3.4	16909060
null	null
abc	null
abc.abc.abc.abc	null
321.123.123.123	null
244.4.4.4	4102444804
255.255.255.255	4294967295
+----------------+---------------+
```
```

The `IpToInt` transformation takes the `source_column` as `"source_column_ip"` and the `target_column` as `"target_column"` and converts the valid IPv4 address strings in the `source_column_ip` column to their corresponding 32-bit integer representation and stores the result in the `target_column` column.

For valid IPv4 address strings (e.g., "192.0.0.1", "10.10.10.10", "1.2.3.4"), the transformation successfully converts them to their integer representation (e.g., 3221225473, 168427722, 16909060). For strings that are not valid IPv4 addresses (e.g., URLs, non-IP strings like "abc", invalid IP formats like "abc.abc.abc.abc"), the `target_column` value is set to `null`. For `null` values in the `source_column_ip` column, the `target_column` value is also set to `null`.

Methods

Data integration transforms

For AWS Glue 4.0 and above, create or update job arguments with `key: --enable-glue-di-transforms, value: true`.

Example job script:

```
from pyspark.context import SparkContext

from awsgluedi.transforms import *
sc = SparkContext()

input_df = spark.createDataFrame(
    [(5,), (0,), (-1,), (2,), (None,)],
    ["source_column"],
)

try:
    df_output = math_functions.IsEven.apply(
        data_frame=input_df,
        spark_context=sc,
        source_column="source_column",
```

```
        target_column="target_column",
        value=None,
        true_string="Even",
        false_string="Not even",
    )
    df_output.show()
except:
    print("Unexpected Error happened ")
    raise
```

Example Sessions using Notebooks

```
%idle_timeout 2880
%glue_version 4.0
%worker_type G.1X
%number_of_workers 5
%region eu-west-1
```

```
%%configure
{
    "--enable-glue-di-transforms": "true"
}
```

```
from pyspark.context import SparkContext
from awsgluedi.transforms import *

sc = SparkContext()

input_df = spark.createDataFrame(
    [(5,), (0,), (-1,), (2,), (None,)],
    ["source_column"],
)

try:
    df_output = math_functions.IsEven.apply(
        data_frame=input_df,
        spark_context=sc,
        source_column="source_column",
        target_column="target_column",
        value=None,
        true_string="Even",
        false_string="Not even",
```

```
    )
    df_output.show()
except:
    print("Unexpected Error happened ")
    raise
```

Example Sessions using AWS CLI

```
aws glue create-session --default-arguments "--enable-glue-di-transforms=true"
```

DI transforms:

- FlagDuplicatesInColumn class
- FormatPhoneNumber class
- FormatCase class
- FillWithMode class
- FlagDuplicateRows class
- RemoveDuplicates class
- MonthName class
- IsEven class
- CryptographicHash class
- Decrypt class
- Encrypt class
- IntToIp class
- IpToInt class

Maven: Bundle the plugin with your Spark applications

You can bundle the transforms dependency with your Spark applications and Spark distributions (version 3.3) by adding the plugin dependency in your Maven `pom.xml` while developing your Spark applications locally.

```
<repositories>
   ...
    <repository>
        <id>aws-glue-etl-artifacts</id>
        <url>https://aws-glue-etl-artifacts.s3.amazonaws.com/release/ </url>
```

```
    </repository>
</repositories>
...
<dependency>
    <groupId>com.amazonaws</groupId>
    <artifactId>AWSGlueTransforms</artifactId>
    <version>4.0.0</version>
</dependency>
```

You can alternatively download the binaries from AWS Glue Maven artifacts directly and include them in your Spark application as follows.

```
#!/bin/bash
sudo wget -v https://aws-glue-etl-artifacts.s3.amazonaws.com/release/com/amazonaws/
AWSGlueTransforms/4.0.0/AWSGlueTransforms-4.0.0.jar -P /usr/lib/spark/jars/
```

Programming AWS Glue ETL scripts in Scala

You can find Scala code examples and utilities for AWS Glue in the AWS Glue samples repository on the GitHub website.

AWS Glue supports an extension of the PySpark Scala dialect for scripting extract, transform, and load (ETL) jobs. The following sections describe how to use the AWS Glue Scala library and the AWS Glue API in ETL scripts, and provide reference documentation for the library.

Contents

        - Job def methods

Using Scala to program AWS Glue ETL scripts

You can automatically generate a Scala extract, transform, and load (ETL) program using the AWS Glue console, and modify it as needed before assigning it to a job. Or, you can write your own program from scratch. For more information, see Configuring job properties for Spark jobs in AWS Glue. AWS Glue then compiles your Scala program on the server before running the associated job.

To ensure that your program compiles without errors and runs as expected, it's important that you load it on a development endpoint in a REPL (Read-Eval-Print Loop) or a Jupyter Notebook and test it there before running it in a job. Because the compile process occurs on the server, you will not have good visibility into any problems that happen there.

Testing a Scala ETL program in a Jupyter notebook on a development endpoint

To test a Scala program on an AWS Glue development endpoint, set up the development endpoint as described in Adding a development endpoint.

Next, connect it to a Jupyter Notebook that is either running locally on your machine or remotely on an Amazon EC2 notebook server. To install a local version of a Jupyter Notebook, follow the instructions in Tutorial: Jupyter notebook in JupyterLab.

The only difference between running Scala code and running PySpark code on your Notebook is that you should start each paragraph on the Notebook with the the following:

```
%spark
```

This prevents the Notebook server from defaulting to the PySpark flavor of the Spark interpreter.

Testing a Scala ETL program in a Scala REPL

You can test a Scala program on a development endpoint using the AWS GlueScala REPL. Follow the instructions in Tutorial: Use a SageMaker AI notebook, except at the end of the SSH-to-REPL command, replace `-t gluepyspark` with `-t glue-spark-shell`. This invokes the AWS Glue Scala REPL.

To close the REPL when you are finished, type `sys.exit`.

Scala script example - streaming ETL

Example

The following example script connects to Amazon Kinesis Data Streams, uses a schema from the Data Catalog to parse a data stream, joins the stream to a static dataset on Amazon S3, and outputs the joined results to Amazon S3 in parquet format.

```
// This script connects to an Amazon Kinesis stream, uses a schema from the data
 catalog to parse the stream,
// joins the stream to a static dataset on Amazon S3, and outputs the joined results to
 Amazon S3 in parquet format.

      .start().awaitTermination()               // start() returns type StreamingQuery
    Job.commit()
  }
}
```

APIs in the AWS Glue Scala library

AWS Glue supports an extension of the PySpark Scala dialect for scripting extract, transform, and load (ETL) jobs. The following sections describe the APIs in the AWS Glue Scala library.

com.amazonaws.services.glue

The **com.amazonaws.services.glue** package in the AWS Glue Scala library contains the following APIs:

- ChoiceOption
- DataSink
- DataSource trait
- DynamicFrame
- DynamicRecord
- GlueContext
- MappingSpec
- ResolveSpec

com.amazonaws.services.glue.ml

The **com.amazonaws.services.glue.ml** package in the AWS Glue Scala library contains the following APIs:

- FillMissingValues
- FindIncrementalMatches
- FindMatches

com.amazonaws.services.glue.dq

The **com.amazonaws.services.glue.dq** package in the AWS Glue Scala library contains the following APIs:

- EvaluateDataQuality

com.amazonaws.services.glue.types

The **com.amazonaws.services.glue.types** package in the AWS Glue Scala library contains the following APIs:

- ArrayNode
- BinaryNode

- BooleanNode
- ByteNode
- DateNode
- DecimalNode
- DoubleNode
- DynamicNode
- FloatNode
- IntegerNode
- LongNode
- MapLikeNode
- MapNode
- NullNode
- ObjectNode
- ScalarNode
- ShortNode
- StringNode
- TimestampNode

com.amazonaws.services.glue.util

The **com.amazonaws.services.glue.util** package in the AWS Glue Scala library contains the following APIs:

- GlueArgParser
- Job

AWS Glue Scala ChoiceOption APIs

Topics

- ChoiceOption trait
- ChoiceOption object
- Case class ChoiceOptionWithResolver
- Case class MatchCatalogSchemaChoiceOption

Package: com.amazonaws.services.glue

ChoiceOption trait

```
trait ChoiceOption extends Serializable
```

ChoiceOption object

ChoiceOption

```
object ChoiceOption
```

A general strategy to resolve choice applicable to all `ChoiceType` nodes in a `DynamicFrame`.

- `val CAST`
- `val MAKE_COLS`
- `val MAKE_STRUCT`
- `val MATCH_CATALOG`
- `val PROJECT`

Def apply

```
def apply(choice: String): ChoiceOption
```

Case class ChoiceOptionWithResolver

```
case class ChoiceOptionWithResolver(name: String, choiceResolver: ChoiceResolver)
 extends ChoiceOption {}
```

Case class MatchCatalogSchemaChoiceOption

```
case class MatchCatalogSchemaChoiceOption() extends ChoiceOption {}
```

Abstract DataSink class

Topics

- Def writeDynamicFrame

- Def pyWriteDynamicFrame
- Def writeDataFrame
- Def pyWriteDataFrame
- Def setCatalogInfo
- Def supportsFormat
- Def setFormat
- Def withFormat
- Def setAccumulableSize
- Def getOutputErrorRecordsAccumulable
- Def errorsAsDynamicFrame
- DataSink object

Package: com.amazonaws.services.glue

```
abstract class DataSink
```

The writer analog to a `DataSource`. `DataSink` encapsulates a destination and a format that a `DynamicFrame` can be written to.

Def writeDynamicFrame

```
def writeDynamicFrame( frame : DynamicFrame,
                       callSite : CallSite = CallSite("Not provided", "")
                     ) : DynamicFrame
```

Def pyWriteDynamicFrame

```
def pyWriteDynamicFrame( frame : DynamicFrame,
                         site : String = "Not provided",
                         info : String = "" )
```

Def writeDataFrame

```
def writeDataFrame(frame: DataFrame,
                   glueContext: GlueContext,
```

```
                    callSite: CallSite = CallSite("Not provided", "")
                    ): DataFrame
```

Def pyWriteDataFrame

```
def pyWriteDataFrame(frame: DataFrame,
                     glueContext: GlueContext,
                     site: String = "Not provided",
                     info: String = ""
                     ): DataFrame
```

Def setCatalogInfo

```
def setCatalogInfo(catalogDatabase: String,
                   catalogTableName : String,
                   catalogId : String = "")
```

Def supportsFormat

```
def supportsFormat( format : String ) : Boolean
```

Def setFormat

```
def setFormat( format : String,
               options : JsonOptions
             ) : Unit
```

Def withFormat

```
def withFormat( format : String,
                options : JsonOptions = JsonOptions.empty
              ) : DataSink
```

Def setAccumulableSize

```
def setAccumulableSize( size : Int ) : Unit
```

Def getOutputErrorRecordsAccumulable

```
def getOutputErrorRecordsAccumulable : Accumulable[List[OutputError], OutputError]
```

Def errorsAsDynamicFrame

```
def errorsAsDynamicFrame : DynamicFrame
```

DataSink object

```
object DataSink
```

Def recordMetrics

```
def recordMetrics( frame : DynamicFrame,
                   ctxt : String
                 ) : DynamicFrame
```

AWS Glue Scala DataSource trait

Package: com.amazonaws.services.glue

A high-level interface for producing a `DynamicFrame`.

```
trait DataSource {

  def getDynamicFrame : DynamicFrame

  def getDynamicFrame( minPartitions : Int,
                       targetPartitions : Int
                     ) : DynamicFrame
  def getDataFrame : DataFrame

  /** @param num: the number of records for sampling.
    * @param options: optional parameters to control sampling behavior. Current
 available parameter for Amazon S3 sources in options:
    *  1. maxSamplePartitions: the maximum number of partitions the sampling will
 read.
    *  2. maxSampleFilesPerPartition: the maximum number of files the sampling will
 read in one partition.
```

```
    */
  def getSampleDynamicFrame(num:Int, options: JsonOptions = JsonOptions.empty):
 DynamicFrame

  def glueContext : GlueContext

  def setFormat( format : String,
                 options : String
               ) : Unit

  def setFormat( format : String,
                 options : JsonOptions
               ) : Unit

  def supportsFormat( format : String ) : Boolean

  def withFormat( format : String,
                  options : JsonOptions = JsonOptions.empty
                ) : DataSource
}
```

AWS Glue Scala DynamicFrame class

Package: com.amazonaws.services.glue

```
class DynamicFrame extends Serializable with Logging  (
           val glueContext : GlueContext,
           _records : RDD[DynamicRecord],
           val name : String = s"",
           val transformationContext : String = DynamicFrame.UNDEFINED,
           callSite : CallSite = CallSite("Not provided", ""),
           stageThreshold : Long = 0,
           totalThreshold : Long = 0,
           prevErrors : => Long = 0,
           errorExpr : => Unit = {} )
```

A `DynamicFrame` is a distributed collection of self-describing DynamicRecord objects.

`DynamicFrames` are designed to provide a flexible data model for ETL (extract, transform, and load) operations. They don't require a schema to create, and you can use them to read and transform data that contains messy or inconsistent values and types. A schema can be computed on demand for those operations that need one.

`DynamicFrames` provide a range of transformations for data cleaning and ETL. They also support conversion to and from SparkSQL DataFrames to integrate with existing code and the many analytics operations that DataFrames provide.

The following parameters are shared across many of the AWS Glue transformations that construct `DynamicFrames`:

- `transformationContext` — The identifier for this `DynamicFrame`. The `transformationContext` is used as a key for job bookmark state that is persisted across runs.
- `callSite` — Provides context information for error reporting. These values are automatically set when calling from Python.

- `stageThreshold` — The maximum number of error records that are allowed from the computation of this `DynamicFrame` before throwing an exception, excluding records that are present in the previous `DynamicFrame`.
- `totalThreshold` — The maximum number of total error records before an exception is thrown, including those from previous frames.

Val errorsCount

```
val errorsCount
```

The number of error records in this `DynamicFrame`. This includes errors from previous operations.

Def applyMapping

```
def applyMapping( mappings : Seq[Product4[String, String, String, String]],
                  caseSensitive : Boolean = true,
                  transformationContext : String = "",
                  callSite : CallSite = CallSite("Not provided", ""),
                  stageThreshold : Long = 0,
                  totalThreshold : Long = 0
                ) : DynamicFrame
```

- `mappings` — A sequence of mappings to construct a new `DynamicFrame`.
- `caseSensitive` — Whether to treat source columns as case sensitive. Setting this to false might help when integrating with case-insensitive stores like the AWS Glue Data Catalog.

Selects, projects, and casts columns based on a sequence of mappings.

Each mapping is made up of a source column and type and a target column and type. Mappings can be specified as either a four-tuple (`source_path`, `source_type`, `target_path`, `target_type`) or a MappingSpec object containing the same information.

In addition to using mappings for simple projections and casting, you can use them to nest or unnest fields by separating components of the path with `'.'` (period).

For example, suppose that you have a `DynamicFrame` with the following schema.

```
{{{
```

```
  root
  |-- name: string
  |-- age: int
  |-- address: struct
  |    |-- state: string
  |    |-- zip: int
}}}
```

You can make the following call to unnest the `state` and `zip` fields.

```
{{{
  df.applyMapping(
   Seq(("name", "string", "name", "string"),
       ("age", "int", "age", "int"),
       ("address.state", "string", "state", "string"),
       ("address.zip", "int", "zip", "int")))
}}}
```

The resulting schema is as follows.

```
{{{
  root
  |-- name: string
  |-- age: int
  |-- state: string
  |-- zip: int
}}}
```

You can also use `applyMapping` to re-nest columns. For example, the following inverts the previous transformation and creates a struct named `address` in the target.

```
{{{
  df.applyMapping(
   Seq(("name", "string", "name", "string"),
       ("age", "int", "age", "int"),
       ("state", "string", "address.state", "string"),
       ("zip", "int", "address.zip", "int")))
}}}
```

Field names that contain '`.`' (period) characters can be quoted by using backticks (` `).

> **Note**
>
> Currently, you can't use the `applyMapping` method to map columns that are nested under arrays.

Def assertErrorThreshold

```
def assertErrorThreshold : Unit
```

An action that forces computation and verifies that the number of error records falls below `stageThreshold` and `totalThreshold`. Throws an exception if either condition fails.

Def count

```
lazy
def count
```

Returns the number of elements in this `DynamicFrame`.

Def dropField

```
def dropField( path : String,
               transformationContext : String = "",
               callSite : CallSite = CallSite("Not provided", ""),
               stageThreshold : Long = 0,
               totalThreshold : Long = 0
             ) : DynamicFrame
```

Returns a new `DynamicFrame` with the specified column removed.

Def dropFields

```
def dropFields( fieldNames : Seq[String],   // The column names to drop.
                transformationContext : String = "",
                callSite : CallSite = CallSite("Not provided", ""),
                stageThreshold : Long = 0,
                totalThreshold : Long = 0
              ) : DynamicFrame
```

Returns a new `DynamicFrame` with the specified columns removed.

You can use this method to delete nested columns, including those inside of arrays, but not to drop specific array elements.

Def dropNulls

```
def dropNulls( transformationContext : String = "",
               callSite : CallSite = CallSite("Not provided", ""),
               stageThreshold : Long = 0,
               totalThreshold : Long = 0 )
```

Returns a new `DynamicFrame` with all null columns removed.

> **Note**
>
> This only removes columns of type `NullType`. Individual null values in other columns are not removed or modified.

Def errorsAsDynamicFrame

```
def errorsAsDynamicFrame
```

Returns a new `DynamicFrame` containing the error records from this `DynamicFrame`.

Def filter

```
def filter( f : DynamicRecord => Boolean,
            errorMsg : String = "",
            transformationContext : String = "",
            callSite : CallSite = CallSite("Not provided"),
            stageThreshold : Long = 0,
            totalThreshold : Long = 0
          ) : DynamicFrame
```

Constructs a new `DynamicFrame` containing only those records for which the function 'f' returns `true`. The filter function 'f' should not mutate the input record.

Def getName

```
def getName : String
```

Returns the name of this DynamicFrame.

Def getNumPartitions

```
def getNumPartitions
```

Returns the number of partitions in this DynamicFrame.

Def getSchemaIfComputed

```
def getSchemaIfComputed : Option[Schema]
```

Returns the schema if it has already been computed. Does not scan the data if the schema has not already been computed.

Def isSchemaComputed

```
def isSchemaComputed : Boolean
```

Returns `true` if the schema has been computed for this DynamicFrame, or `false` if not. If this method returns false, then calling the `schema` method requires another pass over the records in this DynamicFrame.

Def javaToPython

```
def javaToPython : JavaRDD[Array[Byte]]
```

Def join

```
def join( keys1 : Seq[String],
          keys2 : Seq[String],
          frame2 : DynamicFrame,
          transformationContext : String = "",
          callSite : CallSite = CallSite("Not provided", ""),
          stageThreshold : Long = 0,
          totalThreshold : Long = 0
        ) : DynamicFrame
```

- `keys1` — The columns in this DynamicFrame to use for the join.

- keys2 — The columns in frame2 to use for the join. Must be the same length as keys1.
- frame2 — The DynamicFrame to join against.

Returns the result of performing an equijoin with frame2 using the specified keys.

Def map

```
def map( f : DynamicRecord => DynamicRecord,
         errorMsg : String = "",
         transformationContext : String = "",
         callSite : CallSite = CallSite("Not provided", ""),
         stageThreshold : Long = 0,
         totalThreshold : Long = 0
       ) : DynamicFrame
```

Returns a new DynamicFrame constructed by applying the specified function 'f' to each record in this DynamicFrame.

This method copies each record before applying the specified function, so it is safe to mutate the records. If the mapping function throws an exception on a given record, that record is marked as an error, and the stack trace is saved as a column in the error record.

Def mergeDynamicFrames

```
def mergeDynamicFrames( stageDynamicFrame: DynamicFrame,  primaryKeys: Seq[String],
 transformationContext: String = "",
                         options: JsonOptions = JsonOptions.empty, callSite: CallSite =
 CallSite("Not provided"),
                         stageThreshold: Long = 0, totalThreshold: Long = 0):
 DynamicFrame
```

- stageDynamicFrame — The staging DynamicFrame to merge.
- primaryKeys — The list of primary key fields to match records from the source and staging DynamicFrames.
- transformationContext — A unique string that is used to retrieve metadata about the current transformation (optional).
- options — A string of JSON name-value pairs that provide additional information for this transformation.

- `callSite` — Used to provide context information for error reporting.
- `stageThreshold` — A `Long`. The number of errors in the given transformation for which the processing needs to error out.
- `totalThreshold` — A `Long`. The total number of errors up to and including in this transformation for which the processing needs to error out.

Merges this `DynamicFrame` with a staging `DynamicFrame` based on the specified primary keys to identify records. Duplicate records (records with the same primary keys) are not de-duplicated. If there is no matching record in the staging frame, all records (including duplicates) are retained from the source. If the staging frame has matching records, the records from the staging frame overwrite the records in the source in AWS Glue.

The returned `DynamicFrame` contains record A in the following cases:

1. If A exists in both the source frame and the staging frame, then A in the staging frame is returned.
2. If A is in the source table and `A.primaryKeys` is not in the `stagingDynamicFrame` (that means A is not updated in the staging table).

The source frame and staging frame do not need to have the same schema.

Example

```
val mergedFrame: DynamicFrame = srcFrame.mergeDynamicFrames(stageFrame, Seq("id1",
 "id2"))
```

Def printSchema

```
def printSchema : Unit
```

Prints the schema of this `DynamicFrame` to `stdout` in a human-readable format.

Def recomputeSchema

```
def recomputeSchema : Schema
```

Forces a schema recomputation. This requires a scan over the data, but it might "tighten" the schema if there are some fields in the current schema that are not present in the data.

Returns the recomputed schema.

Def relationalize

```
def relationalize( rootTableName : String,
                   stagingPath : String,
                   options : JsonOptions = JsonOptions.empty,
                   transformationContext : String = "",
                   callSite : CallSite = CallSite("Not provided"),
                   stageThreshold : Long = 0,
                   totalThreshold : Long = 0
                 ) : Seq[DynamicFrame]
```

- `rootTableName` — The name to use for the base `DynamicFrame` in the output. `DynamicFrames` that are created by pivoting arrays start with this as a prefix.
- `stagingPath` — The Amazon Simple Storage Service (Amazon S3) path for writing intermediate data.
- `options` — Relationalize options and configuration. Currently unused.

Flattens all nested structures and pivots arrays into separate tables.

You can use this operation to prepare deeply nested data for ingestion into a relational database. Nested structs are flattened in the same manner as the Unnest transform. Additionally, arrays are pivoted into separate tables with each array element becoming a row. For example, suppose that you have a `DynamicFrame` with the following data.

```
{"name": "Nancy", "age": 47, "friends": ["Fred", "Lakshmi"]}
{"name": "Stephanie", "age": 28, "friends": ["Yao", "Phil", "Alvin"]}
{"name": "Nathan", "age": 54, "friends": ["Nicolai", "Karen"]}
```

Run the following code.

```
{{{
  df.relationalize("people", "s3:/my_bucket/my_path", JsonOptions.empty)
}}}
```

This produces two tables. The first table is named "people" and contains the following.

```
{{{
```

```
  {"name": "Nancy", "age": 47, "friends": 1}
  {"name": "Stephanie", "age": 28, "friends": 2}
  {"name": "Nathan", "age": 54, "friends": 3)
}}}
```

Here, the friends array has been replaced with an auto-generated join key. A separate table named `people.friends` is created with the following content.

```
{{{
  {"id": 1, "index": 0, "val": "Fred"}
  {"id": 1, "index": 1, "val": "Lakshmi"}
  {"id": 2, "index": 0, "val": "Yao"}
  {"id": 2, "index": 1, "val": "Phil"}
  {"id": 2, "index": 2, "val": "Alvin"}
  {"id": 3, "index": 0, "val": "Nicolai"}
  {"id": 3, "index": 1, "val": "Karen"}
}}}
```

In this table, '`id`' is a join key that identifies which record the array element came from, '`index`' refers to the position in the original array, and '`val`' is the actual array entry.

The `relationalize` method returns the sequence of `DynamicFrames` created by applying this process recursively to all arrays.

> **Note**
>
> The AWS Glue library automatically generates join keys for new tables. To ensure that join keys are unique across job runs, you must enable job bookmarks.

Def renameField

```
def renameField( oldName : String,
                 newName : String,
                 transformationContext : String = "",
                 callSite : CallSite = CallSite("Not provided", ""),
                 stageThreshold : Long = 0,
                 totalThreshold : Long = 0
               ) : DynamicFrame
```

- `oldName` — The original name of the column.

- newName — The new name of the column.

Returns a new DynamicFrame with the specified field renamed.

You can use this method to rename nested fields. For example, the following code would rename state to state_code inside the address struct.

```
{{{
  df.renameField("address.state", "address.state_code")
}}}
```

Def repartition

```
def repartition( numPartitions : Int,
                 transformationContext : String = "",
                 callSite : CallSite = CallSite("Not provided", ""),
                 stageThreshold : Long = 0,
                 totalThreshold : Long = 0
               ) : DynamicFrame
```

Returns a new DynamicFrame with numPartitions partitions.

Def resolveChoice

```
def resolveChoice( specs : Seq[Product2[String, String]] = Seq.empty[ResolveSpec],
                   choiceOption : Option[ChoiceOption] = None,
                   database : Option[String] = None,
                   tableName : Option[String] = None,
                   transformationContext : String = "",
                   callSite : CallSite = CallSite("Not provided", ""),
                   stageThreshold : Long = 0,
                   totalThreshold : Long = 0
                 ) : DynamicFrame
```

- choiceOption — An action to apply to all ChoiceType columns not listed in the specs sequence.
- database — The Data Catalog database to use with the match_catalog action.
- tableName — The Data Catalog table to use with the match_catalog action.

Returns a new DynamicFrame by replacing one or more ChoiceTypes with a more specific type.

There are two ways to use resolveChoice. The first is to specify a sequence of specific columns and how to resolve them. These are specified as tuples made up of (column, action) pairs.

The following are the possible actions:

- cast:type — Attempts to cast all values to the specified type.
- make_cols — Converts each distinct type to a column with the name columnName_type.
- make_struct — Converts a column to a struct with keys for each distinct type.
- project:type — Retains only values of the specified type.

The other mode for resolveChoice is to specify a single resolution for all ChoiceTypes. You can use this in cases where the complete list of ChoiceTypes is unknown before execution. In addition to the actions listed preceding, this mode also supports the following action:

- match_catalog — Attempts to cast each ChoiceType to the corresponding type in the specified catalog table.

Examples:

Resolve the user.id column by casting to an int, and make the address field retain only structs.

```
{{{
  df.resolveChoice(specs = Seq(("user.id", "cast:int"), ("address", "project:struct")))
}}}
```

Resolve all ChoiceTypes by converting each choice to a separate column.

```
{{{
  df.resolveChoice(choiceOption = Some(ChoiceOption("make_cols")))
}}}
```

Resolve all ChoiceTypes by casting to the types in the specified catalog table.

```
{{{
  df.resolveChoice(choiceOption = Some(ChoiceOption("match_catalog")),
                   database = Some("my_database"),
                   tableName = Some("my_table"))
```

```
}}}
```

Def schema

```
def schema : Schema
```

Returns the schema of this `DynamicFrame`.

The returned schema is guaranteed to contain every field that is present in a record in this `DynamicFrame`. But in a small number of cases, it might also contain additional fields. You can use the Unnest method to "tighten" the schema based on the records in this `DynamicFrame`.

Def selectField

```
def selectField( fieldName : String,
                 transformationContext : String = "",
                 callSite : CallSite = CallSite("Not provided", ""),
                 stageThreshold : Long = 0,
                 totalThreshold : Long = 0
               ) : DynamicFrame
```

Returns a single field as a `DynamicFrame`.

Def selectFields

```
def selectFields( paths : Seq[String],
                  transformationContext : String = "",
                  callSite : CallSite = CallSite("Not provided", ""),
                  stageThreshold : Long = 0,
                  totalThreshold : Long = 0
                ) : DynamicFrame
```

- `paths` — The sequence of column names to select.

Returns a new `DynamicFrame` containing the specified columns.

> **Note**
>
> You can only use the `selectFields` method to select top-level columns. You can use the applyMapping method to select nested columns.

Def show

```
def show( numRows : Int = 20 ) : Unit
```

- numRows — The number of rows to print.

Prints rows from this DynamicFrame in JSON format.

Def simplifyDDBJson

DynamoDB exports with the AWS Glue DynamoDB export connector results in JSON files of specific nested structures. For more information, see Data objects. simplifyDDBJson Simplifies nested columns in a DynamicFrame of this type of data, and returns a new simplified DynamicFrame. If there are multiple types or a Map type contained in a List type, the elements in the List will not be simplified. This method only supports data in the DynamoDB export JSON format. Consider unnest to perform similar changes on other kinds of data.

```
def simplifyDDBJson() : DynamicFrame
```

This method does not take any parameters.

Example input

Consider the following schema generated by a DynamoDB export:

```
root
|-- Item: struct
|    |-- parentMap: struct
|    |    |-- M: struct
|    |    |    |-- childMap: struct
|    |    |    |    |-- M: struct
|    |    |    |    |    |-- appName: struct
|    |    |    |    |    |    |-- S: string
|    |    |    |    |    |-- packageName: struct
|    |    |    |    |    |    |-- S: string
|    |    |    |    |    |-- updatedAt: struct
|    |    |    |    |    |    |-- N: string
|    |-- strings: struct
|    |    |-- SS: array
|    |    |    |-- element: string
|    |-- numbers: struct
```

```
|    |    |-- NS: array
|    |    |    |-- element: string
|    |-- binaries: struct
|    |    |-- BS: array
|    |    |    |-- element: string
|    |-- isDDBJson: struct
|    |    |-- BOOL: boolean
|    |-- nullValue: struct
|    |    |-- NULL: boolean
```

Example code

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.DynamoDbDataSink
import org.apache.spark.SparkContextimport scala.collection.JavaConverters._

object GlueApp {

  def main(sysArgs: Array[String]): Unit = {
    val glueContext = new GlueContext(SparkContext.getOrCreate())
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)

    val dynamicFrame = glueContext.getSourceWithFormat(
      connectionType = "dynamodb",
      options = JsonOptions(Map(
        "dynamodb.export" -> "ddb",
        "dynamodb.tableArn" -> "ddbTableARN",
        "dynamodb.s3.bucket" -> "exportBucketLocation",
        "dynamodb.s3.prefix" -> "exportBucketPrefix",
        "dynamodb.s3.bucketOwner" -> "exportBucketAccountID",
      ))
    ).getDynamicFrame()

    val simplified = dynamicFrame.simplifyDDBJson()
    simplified.printSchema()

    Job.commit()
  }
```

```
}
```

Example output

The `simplifyDDBJson` transform will simplify this to:

```
root
|-- parentMap: struct
|    |-- childMap: struct
|    |    |-- appName: string
|    |    |-- packageName: string
|    |    |-- updatedAt: string
|-- strings: array
|    |-- element: string
|-- numbers: array
|    |-- element: string
|-- binaries: array
|    |-- element: string
|-- isDDBJson: boolean
|-- nullValue: null
```

Def spigot

```
def spigot( path : String,
            options : JsonOptions = new JsonOptions("{}"),
            transformationContext : String = "",
            callSite : CallSite = CallSite("Not provided"),
            stageThreshold : Long = 0,
            totalThreshold : Long = 0
          ) : DynamicFrame
```

Passthrough transformation that returns the same records but writes out a subset of records as a side effect.

- `path` — The path in Amazon S3 to write output to, in the form `s3://bucket//path`.
- `options` — An optional `JsonOptions` map describing the sampling behavior.

Returns a `DynamicFrame` that contains the same records as this one.

By default, writes 100 arbitrary records to the location specified by `path`. You can customize this behavior by using the `options` map. Valid keys include the following:

- topk — Specifies the total number of records written out. The default is 100.
- prob — Specifies the probability (as a decimal) that an individual record is included. Default is 1.

For example, the following call would sample the dataset by selecting each record with a 20 percent probability and stopping after 200 records have been written.

```
{{{
  df.spigot("s3://my_bucket/my_path", JsonOptions(Map("topk" -&gt; 200, "prob" -&gt;
 0.2)))
}}}
```

Def splitFields

```
def splitFields( paths : Seq[String],
                 transformationContext : String = "",
                 callSite : CallSite = CallSite("Not provided", ""),
                 stageThreshold : Long = 0,
                 totalThreshold : Long = 0
               ) : Seq[DynamicFrame]
```

- paths — The paths to include in the first DynamicFrame.

Returns a sequence of two DynamicFrames. The first DynamicFrame contains the specified paths, and the second contains all other columns.

Example

This example takes a DynamicFrame created from the persons table in the legislators database in the AWS Glue Data Catalog and splits the DynamicFrame into two, with the specified fields going into the first DynamicFrame and the remaining fields going into a second DynamicFrame. The example then chooses the first DynamicFrame from the result.

```
val InputFrame = glueContext.getCatalogSource(database="legislators",
 tableName="persons",
transformationContext="InputFrame").getDynamicFrame()

val SplitField_collection = InputFrame.splitFields(paths=Seq("family_name", "name",
 "links.note",
"links.url", "gender", "image", "identifiers.scheme", "identifiers.identifier",
 "other_names.lang",
```

```
"other_names.note", "other_names.name"), transformationContext="SplitField_collection")

val ResultFrame = SplitField_collection(0)
```

Def splitRows

```
def splitRows( paths : Seq[String],
               values : Seq[Any],
               operators : Seq[String],
               transformationContext : String,
               callSite : CallSite,
               stageThreshold : Long,
               totalThreshold : Long
             ) : Seq[DynamicFrame]
```

Splits rows based on predicates that compare columns to constants.

- `paths` — The columns to use for comparison.
- `values` — The constant values to use for comparison.
- `operators` — The operators to use for comparison.

Returns a sequence of two `DynamicFrames`. The first contains rows for which the predicate is true and the second contains those for which it is false.

Predicates are specified using three sequences: '`paths`' contains the (possibly nested) column names, '`values`' contains the constant values to compare to, and '`operators`' contains the operators to use for comparison. All three sequences must be the same length: The nth operator is used to compare the nth column with the nth value.

Each operator must be one of "`!=`", "=", "<=", "<", ">=", or ">".

As an example, the following call would split a `DynamicFrame` so that the first output frame would contain records of people over 65 from the United States, and the second would contain all other records.

```
{{{
  df.splitRows(Seq("age", "address.country"), Seq(65, "USA"), Seq("&gt;=", "="))
}}}
```

Def stageErrorsCount

```
def stageErrorsCount
```

Returns the number of error records created while computing this DynamicFrame. This excludes errors from previous operations that were passed into this DynamicFrame as input.

Def toDF

```
def toDF( specs : Seq[ResolveSpec] = Seq.empty[ResolveSpec] ) : DataFrame
```

Converts this DynamicFrame to an Apache Spark SQL DataFrame with the same schema and records.

> **Note**
>
> Because DataFrames don't support ChoiceTypes, this method automatically converts ChoiceType columns into StructTypes. For more information and options for resolving choice, see resolveChoice.

Def unbox

```
def unbox( path : String,
           format : String,
           optionString : String = "{}",
           transformationContext : String = "",
           callSite : CallSite = CallSite("Not provided"),
           stageThreshold : Long = 0,
           totalThreshold : Long = 0
         ) : DynamicFrame
```

- path — The column to parse. Must be a string or binary.
- format — The format to use for parsing.
- optionString — Options to pass to the format, such as the CSV separator.

Parses an embedded string or binary column according to the specified format. Parsed columns are nested under a struct with the original column name.

For example, suppose that you have a CSV file with an embedded JSON column.

```
name, age, address
Sally, 36, {"state": "NE", "city": "Omaha"}
...
```

After an initial parse, you would get a `DynamicFrame` with the following schema.

```
{{{
  root
  |-- name: string
  |-- age: int
  |-- address: string
}}}
```

You can call `unbox` on the address column to parse the specific components.

```
{{{
  df.unbox("address", "json")
}}}
```

This gives us a `DynamicFrame` with the following schema.

```
{{{
  root
  |-- name: string
  |-- age: int
  |-- address: struct
  |    |-- state: string
  |    |-- city: string
}}}
```

Def unnest

```
def unnest( transformationContext : String = "",
            callSite : CallSite = CallSite("Not Provided"),
            stageThreshold : Long = 0,
            totalThreshold : Long = 0
          ) : DynamicFrame
```

Returns a new `DynamicFrame` with all nested structures flattened. Names are constructed using the '`.`' (period) character.

For example, suppose that you have a `DynamicFrame` with the following schema.

```
{{{
  root
  |-- name: string
  |-- age: int
  |-- address: struct
  |    |-- state: string
  |    |-- city: string
}}}
```

The following call unnests the address struct.

```
{{{
  df.unnest()
}}}
```

The resulting schema is as follows.

```
{{{
  root
  |-- name: string
  |-- age: int
  |-- address.state: string
  |-- address.city: string
}}}
```

This method also unnests nested structs inside of arrays. But for historical reasons, the names of such fields are prepended with the name of the enclosing array and "`.val`".

Def unnestDDBJson

```
unnestDDBJson(transformationContext : String = "",
            callSite : CallSite = CallSite("Not Provided"),
            stageThreshold : Long = 0,
            totalThreshold : Long = 0): DynamicFrame
```

Unnests nested columns in a `DynamicFrame` that are specifically in the DynamoDB JSON structure, and returns a new unnested `DynamicFrame`. Columns that are of an array of struct types will not be unnested. Note that this is a specific type of unnesting transform that behaves differently from the regular `unnest` transform and requires the data to already be in the DynamoDB JSON structure. For more information, see DynamoDB JSON.

For example, the schema of a reading an export with the DynamoDB JSON structure might look like the following:

```
root
|-- Item: struct
|    |-- ColA: struct
|    |    |-- S: string
|    |-- ColB: struct
|    |    |-- S: string
|    |-- ColC: struct
|    |    |-- N: string
|    |-- ColD: struct
|    |    |-- L: array
|    |    |    |-- element: null
```

The `unnestDDBJson()` transform would convert this to:

```
root
|-- ColA: string
|-- ColB: string
|-- ColC: string
|-- ColD: array
|    |-- element: null
```

The following code example shows how to use the AWS Glue DynamoDB export connector, invoke a DynamoDB JSON unnest, and print the number of partitions:

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.DynamoDbDataSink
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._
```

```
object GlueApp {

  def main(sysArgs: Array[String]): Unit = {
    val glueContext = new GlueContext(SparkContext.getOrCreate())
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)

    val dynamicFrame = glueContext.getSourceWithFormat(
      connectionType = "dynamodb",
      options = JsonOptions(Map(
        "dynamodb.export" -> "ddb",
        "dynamodb.tableArn" -> "<test_source>",
        "dynamodb.s3.bucket" -> "<bucket name>",
        "dynamodb.s3.prefix" -> "<bucket prefix>",
        "dynamodb.s3.bucketOwner" -> "<account_id of bucket>",
      ))
    ).getDynamicFrame()

    val unnested = dynamicFrame.unnestDDBJson()
    print(unnested.getNumPartitions())

    Job.commit()
  }

}
```

Def withFrameSchema

```
def withFrameSchema( getSchema : () => Schema ) : DynamicFrame
```

- `getSchema` — A function that returns the schema to use. Specified as a zero-parameter function to defer potentially expensive computation.

Sets the schema of this `DynamicFrame` to the specified value. This is primarily used internally to avoid costly schema recomputation. The passed-in schema must contain all columns present in the data.

Def withName

```
def withName( name : String ) : DynamicFrame
```

- name — The new name to use.

Returns a copy of this DynamicFrame with a new name.

Def withTransformationContext

```
def withTransformationContext( ctx : String ) : DynamicFrame
```

Returns a copy of this DynamicFrame with the specified transformation context.

The DynamicFrame object

Package: com.amazonaws.services.glue

```
object DynamicFrame
```

Def apply

```
def apply( df : DataFrame,
           glueContext : GlueContext
         ) : DynamicFrame
```

Def emptyDynamicFrame

```
def emptyDynamicFrame( glueContext : GlueContext ) : DynamicFrame
```

Def fromPythonRDD

```
def fromPythonRDD( rdd : JavaRDD[Array[Byte]],
                   glueContext : GlueContext
                 ) : DynamicFrame
```

Def ignoreErrors

```
def ignoreErrors( fn : DynamicRecord => DynamicRecord ) : DynamicRecord
```

Def inlineErrors

```
def inlineErrors( msg : String,
                  callSite : CallSite
                ) : (DynamicRecord => DynamicRecord)
```

Def newFrameWithErrors

```
def newFrameWithErrors( prevFrame : DynamicFrame,
                        rdd : RDD[DynamicRecord],
                        name : String = "",
                        transformationContext : String = "",
                        callSite : CallSite,
                        stageThreshold : Long,
                        totalThreshold : Long
                      ) : DynamicFrame
```

AWS Glue Scala DynamicRecord class

Topics

- Def addField
- Def dropField
- Def setError
- Def isError
- Def getError
- Def clearError
- Def write
- Def readFields
- Def clone
- Def schema
- Def getRoot
- Def toJson
- Def getFieldNode
- Def getField
- Def hashCode

- Def equals
- DynamicRecord object
- RecordTraverser trait

Package: com.amazonaws.services.glue

```
class DynamicRecord extends Serializable with Writable with Cloneable
```

A `DynamicRecord` is a self-describing data structure that represents a row of data in the dataset that is being processed. It is self-describing in the sense that you can get the schema of the row that is represented by the `DynamicRecord` by inspecting the record itself. A `DynamicRecord` is similar to a `Row` in Apache Spark.

Def addField

```
def addField( path : String,
              dynamicNode : DynamicNode
            ) : Unit
```

Adds a DynamicNode to the specified path.

- `path` — The path for the field to be added.
- `dynamicNode` — The DynamicNode to be added at the specified path.

Def dropField

```
def dropField(path: String, underRename: Boolean = false): Option[DynamicNode]
```

Drops a DynamicNode from the specified path and returns the dropped node if there is not an array in the specified path.

- `path` — The path to the field to drop.
- `underRename` — True if `dropField` is called as part of a rename transform, or false otherwise (false by default).

Returns a `scala.Option Option` (DynamicNode).

Def setError

```
def setError( error : Error )
```

Sets this record as an error record, as specified by the `error` parameter.

Returns a `DynamicRecord`.

Def isError

```
def isError
```

Checks whether this record is an error record.

Def getError

```
def getError
```

Gets the `Error` if the record is an error record. Returns `scala.Some` Some (Error) if this record is an error record, or otherwise `scala.None` .

Def clearError

```
def clearError
```

Set the `Error` to `scala.None.None` .

Def write

```
override def write( out : DataOutput ) : Unit
```

Def readFields

```
override def readFields( in : DataInput ) : Unit
```

Def clone

```
override def clone : DynamicRecord
```

Clones this record to a new `DynamicRecord` and returns it.

Def schema

```
def schema
```

Gets the Schema by inspecting the record.

Def getRoot

```
def getRoot : ObjectNode
```

Gets the root ObjectNode for the record.

Def toJson

```
def toJson : String
```

Gets the JSON string for the record.

Def getFieldNode

```
def getFieldNode( path : String ) : Option[DynamicNode]
```

Gets the field's value at the specified path as an option of DynamicNode.

Returns scala.Some Some (DynamicNode) if the field exists, or otherwise scala.None.None .

Def getField

```
def getField( path : String ) : Option[Any]
```

Gets the field's value at the specified path as an option of DynamicNode.

Returns scala.Some Some (value).

Def hashCode

```
override def hashCode : Int
```

Def equals

```
override def equals( other : Any )
```

DynamicRecord object

```
object DynamicRecord
```

Def apply

```
def apply( row : Row,
           schema : SparkStructType )
```

Apply method to convert an Apache Spark SQL Row to a DynamicRecord.

- `row` — A Spark SQL Row.
- `schema` — The `Schema` of that row.

Returns a `DynamicRecord`.

RecordTraverser trait

```
trait RecordTraverser {
  def nullValue(): Unit
  def byteValue(value: Byte): Unit
  def binaryValue(value: Array[Byte]): Unit
  def booleanValue(value: Boolean): Unit
  def shortValue(value: Short) : Unit
  def intValue(value: Int) : Unit
  def longValue(value: Long) : Unit
  def floatValue(value: Float): Unit
  def doubleValue(value: Double): Unit
  def decimalValue(value: BigDecimal): Unit
  def stringValue(value: String): Unit
  def dateValue(value: Date): Unit
  def timestampValue(value: Timestamp): Unit
  def objectStart(length: Int): Unit
  def objectKey(key: String): Unit
  def objectEnd(): Unit
  def mapStart(length: Int): Unit
  def mapKey(key: String): Unit
  def mapEnd(): Unit
  def arrayStart(length: Int): Unit
  def arrayEnd(): Unit
```

```
}
```

AWS Glue Scala GlueContext APIs

Package: com.amazonaws.services.glue

```
class GlueContext extends SQLContext(sc) (
           @transient val sc : SparkContext,
           val defaultSourcePartitioner : PartitioningStrategy )
```

`GlueContext` is the entry point for reading and writing a DynamicFrame from and to Amazon Simple Storage Service (Amazon S3), the AWS Glue Data Catalog, JDBC, and so on. This class provides utility functions to create DataSource trait and DataSink objects that can in turn be used to read and write `DynamicFrames`.

You can also use `GlueContext` to set a target number of partitions (default 20) in the `DynamicFrame` if the number of partitions created from the source is less than a minimum threshold for partitions (default 10).

def addIngestionTimeColumns

```
def addIngestionTimeColumns(
         df : DataFrame,
         timeGranularity : String = "") : dataFrame
```

Appends ingestion time columns like `ingest_year`, `ingest_month`, `ingest_day`, `ingest_hour`, `ingest_minute` to the input `DataFrame`. This function is automatically generated in the script generated by the AWS Glue when you specify a Data Catalog table with Amazon S3 as the target. This function automatically updates the partition with ingestion time columns on the output table. This allows the output data to be automatically partitioned on ingestion time without requiring explicit ingestion time columns in the input data.

- `dataFrame` – The `dataFrame` to append the ingestion time columns to.
- `timeGranularity` – The granularity of the time columns. Valid values are "`day`", "`hour`" and "`minute`". For example, if "`hour`" is passed in to the function, the original `dataFrame` will have "`ingest_year`", "`ingest_month`", "`ingest_day`", and "`ingest_hour`" time columns appended.

Returns the data frame after appending the time granularity columns.

Example:

```
glueContext.addIngestionTimeColumns(dataFrame, "hour")
```

def createDataFrameFromOptions

```
def createDataFrameFromOptions( connectionType : String,
                          connectionOptions : JsonOptions,
                          transformationContext : String = "",
                          format : String = null,
                          formatOptions : JsonOptions = JsonOptions.empty
                        ) : DataSource
```

Returns a `DataFrame` created with the specified connection and format. Use this function only with AWS Glue streaming sources.

- `connectionType` – The streaming connection type. Valid values include `kinesis` and `kafka`.
- `connectionOptions` – Connection options, which are different for Kinesis and Kafka. You can find the list of all connection options for each streaming data source at Connection types and options for ETL in AWS Glue for Spark. Note the following differences in streaming connection options:
  - Kinesis streaming sources require `streamARN`, `startingPosition`, `inferSchema`, and `classification`.
  - Kafka streaming sources require `connectionName`, `topicName`, `startingOffsets`, `inferSchema`, and `classification`.
- `transformationContext` – The transformation context to use (optional).
- `format` – A format specification (optional). This is used for an Amazon S3 or an AWS Glue connection that supports multiple formats. For information about the supported formats, see Data format options for inputs and outputs in AWS Glue for Spark
- `formatOptions` – Format options for the specified format. For information about the supported format options, see Data format options.

Example for Amazon Kinesis streaming source:

```
val data_frame_datasource0 =
glueContext.createDataFrameFromOptions(transformationContext = "datasource0",
 connectionType = "kinesis",
```

```
connectionOptions = JsonOptions("""{"streamName": "example_stream", "startingPosition":
 "TRIM_HORIZON", "inferSchema": "true", "classification": "json"}}""""))
```

Example for Kafka streaming source:

```
val data_frame_datasource0 =
glueContext.createDataFrameFromOptions(transformationContext = "datasource0",
 connectionType = "kafka",
connectionOptions = JsonOptions("""{"connectionName": "example_connection",
 "topicName": "example_topic", "startingPosition": "earliest", "inferSchema": "false",
 "classification": "json", "schema":"`column1` STRING, `column2` STRING"}""""))
```

forEachBatch

`forEachBatch(frame, batch_function, options)`

Applies the `batch_function` passed in to every micro batch that is read from the Streaming source.

- `frame` – The DataFrame containing the current micro batch.
- `batch_function` – A function that will be applied for every micro batch.
- `options` – A collection of key-value pairs that holds information about how to process micro batches. The following options are required:
  - `windowSize` – The amount of time to spend processing each batch.
  - `checkpointLocation` – The location where checkpoints are stored for the streaming ETL job.
  - `batchMaxRetries` – The maximum number of times to retry the batch if it fails. The default value is 3. This option is only configurable for Glue version 2.0 and above.

Example:

```
glueContext.forEachBatch(data_frame_datasource0, (dataFrame: Dataset[Row], batchId:
 Long) =>
   {
      if (dataFrame.count() > 0)
        {
          val datasource0 = DynamicFrame(glueContext.addIngestionTimeColumns(dataFrame,
 "hour"), glueContext)
          // @type: DataSink
```

```
          // @args: [database = "tempdb", table_name = "fromoptionsoutput",
 stream_batch_time = "100 seconds",
          //      stream_checkpoint_location = "s3://from-options-testing-eu-central-1/
fromOptionsOutput/checkpoint/",
          //      transformation_ctx = "datasink1"]
          // @return: datasink1
          // @inputs: [frame = datasource0]
          val options_datasink1 = JsonOptions(
             Map("partitionKeys" -> Seq("ingest_year", "ingest_month","ingest_day",
 "ingest_hour"),
             "enableUpdateCatalog" -> true))
          val datasink1 = glueContext.getCatalogSink(
             database = "tempdb",
             tableName = "fromoptionsoutput",
             redshiftTmpDir = "",
             transformationContext = "datasink1",
             additionalOptions = options_datasink1).writeDynamicFrame(datasource0)
        }
   }, JsonOptions("""{"windowSize" : "100 seconds",
         "checkpointLocation" : "s3://from-options-testing-eu-central-1/
fromOptionsOutput/checkpoint/"}"""))
```

def getCatalogSink

```
def getCatalogSink( database : String,
        tableName : String,
        redshiftTmpDir : String = "",
        transformationContext : String = ""
        additionalOptions: JsonOptions = JsonOptions.empty,
        catalogId: String = null
) : DataSink
```

Creates a DataSink that writes to a location specified in a table that is defined in the Data Catalog.

- `database` — The database name in the Data Catalog.
- `tableName` — The table name in the Data Catalog.
- `redshiftTmpDir` — The temporary staging directory to be used with certain data sinks. Set to empty by default.
- `transformationContext` — The transformation context that is associated with the sink to be used by job bookmarks. Set to empty by default.
- `additionalOptions` – Additional options provided to AWS Glue.

- `catalogId` — The catalog ID (account ID) of the Data Catalog being accessed. When null, the default account ID of the caller is used.

Returns the `DataSink`.

def getCatalogSource

```
def getCatalogSource( database : String,
                      tableName : String,
                      redshiftTmpDir : String = "",
                      transformationContext : String = ""
                      pushDownPredicate : String = " "
                      additionalOptions: JsonOptions = JsonOptions.empty,
                      catalogId: String = null
                    ) : DataSource
```

Creates a DataSource trait that reads data from a table definition in the Data Catalog.

- `database` — The database name in the Data Catalog.
- `tableName` — The table name in the Data Catalog.
- `redshiftTmpDir` — The temporary staging directory to be used with certain data sinks. Set to empty by default.
- `transformationContext` — The transformation context that is associated with the sink to be used by job bookmarks. Set to empty by default.
- `pushDownPredicate` – Filters partitions without having to list and read all the files in your dataset. For more information, see Pre-filtering using pushdown predicates.
- `additionalOptions` – A collection of optional name-value pairs. The possible options include those listed in Connection types and options for ETL in AWS Glue for Spark except for `endpointUrl`, `streamName`, `bootstrap.servers`, `security.protocol`, `topicName`, `classification`, and `delimiter`. Another supported option is `catalogPartitionPredicate`:

  `catalogPartitionPredicate` — You can pass a catalog expression to filter based on the index columns. This pushes down the filtering to the server side. For more information, see AWS Glue Partition Indexes. Note that `push_down_predicate` and `catalogPartitionPredicate` use different syntaxes. The former one uses Spark SQL standard syntax and the later one uses JSQL parser.

- `catalogId` — The catalog ID (account ID) of the Data Catalog being accessed. When null, the default account ID of the caller is used.

Returns the `DataSource`.

Example for streaming source

```
val data_frame_datasource0 = glueContext.getCatalogSource(
    database = "tempdb",
    tableName = "test-stream-input",
    redshiftTmpDir = "",
    transformationContext = "datasource0",
    additionalOptions = JsonOptions("""{
        "startingPosition": "TRIM_HORIZON", "inferSchema": "false"}""")
    ).getDataFrame()
```

def getJDBCSink

```
def getJDBCSink( catalogConnection : String,
                 options : JsonOptions,
                 redshiftTmpDir : String = "",
                 transformationContext : String = "",
                 catalogId: String = null
               ) : DataSink
```

Creates a DataSink that writes to a JDBC database that is specified in a `Connection` object in the Data Catalog. The `Connection` object has information to connect to a JDBC sink, including the URL, user name, password, VPC, subnet, and security groups.

- `catalogConnection` — The name of the connection in the Data Catalog that contains the JDBC URL to write to.
- `options` — A string of JSON name-value pairs that provide additional information that is required to write to a JDBC data store. This includes:
  - *dbtable* (required) — The name of the JDBC table. For JDBC data stores that support schemas within a database, specify `schema.table-name`. If a schema is not provided, then the default "public" schema is used. The following example shows an options parameter that points to a schema named `test` and a table named `test_table` in database `test_db`.

    ```
    options = JsonOptions("""{"dbtable": "test.test_table", "database": "test_db"}""")
    ```

  - *database* (required) — The name of the JDBC database.
  - Any additional options passed directly to the SparkSQL JDBC writer. For more information, see Redshift data source for Spark.
- `redshiftTmpDir` — A temporary staging directory to be used with certain data sinks. Set to empty by default.
- `transformationContext` — The transformation context that is associated with the sink to be used by job bookmarks. Set to empty by default.
- `catalogId` — The catalog ID (account ID) of the Data Catalog being accessed. When null, the default account ID of the caller is used.

Example code:

```
getJDBCSink(catalogConnection = "my-connection-name", options =
 JsonOptions("""{"dbtable": "my-jdbc-table", "database": "my-jdbc-db"}"""),
 redshiftTmpDir = "", transformationContext = "datasink4")
```

Returns the `DataSink`.

def getSink

```
def getSink( connectionType : String,
             connectionOptions : JsonOptions,
             transformationContext : String = ""
           ) : DataSink
```

Creates a DataSink that writes data to a destination like Amazon Simple Storage Service (Amazon S3), JDBC, or the AWS Glue Data Catalog, or an Apache Kafka or Amazon Kinesis data stream.

- `connectionType` — The type of the connection. See the section called "Connection parameters".
- `connectionOptions` — A string of JSON name-value pairs that provide additional information to establish the connection with the data sink. See the section called "Connection parameters".
- `transformationContext` — The transformation context that is associated with the sink to be used by job bookmarks. Set to empty by default.

Returns the `DataSink`.

def getSinkWithFormat

```
def getSinkWithFormat( connectionType : String,
                       options : JsonOptions,
                       transformationContext : String = "",
                       format : String = null,
                       formatOptions : JsonOptions = JsonOptions.empty
                     ) : DataSink
```

Creates a DataSink that writes data to a destination like Amazon S3, JDBC, or the Data Catalog, or an Apache Kafka or Amazon Kinesis data stream. Also sets the format for the data to be written out to the destination.

- `connectionType` — The type of the connection. See the section called "Connection parameters".
- `options` — A string of JSON name-value pairs that provide additional information to establish a connection with the data sink. See the section called "Connection parameters".
- `transformationContext` — The transformation context that is associated with the sink to be used by job bookmarks. Set to empty by default.
- `format` — The format of the data to be written out to the destination.
- `formatOptions` — A string of JSON name-value pairs that provide additional options for formatting data at the destination. See Data format options.

Returns the `DataSink`.

def getSource

```
def getSource( connectionType : String,
               connectionOptions : JsonOptions,
               transformationContext : String = ""
               pushDownPredicate
             ) : DataSource
```

Creates a DataSource trait that reads data from a source like Amazon S3, JDBC, or the AWS Glue Data Catalog. Also supports Kafka and Kinesis streaming data sources.

- `connectionType` — The type of the data source. See the section called "Connection parameters".

- `connectionOptions` — A string of JSON name-value pairs that provide additional information for establishing a connection with the data source. For more information, see the section called "Connection parameters".

  A Kinesis streaming source requires the following connection options: `streamARN`, `startingPosition`, `inferSchema`, and `classification`.

  A Kafka streaming source requires the following connection options: `connectionName`, `topicName`, `startingOffsets`, `inferSchema`, and `classification`.
- `transformationContext` — The transformation context that is associated with the sink to be used by job bookmarks. Set to empty by default.
- `pushDownPredicate` — Predicate on partition columns.

Returns the `DataSource`.

Example for Amazon Kinesis streaming source:

```
val kinesisOptions = jsonOptions()
data_frame_datasource0 = glueContext.getSource("kinesis",
 kinesisOptions).getDataFrame()

private def jsonOptions(): JsonOptions = {
    new JsonOptions(
      s"""{"streamARN": "arn:aws:kinesis:eu-central-1:123456789012:stream/
fromOptionsStream",
         |"startingPosition": "TRIM_HORIZON",
         |"inferSchema": "true",
         |"classification": "json"}""".stripMargin)
}
```

Example for Kafka streaming source:

```
val kafkaOptions = jsonOptions()
val data_frame_datasource0 = glueContext.getSource("kafka",
 kafkaOptions).getDataFrame()

private def jsonOptions(): JsonOptions = {
    new JsonOptions(
      s"""{"connectionName": "ConfluentKafka",
         |"topicName": "kafka-auth-topic",
```

```
        |"startingOffsets": "earliest",
        |"inferSchema": "true",
        |"classification": "json"}""".stripMargin)
 }
```

def getSourceWithFormat

```
def getSourceWithFormat( connectionType : String,
                         options : JsonOptions,
                         transformationContext : String = "",
                         format : String = null,
                         formatOptions : JsonOptions = JsonOptions.empty
                       ) : DataSource
```

Creates a DataSource trait that reads data from a source like Amazon S3, JDBC, or the AWS Glue Data Catalog, and also sets the format of data stored in the source.

- `connectionType` – The type of the data source. See the section called "Connection parameters".
- `options` – A string of JSON name-value pairs that provide additional information for establishing a connection with the data source. See the section called "Connection parameters".
- `transformationContext` – The transformation context that is associated with the sink to be used by job bookmarks. Set to empty by default.
- `format` – The format of the data that is stored at the source. When the `connectionType` is "s3", you can also specify `format`. Can be one of "avro", "csv", "grokLog", "ion", "json", "xml", "parquet", or "orc".
- `formatOptions` – A string of JSON name-value pairs that provide additional options for parsing data at the source. See Data format options.

Returns the `DataSource`.

Examples

Create a DynamicFrame from a data source that is a comma-separated values (CSV) file on Amazon S3:

```
val datasource0 = glueContext.getSourceWithFormat(
    connectionType="s3",
```

```
    options =JsonOptions(s"""{"paths": [ "s3://csv/nycflights.csv"]}"""),
    transformationContext = "datasource0",
    format = "csv",
    formatOptions=JsonOptions(s"""{"withHeader":"true","separator": ","}""")
    ).getDynamicFrame()
```

Create a DynamicFrame from a data source that is a PostgreSQL using a JDBC connection:

```
val datasource0 = glueContext.getSourceWithFormat(
    connectionType="postgresql",
    options =JsonOptions(s"""{
      "url":"jdbc:postgresql://databasePostgres-1.rds.amazonaws.com:5432/testdb",
      "dbtable": "public.company",
      "redshiftTmpDir":"",
      "user":"username",
      "password":"password123"
    }"""),
    transformationContext = "datasource0").getDynamicFrame()
```

Create a DynamicFrame from a data source that is a MySQL using a JDBC connection:

```
 val datasource0 = glueContext.getSourceWithFormat(
    connectionType="mysql",
    options =JsonOptions(s"""{
      "url":"jdbc:mysql://databaseMysql-1.rds.amazonaws.com:3306/testdb",
      "dbtable": "athenatest_nycflights13_csv",
      "redshiftTmpDir":"",
      "user":"username",
      "password":"password123"
    }"""),
    transformationContext = "datasource0").getDynamicFrame()
```

def getSparkSession

```
def getSparkSession : SparkSession
```

Gets the `SparkSession` object associated with this GlueContext. Use this SparkSession object to register tables and UDFs for use with `DataFrame` created from DynamicFrames.

Returns the SparkSession.

def startTransaction

```
def startTransaction(readOnly: Boolean):String
```

Start a new transaction. Internally calls the Lake Formation startTransaction API.

- `readOnly` – (Boolean) Indicates whether this transaction should be read only or read and write. Writes made using a read-only transaction ID will be rejected. Read-only transactions do not need to be committed.

Returns the transaction ID.

def commitTransaction

```
def commitTransaction(transactionId: String, waitForCommit: Boolean): Boolean
```

Attempts to commit the specified transaction. `commitTransaction` may return before the transaction has finished committing. Internally calls the Lake Formation commitTransaction API.

- `transactionId` – (String) The transaction to commit.
- `waitForCommit` – (Boolean) Determines whether the `commitTransaction` returns immediately. The default value is true. If false, `commitTransaction` polls and waits until the transaction is committed. The amount of wait time is restricted to 1 minute using exponential backoff with a maximum of 6 retry attempts.

Returns a Boolean to indicate whether the commit is done or not.

def cancelTransaction

```
def cancelTransaction(transactionId: String): Unit
```

Attempts to cancel the specified transaction. Internally calls the Lake Formation CancelTransaction API.

- `transactionId` – (String) The transaction to cancel.

Returns a `TransactionCommittedException` exception if the transaction was previously committed.

def this

```
def this( sc : SparkContext,
          minPartitions : Int,
          targetPartitions : Int )
```

Creates a `GlueContext` object using the specified `SparkContext`, minimum partitions, and target partitions.

- `sc` — The `SparkContext`.
- `minPartitions` — The minimum number of partitions.
- `targetPartitions` — The target number of partitions.

Returns the `GlueContext`.

def this

```
def this( sc : SparkContext )
```

Creates a `GlueContext` object with the provided `SparkContext`. Sets the minimum partitions to 10 and target partitions to 20.

- `sc` — The `SparkContext`.

Returns the `GlueContext`.

def this

```
def this( sparkContext : JavaSparkContext )
```

Creates a `GlueContext` object with the provided `JavaSparkContext`. Sets the minimum partitions to 10 and target partitions to 20.

- `sparkContext` — The `JavaSparkContext`.

Returns the `GlueContext`.

MappingSpec

Package: com.amazonaws.services.glue

MappingSpec case class

```
case class MappingSpec( sourcePath: SchemaPath,
                        sourceType: DataType,
                        targetPath: SchemaPath,
                        targetType: DataTyp
                       ) extends Product4[String, String, String, String] {
  override def _1: String = sourcePath.toString
  override def _2: String = ExtendedTypeName.fromDataType(sourceType)
  override def _3: String = targetPath.toString
  override def _4: String = ExtendedTypeName.fromDataType(targetType)
}
```

- `sourcePath` — The `SchemaPath` of the source field.
- `sourceType` — The `DataType` of the source field.
- `targetPath` — The `SchemaPath` of the target field.
- `targetType` — The `DataType` of the target field.

A `MappingSpec` specifies a mapping from a source path and a source data type to a target path and a target data type. The value at the source path in the source frame appears in the target frame at the target path. The source data type is cast to the target data type.

It extends from `Product4` so that you can handle any `Product4` in your `applyMapping` interface.

MappingSpec object

```
object MappingSpec
```

The `MappingSpec` object has the following members:

Val orderingByTarget

```
val orderingByTarget: Ordering[MappingSpec]
```

Def apply

```
def apply( sourcePath : String,
           sourceType : DataType,
           targetPath : String,
           targetType : DataType
         ) : MappingSpec
```

Creates a `MappingSpec`.

- `sourcePath` — A string representation of the source path.
- `sourceType` — The source `DataType`.
- `targetPath` — A string representation of the target path.
- `targetType` — The target `DataType`.

Returns a `MappingSpec`.

Def apply

```
def apply( sourcePath : String,
           sourceTypeString : String,
           targetPath : String,
           targetTypeString : String
         ) : MappingSpec
```

Creates a `MappingSpec`.

- `sourcePath` — A string representation of the source path.
- `sourceType` — A string representation of the source data type.
- `targetPath` — A string representation of the target path.
- `targetType` — A string representation of the target data type.

Returns a MappingSpec.

Def apply

```
def apply( product : Product4[String, String, String, String] ) : MappingSpec
```

Creates a `MappingSpec`.

- `product` — The `Product4` of the source path, source data type, target path, and target data type.

Returns a `MappingSpec`.

AWS Glue Scala ResolveSpec APIs

Topics

- ResolveSpec object
- ResolveSpec case class

Package: com.amazonaws.services.glue

ResolveSpec object

ResolveSpec

```
object ResolveSpec
```

Def

```
def apply( path : String,
           action : String
         ) : ResolveSpec
```

Creates a `ResolveSpec`.

- `path` — A string representation of the choice field that needs to be resolved.
- `action` — A resolution action. The action can be one of the following: `Project`, `KeepAsStruct`, or `Cast`.

Returns the `ResolveSpec`.

Def

```
def apply( product : Product2[String, String] ) : ResolveSpec
```

Creates a ResolveSpec.

- product — Product2 of: source path, resolution action.

Returns the ResolveSpec.

ResolveSpec case class

```
case class ResolveSpec extends Product2[String, String]  (
           path : SchemaPath,
           action : String )
```

Creates a ResolveSpec.

- path — The SchemaPath of the choice field that needs to be resolved.
- action — A resolution action. The action can be one of the following: Project, KeepAsStruct, or Cast.

ResolveSpec def methods

```
def _1 : String
```

```
def _2 : String
```

AWS Glue Scala ArrayNode APIs

Package: com.amazonaws.services.glue.types

ArrayNode case class

ArrayNode

```
case class ArrayNode extends DynamicNode  (
           value : ArrayBuffer[DynamicNode] )
```

ArrayNode def methods

```
def add( node : DynamicNode )
```

```
def clone
```

```
def equals( other : Any )
```

```
def get( index : Int ) : Option[DynamicNode]
```

```
def getValue
```

```
def hashCode : Int
```

```
def isEmpty : Boolean
```

```
def nodeType
```

```
def remove( index : Int )
```

```
def this
```

```
def toIterator : Iterator[DynamicNode]
```

```
def toJson : String
```

```
def update( index : Int,
            node : DynamicNode )
```

AWS Glue Scala BinaryNode APIs

Package: com.amazonaws.services.glue.types

BinaryNode case class

BinaryNode

```
case class BinaryNode extends ScalarNode(value, TypeCode.BINARY)  (
           value : Array[Byte] )
```

BinaryNode val fields

- ordering

BinaryNode def methods

```
def clone
```

```
def equals( other : Any )
```

```
def hashCode : Int
```

AWS Glue Scala BooleanNode APIs

Package: com.amazonaws.services.glue.types

BooleanNode case class

BooleanNode

```
case class BooleanNode extends ScalarNode(value, TypeCode.BOOLEAN)  (
           value : Boolean )
```

BooleanNode val fields

- ordering

BooleanNode def methods

```
def equals( other : Any )
```

AWS Glue Scala ByteNode APIs

Package: com.amazonaws.services.glue.types

ByteNode case class

ByteNode

```
case class ByteNode extends ScalarNode(value, TypeCode.BYTE)  (
           value : Byte )
```

ByteNode val fields

- ordering

ByteNode def methods

```
def equals( other : Any )
```

AWS Glue Scala DateNode APIs

Package: com.amazonaws.services.glue.types

DateNode case class

DateNode

```
case class DateNode extends ScalarNode(value, TypeCode.DATE)  (
           value : Date )
```

DateNode val fields

- ordering

DateNode def methods

```
def equals( other : Any )
```

```
def this( value : Int )
```

AWS Glue Scala DecimalNode APIs

Package: com.amazonaws.services.glue.types

DecimalNode case class

DecimalNode

```
case class DecimalNode extends ScalarNode(value, TypeCode.DECIMAL)  (
           value : BigDecimal )
```

DecimalNode val fields

- `ordering`

DecimalNode def methods

```
def equals( other : Any )
```

```
def this( value : Decimal )
```

AWS Glue Scala DoubleNode APIs

Package: com.amazonaws.services.glue.types

DoubleNode case class

DoubleNode

```
case class DoubleNode extends ScalarNode(value, TypeCode.DOUBLE)  (
           value : Double )
```

DoubleNode val fields

- `ordering`

DoubleNode def methods

```
def equals( other : Any )
```

AWS Glue Scala DynamicNode APIs

Topics

- DynamicNode class
- DynamicNode object

Package: com.amazonaws.services.glue.types

DynamicNode class

DynamicNode

```
class DynamicNode extends Serializable with Cloneable
```

DynamicNode def methods

```
def getValue : Any
```

Get plain value and bind to the current record:

```
def nodeType : TypeCode
```

```
def toJson : String
```

Method for debug:

```
def toRow( schema : Schema,
           options : Map[String, ResolveOption]
         ) : Row
```

```
def typeName : String
```

DynamicNode object

DynamicNode

```
object DynamicNode
```

DynamicNode def methods

```
def quote( field : String,
           useQuotes : Boolean
         ) : String
```

```
def quote( node : DynamicNode,
```

```
            useQuotes : Boolean
          ) : String
```

EvaluateDataQuality class

AWS Glue Data Quality is in preview release for AWS Glue and is subject to change.

Package: com.amazonaws.services.glue.dq

```
object EvaluateDataQuality
```

Def apply

```
def apply(frame: DynamicFrame,
            ruleset: String,
            publishingOptions: JsonOptions = JsonOptions.empty): DynamicFrame
```

Evaluates a data quality ruleset against a `DynamicFrame`, and returns a new `DynamicFrame` with results of the evaluation. To learn more about AWS Glue Data Quality, see AWS Glue Data Quality.

- `frame` – The `DynamicFrame` that you want to evaluate the data quality of.
- `ruleset` – A Data Quality Definition Language (DQDL) ruleset in string format. To learn more about DQDL, see the Data Quality Definition Language (DQDL) reference guide.
- `publishingOptions` – A dictionary that specifies the following options for publishing evaluation results and metrics:
  - `dataQualityEvaluationContext` – A string that specifies the namespace under which AWS Glue should publish Amazon CloudWatch metrics and the data quality results. The aggregated metrics appear in CloudWatch, while the full results appear in the AWS Glue Studio interface.
    - Required: No
    - Default value: `default_context`
  - `enableDataQualityCloudWatchMetrics` – Specifies whether the results of the data quality evaluation should be published to CloudWatch. You specify a namespace for the metrics using the `dataQualityEvaluationContext` option.
    - Required: No
    - Default value: False

- `enableDataQualityResultsPublishing` – Specifies whether the data quality results should be visible on the **Data Quality** tab in the AWS Glue Studio interface.
  - Required: No
  - Default value: True
- `resultsS3Prefix` – Specifies the Amazon S3 location where AWS Glue can write the data quality evaluation results.
  - Required: No
  - Default value: "" (empty string)

Example

The following example code demonstrates how to evaluate data quality for a `DynamicFrame` before performing a `SelectFields` transform. The script verifies that all data quality rules pass before it attempts the transform.

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.MappingSpec
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._
import com.amazonaws.services.glue.dq.EvaluateDataQuality

object GlueApp {
  def main(sysArgs: Array[String]) {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    // @params: [JOB_NAME]
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)

    // Create DynamicFrame with data
    val Legislators_Area = glueContext.getCatalogSource(database="legislators",
 tableName="areas_json", transformationContext="S3bucket_node1").getDynamicFrame()

    // Define data quality ruleset
    val DQ_Ruleset = """
      Rules = [ColumnExists "id"]
```

```
    """

    // Evaluate data quality
    val DQ_Results = EvaluateDataQuality.apply(frame=Legislators_Area,
 ruleset=DQ_Ruleset, publishingOptions=JsonOptions("""{"dataQualityEvaluationContext":
 "Legislators_Area", "enableDataQualityMetrics": "true",
 "enableDataQualityResultsPublishing": "true"}"""))
    assert(DQ_Results.filter(_.getField("Outcome").contains("Failed")).count == 0,
 "Failing DQ rules for Legislators_Area caused the job to fail.")

    // Script generated for node Select Fields
    val SelectFields_Results = Legislators_Area.selectFields(paths=Seq("id", "name"),
 transformationContext="Legislators_Area")

    Job.commit()
  }
}
```

AWS Glue Scala FloatNode APIs

Package: com.amazonaws.services.glue.types

FloatNode case class

FloatNode

```
case class FloatNode extends ScalarNode(value, TypeCode.FLOAT)  (
           value : Float )
```

FloatNode val fields

- `ordering`

FloatNode def methods

```
def equals( other : Any )
```

FillMissingValues class

Package: com.amazonaws.services.glue.ml

```
object FillMissingValues
```

Def apply

```
def apply(frame: DynamicFrame,
          missingValuesColumn: String,
          outputColumn: String = "",
          transformationContext: String = "",
          callSite: CallSite = CallSite("Not provided", ""),
          stageThreshold: Long = 0,
          totalThreshold: Long = 0): DynamicFrame
```

Fills a dynamic frame's missing values in a specified column and returns a new frame with estimates in a new column. For rows without missing values, the specified column's value is duplicated to the new column.

- `frame` — The DynamicFrame in which to fill missing values. Required.
- `missingValuesColumn` — The column containing missing values (`null` values and empty strings). Required.
- `outputColumn` — The name of the new column that will contain estimated values for all rows whose value was missing. Optional; the default is the value of `missingValuesColumn` suffixed by `"_filled"`.
- `transformationContext` — A unique string that is used to identify state information (optional).
- `callSite` — Used to provide context information for error reporting. (optional).
- `stageThreshold` — The maximum number of errors that can occur in the transformation before it errors out (optional; the default is zero).
- `totalThreshold` — The maximum number of errors that can occur overall before processing errors out (optional; the default is zero).

Returns a new dynamic frame with one additional column that contains estimations for rows with missing values and the present value for other rows.

FindMatches class

Package: com.amazonaws.services.glue.ml

```
object FindMatches
```

Def apply

```
def apply(frame: DynamicFrame,
            transformId: String,
            transformationContext: String = "",
            callSite: CallSite = CallSite("Not provided", ""),
            stageThreshold: Long = 0,
            totalThreshold: Long = 0,
            enforcedMatches: DynamicFrame = null): DynamicFrame,
   computeMatchConfidenceScores: Boolean
```

Find matches in an input frame and return a new frame with a new column containing a unique ID per match group.

- `frame` — The DynamicFrame in which to find matches. Required.
- `transformId` — A unique ID associated with the FindMatches transform to apply on the input frame. Required.
- `transformationContext` — Identifier for this `DynamicFrame`. The `transformationContext` is used as a key for the job bookmark state that is persisted across runs. Optional.
- `callSite` — Used to provide context information for error reporting. These values are automatically set when calling from Python. Optional.
- `stageThreshold` — The maximum number of error records allowed from the computation of this `DynamicFrame` before throwing an exception, excluding records present in the previous `DynamicFrame`. Optional. The default is zero.
- `totalThreshold` — The maximum number of total errors records before an exception is thrown, including those from previous frames. Optional. The default is zero.
- `enforcedMatches` — The frame for enforced matches. Optional. The default is `null`.
- `computeMatchConfidenceScores` — A Boolean value indicating whether to compute a confidence score for each group of matching records. Optional. The default is false.

Returns a new dynamic frame with a unique identifier assigned to each group of matching records.

FindIncrementalMatches class

Package: com.amazonaws.services.glue.ml

```
object FindIncrementalMatches
```

Def apply

```
apply(existingFrame: DynamicFrame,
            incrementalFrame: DynamicFrame,
            transformId: String,
            transformationContext: String = "",
            callSite: CallSite = CallSite("Not provided", ""),
            stageThreshold: Long = 0,
            totalThreshold: Long = 0,
            enforcedMatches: DynamicFrame = null): DynamicFrame,
   computeMatchConfidenceScores: Boolean
```

Find matches across the existing and incremental frames and return a new frame with a column containing a unique ID per match group.

- `existingframe` — An existing frame which has been assigned a matching ID for each group. Required.
- `incrementalframe` — An incremental frame used to find matches against the existing frame. Required.
- `transformId` — A unique ID associated with the FindIncrementalMatches transform to apply on the input frames. Required.
- `transformationContext` — Identifier for this `DynamicFrame`. The `transformationContext` is used as a key for the job bookmark state that is persisted across runs. Optional.
- `callSite` — Used to provide context information for error reporting. These values are automatically set when calling from Python. Optional.
- `stageThreshold` — The maximum number of error records allowed from the computation of this `DynamicFrame` before throwing an exception, excluding records present in the previous `DynamicFrame`. Optional. The default is zero.
- `totalThreshold` — The maximum number of total errors records before an exception is thrown, including those from previous frames. Optional. The default is zero.
- `enforcedMatches` — The frame for enforced matches. Optional. The default is `null`.
- `computeMatchConfidenceScores` — A Boolean value indicating whether to compute a confidence score for each group of matching records. Optional. The default is false.

Returns a new dynamic frame with a unique identifier assigned to each group of matching records.

AWS Glue Scala IntegerNode APIs

Package: com.amazonaws.services.glue.types

IntegerNode case class

IntegerNode

```
case class IntegerNode extends ScalarNode(value, TypeCode.INT)  (
           value : Int )
```

IntegerNode val fields

- `ordering`

IntegerNode def methods

```
def equals( other : Any )
```

AWS Glue Scala LongNode APIs

Package: com.amazonaws.services.glue.types

LongNode case class

LongNode

```
case class LongNode extends ScalarNode(value, TypeCode.LONG)  (
           value : Long )
```

LongNode val fields

- `ordering`

LongNode def methods

```
def equals( other : Any )
```

AWS Glue Scala MapLikeNode APIs

Package: com.amazonaws.services.glue.types

MapLikeNode class

MapLikeNode

```
class MapLikeNode extends DynamicNode  (
          value : mutable.Map[String, DynamicNode] )
```

MapLikeNode def methods

```
def clear : Unit
```

```
def get( name : String ) : Option[DynamicNode]
```

```
def getValue
```

```
def has( name : String ) : Boolean
```

```
def isEmpty : Boolean
```

```
def put( name : String,
         node : DynamicNode
       ) : Option[DynamicNode]
```

```
def remove( name : String ) : Option[DynamicNode]
```

```
def toIterator : Iterator[(String, DynamicNode)]
```

```
def toJson : String
```

```
def toJson( useQuotes : Boolean ) : String
```

Example: Given this JSON:

```
{"foo": "bar"}
```

If `useQuotes == true`, `toJson` yields `{"foo": "bar"}`. If `useQuotes == false`, `toJson` yields `{foo: bar}` @return.

AWS Glue Scala MapNode APIs

Package: com.amazonaws.services.glue.types

MapNode case class

MapNode

```
case class MapNode extends MapLikeNode(value)  (
           value : mutable.Map[String, DynamicNode] )
```

MapNode def methods

```
def clone
```

```
def equals( other : Any )
```

```
def hashCode : Int
```

```
def nodeType
```

```
def this
```

```

AWS Glue Scala GlueArgParser APIs

Package: com.amazonaws.services.glue.util

GlueArgParser object

GlueArgParser

```
object GlueArgParser
```

This is strictly consistent with the Python version of `utils.getResolvedOptions` in the `AWSGlueDataplanePython` package.

GlueArgParser def methods

```
def getResolvedOptions( args : Array[String],
                        options : Array[String]
                      ) : Map[String, String]
```

```
def initParser( userOptionsSet : mutable.Set[String] ) : ArgumentParser
```

Example Retrieving arguments passed to a job

To retrieve job arguments, you can use the `getResolvedOptions` method. Consider the following example, which retrieves a job argument named `aws_region`.

```
val args = GlueArgParser.getResolvedOptions(sysArgs,
 Seq("JOB_NAME","aws_region").toArray)
Job.init(args("JOB_NAME"), glueContext, args.asJava)
val region = args("aws_region")
println(region)
```

AWS Glue Scala job APIs

Package: com.amazonaws.services.glue.util

Job object

Job

```
object Job
```

Job def methods

```
def commit
```

```
def init( jobName : String,
          glueContext : GlueContext,
          args : java.util.Map[String, String] = Map[String, String]().asJava
        ) : this.type
```

```
def init( jobName : String,
          glueContext : GlueContext,
          endpoint : String,
          args : java.util.Map[String, String]
        ) : this.type
```

```
def isInitialized
```

```
def reset
```

```
def runId
```

Features and optimizations for programming AWS Glue for Spark ETL scripts

The following sections describe techniques and values that apply generally to AWS Glue for Spark ETL (extract, transform, and load) programming in any language.

Topics

- Connection types and options for ETL in AWS Glue for Spark

- Data format options for inputs and outputs in AWS Glue for Spark
- AWS Glue Data Catalog support for Spark SQL jobs
- Using job bookmarks
- Using Sensitive Data Detection outside AWS Glue Studio
- AWS Glue Visual Job API

Connection types and options for ETL in AWS Glue for Spark

In AWS Glue for Spark, various PySpark and Scala methods and transforms specify the connection type using a `connectionType` parameter. They specify connection options using a `connectionOptions` or `options` parameter.

The `connectionType` parameter can take the values shown in the following table. The associated `connectionOptions` (or `options`) parameter values for each type are documented in the following sections. Except where otherwise noted, the parameters apply when the connection is used as a source or sink.

For sample code that demonstrates setting and using connection options, see the homepage for each connection type.

connectionType	**Connects to**
dynamodb	Amazon DynamoDB database
kinesis	Amazon Kinesis Data Streams
s3	Amazon S3
documentdb	Amazon DocumentDB (with MongoDB compatibility) database
opensearch	Amazon OpenSearch Service.
redshift	Amazon Redshift database
kafka	Kafka or Amazon Managed Streaming for Apache Kafka
azurecosmos	Azure Cosmos for NoSQL.
azuresql	Azure SQL.

connectionType	Connects to
bigquery	Google BigQuery.
mongodb	MongoDB database, including MongoDB Atlas.
sqlserver	Microsoft SQL Server database (see JDBC connections)
mysql	MySQL database (see JDBC connections)
oracle	Oracle database (see JDBC connections)
postgresql	PostgreSQL database (see JDBC connections)
saphana	SAP HANA.
snowflake	Snowflake data lake
teradata	Teradata Vantage.
vertica	Vertica.
custom.*	Spark, Athena, or JDBC data stores (see Custom and AWS Marketplace connectionType values
marketplace.*	Spark, Athena, or JDBC data stores (see Custom and AWS Marketplace connectionType values)

DynamoDB connections

You can use AWS Glue for Spark to read from and write to tables in DynamoDB in AWS Glue. You connect to DynamoDB using IAM permissions attached to your AWS Glue job. AWS Glue supports writing data into another AWS account's DynamoDB table. For more information, see the section called “Cross-account cross-Region access to DynamoDB tables”.

The original DynamoDB connector uses Glue DynamicFrame objects to work with the data extracted from DynamoDB. AWS Glue 5.0+ introduces a new DynamoDB connector with Spark DataFrame support that provides native Spark DataFrame support.

In addition to the AWS Glue DynamoDB ETL connector, you can read from DynamoDB using the DynamoDB export connector, that invokes a DynamoDB `ExportTableToPointInTime` request

and stores it in an Amazon S3 location you supply, in the format of DynamoDB JSON. AWS Glue then creates a DynamicFrame object by reading the data from the Amazon S3 export location.

The DynamoDB writer is available in AWS Glue version 1.0 or later versions. The AWS Glue DynamoDB export connector is available in AWS Glue version 2.0 or later versions. The new DataFrame-based DynamoDB connector is available in AWS Glue version 5.0 or later versions.

For more information about DynamoDB, consult Amazon DynamoDB documentation.

> **Note**
>
> The DynamoDB ETL reader does not support filters or pushdown predicates.

Configuring DynamoDB connections

To connect to DynamoDB from AWS Glue, grant the IAM role associated with your AWS Glue job permission to interact with DynamoDB. For more information about permissions necessary to read or write from DynamoDB, consult Actions, resources, and condition keys for DynamoDB in the IAM documentation.

In the following situations, you may need additional configuration:

- When using the DynamoDB export connector, you will need to configure IAM so your job can request DynamoDB table exports. Additionally, you will need to identify an Amazon S3 bucket for the export and provide appropriate permissions in IAM for DynamoDB to write to it, and for your AWS Glue job to read from it. For more information, consult Request a table export in DynamoDB.
- If your AWS Glue job has specific Amazon VPC connectivity requirements, use the `NETWORK` AWS Glue connection type to provide network options. Since access to DynamoDB is authorized by IAM, there is no need for a AWS Glue DynamoDB connection type.

Reading from and writing to DynamoDB

The following code examples show how to read from (via the ETL connector) and write to DynamoDB tables. They demonstrate reading from one table and writing to another table.

Python

```
import sys
```

```
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
glue_context= GlueContext(SparkContext.getOrCreate())
job = Job(glue_context)
job.init(args["JOB_NAME"], args)

dyf = glue_context.create_dynamic_frame.from_options(
    connection_type="dynamodb",
    connection_options={"dynamodb.input.tableName": test_source,
        "dynamodb.throughput.read.percent": "1.0",
        "dynamodb.splits": "100"
    }
)
print(dyf.getNumPartitions())

glue_context.write_dynamic_frame_from_options(
    frame=dyf,
    connection_type="dynamodb",
    connection_options={"dynamodb.output.tableName": test_sink,
        "dynamodb.throughput.write.percent": "1.0"
    }
)

job.commit()
```

Scala

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.DynamoDbDataSink
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._

object GlueApp {

  def main(sysArgs: Array[String]): Unit = {
```

```
    val glueContext = new GlueContext(SparkContext.getOrCreate())
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)

    val dynamicFrame = glueContext.getSourceWithFormat(
      connectionType = "dynamodb",
      options = JsonOptions(Map(
        "dynamodb.input.tableName" -> test_source,
        "dynamodb.throughput.read.percent" -> "1.0",
        "dynamodb.splits" -> "100"
      ))
    ).getDynamicFrame()

    print(dynamicFrame.getNumPartitions())

    val dynamoDbSink: DynamoDbDataSink =  glueContext.getSinkWithFormat(
      connectionType = "dynamodb",
      options = JsonOptions(Map(
        "dynamodb.output.tableName" -> test_sink,
        "dynamodb.throughput.write.percent" -> "1.0"
      ))
    ).asInstanceOf[DynamoDbDataSink]

    dynamoDbSink.writeDynamicFrame(dynamicFrame)

    Job.commit()
  }

}
```

Using the DynamoDB export connector

The export connector performs better than the ETL connector when the DynamoDB table size is larger than 80 GB. In addition, given that the export request is conducted outside from the Spark processes in an AWS Glue job, you can enable auto scaling of AWS Glue jobs to save DPU usage during the export request. With the export connector, you also do not need to configure the number of splits for Spark executor parallelism or DynamoDB throughput read percentage.

Note

DynamoDB has specific requirements to invoke the `ExportTableToPointInTime` requests. For more information, see Requesting a table export in DynamoDB. For example, Point-in-Time-Restore (PITR) needs to be enabled on the table to use this connector.
The DynamoDB connector also supports AWS KMS encryption for DynamoDB exports to Amazon S3. Supplying your security configuration in the AWS Glue job configuration enables AWS KMS encryption for a DynamoDB export. The KMS key must be in the same Region as the Amazon S3 bucket.
Note that additional charges for DynamoDB export and Amazon S3 storage costs apply. Exported data in Amazon S3 persists after a job run finishes so you can reuse it without additional DynamoDB exports. A requirement for using this connector is that point-in-time recovery (PITR) is enabled for the table.
The DynamoDB ETL connector or export connector do not support filters or pushdown predicates to be applied at the DynamoDB source.

The following code examples show how to read from (via the export connector) and print the number of partitions.

Python

```
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
glue_context= GlueContext(SparkContext.getOrCreate())
job = Job(glue_context)
job.init(args["JOB_NAME"], args)

dyf = glue_context.create_dynamic_frame.from_options(
    connection_type="dynamodb",
    connection_options={
        "dynamodb.export": "ddb",
        "dynamodb.tableArn": test_source,
        "dynamodb.s3.bucket": bucket_name,
        "dynamodb.s3.prefix": bucket_prefix,
```

```
        "dynamodb.s3.bucketOwner": account_id_of_bucket,
    }
)
print(dyf.getNumPartitions())

job.commit()
```

Scala

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.DynamoDbDataSink
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._

object GlueApp {

  def main(sysArgs: Array[String]): Unit = {
    val glueContext = new GlueContext(SparkContext.getOrCreate())
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)

    val dynamicFrame = glueContext.getSourceWithFormat(
      connectionType = "dynamodb",
      options = JsonOptions(Map(
        "dynamodb.export" -> "ddb",
        "dynamodb.tableArn" -> test_source,
        "dynamodb.s3.bucket" -> bucket_name,
        "dynamodb.s3.prefix" -> bucket_prefix,
        "dynamodb.s3.bucketOwner" -> account_id_of_bucket,
      ))
    ).getDynamicFrame()

    print(dynamicFrame.getNumPartitions())

    Job.commit()
  }

}
```

These examples show how to do the read from (via the export connector) and print the number of partitions from an AWS Glue Data Catalog table that has a dynamodb classification:

Python

```
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
glue_context= GlueContext(SparkContext.getOrCreate())
job = Job(glue_context)
job.init(args["JOB_NAME"], args)

dynamicFrame = glue_context.create_dynamic_frame.from_catalog(
        database=catalog_database,
        table_name=catalog_table_name,
        additional_options={
            "dynamodb.export": "ddb",
            "dynamodb.s3.bucket": s3_bucket,
            "dynamodb.s3.prefix": s3_bucket_prefix
        }
    )
print(dynamicFrame.getNumPartitions())

job.commit()
```

Scala

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.DynamoDbDataSink
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._

object GlueApp {

  def main(sysArgs: Array[String]): Unit = {
```

```
    val glueContext = new GlueContext(SparkContext.getOrCreate())
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)

    val dynamicFrame = glueContext.getCatalogSource(
        database = catalog_database,
        tableName = catalog_table_name,
        additionalOptions = JsonOptions(Map(
            "dynamodb.export" -> "ddb",
            "dynamodb.s3.bucket" -> s3_bucket,
            "dynamodb.s3.prefix" -> s3_bucket_prefix
        ))
    ).getDynamicFrame()
    print(dynamicFrame.getNumPartitions())
)
```

Simplifying usage of DynamoDB export JSON

The DynamoDB exports with the AWS Glue DynamoDB export connector results in JSON files of specific nested structures. For more information, see Data objects. AWS Glue supplies a DynamicFrame transformation, which can unnest such structures into an easier-to-use form for downstream applications.

The transform can be invoked in one of two ways. You can set the connection option `"dynamodb.simplifyDDBJson"` with the value `"true"` when calling a method to read from DynamoDB. You can also call the transform as a method independently available in the AWS Glue library.

Consider the following schema generated by a DynamoDB export:

```
root
|-- Item: struct
|    |-- parentMap: struct
|    |    |-- M: struct
|    |    |    |-- childMap: struct
|    |    |    |    |-- M: struct
|    |    |    |    |    |-- appName: struct
|    |    |    |    |    |    |-- S: string
|    |    |    |    |    |-- packageName: struct
|    |    |    |    |    |    |-- S: string
|    |    |    |    |    |-- updatedAt: struct
|    |    |    |    |    |    |-- N: string
```

```
|    |-- strings: struct
|    |    |-- SS: array
|    |    |    |-- element: string
|    |-- numbers: struct
|    |    |-- NS: array
|    |    |    |-- element: string
|    |-- binaries: struct
|    |    |-- BS: array
|    |    |    |-- element: string
|    |-- isDDBJson: struct
|    |    |-- BOOL: boolean
|    |-- nullValue: struct
|    |    |-- NULL: boolean
```

The `simplifyDDBJson` transform will simplify this to:

```
root
|-- parentMap: struct
|    |-- childMap: struct
|    |    |-- appName: string
|    |    |-- packageName: string
|    |    |-- updatedAt: string
|-- strings: array
|    |-- element: string
|-- numbers: array
|    |-- element: string
|-- binaries: array
|    |-- element: string
|-- isDDBJson: boolean
|-- nullValue: null
```

> **Note**
>
> `simplifyDDBJson` is available in AWS Glue 3.0 and later versions. The `unnestDDBJson` transform is also available to simplify DynamoDB export JSON. We encourage users to transition to `simplifyDDBJson` from `unnestDDBJson`.

Configuring paralleism in DynamoDB operations

To improve performance, you can tune certain parameters available for the DynamoDB connector. Your goal when tuning paralleism parameters is to maximize the use of the provisioned AWS

Glue workers. Then, if you need more performance, we recommend you to scale out your job by increasing the number of DPUs.

You can alter the parallelism in a DynamoDB read operation using the `dynamodb.splits` parameter when using the ETL connector. When reading with the export connector, you do not need to configure the number of splits for Spark executor parallelism. You can alter the parallelism in a DynamoDB write operation with `dynamodb.output.numParallelTasks`.

Reading with the DynamoDB ETL connector

We recommend you to calculate `dynamodb.splits` based on the maximum number of workers set in your job configuration and the following `numSlots` calculation. If autoscaling, the actual number of workers available may change under that cap. For more information about setting the maximum number of workers, see **Number of workers** (`NumberOfWorkers`) in the section called "Configuring Spark job properties".

- `numExecutors = NumberOfWorkers - 1`

  For context, one executor is reserved for the Spark driver; other executors are used to process data.
- `numSlotsPerExecutor =`

  AWS Glue 3.0 and later versions
  - 4 if `WorkerType` is `G.1X`
  - 8 if `WorkerType` is `G.2X`
  - 16 if `WorkerType` is `G.4X`
  - 32 if `WorkerType` is `G.8X`

  AWS Glue 2.0 and legacy versions
  - 8 if `WorkerType` is `G.1X`
  - 16 if `WorkerType` is `G.2X`
- `numSlots = numSlotsPerExecutor * numExecutors`

We recommend you set `dynamodb.splits` to the number of slots available, `numSlots`.

Writing to DynamoDB

The `dynamodb.output.numParallelTasks` parameter is used to determine WCU per Spark task, using the following calculation:

`permittedWcuPerTask = ( TableWCU * dynamodb.throughput.write.percent ) / dynamodb.output.numParallelTasks`

The DynamoDB writer will function best if configuration accurately represents the number of Spark tasks writing to DynamoDB. In some cases, you may need to override the default calculation to improve write performance. If you do not specify this parameter, the permitted WCU per Spark task will be automatically calculated by the following formula:

-
  - `numPartitions = dynamicframe.getNumPartitions()`
  - `numSlots` (as defined previously in this section)
  - `numParallelTasks = min(numPartitions, numSlots)`
- Example 1. DPU=10, WorkerType=Standard. Input DynamicFrame has 100 RDD partitions.
  - `numPartitions = 100`
  - `numExecutors = (10 - 1) * 2 - 1 = 17`
  - `numSlots = 4 * 17 = 68`
  - `numParallelTasks = min(100, 68) = 68`
- Example 2. DPU=10, WorkerType=Standard. Input DynamicFrame has 20 RDD partitions.
  - `numPartitions = 20`
  - `numExecutors = (10 - 1) * 2 - 1 = 17`
  - `numSlots = 4 * 17 = 68`
  - `numParallelTasks = min(20, 68) = 20`

> **Note**
>
> Jobs on legacy AWS Glue versions and those using Standard workers require different methods to calculate the number of slots. If you need to performance tune these jobs, we recommend you transition to supported AWS Glue versions.

DynamoDB connection option reference

Designates a connection to Amazon DynamoDB.

Connection options differ for a source connection and a sink connection.

"connectionType": "dynamodb" with the ETL connector as source

Use the following connection options with `"connectionType": "dynamodb"` as a source, when using the AWS Glue DynamoDB ETL connector:

- `"dynamodb.input.tableName"`: (Required) The DynamoDB table to read from.
- `"dynamodb.throughput.read.percent"`: (Optional) The percentage of read capacity units (RCU) to use. The default is set to "0.5". Acceptable values are from "0.1" to "1.5", inclusive.
  - `0.5` represents the default read rate, meaning that AWS Glue will attempt to consume half of the read capacity of the table. If you increase the value above `0.5`, AWS Glue increases the request rate; decreasing the value below `0.5` decreases the read request rate. (The actual read rate will vary, depending on factors such as whether there is a uniform key distribution in the DynamoDB table.)
  - When the DynamoDB table is in on-demand mode, AWS Glue handles the read capacity of the table as 40000. For exporting a large table, we recommend switching your DynamoDB table to on-demand mode.
- `"dynamodb.splits"`: (Optional) Defines how many splits we partition this DynamoDB table into while reading. The default is set to "1". Acceptable values are from "1" to "1,000,000", inclusive.

  1 represents there is no parallelism. We highly recommend that you specify a larger value for better performance by using the below formula. For more information on appropriately setting a value, see the section called “DynamoDB parallelism”.
- `"dynamodb.sts.roleArn"`: (Optional) The IAM role ARN to be assumed for cross-account access. This parameter is available in AWS Glue 1.0 or later.
- `"dynamodb.sts.roleSessionName"`: (Optional) STS session name. The default is set to "glue-dynamodb-read-sts-session". This parameter is available in AWS Glue 1.0 or later.

"connectionType": "dynamodb" with the AWS Glue DynamoDB export connector as source

Use the following connection options with "connectionType": "dynamodb" as a source, when using the AWS Glue DynamoDB export connector, which is available only for AWS Glue version 2.0 onwards:

- `"dynamodb.export"`: (Required) A string value:
  - If set to ddb enables the AWS Glue DynamoDB export connector where a new `ExportTableToPointInTimeRequest` will be invoked during the AWS Glue job. A

new export will be generated with the location passed from `dynamodb.s3.bucket` and `dynamodb.s3.prefix`.

- If set to `s3` enables the AWS Glue DynamoDB export connector but skips the creation of a new DynamoDB export and instead uses the `dynamodb.s3.bucket` and `dynamodb.s3.prefix` as the Amazon S3 location of a past export of that table.

- `"dynamodb.tableArn"`: (Required) The DynamoDB table to read from.
- `"dynamodb.unnestDDBJson"`: (Optional) Default: false. Valid values: boolean. If set to true, performs an unnest transformation of the DynamoDB JSON structure that is present in exports. It is an error to set `"dynamodb.unnestDDBJson"` and `"dynamodb.simplifyDDBJson"` to true at the same time. In AWS Glue 3.0 and later versions, we recommend you use `"dynamodb.simplifyDDBJson"` for better behavior when simplifying DynamoDB Map types. For more information, see the section called “Simplifying usage of DynamoDB export JSON”.
- `"dynamodb.simplifyDDBJson"`: (Optional) Default: false. Valid values: boolean. If set to true, performs a transformation to simplify the schema of the DynamoDB JSON structure that is present in exports. This has the same purpose as the `"dynamodb.unnestDDBJson"` option but provides better support for DynamoDB Map types or even nested Map types in your DynamoDB table. This option is available in AWS Glue 3.0 and later versions. It is an error to set `"dynamodb.unnestDDBJson"` and `"dynamodb.simplifyDDBJson"` to true at the same time. For more information, see the section called “Simplifying usage of DynamoDB export JSON”.
- `"dynamodb.s3.bucket"`: (Optional) Indicates the Amazon S3 bucket location in which the DynamoDB `ExportTableToPointInTime` process is to be conducted. The file format for the export is DynamoDB JSON.
  - `"dynamodb.s3.prefix"`: (Optional) Indicates the Amazon S3 prefix location inside the Amazon S3 bucket in which the DynamoDB `ExportTableToPointInTime` loads are to be stored. If neither `dynamodb.s3.prefix` nor `dynamodb.s3.bucket` are specified, these values will default to the Temporary Directory location specified in the AWS Glue job configuration. For more information, see Special Parameters Used by AWS Glue.
  - `"dynamodb.s3.bucketOwner"`: Indicates the bucket owner needed for cross-account Amazon S3 access.
- `"dynamodb.sts.roleArn"`: (Optional) The IAM role ARN to be assumed for cross-account access and/or cross-Region access for the DynamoDB table. Note: The same IAM role ARN will be used to access the Amazon S3 location specified for the `ExportTableToPointInTime` request.
- `"dynamodb.sts.roleSessionName"`: (Optional) STS session name. The default is set to "glue-dynamodb-read-sts-session".

- `"dynamodb.exportTime"` (Optional) Valid values: strings representing ISO-8601 instants. A point-in-time at which the export should be made.
- `"dynamodb.sts.region"`: (Required if making a cross-region call using a regional endpoint) The region hosting the DynamoDB table you want to read.

"connectionType": "dynamodb" with the ETL connector as sink

Use the following connection options with `"connectionType": "dynamodb"` as a sink:

- `"dynamodb.output.tableName"`: (Required) The DynamoDB table to write to.
- `"dynamodb.throughput.write.percent"`: (Optional) The percentage of write capacity units (WCU) to use. The default is set to "0.5". Acceptable values are from "0.1" to "1.5", inclusive.
  - `0.5` represents the default write rate, meaning that AWS Glue will attempt to consume half of the write capacity of the table. If you increase the value above 0.5, AWS Glue increases the request rate; decreasing the value below 0.5 decreases the write request rate. (The actual write rate will vary, depending on factors such as whether there is a uniform key distribution in the DynamoDB table).
  - When the DynamoDB table is in on-demand mode, AWS Glue handles the write capacity of the table as `40000`. For importing a large table, we recommend switching your DynamoDB table to on-demand mode.
- `"dynamodb.output.numParallelTasks"`: (Optional) Defines how many parallel tasks write into DynamoDB at the same time. Used to calculate permissive WCU per Spark task. In most cases, AWS Glue will calculate a reasonable default for this value. For more information, see the section called “DynamoDB parallelism”.
- `"dynamodb.output.retry"`: (Optional) Defines how many retries we perform when there is a `ProvisionedThroughputExceededException` from DynamoDB. The default is set to "10".
- `"dynamodb.sts.roleArn"`: (Optional) The IAM role ARN to be assumed for cross-account access.
- `"dynamodb.sts.roleSessionName"`: (Optional) STS session name. The default is set to "glue-dynamodb-write-sts-session".

Cross-account cross-Region access to DynamoDB tables

AWS Glue ETL jobs support both cross-region and cross-account access to DynamoDB tables. AWS Glue ETL jobs support both reading data from another AWS Account's DynamoDB table, and

writing data into another AWS Account's DynamoDB table. AWS Glue also supports both reading from a DynamoDB table in another region, and writing into a DynamoDB table in another region. This section gives instructions on setting up the access, and provides an example script.

The procedures in this section reference an IAM tutorial for creating an IAM role and granting access to the role. The tutorial also discusses assuming a role, but here you will instead use a job script to assume the role in AWS Glue. This tutorial also contains information about general cross-account practices. For more information, see Tutorial: Delegate Access Across AWS Accounts Using IAM Roles in the *IAM User Guide*.

Create a role

Follow step 1 in the tutorial to create an IAM role in account A. When defining the permissions of the role, you can choose to attach existing policies such as `AmazonDynamoDBReadOnlyAccess`, or `AmazonDynamoDBFullAccess` to allow the role to read/write DynamoDB. The following example shows creating a role named `DynamoDBCrossAccessRole`, with the permission policy `AmazonDynamoDBFullAccess`.

Grant access to the role

Follow step 2 in the tutorial in the *IAM User Guide* to allow account B to switch to the newly-created role. The following example creates a new policy with the following statement:

JSON

```
{
  "Version":"2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "sts:AssumeRole",
    "Resource": "arn:aws:iam::111122223333:role/DynamoDBCrossAccessRole"
  }
}
```

Then, you can attach this policy to the group/role/user you would like to use to access DynamoDB.

Assume the role in the AWS Glue job script

Now, you can log in to account B and create an AWS Glue job. To create a job, refer to the instructions at Configuring job properties for Spark jobs in AWS Glue.

In the job script you need to use the `dynamodb.sts.roleArn` parameter to assume the `DynamoDBCrossAccessRole` role. Assuming this role allows you to get the temporary credentials, which need to be used to access DynamoDB in account B. Review these example scripts.

For a cross-account read across regions (ETL connector):

```
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
glue_context= GlueContext(SparkContext.getOrCreate())
job = Job(glue_context)
job.init(args["JOB_NAME"], args)

dyf = glue_context.create_dynamic_frame_from_options(
    connection_type="dynamodb",
    connection_options={
    "dynamodb.region": "us-east-1",
    "dynamodb.input.tableName": "test_source",
    "dynamodb.sts.roleArn": "<DynamoDBCrossAccessRole's ARN>"
    }
)
dyf.show()
job.commit()
```

For a cross-account read across regions (ELT connector):

```
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
glue_context= GlueContext(SparkContext.getOrCreate())
job = Job(glue_context)
job.init(args["JOB_NAME"], args)

dyf = glue_context.create_dynamic_frame_from_options(
    connection_type="dynamodb",
```

```
    connection_options={
        "dynamodb.export": "ddb",
        "dynamodb.tableArn": "<test_source ARN>",
        "dynamodb.sts.roleArn": "<DynamoDBCrossAccessRole's ARN>"
    }
)
dyf.show()
job.commit()
```

For a read and cross-account write across regions:

```
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
glue_context= GlueContext(SparkContext.getOrCreate())
job = Job(glue_context)
job.init(args["JOB_NAME"], args)

dyf = glue_context.create_dynamic_frame_from_options(
    connection_type="dynamodb",
    connection_options={
        "dynamodb.region": "us-east-1",
        "dynamodb.input.tableName": "test_source"
    }
)
dyf.show()

glue_context.write_dynamic_frame_from_options(
    frame=dyf,
    connection_type="dynamodb",
    connection_options={
        "dynamodb.region": "us-west-2",
        "dynamodb.output.tableName": "test_sink",
        "dynamodb.sts.roleArn": "<DynamoDBCrossAccessRole's ARN>"
    }
)

job.commit()
```

DynamoDB connector with Spark DataFrame support

DynamoDB connector with Spark DataFrame support allows you to read from and write to tables in DynamoDB using Spark DataFrame APIs. The connector setup steps are the same as for DynamicFrame-based connector and can be found here.

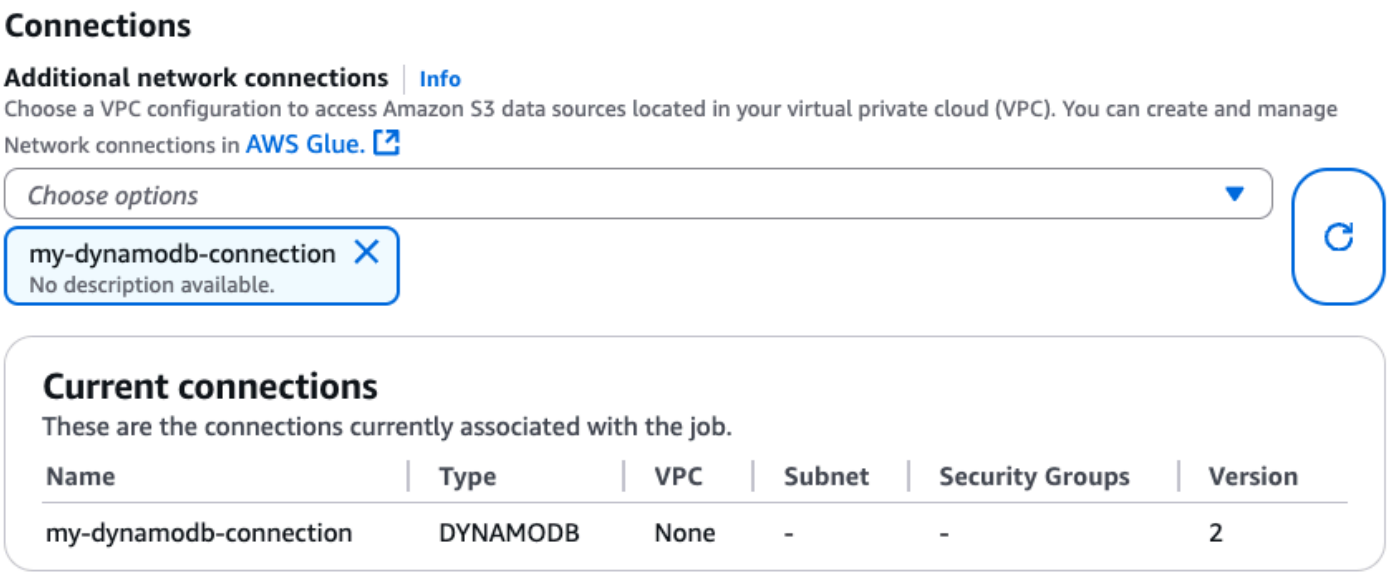
In order to load in the DataFrame-based connector library, make sure to attach a DynamoDB connection to the Glue job.

Note

Glue console UI currently does not support creating a DynamoDB connection. You can use Glue CLI (CreateConnection) to create a DynamoDB connection:

```
aws glue create-connection \
    --connection-input '{ \
        "Name": "my-dynamodb-connection", \
        "ConnectionType": "DYNAMODB", \
        "ConnectionProperties": {}, \
        "ValidateCredentials": false, \
        "ValidateForComputeEnvironments": ["SPARK"] \
    }'
```

Upon creating the DynamoDB connection, you can attach it to your Glue job via CLI (CreateJob, UpdateJob) or directly in the "Job details" page:



Upon ensuring a connection with DYNAMODB Type is attached to your Glue job, you can utilize the following read, write, and export operations from the DataFrame-based connector.

Reading from and writing to DynamoDB with the DataFrame-based connector

The following code examples show how to read from and write to DynamoDB tables via the DataFrame-based connector. They demonstrate reading from one table and writing to another table.

Python

```
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
glue_context= GlueContext(SparkContext.getOrCreate())
spark = glueContext.spark_session
job = Job(glue_context)
job.init(args["JOB_NAME"], args)

# Read from DynamoDB
df = spark.read.format("dynamodb") \
    .option("dynamodb.input.tableName", "test-source") \
```

```
    .option("dynamodb.throughput.read.ratio", "0.5") \
    .option("dynamodb.consistentRead", "false") \
    .load()

print(df.rdd.getNumPartitions())

# Write to DynamoDB
df.write \
  .format("dynamodb") \
  .option("dynamodb.output.tableName", "test-sink") \
  .option("dynamodb.throughput.write.ratio", "0.5") \
  .option("dynamodb.item.size.check.enabled", "true") \
  .save()

job.commit()
```

Scala

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {

    val glueContext = new GlueContext(SparkContext.getOrCreate())
    val spark = glueContext.getSparkSession
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)

    val df = spark.read
      .format("dynamodb")
      .option("dynamodb.input.tableName", "test-source")
      .option("dynamodb.throughput.read.ratio", "0.5")
      .option("dynamodb.consistentRead", "false")
      .load()

    print(df.rdd.getNumPartitions)

    df.write
      .format("dynamodb")
```

```
      .option("dynamodb.output.tableName", "test-sink")
      .option("dynamodb.throughput.write.ratio", "0.5")
      .option("dynamodb.item.size.check.enabled", "true")
      .save()

    job.commit()
  }
}
```

Using DynamoDB export via the DataFrame-based connector

The export operation is preferred to read operation for DynamoDB table sizes larger than 80 GB. The following code examples show how to read from a table, export to S3, and print the number of partitions via the DataFrame-based connector.

> **Note**
>
> The DynamoDB export functionality is available through the Scala `DynamoDBExport` object. Python users can access it via Spark's JVM interop or use the AWS SDK for Python (boto3) with the DynamoDB `ExportTableToPointInTime` API.

Scala

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.util.{GlueArgParser, Job}
import org.apache.spark.SparkContext
import glue.spark.dynamodb.DynamoDBExport
import scala.collection.JavaConverters._

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val glueContext = new GlueContext(SparkContext.getOrCreate())
    val spark = glueContext.getSparkSession
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)

    val options = Map(
      "dynamodb.export" -> "ddb",
      "dynamodb.tableArn" -> "arn:aws:dynamodb:us-east-1:123456789012:table/my-
table",
```

```
      "dynamodb.s3.bucket" -> "my-s3-bucket",
      "dynamodb.s3.prefix" -> "my-s3-prefix",
      "dynamodb.simplifyDDBJson" -> "true"
    )
    val df = DynamoDBExport.fullExport(spark, options)

    print(df.rdd.getNumPartitions)
    df.count()

    Job.commit()
  }
}
```

Configuration Options

Read options

Option	Description	Default
`dynamodb.input.tableName`	DynamoDB table name (required)	-
`dynamodb.throughput.read`	The read capacity units (RCU) to use. If unspecified, `dynamodb.throughput.read.ratio` is used for calculation.	-
`dynamodb.throughput.read.ratio`	The ratio of read capacity units (RCU) to use	0.5
`dynamodb.table.read.capacity`	The read capacity of the on-demand table used for calculating the throughput. This parameter is effective only in on-demand capacity tables. Default to warm throughput read units.	-
`dynamodb.splits`	Defines how many segments used in parallel scan operations. If not provided, connector will calculate a reasonable default value.	-

Option	Description	Default
dynamodb.consistentRead	Whether to use strongly consistent reads	FALSE
dynamodb.input.retry	Defines how many retries we perform when there is a retryable exception.	10

Write options

Option	Description	Default
dynamodb.output.tableName	DynamoDB table name (required)	-
dynamodb.throughput.write	The write capacity units (WCU) to use. If unspecified, dynamodb.throughput.write.ratio is used for calculation.	-
dynamodb.throughput.write.ratio	The ratio of write capacity units (WCU) to use	0.5
dynamodb.table.write.capacity	The write capacity of the on-demand table used for calculating the throughput. This parameter is effective only in on-demand capacity tables. Default to warm throughput write units.	-
dynamodb.item.size.check.enabled	If true, the connector calculate the item size and abort if the size exceeds the maximum size, before writing to DynamoDB table.	TRUE
dynamodb.output.retry	Defines how many retries we perform when there is a retryable exception.	10

Export options

Option	Description	Default
dynamodb.export	If set to ddb enables the AWS Glue DynamoDB export connector where a new ExportTableToPointInTimeRequest will be invoked during the AWS Glue job. A new export will be generated with the location passed from dynamodb.s3.bucket and dynamodb.s3.prefix. If set to s3 enables the AWS Glue DynamoDB export connector but skips the creation of a new DynamoDB export and instead uses the dynamodb.s3.bucket and dynamodb.s3.prefix as the Amazon S3 location of the past exported of that table.	ddb
dynamodb.tableArn	The DynamoDB table to read from. Required if dynamodb.export is set to ddb.	
dynamodb.simplifyDDBJson	If set to true, performs a transformation to simplify the schema of the DynamoDB JSON structure that is present in exports.	FALSE
dynamodb.s3.bucket	The S3 bucket to store temporary data during DynamoDB export (required)	
dynamodb.s3.prefix	The S3 prefix to store temporary data during DynamoDB export	
dynamodb.s3.bucketOwner	Indicate the bucket owner needed for cross-account Amazon S3 access	
dynamodb.s3.sse.algorithm	Type of encryption used on the bucket where temporary data will be stored. Valid values are AES256 and KMS.	

Option	Description	Default
dynamodb.s3.sse.kmsKeyId	The ID of the AWS KMS managed key used to encrypt the S3 bucket where temporary data will be stored (if applicable).	
dynamodb.exportTime	A point-in-time at which the export should be made. Valid values: strings representing ISO-8601 instants.	

General options

Option	Description	Default
dynamodb.sts.roleArn	The IAM role ARN to be assumed for cross-account access	-
dynamodb.sts.roleSessionName	STS session name	glue-dynamodb-sts-session
dynamodb.sts.region	Region for the STS client (for cross-region role assumption)	Same as region option

Kinesis connections

You can use a Kinesis connection to read and write to Amazon Kinesis data streams using information stored in a Data Catalog table, or by providing information to directly access the data stream. You can read information from Kinesis into a Spark DataFrame, then convert it to a AWS Glue DynamicFrame. You can write DynamicFrames to Kinesis in a JSON format. If you directly access the data stream, use these options to provide the information about how to access the data stream.

If you use getCatalogSource or create_data_frame_from_catalog to consume records from a Kinesis streaming source, the job has the Data Catalog database and table name information, and can use that to obtain some basic parameters for reading

from the Kinesis streaming source. If you use `getSource`, `getSourceWithFormat`, `createDataFrameFromOptions` or `create_data_frame_from_options`, you must specify these basic parameters using the connection options described here.

You can specify the connection options for Kinesis using the following arguments for the specified methods in the `GlueContext` class.

- Scala
  - `connectionOptions`: Use with `getSource`, `createDataFrameFromOptions`, `getSink`
  - `additionalOptions`: Use with `getCatalogSource`, `getCatalogSink`
  - `options`: Use with `getSourceWithFormat`, `getSinkWithFormat`
- Python
  - `connection_options`: Use with `create_data_frame_from_options`, `write_dynamic_frame_from_options`
  - `additional_options`: Use with `create_data_frame_from_catalog`, `write_dynamic_frame_from_catalog`
  - `options`: Use with `getSource`, `getSink`

For notes and restrictions about Streaming ETL jobs, consult the section called “Streaming ETL notes and restrictions”.

Configure Kinesis

To connect to a Kinesis data stream in an AWS Glue Spark job, you will need some prerequisites:

- If reading, the AWS Glue job must have Read access level IAM permissions to the Kinesis data stream.
- If writing, the AWS Glue job must have Write access level IAM permissions to the Kinesis data stream.

In certain cases, you will need to configure additional prerequisites:

- If your AWS Glue job is configured with **Additional network connections** (typically to connect to other datasets) and one of those connections provides Amazon VPC **Network options**, this will direct your job to communicate over Amazon VPC. In this case you will also need to configure your Kinesis data stream to communicate over Amazon VPC. You can do this by

creating an interface VPC endpoint between your Amazon VPC and Kinesis data stream. For more information, see Using Kinesis Data Streams with Interface VPC Endpoints.

- When specifying Amazon Kinesis Data Streams in another account, you must setup the roles and policies to allow cross-account access. For more information, see Example: Read From a Kinesis Stream in a Different Account.

For more information about Streaming ETL job prerequisites, consult the section called "Streaming ETL jobs".

Example: Reading from Kinesis streams

Example: Reading from Kinesis streams

Used in conjunction with the section called "forEachBatch".

Example for Amazon Kinesis streaming source:

```
kinesis_options =
   { "streamARN": "arn:aws:kinesis:us-east-2:777788889999:stream/fromOptionsStream",
     "startingPosition": "TRIM_HORIZON",
     "inferSchema": "true",
     "classification": "json"
   }
data_frame_datasource0 =
 glueContext.create_data_frame.from_options(connection_type="kinesis",
 connection_options=kinesis_options)
```

Example: Writing to Kinesis streams

Example: Reading from Kinesis streams

Used in conjunction with the section called "forEachBatch".

Example for Amazon Kinesis streaming source:

```
kinesis_options =
   { "streamARN": "arn:aws:kinesis:us-east-2:777788889999:stream/fromOptionsStream",
     "startingPosition": "TRIM_HORIZON",
     "inferSchema": "true",
     "classification": "json"
```

```
    }
data_frame_datasource0 =
 glueContext.create_data_frame.from_options(connection_type="kinesis",
 connection_options=kinesis_options)
```

Kinesis connection option reference

Designates connection options for Amazon Kinesis Data Streams.

Use the following connection options for Kinesis streaming data sources:

- `"streamARN"` (Required) Used for Read/Write. The ARN of the Kinesis data stream.
- `"classification"` (Required for read) Used for Read. The file format used by the data in the record. Required unless provided through the Data Catalog.
- `"streamName"` – (Optional) Used for Read. The name of a Kinesis data stream to read from. Used with `endpointUrl`.
- `"endpointUrl"` – (Optional) Used for Read. Default: "https://kinesis.us-east-1.amazonaws.com". The AWS endpoint of the Kinesis stream. You do not need to change this unless you are connecting to a special region.
- `"partitionKey"` – (Optional) Used for Write. The Kinesis partition key used when producing records.
- `"delimiter"` (Optional) Used for Read. The value separator used when `classification` is CSV. Default is `","`
- `"startingPosition"`: (Optional) Used for Read. The starting position in the Kinesis data stream to read data from. The possible values are `"latest"`, `"trim_horizon"`, `"earliest"`, or a Timestamp string in UTC format in the pattern `yyyy-mm-ddTHH:MM:SSZ` (where `Z` represents a UTC timezone offset with a +/-. For example "2023-04-04T08:00:00-04:00"). The default value is `"latest"`. Note: the Timestamp string in UTC Format for `"startingPosition"` is supported only for AWS Glue version 4.0 or later.
- `"failOnDataLoss"`: (Optional) Fail the job if any active shard is missing or expired. The default value is `"false"`.
- `"awsSTSRoleARN"`: (Optional) Used for Read/Write. The Amazon Resource Name (ARN) of the role to assume using AWS Security Token Service (AWS STS). This role must have permissions for describe or read record operations for the Kinesis data stream. You must use this parameter when accessing a data stream in a different account. Used in conjunction with `"awsSTSSessionName"`.

- "awsSTSSessionName": (Optional) Used for Read/Write. An identifier for the session assuming the role using AWS STS. You must use this parameter when accessing a data stream in a different account. Used in conjunction with "awsSTSRoleARN".
- "awsSTSEndpoint": (Optional) The AWS STS endpoint to use when connecting to Kinesis with an assumed role. This allows using the regional AWS STS endpoint in a VPC, which is not possible with the default global endpoint.
- "maxFetchTimeInMs": (Optional) Used for Read. The maximum time spent for the job executor to read records for the current batch from the Kinesis data stream, specified in milliseconds (ms). Multiple GetRecords API calls may be made within this time. The default value is 1000.
- "maxFetchRecordsPerShard": (Optional) Used for Read. The maximum number of records to fetch per shard in the Kinesis data stream per microbatch. Note: The client can exceed this limit if the streaming job has already read extra records from Kinesis (in the same get-records call). If maxFetchRecordsPerShard needs to be strict then it needs to be a multiple of maxRecordPerRead. The default value is 100000.
- "maxRecordPerRead": (Optional) Used for Read. The maximum number of records to fetch from the Kinesis data stream in each getRecords operation. The default value is 10000.
- "addIdleTimeBetweenReads": (Optional) Used for Read. Adds a time delay between two consecutive getRecords operations. The default value is "False". This option is only configurable for Glue version 2.0 and above.
- "idleTimeBetweenReadsInMs": (Optional) Used for Read. The minimum time delay between two consecutive getRecords operations, specified in ms. The default value is 1000. This option is only configurable for Glue version 2.0 and above.
- "describeShardInterval": (Optional) Used for Read. The minimum time interval between two ListShards API calls for your script to consider resharding. For more information, see Strategies for Resharding in *Amazon Kinesis Data Streams Developer Guide*. The default value is 1s.
- "numRetries": (Optional) Used for Read. The maximum number of retries for Kinesis Data Streams API requests. The default value is 3.
- "retryIntervalMs": (Optional) Used for Read. The cool-off time period (specified in ms) before retrying the Kinesis Data Streams API call. The default value is 1000.
- "maxRetryIntervalMs": (Optional) Used for Read. The maximum cool-off time period (specified in ms) between two retries of a Kinesis Data Streams API call. The default value is 10000.

- "avoidEmptyBatches": (Optional) Used for Read. Avoids creating an empty microbatch job by checking for unread data in the Kinesis data stream before the batch is started. The default value is "False".
- "schema": (Required when inferSchema set to false) Used for Read. The schema to use to process the payload. If classification is avro the provided schema must be in the Avro schema format. If the classification is not avro the provided schema must be in the DDL schema format.

  The following are schema examples.

  Example in DDL schema format

  ```
  `column1` INT, `column2` STRING , `column3` FLOAT
  ```

  Example in Avro schema format

  ```
  {
    "type":"array",
    "items":
    {
      "type":"record",
      "name":"test",
      "fields":
      [
        {
          "name":"_id",
          "type":"string"
        },
        {
          "name":"index",
          "type":
          [
            "int",
            "string",
            "float"
          ]
        }
      ]
    }
  }
  ```

- "inferSchema": (Optional) Used for Read. The default value is 'false'. If set to 'true', the schema will be detected at runtime from the payload within foreachbatch.

- `"avroSchema"`: (Deprecated) Used for Read. Parameter used to specify a schema of Avro data when Avro format is used. This parameter is now deprecated. Use the `schema` parameter.
- `"addRecordTimestamp"`: (Optional) Used for Read. When this option is set to 'true', the data output will contain an additional column named "__src_timestamp" that indicates the time when the corresponding record received by the stream. The default value is 'false'. This option is supported in AWS Glue version 4.0 or later.
- `"emitConsumerLagMetrics"`: (Optional) Used for Read. When the option is set to 'true', for each batch, it will emit the metrics for the duration between the oldest record received by the stream and the time it arrives in AWS Glue to CloudWatch. The metric's name is "glue.driver.streaming.maxConsumerLagInMs". The default value is 'false'. This option is supported in AWS Glue version 4.0 or later.
- `"fanoutConsumerARN"`: (Optional) Used for Read. The ARN of a Kinesis stream consumer for the stream specified in `streamARN`. Used to enable enhanced fan-out mode for your Kinesis connection. For more information on consuming a Kinesis stream with enhanced fan-out, see the section called “Using enhanced fan-out in Kinesis streaming jobs”.
- `"recordMaxBufferedTime"` – (Optional) Used for Write. Default: 1000 (ms). Maximum time a record is buffered while waiting to be written.
- `"aggregationEnabled"` – (Optional) Used for Write. Default: true. Specifies if records should be aggregated before sending them to Kinesis.
- `"aggregationMaxSize"` – (Optional) Used for Write. Default: 51200 (bytes). If a record is larger than this limit, it will bypass the aggregator. Note Kinesis enforces a limit of 50KB on record size. If you set this beyond 50KB, oversize records will be rejected by Kinesis.
- `"aggregationMaxCount"` – (Optional) Used for Write. Default: 4294967295. Maximum number of items to pack into an aggregated record.
- `"producerRateLimit"` – (Optional) Used for Write. Default: 150 (%). Limits per-shard throughput sent from a single producer (such as your job), as a percentage of the backend limit.
- `"collectionMaxCount"` – (Optional) Used for Write. Default: 500. Maximum number of items to pack into an PutRecords request.
- `"collectionMaxSize"` – (Optional) Used for Write. Default: 5242880 (bytes). Maximum amount of data to send with a PutRecords request.

Using enhanced fan-out in Kinesis streaming jobs

An enhanced fan-out consumer is able to recieve records from a Kinesis stream with dedicated throughput that can be greater than typical consumers. This is done by optimizing the transfer protocol used to provide data to a Kinesis consumer, such as your job. For more information about Kinesis Enhanced Fan-Out, see the Kinesis documentation.

In enhanced fan-out mode, the `maxRecordPerRead` and `idleTimeBetweenReadsInMs` connection options no longer apply, as those parameters are not configurable when using enhanced fan-out. The configuration options for retries perform as described.

Use the following procedures to enable and disable enhanced fan-out for your streaming job. You should register a stream consumer for each job that will consume data from your stream.

To enable enhanced fan-out consumption on your job:

1. Register a stream consumer for your job using the Kinesis API. Follow the instructions to *register a consumer with enhanced fan-out using the Kinesis Data Streams API* in the Kinesis documentation. You will only need to follow the first step - calling RegisterStreamConsumer. Your request should return an ARN, *`consumerARN`*.
2. Set the connection option `fanoutConsumerARN` to *`consumerARN`* in your connection method arguments.
3. Restart your job.

To disable enhanced fan-out consumption on your job:

1. Remove the `fanoutConsumerARN` connection option from your method call.
2. Restart your job.
3. Follow the instructions to *deregister a consumer* in the Kinesis documentation. These instructions apply to the console, but can also be achieved through the Kinesis API. For more information about stream consumer deregistration through the Kinesis API, consult DeregisterStreamConsumer in the Kinesis documentation.

Amazon S3 connections

You can use AWS Glue for Spark to read and write files in Amazon S3. AWS Glue for Spark supports many common data formats stored in Amazon S3 out of the box, including CSV, Avro, JSON, Orc and Parquet. For more information about supported data formats, see the section called “Data

format options". Each data format may support a different set of AWS Glue features. Consult the page for your data format for the specifics of feature support. Additionally, you can read and write versioned files stored in the Hudi, Iceberg and Delta Lake data lake frameworks. For more information about data lake frameworks, see the section called "Data lake frameworks".

With AWS Glue you can partition your Amazon S3 objects into a folder structure while writing, then retrieve it by partition to improve performance using simple configuration. You can also set configuration to group small files together when transforming your data to improve performance. You can read and write `bzip2` and `gzip` archives in Amazon S3.

Topics

- Configuring S3 connections
- Amazon S3 connection option reference
- Deprecated connection syntaxes for data formats
- Excluding Amazon S3 storage classes
- Using Amazon S3 Express One Zone with AWS Glue
- Managing partitions for ETL output in AWS Glue
- Reading input files in larger groups
- Amazon VPC endpoints for Amazon S3

Configuring S3 connections

To connect to Amazon S3 in a AWS Glue with Spark job, you will need some prerequisites:

- The AWS Glue job must have IAM permissions for relevant Amazon S3 buckets.

In certain cases, you will need to configure additional prerequisites:

- When configuring cross-account access, appropriate access controls on the Amazon S3 bucket.
- For security reasons, you may choose to route your Amazon S3 requests through an Amazon VPC. This approach can introduce bandwidth and availability challenges. For more information, see the section called "Amazon VPC endpoints for Amazon S3".

Amazon S3 connection option reference

Designates a connection to Amazon S3.

Since Amazon S3 manages files rather than tables, in addition to specifying the connection properties provided in this document, you will need to specify additional configuration about your file type. You specify this information through data format options. For more information about format options, see the section called "Data format options". You can also specify this information by integrating with the AWS Glue Data Catalog.

For an example of the distinction between connection options and format options, consider how the the section called "create_dynamic_frame_from_options" method takes `connection_type`, `connection_options`, `format` and `format_options`. This section specifically discusses parameters provided to `connection_options`.

Use the following connection options with `"connectionType": "s3"`:

- `"paths"`: (Required) A list of the Amazon S3 paths to read from.
- `"exclusions"`: (Optional) A string containing a JSON list of Unix-style glob patterns to exclude. For example, `"[\"**.pdf\"]"` excludes all PDF files. For more information about the glob syntax that AWS Glue supports, see Include and Exclude Patterns.
- `"compressionType"`: or `"compression"`: (Optional) Specifies how the data is compressed. Use `"compressionType"` for Amazon S3 sources and `"compression"` for Amazon S3 targets. This is generally not necessary if the data has a standard file extension. Possible values are `"gzip"` and `"bzip2"`). Additional compression formats may be supported for specific formats. For the specifics of feature support, consult the data format page.
- `"groupFiles"`: (Optional) Grouping files is turned on by default when the input contains more than 50,000 files. To turn on grouping with fewer than 50,000 files, set this parameter to `"inPartition"`. To disable grouping when there are more than 50,000 files, set this parameter to `"none"`.
- `"groupSize"`: (Optional) The target group size in bytes. The default is computed based on the input data size and the size of your cluster. When there are fewer than 50,000 input files, `"groupFiles"` must be set to `"inPartition"` for this to take effect.
- `"recurse"`: (Optional) If set to true, recursively reads files in all subdirectories under the specified paths.
- `"maxBand"`: (Optional, advanced) This option controls the duration in milliseconds after which the `s3` listing is likely to be consistent. Files with modification timestamps falling within the last `maxBand` milliseconds are tracked specially when using `JobBookmarks` to account for Amazon S3 eventual consistency. Most users don't need to set this option. The default is 900000 milliseconds, or 15 minutes.

- `"maxFilesInBand"`: (Optional, advanced) This option specifies the maximum number of files to save from the last `maxBand` seconds. If this number is exceeded, extra files are skipped and only processed in the next job run. Most users don't need to set this option.
- `"isFailFast"`: (Optional) This option determines if an AWS Glue ETL job throws reader parsing exceptions. If set to `true`, jobs fail fast if four retries of the Spark task fail to parse the data correctly.
- `"catalogPartitionPredicate"`: (Optional) Used for Read. The contents of a SQL `WHERE` clause. Used when reading from Data Catalog tables with a very large quantity of partitions. Retrieves matching partitions from Data Catalog indices. Used with `push_down_predicate`, an option on the the section called “create_dynamic_frame_from_catalog” method (and other similar methods). For more information, see the section called “Catalog partition predicates”.
- `"partitionKeys"`: (Optional) Used for Write. An array of column label strings. AWS Glue will partition your data as specified by this configuration. For more information, see the section called “Writing partitions”.
- `"excludeStorageClasses"`: (Optional) Used for Read. An array of strings specifying Amazon S3 storage classes. AWS Glue will exclude Amazon S3 objects based on this configuration. For more information, see the section called “Excluding Amazon S3 storage classes”.

Deprecated connection syntaxes for data formats

Certain data formats can be accessed using a specific connection type syntax. This syntax is deprecated. We recommend you specify your formats using the `s3` connection type and the format options provided in the section called “Data format options” instead.

"connectionType": "Orc"

Designates a connection to files stored in Amazon S3 in the Apache Hive Optimized Row Columnar (ORC) file format.

Use the following connection options with `"connectionType": "orc"`:

- `paths`: (Required) A list of the Amazon S3 paths to read from.
- *(Other option name/value pairs)*: Any additional options, including formatting options, are passed directly to the SparkSQL `DataSource`.

"connectionType": "parquet"

Designates a connection to files stored in Amazon S3 in the Apache Parquet file format.

Use the following connection options with `"connectionType": "parquet"`:

- `paths`: (Required) A list of the Amazon S3 paths to read from.
- *(Other option name/value pairs)*: Any additional options, including formatting options, are passed directly to the SparkSQL `DataSource`.

Excluding Amazon S3 storage classes

If you're running AWS Glue ETL jobs that read files or partitions from Amazon Simple Storage Service (Amazon S3), you can exclude some Amazon S3 storage class types.

The following storage classes are available in Amazon S3:

- `STANDARD` — For general-purpose storage of frequently accessed data.
- `INTELLIGENT_TIERING` — For data with unknown or changing access patterns.
- `STANDARD_IA` and `ONEZONE_IA` — For long-lived, but less frequently accessed data.
- `GLACIER`, `DEEP_ARCHIVE`, and `REDUCED_REDUNDANCY` — For long-term archive and digital preservation.
- `EXPRESS_ONEZONE` — For latency-sensitive applications that require single-digit millisecond data access. (Supported starting AWS Glue version 5.1)

For more information, see Amazon S3 Storage Classes in the *Amazon S3 Developer Guide*.

The examples in this section show how to exclude the `GLACIER` and `DEEP_ARCHIVE` storage classes. These classes allow you to list files, but they won't let you read the files unless they are restored. (For more information, see Restoring Archived Objects in the *Amazon S3 Developer Guide*.)

By using storage class exclusions, you can ensure that your AWS Glue jobs will work on tables that have partitions across these storage class tiers. Without exclusions, jobs that read data from these tiers fail with the following error: AmazonS3Exception: The operation is not valid for the object's storage class.

There are different ways that you can filter Amazon S3 storage classes in AWS Glue.

Topics

- Excluding Amazon S3 storage classes when creating a Dynamic Frame
- Excluding Amazon S3 storage classes on a Data Catalog table

Excluding Amazon S3 storage classes when creating a Dynamic Frame

To exclude Amazon S3 storage classes while creating a dynamic frame, use `excludeStorageClasses` in `additionalOptions`. AWS Glue automatically uses its own Amazon S3 `Lister` implementation to list and exclude files corresponding to the specified storage classes.

The following Python and Scala examples show how to exclude the `GLACIER` and `DEEP_ARCHIVE` storage classes when creating a dynamic frame.

Python example:

```
glueContext.create_dynamic_frame.from_catalog(
    database = "my_database",
    tableName = "my_table_name",
    redshift_tmp_dir = "",
    transformation_ctx = "my_transformation_context",
    additional_options = {
        "excludeStorageClasses" : ["GLACIER", "DEEP_ARCHIVE"]
    }
)
```

Scala example:

```
val* *df = glueContext.getCatalogSource(
    nameSpace, tableName, "", "my_transformation_context",
    additionalOptions = JsonOptions(
        Map("excludeStorageClasses" -> List("GLACIER", "DEEP_ARCHIVE"))
    )
).getDynamicFrame()
```

Excluding Amazon S3 storage classes on a Data Catalog table

You can specify storage class exclusions to be used by an AWS Glue ETL job as a table parameter in the AWS Glue Data Catalog. You can include this parameter in the `CreateTable` operation using the AWS Command Line Interface (AWS CLI) or programmatically using the API. For more information, see Table Structure and CreateTable.

You can also specify excluded storage classes on the AWS Glue console.

To exclude Amazon S3 storage classes (console)

1. Sign in to the AWS Management Console and open the AWS Glue console at https://console.aws.amazon.com/glue/.
2. In the navigation pane on the left, choose **Tables**.
3. Choose the table name in the list, and then choose **Edit table**.
4. In **Table properties**, add **`excludeStorageClasses`** as a key and **`[\"GLACIER\", \"DEEP_ARCHIVE\"]`** as a value.
5. Choose **Apply**.

Using Amazon S3 Express One Zone with AWS Glue

With AWS Glue version 5.1 and higher, you can read and write data in Amazon S3 Express One Zone directory buckets from your ETL jobs. S3 Express One Zone is a high-performance, single-zone Amazon S3 storage class that delivers consistent, single-digit millisecond data access for latency-sensitive applications.

Prerequisites

Before you can use S3 Express One Zone with AWS Glue, you must have the following:

- An AWS Glue job running version 5.1 or higher.
- An S3 directory bucket created in the same region as your AWS Glue job. Directory buckets do not support cross-region access. For more information, see Creating directory buckets in the *Amazon S3 User Guide*.
- The `s3express:CreateSession` permission on your IAM role. When S3 Express One Zone performs an action on a directory bucket, it calls `CreateSession` on your behalf.

IAM permissions

Add the following permission to your AWS Glue job's IAM role to allow access to S3 Express One Zone directory buckets:

```
{
    "Version": "2012-10-17",
    "Statement": [
```

```
        {
            "Effect": "Allow",
            "Action": "s3express:CreateSession",
            "Resource": "arn:aws:s3express:*:*:bucket/EXAMPLE-BUCKET--az-id--x-s3"
        }
    ]
}
```

Replace *EXAMPLE-BUCKET* with your directory bucket name and *az-id* with the Availability Zone ID (for example, `use1-az4`).

Reading and writing data

AWS Glue version 5.1+ supports accessing S3 Express One Zone directory buckets using both the `s3://` and `s3a://` URI schemes. No additional configuration is required.

The following example shows how to read and write data from an S3 Express One Zone directory bucket in a AWS Glue ETL job:

```
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

# S3 Express One Zone directory bucket path
express_path = "s3://EXAMPLE-BUCKET--use1-az4--x-s3/my-data/"

# Read data from S3 Express One Zone
df = spark.read.parquet(express_path)

# Write data to S3 Express One Zone
df.write.mode("overwrite").parquet(express_path + "output/")
```

You can also use DynamicFrames with S3 Express One Zone:

```
# Read with DynamicFrame
dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type="s3",
    connection_options={"paths": [express_path]},
```

```
    format="parquet"
)

# Write with DynamicFrame
glueContext.write_dynamic_frame.from_options(
    frame=dynamicFrame,
    connection_type="s3",
    connection_options={"path": express_path + "output/"},
    format="parquet"
)
```

Managing partitions for ETL output in AWS Glue

Partitioning is an important technique for organizing datasets so they can be queried efficiently. It organizes data in a hierarchical directory structure based on the distinct values of one or more columns.

For example, you might decide to partition your application logs in Amazon Simple Storage Service (Amazon S3) by date, broken down by year, month, and day. Files that correspond to a single day's worth of data are then placed under a prefix such as `s3://my_bucket/logs/year=2018/month=01/day=23/`. Systems like Amazon Athena, Amazon Redshift Spectrum, and now AWS Glue can use these partitions to filter data by partition value without having to read all the underlying data from Amazon S3.

Crawlers not only infer file types and schemas, they also automatically identify the partition structure of your dataset when they populate the AWS Glue Data Catalog. The resulting partition columns are available for querying in AWS Glue ETL jobs or query engines like Amazon Athena.

After you crawl a table, you can view the partitions that the crawler created. In the AWS Glue console, choose **Tables** in the left navigation pane. Choose the table created by the crawler, and then choose **View Partitions**.

For Apache Hive-style partitioned paths in `key=val` style, crawlers automatically populate the column name using the key name. Otherwise, it uses default names like `partition_0`, `partition_1`, and so on. You can change the default names on the console. To do so, navigate to the table. Check if indexes exist under the **Indexes** tab. If that's the case, you need to delete them to proceed (you can recreate them using the new column names afterwards). Then, choose **Edit Schema**, and modify the names of the partition columns there.

In your ETL scripts, you can then filter on the partition columns. Because the partition information is stored in the Data Catalog, use the `from_catalog` API calls to include the partition columns

in the DynamicFrame. For example, use `create_dynamic_frame.from_catalog` instead of `create_dynamic_frame.from_options`.

Partitioning is an optimization technique that reduces data scan. For more information about the process of identifying when this technique is appropriate, consult Reduce the amount of data scan in the *Best practices for performance tuning AWS Glue for Apache Spark jobs* guide on AWS Prescriptive Guidance.

Pre-filtering using pushdown predicates

In many cases, you can use a pushdown predicate to filter on partitions without having to list and read all the files in your dataset. Instead of reading the entire dataset and then filtering in a DynamicFrame, you can apply the filter directly on the partition metadata in the Data Catalog. Then you only list and read what you actually need into a DynamicFrame.

For example, in Python, you could write the following.

```
glue_context.create_dynamic_frame.from_catalog(
    database = "my_S3_data_set",
    table_name = "catalog_data_table",
    push_down_predicate = my_partition_predicate)
```

This creates a DynamicFrame that loads only the partitions in the Data Catalog that satisfy the predicate expression. Depending on how small a subset of your data you are loading, this can save a great deal of processing time.

The predicate expression can be any Boolean expression supported by Spark SQL. Anything you could put in a `WHERE` clause in a Spark SQL query will work. For example, the predicate expression `pushDownPredicate = "(year=='2017' and month=='04')"` loads only the partitions in the Data Catalog that have both `year` equal to 2017 and `month` equal to 04. For more information, see the Apache Spark SQL documentation, and in particular, the Scala SQL functions reference.

Server-side filtering using catalog partition predicates

The `push_down_predicate` option is applied after listing all the partitions from the catalog and before listing files from Amazon S3 for those partitions. If you have a lot of partitions for a table, catalog partition listing can still incur additional time overhead. To address this overhead, you can use server-side partition pruning with the `catalogPartitionPredicate` option that uses partition indexes in the AWS Glue Data Catalog. This makes partition

filtering much faster when you have millions of partitions in one table. You can use both `push_down_predicate` and `catalogPartitionPredicate` in `additional_options` together if your `catalogPartitionPredicate` requires predicate syntax that is not yet supported with the catalog partition indexes.

Python:

```
dynamic_frame = glueContext.create_dynamic_frame.from_catalog(
    database=dbname,
    table_name=tablename,
    transformation_ctx="datasource0",
    push_down_predicate="day>=10 and customer_id like '10%'",
    additional_options={"catalogPartitionPredicate":"year='2021' and month='06'"}
)
```

Scala:

```
val dynamicFrame = glueContext.getCatalogSource(
    database = dbname,
    tableName = tablename,
    transformationContext = "datasource0",
    pushDownPredicate="day>=10 and customer_id like '10%'",
    additionalOptions = JsonOptions("""{
        "catalogPartitionPredicate": "year='2021' and month='06'"}""")
    ).getDynamicFrame()
```

> **Note**
>
> The `push_down_predicate` and `catalogPartitionPredicate` use different syntaxes. The former one uses Spark SQL standard syntax and the later one uses JSQL parser.

Writing partitions

By default, a DynamicFrame is not partitioned when it is written. All of the output files are written at the top level of the specified output path. Until recently, the only way to write a DynamicFrame into partitions was to convert it to a Spark SQL DataFrame before writing.

However, DynamicFrames now support native partitioning using a sequence of keys, using the `partitionKeys` option when you create a sink. For example, the following Python code writes out

a dataset to Amazon S3 in the Parquet format, into directories partitioned by the type field. From there, you can process these partitions using other systems, such as Amazon Athena.

```
glue_context.write_dynamic_frame.from_options(
    frame = projectedEvents,
    connection_type = "s3",
    connection_options = {"path": "$outpath", "partitionKeys": ["type"]},
    format = "parquet")
```

Reading input files in larger groups

You can set properties of your tables to enable an AWS Glue ETL job to group files when they are read from an Amazon S3 data store. These properties enable each ETL task to read a group of input files into a single in-memory partition, this is especially useful when there is a large number of small files in your Amazon S3 data store. When you set certain properties, you instruct AWS Glue to group files within an Amazon S3 data partition and set the size of the groups to be read. You can also set these options when reading from an Amazon S3 data store with the `create_dynamic_frame.from_options` method.

To enable grouping files for a table, you set key-value pairs in the parameters field of your table structure. Use JSON notation to set a value for the parameter field of your table. For more information about editing the properties of a table, see Viewing and managing table details.

You can use this method to enable grouping for tables in the Data Catalog with Amazon S3 data stores.

groupFiles

Set **groupFiles** to `inPartition` to enable the grouping of files within an Amazon S3 data partition. AWS Glue automatically enables grouping if there are more than 50,000 input files, as in the following example.

```
'groupFiles': 'inPartition'
```

groupSize

Set **groupSize** to the target size of groups in bytes. The **groupSize** property is optional, if not provided, AWS Glue calculates a size to use all the CPU cores in the cluster while still reducing the overall number of ETL tasks and in-memory partitions.

For example, the following sets the group size to 1 MB.

```
'groupSize': '1048576'
```

Note that the `groupsize` should be set with the result of a calculation. For example 1024 * 1024 = 1048576.

recurse

Set **recurse** to `True` to recursively read files in all subdirectories when specifying `paths` as an array of paths. You do not need to set **recurse** if `paths` is an array of object keys in Amazon S3, or if the input format is parquet/orc, as in the following example.

```
'recurse':True
```

If you are reading from Amazon S3 directly using the `create_dynamic_frame.from_options` method, add these connection options. For example, the following attempts to group files into 1 MB groups.

```
df = glueContext.create_dynamic_frame.from_options("s3", {'paths': ["s3://s3path/"],
 'recurse':True, 'groupFiles': 'inPartition', 'groupSize': '1048576'}, format="json")
```

> **Note**
>
> `groupFiles` is supported for DynamicFrames created from the following data formats: csv, ion, grokLog, json, and xml. This option is not supported for avro, parquet, and orc.

Amazon VPC endpoints for Amazon S3

For security reasons, many AWS customers run their applications within an Amazon Virtual Private Cloud environment (Amazon VPC). With Amazon VPC, you can launch Amazon EC2 instances into a virtual private cloud, which is logically isolated from other networks—including the public internet.

With an Amazon VPC, you have control over its IP address range, subnets, routing tables, network gateways, and security settings.

> **Note**
>
> If you created your AWS account after 2013-12-04, you already have a default VPC in each AWS Region. You can immediately start using your default VPC without any additional configuration.
> For more information, see Your Default VPC and Subnets in the Amazon VPC User Guide.

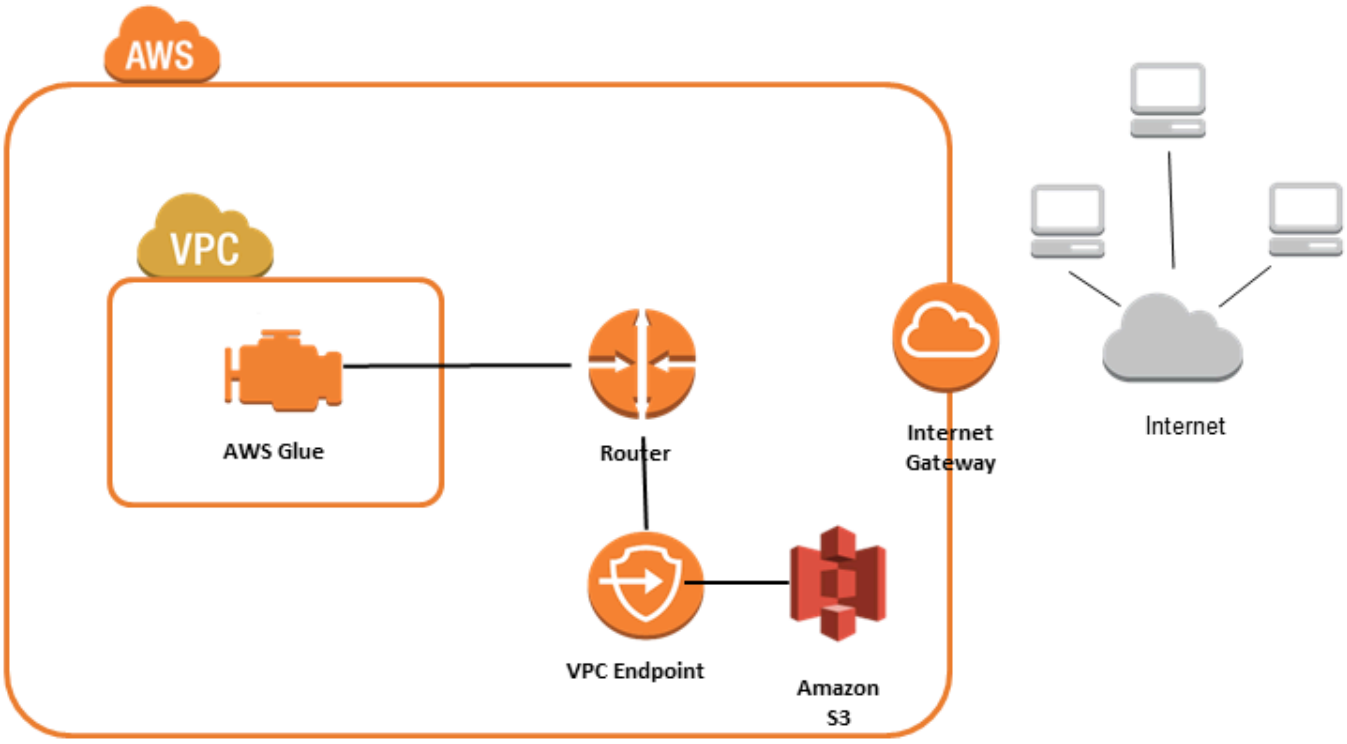
Many customers have legitimate privacy and security concerns about sending and receiving data across the public internet. Customers can address these concerns by using a virtual private network (VPN) to route all Amazon S3 network traffic through their own corporate network infrastructure. However, this approach can introduce bandwidth and availability challenges.

VPC endpoints for Amazon S3 can alleviate these challenges. A VPC endpoint for Amazon S3 enables AWS Glue to use private IP addresses to access Amazon S3 with no exposure to the public internet. AWS Glue does not require public IP addresses, and you don't need an internet gateway, a NAT device, or a virtual private gateway in your VPC. You use endpoint policies to control access to Amazon S3. Traffic between your VPC and the AWS service does not leave the Amazon network.

When you create a VPC endpoint for Amazon S3, any requests to an Amazon S3 endpoint within the Region (for example, *s3.us-west-2.amazonaws.com*) are routed to a private Amazon S3 endpoint within the Amazon network. You don't need to modify your applications running on Amazon EC2 instances in your VPC—the endpoint name remains the same, but the route to Amazon S3 stays entirely within the Amazon network, and does not access the public internet.

For more information about VPC endpoints, see VPC Endpoints in the Amazon VPC User Guide.

The following diagram shows how AWS Glue can use a VPC endpoint to access Amazon S3.



To set up access for Amazon S3

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the left navigation pane, choose **Endpoints**.
3. Choose **Create Endpoint**, and follow the steps to create an Amazon S3 VPC endpoint of type Gateway.

Amazon DocumentDB connections

You can use AWS Glue for Spark to read from and write to tables in Amazon DocumentDB. You can connect to Amazon DocumentDB using credentials stored in AWS Secrets Manager through a AWS Glue connection.

For more information about Amazon DocumentDB, consult the Amazon DocumentDB documentation.

> **Note**
>
> Amazon DocumentDB elastic clusters are not currently supported when using the AWS Glue connector. For more information about elastic clusters, see Using Amazon DocumentDB elastic clusters.

Reading and writing to Amazon DocumentDB collections

> **Note**
>
> When you create an ETL job that connects to Amazon DocumentDB, for the `Connections` job property, you must designate a connection object that specifies the virtual private cloud (VPC) in which Amazon DocumentDB is running. For the connection object, the connection type must be `JDBC`, and the `JDBC URL` must be `mongo://<DocumentDB_host>:27017`.

> **Note**
>
> These code samples were developed for AWS Glue 3.0. To migrate to AWS Glue 4.0, consult the section called "MongoDB". The `uri` parameter has changed.

> **Note**
>
> When using Amazon DocumentDB, `retryWrites` must be set to false in certain situations, such as when the document written specifies `_id`. For more information, consult Functional Differences with MongoDB in the Amazon DocumentDB documentation.

The following Python script demonstrates using connection types and connection options for reading and writing to Amazon DocumentDB.

```
import sys
```

```
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext, SparkConf
from awsglue.context import GlueContext
from awsglue.job import Job
import time

## @params: [JOB_NAME]
args = getResolvedOptions(sys.argv, ['JOB_NAME'])

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

job = Job(glueContext)
job.init(args['JOB_NAME'], args)

output_path = "s3://some_bucket/output/" + str(time.time()) + "/"
documentdb_uri = "mongodb://<mongo-instanced-ip-address>:27017"
documentdb_write_uri = "mongodb://<mongo-instanced-ip-address>:27017"

read_docdb_options = {
    "uri": documentdb_uri,
    "database": "test",
    "collection": "coll",
    "username": "username",
    "password": "1234567890",
    "ssl": "true",
    "ssl.domain_match": "false",
    "partitioner": "MongoSamplePartitioner",
    "partitionerOptions.partitionSizeMB": "10",
    "partitionerOptions.partitionKey": "_id"
}

write_documentdb_options = {
    "retryWrites": "false",
    "uri": documentdb_write_uri,
    "database": "test",
    "collection": "coll",
    "username": "username",
    "password": "pwd"
}

# Get DynamicFrame from  DocumentDB
```

```
dynamic_frame2 =
 glueContext.create_dynamic_frame.from_options(connection_type="documentdb",

 connection_options=read_docdb_options)

# Write DynamicFrame to MongoDB and DocumentDB
glueContext.write_dynamic_frame.from_options(dynamic_frame2,
 connection_type="documentdb",

 connection_options=write_documentdb_options)

job.commit()
```

The following Scala script demonstrates using connection types and connection options for reading and writing to Amazon DocumentDB.

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.MappingSpec
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.DynamicFrame
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._

object GlueApp {
  val DOC_URI: String = "mongodb://<mongo-instanced-ip-address>:27017"
  val DOC_WRITE_URI: String = "mongodb://<mongo-instanced-ip-address>:27017"
  lazy val documentDBJsonOption = jsonOptions(DOC_URI)
  lazy val writeDocumentDBJsonOption = jsonOptions(DOC_WRITE_URI)
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)

    // Get DynamicFrame from DocumentDB
    val resultFrame2: DynamicFrame = glueContext.getSource("documentdb",
 documentDBJsonOption).getDynamicFrame()

    // Write DynamicFrame to DocumentDB
    glueContext.getSink("documentdb", writeJsonOption).writeDynamicFrame(resultFrame2)
```

```
    Job.commit()
  }

  private def jsonOptions(uri: String): JsonOptions = {
    new JsonOptions(
      s"""{"uri": "${uri}",
         |"database":"test",

         |"ssl.domain_match":"false",
         |"partitioner": "MongoSamplePartitioner",
         |"partitionerOptions.partitionSizeMB": "10",
         |"partitionerOptions.partitionKey": "_id"}""".stripMargin)
  }
}
```

Amazon DocumentDB connection option reference

Designates a connection to Amazon DocumentDB (with MongoDB compatibility).

Connection options differ for a source connection and a sink connection.

"connectionType": "Documentdb" as source

Use the following connection options with `"connectionType": "documentdb"` as a source:

- `"uri"`: (Required) The Amazon DocumentDB host to read from, formatted as `mongodb://<host>:<port>`.
- `"database"`: (Required) The Amazon DocumentDB database to read from.
- `"collection"`: (Required) The Amazon DocumentDB collection to read from.
- `"username"`: (Required) The Amazon DocumentDB user name.
- `"password"`: (Required) The Amazon DocumentDB password.
- `"ssl"`: (Required if using SSL) If your connection uses SSL, then you must include this option with the value `"true"`.
- `"ssl.domain_match"`: (Required if using SSL) If your connection uses SSL, then you must include this option with the value `"false"`.

- "batchSize": (Optional): The number of documents to return per batch, used within the cursor of internal batches.
- "partitioner": (Optional): The class name of the partitioner for reading input data from Amazon DocumentDB. The connector provides the following partitioners:
  - MongoDefaultPartitioner (default) (Not supported in AWS Glue 4.0)
  - MongoSamplePartitioner (Not supported in AWS Glue 4.0)
  - MongoShardedPartitioner
  - MongoSplitVectorPartitioner
  - MongoPaginateByCountPartitioner
  - MongoPaginateBySizePartitioner (Not supported in AWS Glue 4.0)
- "partitionerOptions" (Optional): Options for the designated partitioner. The following options are supported for each partitioner:
  - MongoSamplePartitioner: partitionKey, partitionSizeMB, samplesPerPartition
  - MongoShardedPartitioner: shardkey
  - MongoSplitVectorPartitioner: partitionKey, partitionSizeMB
  - MongoPaginateByCountPartitioner: partitionKey, numberOfPartitions
  - MongoPaginateBySizePartitioner: partitionKey, partitionSizeMB

  For more information about these options, see Partitioner Configuration in the MongoDB documentation.

"connectionType": "Documentdb" as sink

Use the following connection options with "connectionType": "documentdb" as a sink:

- "uri": (Required) The Amazon DocumentDB host to write to, formatted as mongodb://<host>:<port>.
- "database": (Required) The Amazon DocumentDB database to write to.
- "collection": (Required) The Amazon DocumentDB collection to write to.
- "username": (Required) The Amazon DocumentDB user name.
- "password": (Required) The Amazon DocumentDB password.
- "extendedBsonTypes": (Optional) If true, allows extended BSON types when writing data to Amazon DocumentDB. The default is true.

- `"replaceDocument"`: (Optional) If `true`, replaces the whole document when saving datasets that contain an `_id` field. If `false`, only fields in the document that match the fields in the dataset are updated. The default is `true`.
- `"maxBatchSize"`: (Optional): The maximum batch size for bulk operations when saving data. The default is 512.
- `"retryWrites"`: (Optional): Automatically retry certain write operations a single time if AWS Glue encounters a network error.

OpenSearch Service connections

You can use AWS Glue for Spark to read from and write to tables in OpenSearch Service in AWS Glue 4.0 and later versions. You can define what to read from OpenSearch Service with an OpenSearch query. You connect to OpenSearch Service using HTTP basic authentication credentials stored in AWS Secrets Manager through a AWS Glue connection. This feature is not compatible with OpenSearch Service serverless.

For more information about Amazon OpenSearch Service, see the Amazon OpenSearch Service documentation.

Configuring OpenSearch Service connections

To connect to OpenSearch Service from AWS Glue, you will need to create and store your OpenSearch Service credentials in a AWS Secrets Manager secret, then associate that secret with a OpenSearch Service AWS Glue connection.

Prerequisites:

- Identify the domain endpoint, *`aosEndpoint`* and port, *`aosPort`* you would like to read from, or create the resource by following instructions in the Amazon OpenSearch Service documentation. For more information on creating a domain, see Creating and managing Amazon OpenSearch Service domains in the Amazon OpenSearch Service documentation.

  An Amazon OpenSearch Service domain endpoint will have the following default form, https://search-*`domainName`*-*`unstructuredIdContent`*.*`region`*.es.amazonaws.com. For more information on identifying your domain endpoint, see Creating and managing Amazon OpenSearch Service domains in the Amazon OpenSearch Service documentation.

  Identify or generate HTTP basic authentication credentials, *`aosUser`* and *`aosPassword`* for your domain.

To configure a connection to OpenSearch Service:

1. In AWS Secrets Manager, create a secret using your OpenSearch Service credentials. To create a secret in Secrets Manager, follow the tutorial available in Create an AWS Secrets Manager secret in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
   - When selecting **Key/value pairs**, create a pair for the key USERNAME with the value *aosUser*.
   - When selecting **Key/value pairs**, create a pair for the key PASSWORD with the value *aosPassword*.
2. In the AWS Glue console, create a connection by following the steps in the section called "Adding an AWS Glue connection". After creating the connection, keep the connection name, *connectionName*, for future use in AWS Glue.
   - When selecting a **Connection type**, select OpenSearch Service.
   - When selecting a Domain endpoint, provide *aosEndpoint*.
   - When selecting a port, provide *aosPort*.
   - When selecting an **AWS Secret**, provide *secretName*.

After creating a AWS Glue OpenSearch Service connection, you will need to perform the following steps before running your AWS Glue job:

- Grant the IAM role associated with your AWS Glue job permission to read *secretName*.
- In your AWS Glue job configuration, provide *connectionName* as an **Additional network connection**.

Reading from OpenSearch Service indexes

Prerequisites:

- A OpenSearch Service index you would like to read from, *aosIndex*.
- A AWS Glue OpenSearch Service connection configured to provide auth and network location information. To acquire this, complete the steps in the previous procedure, *To configure a connection to OpenSearch Service*. You will need the name of the AWS Glue connection, *connectionName*.

This example reads an index from Amazon OpenSearch Service. You will need to provide the pushdown parameter.

For example:

```
opensearch_read = glueContext.create_dynamic_frame.from_options(
    connection_type="opensearch",
    connection_options={
        "connectionName": "connectionName",
        "opensearch.resource": "aosIndex",
        "pushdown": "true",
    }
)
```

You can also provide a query string to filter the results returned in your DynamicFrame. You will need to configure `opensearch.query`.

`opensearch.query` can take a URL query parameter string *`queryString`* or a query DSL JSON object *`queryObject`*. For more information about the query DSL, see Query DSL in the OpenSearch documentation. To provide a URL query parameter string, prepend ?q= to your query, as you would in a fully qualified URL. To provide a query DSL object, string escape the JSON object before providing it.

For example:

```
            queryObject = "{ "query": { "multi_match": { "query": "Sample", "fields":
 [ "sample" ] } } }"
            queryString = "?q=queryString"

            opensearch_read_query = glueContext.create_dynamic_frame.from_options(
    connection_type="opensearch",
    connection_options={
        "connectionName": "connectionName",
        "opensearch.resource": "aosIndex",
        "opensearch.query": queryString,
        "pushdown": "true",
    }
)
```

For more information about how to build a query outside of its specific syntax, see Query string syntax in the OpenSearch documentation.

When reading from OpenSearch collections that contain array type data, you must specify which fields are array type in your method call using the `opensearch.read.field.as.array.include` parameter.

For example, when reading the following document, you will encounter the `genre` and `actor` array fields:

```
{
    "_index": "movies",
    "_id": "2",
    "_version": 1,
    "_seq_no": 0,
    "_primary_term": 1,
    "found": true,
    "_source": {
        "director": "Frankenheimer, John",
        "genre": [
            "Drama",
            "Mystery",
            "Thriller",
            "Crime"
        ],
        "year": 1962,
        "actor": [
            "Lansbury, Angela",
            "Sinatra, Frank",
            "Leigh, Janet",
            "Harvey, Laurence",
            "Silva, Henry",
            "Frees, Paul",
            "Gregory, James",
            "Bissell, Whit",
            "McGiver, John",
            "Parrish, Leslie",
            "Edwards, James",
            "Flowers, Bess",
            "Dhiegh, Khigh",
            "Payne, Julie",
            "Kleeb, Helen",
            "Gray, Joe",
            "Nalder, Reggie",
            "Stevens, Bert",
            "Masters, Michael",
```

```
            "Lowell, Tom"
        ],
        "title": "The Manchurian Candidate"
    }
}
```

In this case, you would include those field names in your method call. For example:

```
"opensearch.read.field.as.array.include": "genre,actor"
```

If your array field is nested inside of your document structure, refer to it using dot notation: `"genre,actor,foo.bar.baz"`. This would specify an array `baz` included in your source document through the embedded document `foo` containing the embedded document `bar`.

Writing to OpenSearch Service tables

This example writes information from an existing DynamicFrame, *`dynamicFrame`* to OpenSearch Service. If the index already has information, AWS Glue will append data from your DynamicFrame. You will need to provide the `pushdown` parameter.

Prerequisites:

- A OpenSearch Service table you would like to write to. You will need identification information for the table. Let's call this *`tableName`*.
- A AWS Glue OpenSearch Service connection configured to provide auth and network location information. To acquire this, complete the steps in the previous procedure, *To configure a connection to OpenSearch Service*. You will need the name of the AWS Glue connection, *`connectionName`*.

For example:

```
glueContext.write_dynamic_frame.from_options(
    frame=dynamicFrame,
    connection_type="opensearch",
    connection_options={
      "connectionName": "connectionName",
      "opensearch.resource": "aosIndex",
    },
)
```

OpenSearch Service connection option reference

- `connectionName` — Required. Used for Read/Write. The name of a AWS Glue OpenSearch Service connection configured to provide auth and network location information to your connection method.
- `opensearch.resource` — Required. Used for Read/Write. Valid Values: OpenSearch index names. The name of the index your connection method will interact with.
- `opensearch.query` — Used for Read. Valid Values: String escaped JSON or, when this string begins with `?`, the search part of a URL. An OpenSearch query that filters what should be retrieved when reading. For more information on using this parameter, consult the previous section the section called “Read from OpenSearch Service”.
- `pushdown` — Required if. Used for Read. Valid Values: boolean. Instructs Spark to pass read queries down to OpenSearch so the database only returns relevant documents.
- `opensearch.read.field.as.array.include` — Required if reading array type data. Used for Read. Valid Values: comma separated lists of field names. Specifies fields to read as arrays from OpenSearch documents. For more information on using this parameter, consult the previous section the section called “Read from OpenSearch Service”.

Redshift connections

You can use AWS Glue for Spark to read from and write to tables in Amazon Redshift databases. When connecting to Amazon Redshift databases, AWS Glue moves data through Amazon S3 to achieve maximum throughput, using the Amazon Redshift SQL `COPY` and `UNLOAD` commands. In AWS Glue 4.0 and later, you can use the Amazon Redshift integration for Apache Spark to read and write with optimizations and features specific to Amazon Redshift beyond those available when connecting through previous versions.

Learn about how AWS Glue is making it easier than ever for Amazon Redshift users to migrate to AWS Glue for serverless data integration and ETL.

Configuring Redshift connections

To use Amazon Redshift clusters in AWS Glue, you will need some prerequisites:

- An Amazon S3 directory to use for temporary storage when reading from and writing to the database.
- An Amazon VPC enabling communication between your Amazon Redshift cluster, your AWS Glue job and your Amazon S3 directory.

- Appropriate IAM permissions on the AWS Glue job and Amazon Redshift cluster.

Configuring IAM roles

Set up the role for the Amazon Redshift cluster

Your Amazon Redshift cluster needs to be able to read and write to Amazon S3 in order to integrate with AWS Glue jobs. To allow this, you can associate IAM roles with the Amazon Redshift cluster you want to connect to. Your role should have a policy allowing read from and write to your Amazon S3 temporary directory. Your role should have a trust relationship allowing the `redshift.amazonaws.com` service to `AssumeRole`.

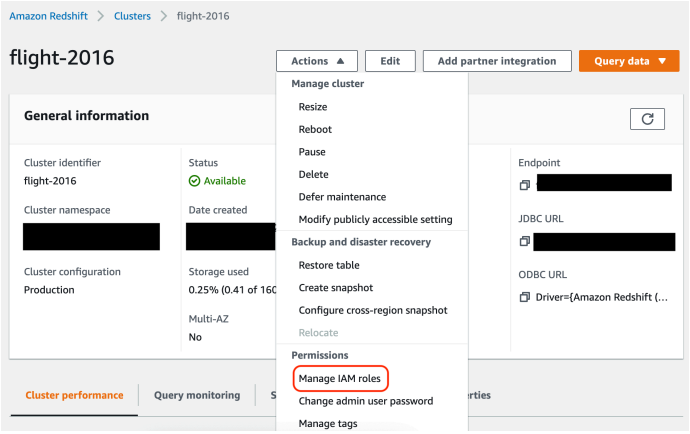
To associate an IAM role with Amazon Redshift

1. **Prerequisites:** An Amazon S3 bucket or directory used for the temporary storage of files.
2. Identify which Amazon S3 permissions your Amazon Redshift cluster will need. When moving data to and from an Amazon Redshift cluster, AWS Glue jobs issue COPY and UNLOAD statements against Amazon Redshift. If your job modifies a table in Amazon Redshift, AWS Glue will also issue CREATE LIBRARY statements. For information on specific Amazon S3 permissions required for Amazon Redshift to execute these statements, refer to the Amazon Redshift documentation: Amazon Redshift: Permissions to access other AWS Resources.
3. In the IAM console, create an IAM policy with the necessary permissions. For more information about creating a policy Creating IAM policies.
4. In the IAM console, create a role and trust relationship allowing Amazon Redshift to assume the role. Follow the instructions in the IAM documentation To create a role for an AWS service (console)
   - When asked to choose an AWS service use case, choose "Redshift - Customizable".
   - When asked to attach a policy, choose the policy you previously defined.

> **Note**
>
> For more information about configuring roles for Amazon Redshift, see Authorizing Amazon Redshift to access other AWS services on your behalf in the Amazon Redshift documentation.

5. In the Amazon Redshift console, associate the role with your Amazon Redshift cluster. Follow the instructions in the Amazon Redshift documentation.

   Select the highlighted option in the Amazon Redshift console to configure this setting:



> **Note**
>
> By default, AWS Glue jobs pass Amazon Redshift temporary credentials that are created using the role that you specified to run the job. We do not recommend using these credentials. For security purposes, these credentials expire after 1 hour.

Set up the role for the AWS Glue job

The AWS Glue job needs a role to access the Amazon S3 bucket. You do not need IAM permissions for the Amazon Redshift cluster, your access is controlled by connectivity in Amazon VPC and your database credentials.

Set up Amazon VPC

To set up access for Amazon Redshift data stores

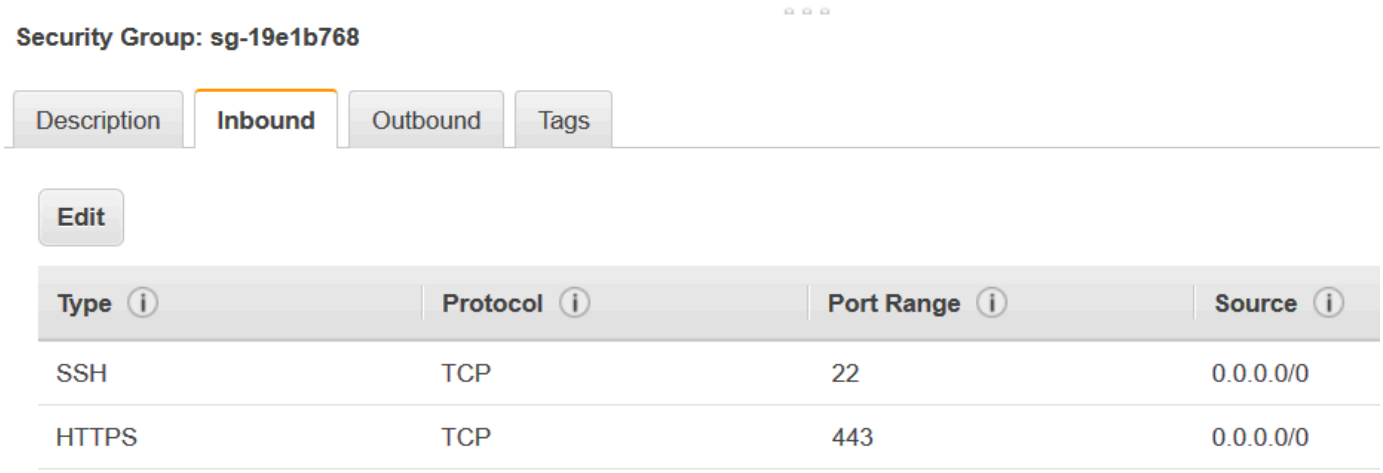
1. Sign in to the AWS Management Console and open the Amazon Redshift console at https://console.aws.amazon.com/redshiftv2/.
2. In the left navigation pane, choose **Clusters**.
3. Choose the cluster name that you want to access from AWS Glue.

4. In the **Cluster Properties** section, choose a security group in **VPC security groups** to allow AWS Glue to use. Record the name of the security group that you chose for future reference. Choosing the security group opens the Amazon EC2 console **Security Groups** list.
5. Choose the security group to modify and navigate to the **Inbound** tab.
6. Add a self-referencing rule to allow AWS Glue components to communicate. Specifically, add or confirm that there is a rule of **Type** `All TCP`, **Protocol** is `TCP`, **Port Range** includes all ports, and whose **Source** is the same security group name as the **Group ID**.

   The inbound rule looks similar to the following:

Type	Protocol	Port range	Source
All TCP	TCP	0–65535	*database-security-group*

   For example:



7. Add a rule for outbound traffic also. Either open outbound traffic to all ports, for example:

Type	Protocol	Port range	Destination
All Traffic	ALL	ALL	0.0.0.0/0

   Or create a self-referencing rule where **Type** `All TCP`, **Protocol** is `TCP`, **Port Range** includes all ports, and whose **Destination** is the same security group name as the **Group ID**. If using an

Amazon S3 VPC endpoint, also add an HTTPS rule for Amazon S3 access. The *s3-prefix-list-id* is required in the security group rule to allow traffic from the VPC to the Amazon S3 VPC endpoint.

For example:

Type	Protocol	Port range	Destination
All TCP	TCP	0–65535	*security-group*
HTTPS	TCP	443	*s3-prefix-list-id*

Set up AWS Glue

You will need to create an AWS Glue Data Catalog connection that provides Amazon VPC connection information.

To configure Amazon Redshift Amazon VPC connectivity to AWS Glue in the console

1. Create a Data Catalog connection by following the steps in: the section called "Adding an AWS Glue connection". After creating the connection, keep the connection name, *connectionName*, for the next step.

   - When selecting a **Connection type**, select **Amazon Redshift**.
   - When selecting a **Redshift cluster**, select your cluster by name.
   - Provide default connection information for a Amazon Redshift user on your cluster.
   - Your Amazon VPC settings will be automatically configured.

   > **Note**
   >
   > You will need to manually provide `PhysicalConnectionRequirements` for your Amazon VPC when creating an **Amazon Redshift** connection through the AWS SDK.

2. In your AWS Glue job configuration, provide *connectionName* as an **Additional network connection**.

Example: Reading from Amazon Redshift tables

You can read from Amazon Redshift clusters and Amazon Redshift serverless environments.

Prerequisites: An Amazon Redshift table you would like to read from. Follow the steps in the previous section the section called "Configure Redshift" after which you should have the Amazon S3 URI for a temporary directory, *temp-s3-dir* and an IAM role, *rs-role-name*, (in account *role-account-id*).

Using the Data Catalog

Additional Prerequisites: A Data Catalog Database and Table for the Amazon Redshift table you would like to read from. For more information about Data Catalog, see *Data discovery and cataloging*. After creating a entry for your Amazon Redshift table you will identify your connection with a *redshift-dc-database-name* and *redshift-table-name*.

Configuration: In your function options you will identify your Data Catalog Table with the `database` and `table_name` parameters. You will identify your Amazon S3 temporary directory with `redshift_tmp_dir`. You will also provide *rs-role-name* using the `aws_iam_role` key in the `additional_options` parameter.

```
 glueContext.create_dynamic_frame.from_catalog(
    database = "redshift-dc-database-name",
    table_name = "redshift-table-name",
    redshift_tmp_dir = args["temp-s3-dir"],
    additional_options = {"aws_iam_role": "arn:aws:iam::role-account-id:role/rs-
role-name"})
```

Connecting directly

Additional Prerequisites: You will need the name of your Amazon Redshift table (*redshift-table-name*. You will need the JDBC connection information for the Amazon Redshift cluster storing that table. You will supply your connection information with *host*, *port*, *redshift-database-name*, *username* and *password*.

You can retrieve your connection information from the Amazon Redshift console when working with Amazon Redshift clusters. When using Amazon Redshift serverless, consult Connecting to Amazon Redshift Serverless in the Amazon Redshift documentation.

Configuration: In your function options you will identify your connection parameters with `url`, `dbtable`, `user` and `password`. You will identify your Amazon S3 temporary directory with `redshift_tmp_dir`. You can specify your IAM role using `aws_iam_role` when you use `from_options`. The syntax is similar to connecting through the Data Catalog, but you put the parameters in the `connection_options` map.

It is bad practice to hardcode passwords into AWS Glue scripts. Consider storing your passwords in AWS Secrets Manager and retrieving them in your script with SDK for Python (Boto3).

```
my_conn_options = {
    "url": "jdbc:redshift://host:port/redshift-database-name",
    "dbtable": "redshift-table-name",
    "user": "username",
    "password": "password",
    "redshiftTmpDir": args["temp-s3-dir"],
    "aws_iam_role": "arn:aws:iam::account id:role/rs-role-name"
}

df = glueContext.create_dynamic_frame.from_options("redshift", my_conn_options)
```

Example: Writing to Amazon Redshift tables

You can write to Amazon Redshift clusters and Amazon Redshift serverless environments.

Prerequisites: An Amazon Redshift cluster and follow the steps in the previous section the section called "Configure Redshift" after which you should have the Amazon S3 URI for a temporary directory, *`temp-s3-dir`* and an IAM role, *`rs-role-name`*, (in account *`role-account-id`*). You will also need a `DynamicFrame` whose contents you would like to write to the database.

Using the Data Catalog

Additional Prerequisites A Data Catalog Database for the Amazon Redshift cluster and table you would like to write to. For more information about Data Catalog, see *Data discovery and cataloging*. You will identify your connection with *`redshift-dc-database-name`* and the target table with *`redshift-table-name`*.

Configuration: In your function options you will identify your Data Catalog Database with the `database` parameter, then provide table with `table_name`. You will identify your Amazon S3

temporary directory with `redshift_tmp_dir`. You will also provide *`rs-role-name`* using the `aws_iam_role` key in the `additional_options` parameter.

```
 glueContext.write_dynamic_frame.from_catalog(
    frame = input dynamic frame,
    database = "redshift-dc-database-name",
    table_name = "redshift-table-name",
    redshift_tmp_dir = args["temp-s3-dir"],
    additional_options = {"aws_iam_role": "arn:aws:iam::account-id:role/rs-role-
name"})
```

Connecting through a AWS Glue connection

You can connect to Amazon Redshift directly using the `write_dynamic_frame.from_options` method. However, rather than insert your connection details directly into your script, you can reference connection details stored in a Data Catalog connection with the `from_jdbc_conf` method. You can do this without crawling or creating Data Catalog tables for your database. For more information about Data Catalog connections, see *Connecting to data*.

Additional Prerequisites: A Data Catalog connection for your database, a Amazon Redshift table you would like to read from

Configuration: you will identify your Data Catalog connection with *`dc-connection-name`*. You will identify your Amazon Redshift database and table with *`redshift-table-name`* and *`redshift-database-name`*. You will provide your Data Catalog connection information with `catalog_connection` and your Amazon Redshift information with `dbtable` and `database`. The syntax is similar to connecting through the Data Catalog, but you put the parameters in the `connection_options` map.

```
my_conn_options = {
    "dbtable": "redshift-table-name",
    "database": "redshift-database-name",
    "aws_iam_role": "arn:aws:iam::role-account-id:role/rs-role-name"
}

glueContext.write_dynamic_frame.from_jdbc_conf(
    frame = input dynamic frame,
```

```
    catalog_connection = "dc-connection-name",
    connection_options = my_conn_options,
    redshift_tmp_dir = args["temp-s3-dir"])
```

Amazon Redshift connection option reference

The basic connection options used for all AWS Glue JDBC connections to set up information like `url`, `user` and `password` are consistent across all JDBC types. For more information about standard JDBC parameters, see the section called “JDBC connection parameters”.

The Amazon Redshift connection type takes some additional connection options:

- `"redshiftTmpDir"`: (Required) The Amazon S3 path where temporary data can be staged when copying out of the database.
- `"aws_iam_role"`: (Optional) ARN for an IAM role. The AWS Glue job will pass this role to the Amazon Redshift cluster to grant the cluster permissions needed to complete instructions from the job.

Additional connection options available in AWS Glue 4.0+

You can also pass options for the new Amazon Redshift connector through AWS Glue connection options. For a complete list of supported connector options, see the *Spark SQL parameters* section in Amazon Redshift integration for Apache Spark.

For you convenience, we reiterate certain new options here:

Name	Required	Default	Description
autopushdown	No	TRUE	Applies predicate and query pushdown by capturing and analyzing the Spark logical plans for SQL operations. The operations are translated into a

Name	Required	Default	Description
			SQL query, and then run in Amazon Redshift to improve performance.
autopushdown.s3_result_cache	No	FALSE	Caches the SQL query to unload data for Amazon S3 path mapping in memory so that the same query doesn't need to run again in the same Spark session. Only supported when `autopushdown` is enabled.
unload_s3_format	No	PARQUET	PARQUET - Unloads the query results in Parquet format. TEXT - Unloads the query results in pipe-delimited text format.
sse_kms_key	No	N/A	The AWS SSE-KMS key to use for encryption during UNL0AD operations instead of the default encryption for AWS.

Name	Required	Default	Description
extracopyoptions	No	N/A	A list of extra options to append to the Amazon Redshift `COPY`command when loading data, such as `TRUNCATECOLUMNS` or `MAXERROR n` (for other options see COPY: Optional parameters). Note that because these options are appended to the end of the `COPY` command, only options that make sense at the end of the command can be used. That should cover most possible use cases.
csvnullstring (experimental)	No	NULL	The String value to write for nulls when using the CSV `tempformat` . This should be a value that doesn't appear in your actual data.

These new parameters can be used in the following ways.

New options for performance improvement

The new connector introduces some new performance improvement options:

- `autopushdown`: Enabled by default.
- `autopushdown.s3_result_cache`: Disabled by default.
- `unload_s3_format`: PARQUET by default.

For information about using these options, see Amazon Redshift integration for Apache Spark. We recommend that you don't turn on `autopushdown.s3_result_cache` when you have mixed read and write operations because the cached results might contain stale information. The option `unload_s3_format` is set to PARQUET by default for the UNLOAD command, to improve performance and reduce storage cost. To use the UNLOAD command default behavior, reset the option to TEXT.

New encryption option for reading

By default, the data in the temporary folder that AWS Glue uses when it reads data from the Amazon Redshift table is encrypted using SSE-S3 encryption. To use customer managed keys from AWS Key Management Service (AWS KMS) to encrypt your data, you can set up `("sse_kms_key" # kmsKey)` where ksmKey is the key ID from AWS KMS, instead of the legacy setting option `("extraunloadoptions" # s"ENCRYPTED KMS_KEY_ID '$kmsKey'")` in AWS Glue version 3.0.

```
datasource0 = glueContext.create_dynamic_frame.from_catalog(
  database = "database-name",
  table_name = "table-name",
  redshift_tmp_dir = args["TempDir"],
  additional_options = {"sse_kms_key":"<KMS_KEY_ID>"},
  transformation_ctx = "datasource0"
)
```

Support IAM-based JDBC URL

The new connector supports an IAM-based JDBC URL so you don't need to pass in a user/password or secret. With an IAM-based JDBC URL, the connector uses the job runtime role to access to the Amazon Redshift data source.

Step 1: Attach the following minimal required policy to your AWS Glue job runtime role.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": "redshift:GetClusterCredentials",
            "Resource": [
                "arn:aws:redshift:us-east-1:111122223333:dbgroup:<cluster name>/
*",
                "arn:aws:redshift:*:111122223333:dbuser:*/*",
                "arn:aws:redshift:us-east-1:111122223333:dbname:<cluster name>/
<database name>"
            ]
        },
        {
            "Sid": "VisualEditor1",
            "Effect": "Allow",
            "Action": "redshift:DescribeClusters",
            "Resource": "*"
        }
    ]
}
```

Step 2: Use the IAM-based JDBC URL as follows. Specify a new option `DbUser` with the Amazon Redshift user name that you're connecting with.

```
conn_options = {
     // IAM-based JDBC URL
    "url": "jdbc:redshift:iam://<cluster name>:<region>/<database name>",
    "dbtable": dbtable,
    "redshiftTmpDir": redshiftTmpDir,
    "aws_iam_role": aws_iam_role,
    "DbUser": "<Redshift User name>" // required for IAM-based JDBC URL
    }

redshift_write = glueContext.write_dynamic_frame.from_options(
    frame=dyf,
    connection_type="redshift",
```

```
    connection_options=conn_options
)

redshift_read = glueContext.create_dynamic_frame.from_options(
    connection_type="redshift",
    connection_options=conn_options
)
```

> **Note**
>
> A `DynamicFrame` currently only supports an IAM-based JDBC URL with a `DbUser` in the `GlueContext.create_dynamic_frame.from_options` workflow.

Migrating from AWS Glue version 3.0 to version 4.0

In AWS Glue 4.0, ETL jobs have access to a new Amazon Redshift Spark connector and a new JDBC driver with different options and configuration. The new Amazon Redshift connector and driver are written with performance in mind, and keep transactional consistency of your data. These products are documented in the Amazon Redshift documentation. For more information, see:

- Amazon Redshift integration for Apache Spark
- Amazon Redshift JDBC driver, version 2.1

Table/column names and identifiers restriction

The new Amazon Redshift Spark connector and driver have a more restricted requirement for the Redshift table name. For more information, see Names and identifiers to define your Amazon Redshift table name. The job bookmark workflow might not work with a table name that doesn't match the rules and with certain characters, such as a space.

If you have legacy tables with names that don't conform to the Names and identifiers rules and see issues with bookmarks (jobs reprocessing old Amazon Redshift table data), we recommend that you rename your table names. For more information, see ALTER TABLE examples.

Default tempformat change in Dataframe

The AWS Glue version 3.0 Spark connector defaults the `tempformat` to CSV while writing to Amazon Redshift. To be consistent, in AWS Glue version 3.0, the `DynamicFrame` still defaults the

`tempformat` to use CSV. If you've previously used Spark Dataframe APIs directly with the Amazon Redshift Spark connector, you can explicitly set the `tempformat` to CSV in the `DataframeReader` /`Writer` options. Otherwise, `tempformat` defaults to `AVRO` in the new Spark connector.

Behavior change: map Amazon Redshift data type REAL to Spark data type FLOAT instead of DOUBLE

In AWS Glue version 3.0, Amazon Redshift `REAL` is converted to a Spark `DOUBLE` type. The new Amazon Redshift Spark connector has updated the behavior so that the Amazon Redshift `REAL` type is converted to, and back from, the Spark `FLOAT` type. If you have a legacy use case where you still want the Amazon Redshift `REAL` type to be mapped to a Spark `DOUBLE` type, you can use the following workaround:

- For a `DynamicFrame`, map the `Float` type to a `Double` type with `DynamicFrame.ApplyMapping`. For a `Dataframe`, you need to use `cast`.

Code example:

```
dyf_cast = dyf.apply_mapping([('a', 'long', 'a', 'long'), ('b', 'float', 'b',
 'double')])
```

Handling VARBYTE Data Type

When working with AWS Glue 3.0 and Amazon Redshift data types, AWS Glue 3.0 converts Amazon Redshift `VARBYTE` to Spark `STRING` type. However, the latest Amazon Redshift Spark connector doesn't support the `VARBYTE` data type. To work around this limitation, you can create a Redshift view that transforms `VARBYTE` columns to a supported data type. Then, use the new connector to load data from this view instead of the original table, which ensures compatibility while maintaining access to your `VARBYTE` data.

Example for Redshift query:

```
CREATE VIEW view_name AS SELECT FROM_VARBYTE(varbyte_column, 'hex') FROM table_name
```

Kafka connections

You can use a Kafka connection to read and write to Kafka data streams using information stored in a Data Catalog table, or by providing information to directly access the data stream. The connection supports a Kafka cluster or an Amazon Managed Streaming for Apache Kafka cluster.

You can read information from Kafka into a Spark DataFrame, then convert it to a AWS Glue DynamicFrame. You can write DynamicFrames to Kafka in a JSON format. If you directly access the data stream, use these options to provide the information about how to access the data stream.

If you use `getCatalogSource` or `create_data_frame_from_catalog` to consume records from a Kafka streaming source, or `getCatalogSink` or `write_dynamic_frame_from_catalog` to write records to Kafka, and the job has the Data Catalog database and table name information, and can use that to obtain some basic parameters for reading from the Kafka streaming source. If you use `getSource`, `getCatalogSink`, `getSourceWithFormat`, `getSinkWithFormat`, `createDataFrameFromOptions` or `create_data_frame_from_options`, or `write_dynamic_frame_from_catalog`, you must specify these basic parameters using the connection options described here.

You can specify the connection options for Kafka using the following arguments for the specified methods in the `GlueContext` class.

- Scala
  - `connectionOptions`: Use with `getSource`, `createDataFrameFromOptions`, `getSink`
  - `additionalOptions`: Use with `getCatalogSource`, `getCatalogSink`
  - `options`: Use with `getSourceWithFormat`, `getSinkWithFormat`
- Python
  - `connection_options`: Use with `create_data_frame_from_options`, `write_dynamic_frame_from_options`
  - `additional_options`: Use with `create_data_frame_from_catalog`, `write_dynamic_frame_from_catalog`
  - `options`: Use with `getSource`, `getSink`

For notes and restrictions about streaming ETL jobs, consult the section called “Streaming ETL notes and restrictions”.

Topics

- Configure Kafka
- Example: Reading from Kafka streams
- Example: Writing to Kafka streams
- Kafka connection option reference

Configure Kafka

There are no AWS prerequisites to connecting to Kafka streams available through the internet.

You can create a AWS Glue Kafka connection to manage your connection credentials. For more information, see the section called "Creating a connection for a Kafka data stream". In your AWS Glue job configuration, provide *connectionName* as an **Additional network connection**, then, in your method call, provide *connectionName* to the connectionName parameter.

In certain cases, you will need to configure additional prerequisites:

- If using Amazon Managed Streaming for Apache Kafka with IAM authentication, you will need appropriate IAM configuration.
- If using Amazon Managed Streaming for Apache Kafka within an Amazon VPC, you will need appropriate Amazon VPC configuration. You will need to create a AWS Glue connection that provides Amazon VPC connection information. You will need your job configuration to include the AWS Glue connection as an **Additional network connection**.

For more information about Streaming ETL job prerequisites, consult the section called "Streaming ETL jobs".

Example: Reading from Kafka streams

Used in conjunction with the section called "forEachBatch".

Example for Kafka streaming source:

```
kafka_options =
    { "connectionName": "ConfluentKafka",
      "topicName": "kafka-auth-topic",
      "startingOffsets": "earliest",
      "inferSchema": "true",
      "classification": "json"
    }
data_frame_datasource0 =
 glueContext.create_data_frame.from_options(connection_type="kafka",
 connection_options=kafka_options)
```

Example: Writing to Kafka streams

Examples for writing to Kafka:

Example with the `getSink` method:

```
data_frame_datasource0 =
glueContext.getSink(
 connectionType="kafka",
 connectionOptions={
  JsonOptions("""{
   "connectionName": "ConfluentKafka",
   "classification": "json",
   "topic": "kafka-auth-topic",
   "typeOfData": "kafka"}
  """)},
 transformationContext="dataframe_ApacheKafka_node1711729173428")
 .getDataFrame()
```

Example with the `write_dynamic_frame.from_options` method:

```
kafka_options =
    { "connectionName": "ConfluentKafka",
      "topicName": "kafka-auth-topic",
      "classification": "json"
    }
data_frame_datasource0 =
 glueContext.write_dynamic_frame.from_options(connection_type="kafka",
 connection_options=kafka_options)
```

Kafka connection option reference

When reading, use the following connection options with `"connectionType": "kafka"`:

- `"bootstrap.servers"` (Required) A list of bootstrap server URLs, for example, as `b-1.vpc-test-2.o4q88o.c6.kafka.us-east-1.amazonaws.com:9094`. This option must be specified in the API call or defined in the table metadata in the Data Catalog.
- `"security.protocol"` (Required) The protocol used to communicate with brokers. The possible values are `"SSL"` or `"PLAINTEXT"`.
- `"topicName"` (Required) A comma-separated list of topics to subscribe to. You must specify one and only one of `"topicName"`, `"assign"` or `"subscribePattern"`.
- `"assign"`: (Required) A JSON string specifying the specific `TopicPartitions` to consume. You must specify one and only one of `"topicName"`, `"assign"` or `"subscribePattern"`.

Example: '{"topicA":[0,1],"topicB":[2,4]}'

- `"subscribePattern"`: (Required) A Java regex string that identifies the topic list to subscribe to. You must specify one and only one of `"topicName"`, `"assign"` or `"subscribePattern"`.

  Example: 'topic.*'

- `"classification"` (Required) The file format used by the data in the record. Required unless provided through the Data Catalog.
- `"delimiter"` (Optional) The value separator used when `classification` is CSV. Default is `","`
- `"startingOffsets"`: (Optional) The starting position in the Kafka topic to read data from. The possible values are `"earliest"` or `"latest"`. The default value is `"latest"`.
- `"startingTimestamp"`: (Optional, supported only for AWS Glue version 4.0 or later) The Timestamp of the record in the Kafka topic to read data from. The possible value is a Timestamp string in UTC format in the pattern `yyyy-mm-ddTHH:MM:SSZ` (where `Z` represents a UTC timezone offset with a +/-. For example: "2023-04-04T08:00:00-04:00").

  Note: Only one of 'startingOffsets' or 'startingTimestamp' can be present in the Connection Options list of the AWS Glue streaming script, including both these properties will result in job failure.

- `"endingOffsets"`: (Optional) The end point when a batch query is ended. Possible values are either `"latest"` or a JSON string that specifies an ending offset for each `TopicPartition`.

  For the JSON string, the format is `{"topicA":{"0":23,"1":-1},"topicB":{"0":-1}}`. The value `-1` as an offset represents `"latest"`.

- `"pollTimeoutMs"`: (Optional) The timeout in milliseconds to poll data from Kafka in Spark job executors. The default value is `600000`.
- `"numRetries"`: (Optional) The number of times to retry before failing to fetch Kafka offsets. The default value is `3`.
- `"retryIntervalMs"`: (Optional) The time in milliseconds to wait before retrying to fetch Kafka offsets. The default value is `10`.
- `"maxOffsetsPerTrigger"`: (Optional) The rate limit on the maximum number of offsets that are processed per trigger interval. The specified total number of offsets is proportionally split across `topicPartitions` of different volumes. The default value is null, which means that the consumer reads all offsets until the known latest offset.

- `"minPartitions"`: (Optional) The desired minimum number of partitions to read from Kafka. The default value is null, which means that the number of spark partitions is equal to the number of Kafka partitions.
- `"includeHeaders"`: (Optional) Whether to include the Kafka headers. When the option is set to "true", the data output will contain an additional column named "glue_streaming_kafka_headers" with type `Array[Struct(key: String, value: String)]`. The default value is "false". This option is available in AWS Glue version 3.0 or later.
- `"schema"`: (Required when inferSchema set to false) The schema to use to process the payload. If classification is `avro` the provided schema must be in the Avro schema format. If the classification is not `avro` the provided schema must be in the DDL schema format.

  The following are schema examples.

  Example in DDL schema format

  ```
  'column1' INT, 'column2' STRING , 'column3' FLOAT
  ```

  Example in Avro schema format

  ```
  {
  "type":"array",
  "items":
  {
  "type":"record",
  "name":"test",
  "fields":
  [
    {
      "name":"_id",
      "type":"string"
    },
    {
      "name":"index",
      "type":
      [
        "int",
        "string",
        "float"
      ]
    }
  ]
  ```

```
}
}
```

- `"inferSchema"`: (Optional) The default value is 'false'. If set to 'true', the schema will be detected at runtime from the payload within `foreachbatch`.
- `"avroSchema"`: (Deprecated) Parameter used to specify a schema of Avro data when Avro format is used. This parameter is now deprecated. Use the `schema` parameter.
- `"addRecordTimestamp"`: (Optional) When this option is set to 'true', the data output will contain an additional column named "__src_timestamp" that indicates the time when the corresponding record received by the topic. The default value is 'false'. This option is supported in AWS Glue version 4.0 or later.
- `"emitConsumerLagMetrics"`: (Optional) When the option is set to 'true', for each batch, it will emit the metrics for the duration between the oldest record received by the topic and the time it arrives in AWS Glue to CloudWatch. The metric's name is "glue.driver.streaming.maxConsumerLagInMs". The default value is 'false'. This option is supported in AWS Glue version 4.0 or later.

When writing, use the following connection options with `"connectionType": "kafka"`:

- `"connectionName"` (Required) Name of the AWS Glue connection used to connect to the Kafka cluster (similar to Kafka source).
- `"topic"` (Required) If a topic column exists then its value is used as the topic when writing the given row to Kafka, unless the topic configuration option is set. That is, the `topic` configuration option overrides the topic column.
- `"partition"` (Optional) If a valid partition number is specified, that `partition` will be used when sending the record.

  If no partition is specified but a `key` is present, a partition will be chosen using a hash of the key.

  If neither `key` nor `partition` is present, a partition will be chosen based on sticky partitioning those changes when at least batch.size bytes are produced to the partition.
- `"key"` (Optional) Used for partitioning if `partition` is null.
- `"classification"` (Optional) The file format used by the data in the record. We only support JSON, CSV and Avro.

With Avro format, we can provide a custom avroSchema to serialize with, but note that this needs to be provided on the source for deserializing as well. Else, by default it uses the Apache AvroSchema for serializing.

Additionally, you can fine-tune the Kafka sink as required by updating the Kafka producer configuration parameters. Note that there is no allow listing on connection options, all the key-value pairs are persisted on the sink as is.

However, there is a small deny list of options that will not take effect. For more information, see Kafka specific configurations.

Azure Cosmos DB connections

You can use AWS Glue for Spark to read from and write to existing containers in Azure Cosmos DB using the NoSQL API in AWS Glue 4.0 and later versions. You can define what to read from Azure Cosmos DB with a SQL query. You connect to Azure Cosmos DB using an Azure Cosmos DB Key stored in AWS Secrets Manager through a AWS Glue connection.

For more information about Azure Cosmos DB for NoSQL, consult the Azure documentation.

Configuring Azure Cosmos DB connections

To connect to Azure Cosmos DB from AWS Glue, you will need to create and store your Azure Cosmos DB Key in a AWS Secrets Manager secret, then associate that secret with a Azure Cosmos DB AWS Glue connection.

Prerequisites:

- In Azure, you will need to identify or generate an Azure Cosmos DB Key for use by AWS Glue, `cosmosKey`. For more information, see Secure access to data in Azure Cosmos DB in the Azure documentation.

To configure a connection to Azure Cosmos DB:

1. In AWS Secrets Manager, create a secret using your Azure Cosmos DB Key. To create a secret in Secrets Manager, follow the tutorial available in Create an AWS Secrets Manager secret in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *`secretName`* for the next step.

- When selecting **Key/value pairs**, create a pair for the key `spark.cosmos.accountKey` with the value *cosmosKey*.

2. In the AWS Glue console, create a connection by following the steps in the section called "Adding an AWS Glue connection". After creating the connection, keep the connection name, *connectionName*, for future use in AWS Glue.

   - When selecting a **Connection type**, select Azure Cosmos DB.
   - When selecting an **AWS Secret**, provide *secretName*.

After creating a AWS Glue Azure Cosmos DB connection, you will need to perform the following steps before running your AWS Glue job:

- Grant the IAM role associated with your AWS Glue job permission to read *secretName*.
- In your AWS Glue job configuration, provide *connectionName* as an **Additional network connection**.

Reading from Azure Cosmos DB for NoSQL containers

Prerequisites:

- A Azure Cosmos DB for NoSQL container you would like to read from. You will need identification information for the container.

  An Azure Cosmos for NoSQL container is identified by its database and container. You must provide the database, *cosmosDBName*, and container, *cosmosContainerName*, names when connecting to the Azure Cosmos for NoSQL API.
- A AWS Glue Azure Cosmos DB connection configured to provide auth and network location information. To acquire this, complete the steps in the previous procedure, *To configure a connection to Azure Cosmos DB*. You will need the name of the AWS Glue connection, *connectionName*.

For example:

```
azurecosmos_read = glueContext.create_dynamic_frame.from_options(
    connection_type="azurecosmos",
    connection_options={
```

```
    "connectionName": connectionName,
    "spark.cosmos.database": cosmosDBName,
    "spark.cosmos.container": cosmosContainerName,
    }
)
```

You can also provide a SELECT SQL query, to filter the results returned to your DynamicFrame. You will need to configure `query`.

For example:

```
azurecosmos_read_query = glueContext.create_dynamic_frame.from_options(
    connection_type="azurecosmos",
    connection_options={
        "connectionName": "connectionName",
        "spark.cosmos.database": cosmosDBName,
        "spark.cosmos.container": cosmosContainerName,
        "spark.cosmos.read.customQuery": "query"
    }
)
```

Writing to Azure Cosmos DB for NoSQL containers

This example writes information from an existing DynamicFrame, *dynamicFrame* to Azure Cosmos DB. If the container already has information, AWS Glue will append data from your DynamicFrame. If the information in the container has a different schema from the information you write, you will run into errors.

Prerequisites:

- A Azure Cosmos DB table you would like to write to. You will need identification information for the container. **You must create the container before calling the connection method.**

  An Azure Cosmos for NoSQL container is identified by its database and container. You must provide the database, *cosmosDBName*, and container, *cosmosContainerName*, names when connecting to the Azure Cosmos for NoSQL API.
- A AWS Glue Azure Cosmos DB connection configured to provide auth and network location information. To acquire this, complete the steps in the previous procedure, *To configure a connection to Azure Cosmos DB*. You will need the name of the AWS Glue connection, *connectionName*.

For example:

```
azurecosmos_write = glueContext.write_dynamic_frame.from_options(
    frame=dynamicFrame,
    connection_type="azurecosmos",
    connection_options={
    "connectionName": connectionName,
    "spark.cosmos.database": cosmosDBName,
    "spark.cosmos.container": cosmosContainerName
)
```

Azure Cosmos DB connection option reference

- `connectionName` — Required. Used for Read/Write. The name of a AWS Glue Azure Cosmos DB connection configured to provide auth and network location information to your connection method.
- `spark.cosmos.database` — Required. Used for Read/Write. Valid Values: database names. Azure Cosmos DB for NoSQL database name.
- `spark.cosmos.container` — Required. Used for Read/Write. Valid Values: container names. Azure Cosmos DB for NoSQL container name.
- `spark.cosmos.read.customQuery` — Used for Read. Valid Values: SELECT SQL queries. Custom query to select documents to be read.

Azure SQL connections

You can use AWS Glue for Spark to read from and write to tables on Azure SQL Managed Instances in AWS Glue 4.0 and later versions. You can define what to read from Azure SQL with a SQL query. You connect to Azure SQL using user and password credentials stored in AWS Secrets Manager through a AWS Glue connection.

For more information about Azure SQL, consult the Azure SQL documentation.

Configuring Azure SQL connections

To connect to Azure SQL from AWS Glue, you will need to create and store your Azure SQL credentials in a AWS Secrets Manager secret, then associate that secret with a Azure SQL AWS Glue connection.

To configure a connection to Azure SQL:

1. In AWS Secrets Manager, create a secret using your Azure SQL credentials. To create a secret in Secrets Manager, follow the tutorial available in Create an AWS Secrets Manager secret in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.

   - When selecting **Key/value pairs**, create a pair for the key `user` with the value *azuresqlUsername*.
   - When selecting **Key/value pairs**, create a pair for the key `password` with the value *azuresqlPassword*.

2. In the AWS Glue console, create a connection by following the steps in the section called "Adding an AWS Glue connection". After creating the connection, keep the connection name, *connectionName*, for future use in AWS Glue.

   - When selecting a **Connection type**, select Azure SQL.
   - When providing **Azure SQL URL**, provide a JDBC endpoint URL.

     The URL must be in the following format:
     `jdbc:sqlserver://`*databaseServerName*`:`*databasePort*`;databaseName=`*azuresqlDBnam*

     AWS Glue requires the following URL properties:

     - `databaseName` – A default database in Azure SQL to connect to.

     For more information about JDBC URLs for Azure SQL Managed Instances, see the Microsoft documentation.

   - When selecting an **AWS Secret**, provide *secretName*.

After creating a AWS Glue Azure SQL connection, you will need to perform the following steps before running your AWS Glue job:

- Grant the IAM role associated with your AWS Glue job permission to read *secretName*.
- In your AWS Glue job configuration, provide *connectionName* as an **Additional network connection**.

Reading from Azure SQL tables

Prerequisites:

- A Azure SQL table you would like to read from. You will need identification information for the table, *`databaseName`* and *`tableIdentifier`*.

  An Azure SQL table is identified by its database, schema and table name. You must provide the database name and table name when connecting to Azure SQL. You also must provide the schema if it is not the default, "public". Database is provided through a URL property in *`connectionName`* , schema and table name through the `dbtable`.
- A AWS Glue Azure SQL connection configured to provide auth information. Complete the steps in the previous procedure, *To configure a connection to Azure SQL* to configure your auth information. You will need the name of the AWS Glue connection, *`connectionName`*.

For example:

```
azuresql_read_table = glueContext.create_dynamic_frame.from_options(
    connection_type="azuresql",
    connection_options={
        "connectionName": "connectionName",
        "dbtable": "tableIdentifier"
    }
)
```

You can also provide a SELECT SQL query, to filter the results returned to your DynamicFrame. You will need to configure `query`.

For example:

```
azuresql_read_query = glueContext.create_dynamic_frame.from_options(
    connection_type="azuresql",
    connection_options={
        "connectionName": "connectionName",
        "query": "query"
    }
)
```

Writing to Azure SQL tables

This example writes information from an existing DynamicFrame, *dynamicFrame* to Azure SQL. If the table already has information, AWS Glue will append data from your DynamicFrame.

Prerequisites:

- A Azure SQL table you would like to write to. You will need identification information for the table, *databaseName* and *tableIdentifier*.

  An Azure SQL table is identified by its database, schema and table name. You must provide the database name and table name when connecting to Azure SQL. You also must provide the schema if it is not the default, "public". Database is provided through a URL property in *connectionName* , schema and table name through the `dbtable`.
- Azure SQL auth information. Complete the steps in the previous procedure, *To configure a connection to Azure SQL* to configure your auth information. You will need the name of the AWS Glue connection, *connectionName*.

For example:

```
azuresql_write = glueContext.write_dynamic_frame.from_options(
    connection_type="azuresql",
    connection_options={
        "connectionName": "connectionName",
        "dbtable": "tableIdentifier"
    }
)
```

Azure SQL connection option reference

- `connectionName` — Required. Used for Read/Write. The name of a AWS Glue Azure SQL connection configured to provide auth information to your connection method.
- `databaseName` — Used for Read/Write. Valid Values: Azure SQL database names. The name of the database in Azure SQL to connect to.
- `dbtable` — Required for writing, required for reading unless `query` is provided. Used for Read/Write. Valid Values: Names of Azure SQL tables, or period separated schema/table name combinations. Used to specify the table and schema that identify the table to connect to. The default schema is "public". If your table is in a non-default schema, provide this information in the form *schemaName*.*tableName*.

- `query` — Used for Read. A Transact-SQL SELECT query defining what should be retrieved when reading from Azure SQL. For more information, see the Microsoft documentation.

BigQuery connections

You can use AWS Glue for Spark to read from and write to tables in Google BigQuery in AWS Glue 4.0 and later versions. You can read from BigQuery with a Google SQL query. You connect to BigQuery using credentials stored in AWS Secrets Manager through a AWS Glue connection.

For more information about Google BigQuery, see the Google Cloud BigQuery website.

Configuring BigQuery connections

To connect to Google BigQuery from AWS Glue, you will need to create and store your Google Cloud Platform credentials in a AWS Secrets Manager secret, then associate that secret with a Google BigQuery AWS Glue connection.

To configure a connection to BigQuery:

1. In Google Cloud Platform, create and identify relevant resources:
   - Create or identify a GCP project containing BigQuery tables you would like to connect to.
   - Enable the BigQuery API. For more information, see Use the BigQuery Storage Read API to read table data .
2. In Google Cloud Platform, create and export service account credentials:

   You can use the BigQuery credentials wizard to expedite this step: Create credentials.

   To create a service account in GCP, follow the tutorial available in Create service accounts.
   - When selecting **project**, select the project containing your BigQuery table.
   - When selecting GCP IAM roles for your service account, add or create a role that would grant appropriate permissions to run BigQuery jobs to read, write or create BigQuery tables.

   To create credentials for your service account, follow the tutorial available in Create a service account key.
   - When selecting key type, select **JSON**.

You should now have downloaded a JSON file with credentials for your service account. It should look similar to the following:

```
{
  "type": "service_account",
  "project_id": "*****",
  "private_key_id": "*****",
  "private_key": "*****",
  "client_email": "*****",
  "client_id": "*****",
  "auth_uri": "https://accounts.google.com/o/oauth2/auth",
  "token_uri": "https://oauth2.googleapis.com/token",
  "auth_provider_x509_cert_url": "https://www.googleapis.com/oauth2/v1/certs",
  "client_x509_cert_url": "*****",
  "universe_domain": "googleapis.com"
}
```

3. Upload your credentials JSON file to an appropriately secure Amazon S3 location. Retain the path to the file, *s3secretpath* for future steps.
4. In AWS Secrets Manager, create a secret using your Google Cloud Platform credentials. To create a secret in Secrets Manager, follow the tutorial available in Create an AWS Secrets Manager secret in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.

   When creating Key/value pairs, specify keys and values as followings:

   - For `token_uri`, `client_x509_cert_url`, `private_key_id`, `project_id`, `universe_domain`, `auth_provider_x509_cert_url`, `auth_uri`, `client_email`, `private_key`, `type`, `client_id` keys, specify the corresponding values in the downloaded JSON file.
   - For `spark.hadoop.google.cloud.auth.service.account.json.keyfile` key, specify the *s3secretpath*.
5. In the AWS Glue Data Catalog, create a connection by following the steps in the section called "Adding an AWS Glue connection". After creating the connection, keep the connection name, *connectionName*, for the next step.

   - When selecting a **Connection type**, select Google BigQuery.
   - When selecting an **AWS Secret**, provide *secretName*.

6. Grant the IAM role associated with your AWS Glue job permission to read *secretName*.
7. In your AWS Glue job configuration, provide *connectionName* as an **Additional network connection**.

Reading from BigQuery tables

Prerequisites:

- A BigQuery table you would like to read from. You will need the BigQuery table and dataset names, in the form `[dataset].[table]`. Let's call this *tableName*.
- The billing project for the BigQuery table. You will need the name of the project, *parentProject*. If there is no billing parent project, use the project containing the table.
- BigQuery auth information. Complete the steps *To manage your connection credentials with AWS Glue* to configure your auth information. You will need the name of the AWS Glue connection, *connectionName*.

For example:

```
bigquery_read = glueContext.create_dynamic_frame.from_options(
    connection_type="bigquery",
    connection_options={
        "connectionName": "connectionName",
        "parentProject": "parentProject",
        "sourceType": "table",
        "table": "tableName",
    }
```

You can also provide a query, to filter the results returned to your DynamicFrame. You will need to configure `query`, `sourceType`, `viewsEnabled` and `materializationDataset`.

For example:

Additional prerequisites:

You will need to create or identify a BigQuery dataset, *materializationDataset*, where BigQuery can write materialized views for your queries.

You will need to grant appropriate GCP IAM permissions to your service account to create tables in *materializationDataset*.

```
glueContext.create_dynamic_frame.from_options(
            connection_type="bigquery",
            connection_options={
                "connectionName": "connectionName",
                "materializationDataset": materializationDataset,
                "parentProject": "parentProject",
                "viewsEnabled": "true",
                "sourceType": "query",
                "query": "select * from bqtest.test"
            }
        )
```

Writing to BigQuery tables

This example writes directly to the BigQuery service. BigQuery also supports the "indirect" writing method. For more information about configuring indirect writes, see the section called “Using indirect write with Google BigQuery”.

Prerequisites:

- A BigQuery table you would like to write to. You will need the BigQuery table and dataset names, in the form `[dataset].[table]`. You can also provide a new table name that will automatically be created. Let's call this *tableName*.
- The billing project for the BigQuery table. You will need the name of the project, *parentProject*. If there is no billing parent project, use the project containing the table.
- BigQuery auth information. Complete the steps *To manage your connection credentials with AWS Glue* to configure your auth information. You will need the name of the AWS Glue connection, *connectionName*.

For example:

```
bigquery_write = glueContext.write_dynamic_frame.from_options(
    frame=frameToWrite,
    connection_type="bigquery",
    connection_options={
        "connectionName": "connectionName",
```

```
        "parentProject": "parentProject",
        "writeMethod": "direct",
        "table": "tableName",
    }
)
```

BigQuery connection option reference

- `project` — Default: Google Cloud service account default. Used for Read/Write. The name of a Google Cloud project associated with your table.
- `table` — (Required) Used for Read/Write. The name of your BigQuery table in the format `[[project:]dataset.]`.
- `dataset` — Required when not defined through the `table` option. Used for Read/Write. The name of the dataset containing your BigQuery table.
- `parentProject` — Default: Google Cloud service account default. Used for Read/Write. The name of a Google Cloud project associated with `project` used for billing.
- `sourceType` — Used for Read. Required when reading. Valid Values: `table`, `query` Informs AWS Glue of whether you will read by table or by query.
- `materializationDataset` — Used for Read. Valid Values: strings. The name of a BigQuery dataset used to store materializations for views.
- `viewsEnabled` — Used for Read. Default: false. Valid Values: true, false. Configures whether BigQuery will use views.
- `query` — Used for Read. Used when `viewsEnabled` is true. A GoogleSQL DQL query.
- `temporaryGcsBucket` — Used for Write. Required when `writeMethod` is set to default (`indirect`). Name of a Google Cloud Storage bucket used to store an intermediate form of your data while writing to BigQuery.
- `writeMethod` — Default: `indirect`. Valid Values: `direct`, `indirect`. Used for Write. Specifies the method used to write your data.
  - If set to `direct`, your connector will write using the BigQuery Storage Write API.
  - If set to `indirect`, you connector will write to Google Cloud Storage, then transfer it to BigQuery using a load operation. Your Google Cloud service account will need appropriate GCS permissions.

Using indirect write with Google BigQuery

This example uses indirect write, which writes data to Google Cloud Storage and copies it to Google BigQuery.

Prerequisites:

You will need a temporary Google Cloud Storage bucket, *temporaryBucket*.

The GCP IAM role for AWS Glue's GCP service account will need appropriate GCS permissions to access *temporaryBucket*.

Additional Configuration:

To configure indirect write with BigQuery:

1. Assess the section called "Configuring BigQuery" and locate or redownload your GCP credentials JSON file. Identify *secretName*, the AWS Secrets Manager secret for the Google BigQuery AWS Glue connection used in your job.
2. Upload your credentials JSON file to an appropriately secure Amazon S3 location. Retain the path to the file, *s3secretpath* for future steps.
3. Edit *secretName*, adding the `spark.hadoop.google.cloud.auth.service.account.json.keyfile` key. Set the value to *s3secretpath*.
4. Grant your AWS Glue job Amazon S3 IAM permissions to access *s3secretpath*.

You can now provide your temporary GCS bucket location to your write method. You do not need to provide `writeMethod`, as `indirect` is historically the default.

```
bigquery_write = glueContext.write_dynamic_frame.from_options(
    frame=frameToWrite,
    connection_type="bigquery",
    connection_options={
        "connectionName": "connectionName",
        "parentProject": "parentProject",
        "temporaryGcsBucket": "temporaryBucket",
        "table": "tableName",
    }
)
```

JDBC connections

Certain, typically relational, database types support connecting through the JDBC standard. For more information about JDBC, see the Java JDBC API documentation. AWS Glue natively supports connecting to certain databases through their JDBC connectors - the JDBC libraries are provided in AWS Glue Spark jobs. When connecting to these database types using AWS Glue libraries, you have access to a standard set of options.

The JDBC connectionType values include the following:

- `"connectionType": "sqlserver"`: Designates a connection to a Microsoft SQL Server database.
- `"connectionType": "mysql"`: Designates a connection to a MySQL database.
- `"connectionType": "oracle"`: Designates a connection to an Oracle database.
- `"connectionType": "postgresql"`: Designates a connection to a PostgreSQL database.
- `"connectionType": "redshift"`: Designates a connection to an Amazon Redshift database. For more information, see the section called “Redshift connections”.

The following table lists the JDBC driver versions that AWS Glue supports.

Product	JDBC driver versions for Glue 5.1	JDBC driver versions for Glue 5.0	JDBC driver versions for Glue 4.0	JDBC driver versions for Glue 3.0	JDBC driver versions for Glue 0.9, 1.0, 2.0
Microsoft SQL Server	10.2.0	10.2.0	9.4.0	7.x	6.x
MySQL	8.0.33	8.0.33	8.0.23	8.0.23	5.1
Oracle Database	23.3.0.23.09	23.3.0.23.09	21.7	21.1	11.2
PostgreSQL	42.7.3	42.7.3	42.3.6	42.2.18	42.1.x
Amazon Redshift *	redshift-jdbc42-2.1.0.29	redshift-jdbc42-2.1.0.29	redshift-jdbc42-2.1.0.16	redshift-jdbc41-1.2.12.1017	redshift-jdbc41-1.2.12.1017

* For the Amazon Redshift connection type, all other option name/value pairs that are included in connection options for a JDBC connection, including formatting options, are passed directly to the underlying SparkSQL DataSource. In AWS Glue with Spark jobs in AWS Glue 4.0 and later versions, the AWS Glue native connector for Amazon Redshift uses the Amazon Redshift integration for Apache Spark. For more information see Amazon Redshift integration for Apache Spark. In previous versions, see Amazon Redshift data source for Spark.

To configure your Amazon VPC to connect to Amazon RDS data stores using JDBC, refer to the section called "Setting up Amazon VPC to connect to Amazon RDS data stores".

> **Note**
>
> AWS Glue jobs are only associated with one subnet during a run. This may impact your ability to connect to multiple data sources through the same job. This behavior is not limited to JDBC sources.

Topics

- JDBC connection option reference
- Use sampleQuery
- Use custom JDBC driver
- Reading from JDBC tables in parallel
- Setting up Amazon VPC for JDBC connections to Amazon RDS data stores from AWS Glue

JDBC connection option reference

If you already have a JDBC AWS Glue connection defined, you can reuse the configuration properties defined in it, such as: url, user and password; so you don't have to specify them in the code as connection options. This feature is available in AWS Glue 3.0 and later versions. To do so, use the following connection properties:

- `"useConnectionProperties"`: Set it to "true" to indicate you want to use the configuration from a connection.
- `"connectionName"`: Enter the connection name to retrieve the configuration from, the connection must be defined in the same region as the job.

Use these connection options with JDBC connections:

- `"url"`: (Required) The JDBC URL for the database.
- `"dbtable"`: (Required) The database table to read from. For JDBC data stores that support schemas within a database, specify `schema.table-name`. If a schema is not provided, then the default "public" schema is used.
- `"user"`: (Required) The user name to use when connecting.
- `"password"`: (Required) The password to use when connecting.
- (Optional) The following options allow you to supply a custom JDBC driver. Use these options if you must use a driver that AWS Glue does not natively support.

  ETL jobs can use different JDBC driver versions for the data source and target, even if the source and target are the same database product. This allows you to migrate data between source and target databases with different versions. To use these options, you must first upload the JAR file of the JDBC driver to Amazon S3.

  - `"customJdbcDriverS3Path"`: The Amazon S3 path of the custom JDBC driver.
  - `"customJdbcDriverClassName"`: The class name of JDBC driver.
- `"bulkSize"`: (Optional) Used to configure parallel inserts for speeding up bulk loads into JDBC targets. Specify an integer value for the degree of parallelism to use when writing or inserting data. This option is helpful for improving the performance of writes into databases such as the Arch User Repository (AUR).
- `"hashfield"` (Optional) A string, used to specify the name of a column in the JDBC table to be used to divide the data into partitions when reading from JDBC tables in parallel. Provide "hashfield" OR "hashexpression". For more information, see the section called “Reading from JDBC in parallel”.
- `"hashexpression"` (Optional) A SQL select clause returning a whole number. Used to divide the data in a JDBC table into partitions when reading from JDBC tables in parallel. Provide "hashfield" OR "hashexpression". For more information, see the section called “Reading from JDBC in parallel”.
- `"hashpartitions"` (Optional) A positive integer. Used to specify the number of parallel reads of the JDBC table when reading from JDBC tables in parallel. Default: 7. For more information, see the section called “Reading from JDBC in parallel”.
- `"sampleQuery"`: (Optional) A custom SQL query statement. Used to specify a subset of information in a table to retrieve a sample of the table contents. **When configured without**

regard to your data, it can be less efficient than DynamicFrame methods, causing timeouts or out of memory errors. For more information, see the section called “Use sampleQuery”.

- `"enablePartitioningForSampleQuery"`: (Optional) A boolean. Default: false. Used to enable reading from JDBC tables in parallel when specifying `sampleQuery`. **If set to true, `sampleQuery` must end with "where" or "and" for AWS Glue to append partitioning conditions.** For more information, see the section called “Use sampleQuery”.
- `"sampleSize"`: (Optional) A positive integer. Limits the number of rows returned by the sample query. Works only when `enablePartitioningForSampleQuery` is true. If partitioning is not enabled, you should instead directly add `"limit x"` in the `sampleQuery` to limit the size. For more information, see the section called “Use sampleQuery”.

Use sampleQuery

This section explains how to use `sampleQuery`, `sampleSize` and `enablePartitioningForSampleQuery`.

`sampleQuery` can be an efficient way to sample a few rows of your dataset. By default, the query is run by a single executor. When configured without regard to your data, it can be less efficient than DynamicFrame methods, causing timeouts or out of memory errors. Running SQL on the underlying database as part of your ETL pipeline is generally only needed for performance purposes. If you are trying to preview a few rows of your dataset, consider using the section called “show”. If you are trying to transform your dataset using SQL, consider using the section called “toDF” to define a SparkSQL transform against your data in a DataFrame form.

While your query may manipulate a variety of tables, `dbtable` remains required.

Using sampleQuery to retrieve a sample of your table

When using default sampleQuery behavior to retrieve a sample of your data, AWS Glue does not expect substantial throughput, so it runs your query on a single executor. In order to limit the data you provide and not cause performance problems, we suggest you provide SQL with a `LIMIT` clause.

Example Use sampleQuery without partitioning

The following code example shows how to use `sampleQuery` without partitioning.

```
//A full sql query statement.
val query = "select name from $tableName where age > 0 limit 1"
```

```
val connectionOptions = JsonOptions(Map(
    "url" -> url,
    "dbtable" -> tableName,
    "user" -> user,
    "password" -> password,
    "sampleQuery" -> query ))
val dyf = glueContext.getSource("mysql", connectionOptions)
          .getDynamicFrame()
```

Using sampleQuery against larger datasets

If you're reading a large dataset, you might need to enable JDBC partitioning to query a table in parallel. For more information, see the section called “Reading from JDBC in parallel”. To use `sampleQuery` with JDBC partitioning, set `enablePartitioningForSampleQuery` to true. Enabling this feature requires you to make some changes to your `sampleQuery`.

When using JDBC partitioning with `sampleQuery`, your query must end with "where" or "and" for AWS Glue to append partitioning conditions.

If you would like to limit the results of your sampleQuery when reading from JDBC tables in parallel, set the `"sampleSize"` parameter rather than specifying a `LIMIT` clause.

Example Use sampleQuery with JDBC partitioning

The following code example shows how to use `sampleQuery` with JDBC partitioning.

```
//note that the query should end with "where" or "and" if use with JDBC partitioning.
val query = "select name from $tableName where age > 0 and"

//Enable JDBC partitioning by setting hashfield.
//to use sampleQuery with partitioning, set enablePartitioningForSampleQuery.
//use sampleSize to limit the size of returned data.
val connectionOptions = JsonOptions(Map(
    "url" -> url,
    "dbtable" -> tableName,
    "user" -> user,
    "password" -> password,
    "hashfield" -> primaryKey,
    "sampleQuery" -> query,
    "enablePartitioningForSampleQuery" -> true,
    "sampleSize" -> "1" ))
val dyf = glueContext.getSource("mysql", connectionOptions)
          .getDynamicFrame()
```

Notes and Restrictions:

Sample queries cannot be used together with job bookmarks. The bookmark state will be ignored when configuration for both are provided.

Use custom JDBC driver

The following code examples show how to read from and write to JDBC databases with custom JDBC drivers. They demonstrate reading from one version of a database product, and writing to a later version of the same product.

Python

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext, SparkConf
from awsglue.context import GlueContext
from awsglue.job import Job
import time
from pyspark.sql.types import StructType, StructField, IntegerType, StringType

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

# Construct JDBC connection options

  }
}
```

Reading from JDBC tables in parallel

You can set properties of your JDBC table to enable AWS Glue to read data in parallel. When you set certain properties, you instruct AWS Glue to run parallel SQL queries against logical partitions of your data. You can control partitioning by setting a hash field or a hash expression. You can also control the number of parallel reads that are used to access your data.

Reading from JDBC tables in parallel is an optimization technique that may improve performance. For more information about the process of identifying when this technique is appropriate, consult Reduce the amount of data scan in the *Best practices for performance tuning AWS Glue for Apache Spark jobs* guide on AWS Prescriptive Guidance.

To enable parallel reads, you can set key-value pairs in the parameters field of your table structure. Use JSON notation to set a value for the parameter field of your table. For more information about editing the properties of a table, see Viewing and managing table details. You can also enable parallel reads when you call the ETL (extract, transform, and load) methods `create_dynamic_frame_from_options` and `create_dynamic_frame_from_catalog`. For more information about specifying options in these methods, see from_options and from_catalog.

You can use this method for JDBC tables, that is, most tables whose base data is a JDBC data store. These properties are ignored when reading Amazon Redshift and Amazon S3 tables.

hashfield

Set `hashfield` to the name of a column in the JDBC table to be used to divide the data into partitions. For best results, this column should have an even distribution of values to spread the data between partitions. This column can be of any data type. AWS Glue generates non-overlapping queries that run in parallel to read the data partitioned by this column. For example, if your data is evenly distributed by month, you can use the `month` column to read each month of data in parallel.

```
'hashfield': 'month'
```

AWS Glue creates a query to hash the field value to a partition number and runs the query for all partitions in parallel. To use your own query to partition a table read, provide a `hashexpression` instead of a `hashfield`.

hashexpression

Set `hashexpression` to an SQL expression (conforming to the JDBC database engine grammar) that returns a whole number. A simple expression is the name of any numeric column in the table. AWS Glue generates SQL queries to read the JDBC data in parallel using the `hashexpression` in the `WHERE` clause to partition data.

For example, use the numeric column `customerID` to read data partitioned by a customer number.

```
'hashexpression': 'customerID'
```

To have AWS Glue control the partitioning, provide a `hashfield` instead of a `hashexpression`.

hashpartitions

Set `hashpartitions` to the number of parallel reads of the JDBC table. If this property is not set, the default value is 7.

For example, set the number of parallel reads to `5` so that AWS Glue reads your data with five queries (or fewer).

```
'hashpartitions': '5'
```

Setting up Amazon VPC for JDBC connections to Amazon RDS data stores from AWS Glue

When using JDBC to connect to databases in Amazon RDS, you will need to perform additional setup. To enable AWS Glue components to communicate with Amazon RDS, you must set up access to your Amazon RDS data stores in Amazon VPC. To enable AWS Glue to communicate between its components, specify a security group with a self-referencing inbound rule for all TCP ports. By creating a self-referencing rule, you can restrict the source to the same security group in the VPC. A self-referencing rule will not open the VPC to all networks. The default security group for your VPC might already have a self-referencing inbound rule for ALL Traffic.

To set up access between AWS Glue and Amazon RDS data stores

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the Amazon RDS console, identify the security group(s) used to control access to your Amazon RDS database.

   In the left navigation pane, choose **Databases**, then select the instance you would like to connect to from the list in the main pane.

   In the database detail page, find **VPC security groups** on the **Connectivity & security** tab.
3. Based on your network architecture, identify which associated security group is best to modify to allow access for the AWS Glue service. Save its name, *`database-security-group`* for future reference. If there is no appropriate security group, follow the directions to Provide access to your DB instance in your VPC by creating a security group in the Amazon RDS documentation.
4. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
5. In the Amazon VPC console, identify how to update *`database-security-group`*.

   In the left navigation pane, choose **Security groups**, then select *`database-security-group`* from the list in the main pane.

6. Identify the security group ID for *database-security-group*, *database-sg-id*. Save it for future reference.

   In the security group detail page, find **Security group ID**.

7. Alter the inbound rules for *database-security-group*, add a self-referencing rule to allow AWS Glue components to communicate. Specifically, add or confirm that there is a rule where **Type** is `All TCP`, **Protocol** is `TCP`, **Port Range** includes all ports, and **Source** is *database-sg-id*. Verify that the security group you have entered for **Source** is the same as the security group you are editing.

   In the security group detail page, select **Edit inbound rules**.

   The inbound rule looks similar to this:

Type	Protocol	Port range	Source
All TCP	TCP	0–65535	*database-sg-id*

8. Add rules for outbound traffic.

   In the security group detail page, select **Edit outbound rules**.

   If you security group allows all outbound traffic, you do not need separate rules. For example:

Type	Protocol	Port range	Destination
All Traffic	ALL	ALL	0.0.0.0/0

   If your network architecture is designed for you to restrict outbound traffic, create the following outbound rules:

   Create a self-referencing rule where **Type** is `All TCP`, **Protocol** is `TCP`, **Port Range** includes all ports, and **Destination** is *database-sg-id*. Verify that the security group you have entered for **Destination** is the same as the security group you are editing.

   If using an Amazon S3 VPC endpoint, add an HTTPS rule to allow traffic from the VPC to Amazon S3. Create a rule where **Type** is `HTTPS`, **Protocol** is `TCP`, **Port Range** is `443` and **Destination** is the ID of the managed prefix list for the Amazon S3 gateway endpoint, *s3-*

prefix-list-id. For more information about prefix lists and Amazon S3 gateway endpoints, see Gateway endpoints for Amazon S3 in the Amazon VPC documentation.

For example:

Type	Protocol	Port range	Destination
All TCP	TCP	0–65535	*database-sg-id*
HTTPS	TCP	443	*s3-prefix-list-id*

MongoDB connections

You can use AWS Glue for Spark to read from and write to tables in MongoDB and MongoDB Atlas in AWS Glue 4.0 and later versions. You can connect to MongoDB using username and password credentials credentials stored in AWS Secrets Manager through a AWS Glue connection.

For more information about MongoDB, consult the MongoDB documentation.

Configuring MongoDB connections

To connect to MongoDB from AWS Glue, you will need your MongoDB credentials, *mongodbUser* and *mongodbPass*.

To connect to MongoDB from AWS Glue, you may need some prerequisites:

- If your MongoDB instance is in an Amazon VPC, configure Amazon VPC to allow your AWS Glue job to communicate with the MongoDB instance without traffic traversing the public internet.

  In Amazon VPC, identify or create a **VPC**, **Subnet** and **Security group** that AWS Glue will use while executing the job. Additionally, you need to ensure Amazon VPC is configured to permit network traffic between your MongoDB instance and this location. Based on your network layout, this may require changes to security group rules, Network ACLs, NAT Gateways and Peering connections.

You can then proceed to configure AWS Glue for use with MongoDB.

To configure a connection to MongoDB:

1. Optionally, in AWS Secrets Manager, create a secret using your MongoDB credentials. To create a secret in Secrets Manager, follow the tutorial available in Create an AWS Secrets Manager secret in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.

   - When selecting **Key/value pairs**, create a pair for the key `username` with the value *mongodbUser*.

     When selecting **Key/value pairs**, create a pair for the key `password` with the value *mongodbPass*.

2. In the AWS Glue console, create a connection by following the steps in the section called "Adding an AWS Glue connection". After creating the connection, keep the connection name, *connectionName*, for future use in AWS Glue.

   - When selecting a **Connection type**, select **MongoDB** or **MongoDB Atlas**.
   - When selecting **MongoDB URL** or **MongoDB Atlas URL**, provide the hostname of your MongoDB instance.

     A MongoDB URL is provided in the format `mongodb://`*mongoHost*`:`*mongoPort*`/`*mongoDBname*.

     A MongoDB Atlas URL is provided in the format `mongodb+srv://`*mongoHost*`/`*mongoDBname*.
   - If you chose to create an Secrets Manager secret, choose the AWS Secrets Manager **Credential type**.

     Then, in **AWS Secret** provide *secretName*.
   - If you choose to provide **Username and password**, provide *mongodbUser* and *mongodbPass*.

3. In the following situations, you may require additional configuration:

   - For MongoDB instances hosted on AWS in an Amazon VPC
     - You will need to provide Amazon VPC connection information to the AWS Glue connection that defines your MongoDB security credentials. When creating or updating your connection, set **VPC**, **Subnet** and **Security groups** in **Network options**.

After creating a AWS Glue MongoDB connection, you will need to perform the following actions before calling your connection method:

- If you chose to create an Secrets Manager secret, grant the IAM role associated with your AWS Glue job permission to read *secretName*.
- In your AWS Glue job configuration, provide *connectionName* as an **Additional network connection**.

To use your AWS Glue MongoDB connection in AWS Glue for Spark, provide the `connectionName` option in your connection method call. Alternatively, you can follow the steps in the section called "Integrating with MongoDB" to use the connection in conjunction with the AWS Glue Data Catalog.

Reading from MongoDB using a AWS Glue connection

Prerequisites:

- A MongoDB collection you would like to read from. You will need identification information for the collection.

  A MongoDB collection is identified by a database name and a collection name, *mongodbName*, *mongodbCollection*.
- A AWS Glue MongoDB connection configured to provide auth information. Complete the steps in the previous procedure, *To configure a connection to MongoDB* to configure your auth information. You will need the name of the AWS Glue connection, *connectionName*.

For example:

```
mongodb_read = glueContext.create_dynamic_frame.from_options(
    connection_type="mongodb",
    connection_options={
        "connectionName": "connectionName",
        "database": "mongodbName",
        "collection": "mongodbCollection",
        "partitioner":
 "com.mongodb.spark.sql.connector.read.partitioner.SinglePartitionPartitioner",
        "partitionerOptions.partitionSizeMB": "10",
        "partitionerOptions.partitionKey": "_id",
        "disableUpdateUri": "false",
    }
```

```
)
```

Writing to MongoDB tables

This example writes information from an existing DynamicFrame, *dynamicFrame* to MongoDB.

Prerequisites:

- A MongoDB collection you would like to write to. You will need identification information for the collection.

  A MongoDB collection is identified by a database name and a collection name, *mongodbName*, *mongodbCollection*.
- A AWS Glue MongoDB connection configured to provide auth information. Complete the steps in the previous procedure, *To configure a connection to MongoDB* to configure your auth information. You will need the name of the AWS Glue connection, *connectionName*.

For example:

```
glueContext.write_dynamic_frame.from_options(
    frame=dynamicFrame,
    connection_type="mongodb",
    connection_options={
        "connectionName": "connectionName",
        "database": "mongodbName",
        "collection": "mongodbCollection",
        "disableUpdateUri": "false",
        "retryWrites": "false",
    },
)
```

Reading and writing to MongoDB tables

This example writes information from an existing DynamicFrame, *dynamicFrame* to MongoDB.

Prerequisites:

- A MongoDB collection you would like to read from. You will need identification information for the collection.

A MongoDB collection you would like to write to. You will need identification information for the collection.

A MongoDB collection is identified by a database name and a collection name, *mongodbName*, *mongodbCollection*.

- MongoDB auth information, *mongodbUser* and *mongodbPassword*.

For example:

Python

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext, SparkConf
from awsglue.context import GlueContext
from awsglue.job import Job
import time

## @params: [JOB_NAME]
args = getResolvedOptions(sys.argv, ['JOB_NAME'])

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

job = Job(glueContext)
job.init(args['JOB_NAME'], args)

output_path = "s3://some_bucket/output/" + str(time.time()) + "/"
mongo_uri = "mongodb://<mongo-instanced-ip-address>:27017"
mongo_ssl_uri = "mongodb://<mongo-instanced-ip-address>:27017"
write_uri = "mongodb://<mongo-instanced-ip-address>:27017"

read_mongo_options = {
    "uri": mongo_uri,
    "database": "mongodbName",
    "collection": "mongodbCollection",
    "username": "mongodbUsername",
    "password": "mongodbPassword",
    "partitioner": "MongoSamplePartitioner",
```

```
    "partitionerOptions.partitionSizeMB": "10",
    "partitionerOptions.partitionKey": "_id"}

ssl_mongo_options = {
    "uri": mongo_ssl_uri,
    "database": "mongodbName",
    "collection": "mongodbCollection",
    "ssl": "true",
    "ssl.domain_match": "false"
}

write_mongo_options = {
    "uri": write_uri,
    "database": "mongodbName",
    "collection": "mongodbCollection",
    "username": "mongodbUsername",
    "password": "mongodbPassword",
}

# Get DynamicFrame from MongoDB
dynamic_frame =
 glueContext.create_dynamic_frame.from_options(connection_type="mongodb",

 connection_options=read_mongo_options)

# Write DynamicFrame to MongoDB
glueContext.write_dynamic_frame.from_options(dynamicFrame,
 connection_type="mongodb", connection_options=write_mongo_options)

job.commit()
```

Scala

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.MappingSpec
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.DynamicFrame
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._
```

```
object GlueApp {
  val DEFAULT_URI: String = "mongodb://<mongo-instanced-ip-address>:27017"
  val WRITE_URI: String = "mongodb://<mongo-instanced-ip-address>:27017"
  lazy val defaultJsonOption = jsonOptions(DEFAULT_URI)
  lazy val writeJsonOption = jsonOptions(WRITE_URI)
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)

    // Get DynamicFrame from MongoDB
    val dynamicFrame: DynamicFrame = glueContext.getSource("mongodb",
 defaultJsonOption).getDynamicFrame()

    // Write DynamicFrame to MongoDB
    glueContext.getSink("mongodb", writeJsonOption).writeDynamicFrame(dynamicFrame)

    Job.commit()
  }

  private def jsonOptions(uri: String): JsonOptions = {
    new JsonOptions(
      s"""{"uri": "${uri}",
         |"database":"mongodbName",
         |"collection":"mongodbCollection",
         |"username": "mongodbUsername",
         |"password": "mongodbPassword",
         |"ssl":"true",
         |"ssl.domain_match":"false",
         |"partitioner": "MongoSamplePartitioner",
         |"partitionerOptions.partitionSizeMB": "10",
         |"partitionerOptions.partitionKey": "_id"}""".stripMargin)
  }
}
```

MongoDB connection option reference

Designates a connection to MongoDB. Connection options differ for a source connection and a sink connection.

These connection properties are shared between source and sink connections:

- `connectionName` — Used for Read/Write. The name of a AWS Glue MongoDB connection configured to provide auth and networking information to your connection method. When a AWS Glue connection is configured as described in the previous section, the section called "Configuring MongoDB", providing `connectionName` will replace the need to provide the `"uri"`, `"username"` and `"password"` connection options.
- `"uri"`: (Required) The MongoDB host to read from, formatted as `mongodb://<host>:<port>`. Used in AWS Glue versions prior to AWS Glue 4.0.
- `"connection.uri"`: (Required) The MongoDB host to read from, formatted as `mongodb://<host>:<port>`. Used in AWS Glue 4.0 and later versions.
- `"username"`: (Required) The MongoDB user name.
- `"password"`: (Required) The MongoDB password.
- `"database"`: (Required) The MongoDB database to read from. This option can also be passed in `additional_options` when calling `glue_context.create_dynamic_frame_from_catalog` in your job script.
- `"collection"`: (Required) The MongoDB collection to read from. This option can also be passed in `additional_options` when calling `glue_context.create_dynamic_frame_from_catalog` in your job script.

"connectionType": "mongodb" as source

Use the following connection options with `"connectionType": "mongodb"` as a source:

- `"ssl"`: (Optional) If `true`, initiates an SSL connection. The default is `false`.
- `"ssl.domain_match"`: (Optional) If `true` and `ssl` is `true`, domain match check is performed. The default is `true`.
- `"batchSize"`: (Optional): The number of documents to return per batch, used within the cursor of internal batches.
- `"partitioner"`: (Optional): The class name of the partitioner for reading input data from MongoDB. The connector provides the following partitioners:
  - `MongoDefaultPartitioner` (default) (Not supported in AWS Glue 4.0)
  - `MongoSamplePartitioner` (Requires MongoDB 3.2 or later) (Not supported in AWS Glue 4.0)
  - `MongoShardedPartitioner` (Not supported in AWS Glue 4.0)
  - `MongoSplitVectorPartitioner` (Not supported in AWS Glue 4.0)
  - `MongoPaginateByCountPartitioner` (Not supported in AWS Glue 4.0)

  - `MongoPaginateBySizePartitioner` (Not supported in AWS Glue 4.0)
  - `com.mongodb.spark.sql.connector.read.partitioner.SinglePartitionPartitioner`
  - `com.mongodb.spark.sql.connector.read.partitioner.ShardedPartitioner`
  - `com.mongodb.spark.sql.connector.read.partitioner.PaginateIntoPartitionsPartit`
- `"partitionerOptions"` (Optional): Options for the designated partitioner. The following options are supported for each partitioner:
  - `MongoSamplePartitioner`: `partitionKey`, `partitionSizeMB`, `samplesPerPartition`
  - `MongoShardedPartitioner`: `shardkey`
  - `MongoSplitVectorPartitioner`: `partitionKey`, `partitionSizeMB`
  - `MongoPaginateByCountPartitioner`: `partitionKey`, `numberOfPartitions`
  - `MongoPaginateBySizePartitioner`: `partitionKey`, `partitionSizeMB`

  For more information about these options, see Partitioner Configuration in the MongoDB documentation.

"connectionType": "mongodb" as sink

Use the following connection options with `"connectionType": "mongodb"` as a sink:

- `"ssl"`: (Optional) If `true`, initiates an SSL connection. The default is `false`.
- `"ssl.domain_match"`: (Optional) If `true` and `ssl` is `true`, domain match check is performed. The default is `true`.
- `"extendedBsonTypes"`: (Optional) If `true`, allows extended BSON types when writing data to MongoDB. The default is `true`.
- `"replaceDocument"`: (Optional) If `true`, replaces the whole document when saving datasets that contain an `_id` field. If `false`, only fields in the document that match the fields in the dataset are updated. The default is `true`.
- `"maxBatchSize"`: (Optional): The maximum batch size for bulk operations when saving data. The default is 512.
- `"retryWrites"`: (Optional): Automatically retry certain write operations a single time if AWS Glue encounters a network error.

SAP HANA connections

You can use AWS Glue for Spark to read from and write to tables in SAP HANA in AWS Glue 4.0 and later versions. You can define what to read from SAP HANA with a SQL query. You connect to SAP HANA using JDBC credentials stored in AWS Secrets Manager through a AWS Glue SAP HANA connection.

For more information about SAP HANA JDBC, consult the SAP HANA documentation.

Configuring SAP HANA connections

To connect to SAP HANA from AWS Glue, you will need to create and store your SAP HANA credentials in a AWS Secrets Manager secret, then associate that secret with a SAP HANA AWS Glue connection. You will need to configure network connectivity between your SAP HANA service and AWS Glue.

To connect to SAP HANA, you may need some prerequisites:

- If your SAP HANA service is in an Amazon VPC, configure Amazon VPC to allow your AWS Glue job to communicate with the SAP HANA service without traffic traversing the public internet.

  In Amazon VPC, identify or create a **VPC**, **Subnet** and **Security group** that AWS Glue will use while executing the job. Additionally, you need to ensure Amazon VPC is configured to permit network traffic between your SAP HANA endpoint and this location. Your job will need to establish a TCP connection with your SAP HANA JDBC port. For more information about SAP HANA ports, see the SAP HANA documentation. Based on your network layout, this may require changes to security group rules, Network ACLs, NAT Gateways and Peering connections.
- There are no additional prerequisites if your SAP HANA endpoint is internet accesible.

To configure a connection to SAP HANA:

1. In AWS Secrets Manager, create a secret using your SAP HANA credentials. To create a secret in Secrets Manager, follow the tutorial available in Create an AWS Secrets Manager secret in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.

   - When selecting **Key/value pairs**, create a pair for the key `username`/`USERNAME` with the value *saphanaUsername*.

- When selecting **Key/value pairs**, create a pair for the key `password/PASSWORD` with the value *saphanaPassword*.

2. In the AWS Glue console, create a connection by following the steps in the section called "Adding an AWS Glue connection". After creating the connection, keep the connection name, *connectionName*, for future use in AWS Glue.

   - When selecting a **Connection type**, select SAP HANA.
   - When providing **SAP HANA URL**, provide the URL for your instance.

     SAP HANA JDBC URLs are in the form `jdbc:sap://`*saphanaHostname*`:`*saphanaPort*`/?`*databaseName*`=`*saphanaDBname*`,`*Paramete*

     AWS Glue requires the following JDBC URL parameters:

     - `databaseName` – A default database in SAP HANA to connect to.
   - When selecting an **AWS Secret**, provide *secretName*.

After creating a AWS Glue SAP HANA connection, you will need to perform the following steps before running your AWS Glue job:

- Grant the IAM role associated with your AWS Glue job permission to read *secretName*.
- In your AWS Glue job configuration, provide *connectionName* as an **Additional network connection**.

Reading from SAP HANA tables

Prerequisites:

- A SAP HANA table you would like to read from. You will need identification information for the table.

  A table can be specified with a SAP HANA table name and schema name, in the form *schemaName*`.`*tableName*. The schema name and "." separator are not required if the table is in the default schema, "public". Call this *tableIdentifier*. Note that the database is provided as a JDBC URL parameter in `connectionName`.
- A AWS Glue SAP HANA connection configured to provide auth information. Complete the steps in the previous procedure, *To configure a connection to SAP HANA* to configure your auth information. You will need the name of the AWS Glue connection, *connectionName*.

For example:

```
saphana_read_table = glueContext.create_dynamic_frame.from_options(
    connection_type="saphana",
    connection_options={
        "connectionName": "connectionName",
        "dbtable": "tableIdentifier",
    }
)
```

You can also provide a SELECT SQL query, to filter the results returned to your DynamicFrame. You will need to configure `query`.

For example:

```
saphana_read_query = glueContext.create_dynamic_frame.from_options(
    connection_type="saphana",
    connection_options={
        "connectionName": "connectionName",
        "query": "query"
    }
)
```

Writing to SAP HANA tables

This example writes information from an existing DynamicFrame, *`dynamicFrame`* to SAP HANA. If the table already has information, AWS Glue will error.

Prerequisites:

- A SAP HANA table you would like to write to.

  A table can be specified with a SAP HANA table name and schema name, in the form *`schemaName`*`.`*`tableName`*. The schema name and "." separator are not required if the table is in the default schema, "public". Call this *`tableIdentifier`*. Note that the database is provided as a JDBC URL parameter in `connectionName`.
- SAP HANA auth information. Complete the steps in the previous procedure, *To configure a connection to SAP HANA* to configure your auth information. You will need the name of the AWS Glue connection, *`connectionName`*.

For example:

```
options = {
    "connectionName": "connectionName",
    "dbtable": 'tableIdentifier'
}

    saphana_write = glueContext.write_dynamic_frame.from_options(
        frame=dynamicFrame,
        connection_type="saphana",
        connection_options=options
)
```

SAP HANA connection option reference

- `connectionName` — Required. Used for Read/Write. The name of a AWS Glue SAP HANA connection configured to provide auth and networking information to your connection method.
- `databaseName` — Used for Read/Write. Valid Values: names of databases in SAP HANA. Name of database to connect to.
- `dbtable` — Required for writing, required for reading unless `query` is provided. Used for Read/Write. Valid Values: contents of a SAP HANA SQL FROM clause. Identifies a table in SAP HANA to connect to. You may also provide other SQL than a table name, such as a subquery. For more information, see the From clause in the SAP HANA documentation.
- `query` — Used for Read. A SAP HANA SQL SELECT query defining what should be retrieved when reading from SAP HANA.

Snowflake connections

You can use AWS Glue for Spark to read from and write to tables in Snowflake in AWS Glue 4.0 and later versions. You can read from Snowflake with a SQL query. You can connect to Snowflake using one of three methods - basic authentication (using username and password), OAuth authentication, or key-pair authentication. You can refer to Snowflake credentials stored in AWS Secrets Manager through the AWS Glue Data connections. Data connection Snowflake credentials for AWS Glue for Spark are stored separately from Data Catalog Snowflake credentials for crawlers. You must choose a `SNOWFLAKE` type connection and not a `JDBC` type connection configured to connect to Snowflake.

For more information about Snowflake, see the Snowflake website. For more information about Snowflake on AWS, see Snowflake Data Warehouse on Amazon Web Services.

Configuring Snowflake connections

There are no AWS prerequisites to connecting to Snowflake databases available through the internet.

Optionally, you can perform the following configuration to manage your connection credentials with AWS Glue.

To manage your connection credentials with AWS Glue

1. In AWS Secrets Manager, create a secret using your Snowflake credentials. To create a secret in Secrets Manager, follow the tutorial available in Create an AWS Secrets Manager secret in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.

   - For OAuth authentication:
     - When selecting **Key/value pairs**, create a pair for *snowflakeUser* with the key `sfUser`
     - When selecting **Key/value pairs**, create a pair for *OAUTH_CLIENT_SECRET* with the key `USER_MANAGED_CLIENT_APPLICATION_CLIENT_SECRET`
   - For Key-pair authentication:
     - When selecting **Key/value pairs**, create a pair for *snowflakeUser* with the key `sfUser`
     - When selecting **Key/value pairs**, create a pair for *private key* with the key `pem_private_key`
   - For basic authentication:
     - When selecting **Key/value pairs**, create a pair for *snowflakeUser* with the key `USERNAME`
     - When selecting **Key/value pairs**, create a pair for *snowflakePassword* with the key `PASSWORD`
   - When selecting **Key/value pairs**, you can provide your Snowflake warehouse with the key `sfWarehouse`.
   - When selecting **Key/value pairs**, you can provide additional Snowflake connection properties using their corresponding Spark property names as keys. Supported properties include:
     - `sfDatabase` - Snowflake database name
     - `sfSchema` - Snowflake schema name
     - `sfRole` - Snowflake role name

2. In the AWS Glue Studio Console, create a connection by choosing **Data Connections**, then **Create connection**. Following the steps in the connection wizard to complete the process:
   - When selecting a **Data source**, select Snowflake, then choose **Next**.
   - Enter the connection details such as host and port. When entering the host **Snowflake URL**, provide the URL of your Snowflake instance. The URL will typically use a hostname in the form *`account_identifier`*`.snowflakecomputing.com`. However, the URL format may vary depending on your Snowflake account type (for example, AWS, Azure, or Snowflake-hosted).
   - When selecting the IAM service role, choose from the drop-down menu. This is the IAM role from your account that will be used to access AWS Secrets Manager and assign IP if VPC is specified.
   - When selecting an **AWS Secret**, provide *`secretName`*.
3. In the next step in the wizard, set properties for your Snowflake connection.
4. In the final step in the wizard, review your settings and then complete the process to create your connection.

For Snowflake hosted on AWS in an Amazon VPC, you may require the following:

- You will need appropriate Amazon VPC configuration for Snowflake. For more information on how to configure your Amazon VPC, consult AWS PrivateLink & Snowflake in the Snowflake documentation.
- You will need appropriate Amazon VPC configuration for AWS Glue. the section called "Configuring interface VPC endpoints (AWS PrivateLink) for AWS Glue ".
- You will need to create a AWS Glue Data Catalog connection that provides Amazon VPC connection information (in addition to the id of an AWS Secrets Manager secret that defines your Snowflake security credentials). Your URL will change when using AWS PrivateLink, as described in the Snowflake documentation linked in a previous item.
- You will need your job configuration in include the Data Catalog connection as an **Additional network connection**.

Reading from Snowflake tables

Prerequisites: A Snowflake table you would like to read from. You will need the Snowflake table name, *`tableName`*. If your Snowflake user does not have a default namespace set, you

will need the Snowflake database name, *databaseName* and the schema name *schemaName*. Additionally, if your Snowflake user does not have a default warehouse set, you will need a warehouse name *warehouseName*. To select which **Additional network connection** to connect with, the `connectionName` parameter will be used.

```
snowflake_read = glueContext.create_dynamic_frame.from_options(
  connection_type="snowflake",
  connection_options={
        "connectionName": "connectionName",
        "dbtable": "tableName",
        "sfDatabase": "databaseName",
        "sfSchema": "schemaName",
        "sfWarehouse": "warehouseName",
    }
)
```

Additionally, you can use the `autopushdown` and `query` parameters to read a portion of a Snowflake table. This can be substantially more efficient than filtering your results after they have been loaded into Spark. Consider an example where all sales are stored in the same table, but you only need to analyze sales from a certain store on holidays. If that information is stored in the table, you could use predicate pushdown to retrieve the results as follows:

```
snowflake_node = glueContext.create_dynamic_frame.from_options(
    connection_type="snowflake",
    connection_options={
        "autopushdown": "on",
        "query": "select * from sales where store='1' and IsHoliday='TRUE'",
        "connectionName": "snowflake-glue-conn",
        "sfDatabase": "databaseName",
        "sfSchema": "schemaName",
        "sfWarehouse": "warehouseName",
    }
)
```

Writing to Snowflake tables

Prerequisites: A Snowflake database you would like to write to. You will need a current or desired table name, *tableName*. If your Snowflake user does not have a default namespace set, you will need the Snowflake database name, *databaseName* and the schema name *schemaName*. Additionally, if your Snowflake user does not have a default warehouse set, you will need a

warehouse name *warehouseName*. To select which **Additional network connection** to connect with, the connectionName parameter will be used.

```
glueContext.write_dynamic_frame.from_options(
    connection_type="snowflake",
    connection_options={
        "connectionName": "connectionName",
        "dbtable": "tableName",
        "sfDatabase": "databaseName",
        "sfSchema": "schemaName",
        "sfWarehouse": "warehouseName",
    },
)
```

Snowflake connection option reference

The Snowflake connection type takes the following connection options:

You can retrieve some of the parameters in this section from a AWS Glue connection (`sfUrl`, `sfUser`, `sfPassword`), in which case you are not required to provide them. You can do this by providing the parameter `connectionName`.

You can retrieve connection parameters from AWS Secrets Manager secrets using the `secretId` parameter. When using Secrets Manager, the following Spark properties can be automatically retrieved if present in the secret:

- `sfUser` (using key `USERNAME` or `sfUser`)
- `sfPassword` (using key `PASSWORD` or `sfPassword`, when using basic authentication)
- `sfWarehouse` (using key `sfWarehouse`)
- `sfDatabase` (using key `sfDatabase`)
- `sfSchema` (using key `sfSchema`)
- `sfRole` (using key `sfRole`)
- `pem_private_key` (using key `pem_private_key`, when using key-pair authentication)
- `USER_MANAGED_CLIENT_APPLICATION_CLIENT_SECRET` (when using OAuth authentication)

Property Precedence Order: When the same property is specified in multiple locations, AWS Glue uses the following precedence order (highest to lowest):

1. Explicitly provided connection options in your job code
2. Glue connection properties
3. AWS Secrets Manager secret values (when `secretId` is specified)
4. Snowflake user defaults

The following parameters are used generally when connecting to Snowflake.

- `sfDatabase` — Required if a user default is not set in Snowflake. Used for Read/Write. The database to use for the session after connecting.
- `sfSchema` — Required if a user default is not set in Snowflake. Used for Read/Write. The schema to use for the session after connecting.
- `sfWarehouse` — Required if a user default is not set in Snowflake. Used for Read/Write. The default virtual warehouse to use for the session after connecting.
- `sfRole` — Required if a user default is not set in Snowflake. Used for Read/Write. The default security role to use for the session after connecting.
- `sfUrl` — (Required) Used for Read/Write. Specifies the hostname for your account in the following format: *`account_identifier`*`.snowflakecomputing.com`. For more information about account identifiers, see Account Identifiers in the Snowflake documentation.
- `sfUser` — (Required) Used for Read/Write. Login name for the Snowflake user.
- `sfPassword` — (Required when using basic authnetication) Used for Read/Write. Password for the Snowflake user.
- `dbtable` — Required when working with full tables. Used for Read/Write. The name of the table to be read or the table to which data is written. When reading, all columns and records are retrieved.
- `pem_private_key` — (Required when using key-pair authentication) Used for Read/Write. An unencrypted b64-encoded private key string. The private key for the Snowflake user. It is common to copy this out of a PEM file. For more information, see Key-pair authentication and key-pair rotation in the Snowflake documentation.
- `USER_MANAGED_CLIENT_APPLICATION_CLIENT_SECRET` — (Required when using OAuth Authentication) Used for both read and write operations. This value corresponds to the OAUTH_CLIENT_SECRET, which can be obtained from the Snowflake security integration configured to enable OAuth-based authentication for your account. For more details, refer to your Snowflake OAuth security integration setup documentation - Configure Snowflake OAuth for custom clients.

- `query` — Required when reading with a query. Used for Read. The exact query (`SELECT` statement) to run

The following options are used to configure specific behaviors during the process of connecting to Snowflake.

- `preactions` — Used for Read/Write. Valid Values: Semicolon separated list of SQL statements as String. SQL statements run before data is transferred between AWS Glue and Snowflake. If a statement contains `%s`, the `%s` is replaced with the table name referenced for the operation.
- `postactions` — Used for Read/Write. SQL statements run after data is transferred between AWS Glue and Snowflake. If a statement contains `%s`, the `%s` is replaced with the table name referenced for the operation.
- `autopushdown` — Default: `"on"`. Valid Values: `"on"`, `"off"`. This parameter controls whether automatic query pushdown is enabled. If pushdown is enabled, then when a query is run on Spark, if part of the query can be "pushed down" to the Snowflake server, it is pushed down. This improves performance of some queries. For information about whether your query can be pushed down, consult Pushdown in the Snowflake documentation.

Additionally, some of the options available on the Snowflake Spark connector may be supported in AWS Glue. For more information about options available on the Snowflake Spark connector, see Setting Configuration Options for the Connector in the Snowflake documentation.

Snowflake authentication methods

AWS Glue supports the following authentication methods for connecting to Snowflake:

- **Basic authentication:** Provide `sfUser` and `sfPassword` parameters.
- **Key-pair authentication:** Provide `sfUser` and `pem_private_key` parameters. When using key-pair authentication, the `sfPassword` parameter is not required.
- **OAuth authentication:** The Snowflake Connector supports the AUTHORIZATION_CODE grant type to request access to your Snowflake data. This grant type is referred to as “3-legged OAuth”, as it involves redirecting users to a third-party authorization server where they can authenticate and approve access. This method is used when creating a connection through the AWS Glue Console.
  - **Prerequisite:** To use this authentication method, ensure the following setup is complete:

- **Configure Snowflake OAuth for a custom client** by following the official Snowflake documentation: Configure Snowflake OAuth for custom clients.
- **Set the correct redirect URI** when creating the Snowflake security integration. For example: If you are creating the connection in the DUB (eu-west-1) region, your redirect URI should be: `https://eu-west-1.console.aws.amazon.com/gluestudio/oauth`
- After creating the security integration, retain the following information for use when creating the Glue connection:
  - OAUTH_CLIENT_ID: This value should be provided as User Managed Client Application Client ID on the Glue connection creation page.
  - OAUTH_CLIENT_SECRET: This value should be stored in the AWS Secret used for the connection, under the key USER_MANAGED_CLIENT_APPLICATION_CLIENT_SECRET.

- OAuth Scopes — (Optional) Defines the specific permissions or levels of access requested from the Snowflake account. For example, a scope might limit access to a particular resource or operation.
  - This value can be specified in the following format: `session:role:Snowflake_Role_Name`
  - Example: `session:role:ANALYST_ROLE`
- Authorization Code URL — (Required) The endpoint where the user is redirected to log in and grant authorization.
  - Example: `https://host/oauth/authorize`
- Authorization Token URL — (Required) The endpoint used to exchange the authorization code for an access token.
  - Example: `https://host/oauth/token-request`
- User Managed Client Application Client Id — (Required) The unique identifier for your registered OAuth client application in Snowflake
- AWS Secret — (Required) Refers to an AWS Secrets Manager secret containing the following key-value pairs:
  - sfUser - The Snowflake username
  - USER_MANAGED_CLIENT_APPLICATION_CLIENT_SECRET - The client secret associated with the OAuth client application

All three authentication methods are fully supported and can be configured using any combination of connection options, Glue connections, or AWS Secrets Manager secrets.

Snowflake connector limitations

Connecting to Snowflake with AWS Glue for Spark is subject to the following limitations.

- This connector does not support job bookmarks. For more information about job bookmarks, see the section called "Tracking processed data using job bookmarks".
- This connector does not support Snowflake reads and writes through tables in the AWS Glue Data Catalog using the `create_dynamic_frame.from_catalog` and `write_dynamic_frame.from_catalog` methods.
- This connector supports basic authentication, key-pair authentication, and OAuth authentication. Other authentication methods (such as SAML) are not currently supported.
- This connector is not supported within streaming jobs.
- This connector supports `SELECT` statement based queries when retrieving information (such as with the `query` parameter). Other kind of queries (such as `SHOW`, `DESC`, or DML statements) are not supported.
- Snowflake limits the size of query text (i.e. SQL statements) submitted through Snowflake clients to 1 MB per statement. For more details, see Limits on Query Text Size.

Teradata Vantage connections

You can use AWS Glue for Spark to read from and write to existing tables in Teradata Vantage in AWS Glue 4.0 and later versions. You can define what to read from Teradata with a SQL query. You can connect to Teradata using username and password credentials stored in AWS Secrets Manager through a AWS Glue connection.

For more information about Teradata, consult the Teradata documentation

Configuring Teradata connections

To connect to Teradata from AWS Glue, you will need to create and store your Teradata credentials in an AWS Secrets Manager secret, then associate that secret with a AWS Glue Teradata connection. If your Teradata instance is in an Amazon VPC, you will also need to provide networking options to your AWS Glue Teradata connection.

To connect to Teradata from AWS Glue, you may need some prerequisites:

- If you are accessing your Teradata environment through Amazon VPC, configure Amazon VPC to allow your AWS Glue job to communicate with the Teradata environment. We discourage accessing the Teradata environment over the public internet.

In Amazon VPC, identify or create a **VPC**, **Subnet** and **Security group** that AWS Glue will use while executing the job. Additionally, you need to ensure Amazon VPC is configured to permit network traffic between your Teradata instance and this location. Your job will need to establish a TCP connection with your Teradata client port. For more information about Teradata ports, see the Teradata documentation.

Based on your network layout, secure VPC connectivity may require changes in Amazon VPC and other networking services. For more information about AWS connectivity, consult AWS Connectivity Options in the Teradata documentation.

To configure a AWS Glue Teradata connection:

1. In your Teradata configuration, identify or create a user and password AWS Glue will connect with, *teradataUser* and *teradataPassword*. For more information, consult Vantage Security Overview in the Teradata documentation.
2. In AWS Secrets Manager, create a secret using your Teradata credentials. To create a secret in Secrets Manager, follow the tutorial available in Create an AWS Secrets Manager secret in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.

   - When selecting **Key/value pairs**, create a pair for the key `user` with the value *teradataUsername*.
   - When selecting **Key/value pairs**, create a pair for the key `password` with the value *teradataPassword*.
3. In the AWS Glue console, create a connection by following the steps in the section called "Adding an AWS Glue connection". After creating the connection, keep the connection name, *connectionName*, for the next step.

   - When selecting a **Connection type**, select Teradata.
   - When providing **JDBC URL**, provide the URL for your instance. You can also hardcode certain comma separated connection parameters in your JDBC URL. The URL must conform to the following format: `jdbc:teradata://`*teradataHostname*`/`*ParameterName*`=`*ParameterValue*`,`*ParameterName*

     Supported URL parameters include:

     - `DATABASE`– name of database on host to access by default.

- DBS_PORT– the database port, used when running on a nonstandard port.
- When selecting a **Credential type**, select **AWS Secrets Manager**, then set **AWS Secret** to *secretName*.

4. In the following situations, you may require additional configuration:

   - For Teradata instances hosted on AWS in an Amazon VPC
     - You will need to provide Amazon VPC connection information to the AWS Glue connection that defines your Teradata security credentials. When creating or updating your connection, set **VPC**, **Subnet** and **Security groups** in **Network options**.

After creating a AWS Glue Teradata connection, you will need to perform the following steps before calling your connection method.

- Grant the IAM role associated with your AWS Glue job permission to read *secretName*.
- In your AWS Glue job configuration, provide *connectionName* as an **Additional network connection**.

Reading from Teradata

Prerequisites:

- A Teradata table you would like to read from. You will need the table name, *tableName*.
- A AWS Glue Teradata connection configured to provide auth information. Complete the steps *To configure a connection to Teradata* to configure your auth information. You will need the name of the AWS Glue connection, *connectionName*.

For example:

```
teradata_read_table = glueContext.create_dynamic_frame.from_options(
    connection_type="teradata",
    connection_options={
        "connectionName": "connectionName",
        "dbtable": "tableName"
    }
)
```

You can also provide a SELECT SQL query, to filter the results returned to your DynamicFrame. You will need to configure `query`.

For example:

```
teradata_read_query = glueContext.create_dynamic_frame.from_options(
    connection_type="teradata",
    connection_options={
        "connectionName": "connectionName",
        "query": "query"
    }
)
```

Writing to Teradata tables

Prerequisites: A Teradata table you would like to write to, *`tableName`*. **You must create the table before calling the connection method.**

For example:

```
teradata_write = glueContext.write_dynamic_frame.from_options(
    connection_type="teradata",
    connection_options={
        "connectionName": "connectionName",
        "dbtable": "tableName"
    }
)
```

Teradata connection option reference

- `connectionName` — Required. Used for Read/Write. The name of a AWS Glue Teradata connection configured to provide auth and networking information to your connection method.
- `dbtable` — Required for writing, required for reading unless `query` is provided. Used for Read/Write. The name of a table your connection method will interact with.
- `query` — Used for Read. A SELECT SQL query defining what should be retrieved when reading from Teradata.

Teradata Vantage NOS connections

Teradata NOS (Native Object Store) connection is a new connection for Teradata Vantage which leverages Teradata WRITE_NOS query to read from existing tables and READ_NOS query to write to tables. These queries uses Amazon S3 as a staging directory, and therefore the Teradata NOS connector is faster than the existing Teradata connector (JDBC-based) especially in handling large amount of data.

You can use the Teradata NOS connection in AWS Glue for Spark to read from and write to existing tables in Teradata Vantage in AWS Glue 5.0 and later versions. You can define what to read from Teradata with a SQL query. You can connect to Teradata using username and password credentials stored in AWS Secrets Manager through a AWS Glue connection.

For more information about Teradata, consult the Teradata documentation.

Topics

- Creating a Teradata NOS connection
- Reading from Teradata tables
- Writing to Teradata tables
- Teradata connection option reference
- Provide Options in AWS Glue Visual ETL UI

Creating a Teradata NOS connection

To connect to Teradata NOS from AWS Glue, you will need to create and store your Teradata credentials in an AWS Secrets Manager secret, then associate that secret with a AWS Glue Teradata NOS connection. If your Teradata instance is in an Amazon VPC, you will also need to provide networking options to your AWS Glue Teradata NOS connection.

Prerequisites:

- If you are accessing your Teradata environment through Amazon VPC, configure Amazon VPC to allow your AWS Glue job to communicate with the Teradata environment. We discourage accessing the Teradata environment over the public internet.
- In Amazon VPC, identify or create a VPC, Subnet and Security group that AWS Glue will use while executing the job. Additionally, you need to ensure Amazon VPC is configured to permit network traffic between your Teradata instance and this location. Your job will need to establish a TCP

connection with your Teradata client port. For more information about Teradata ports, see the Security Groups for Teradata Vantage .

- Based on your network layout, secure VPC connectivity may require changes in Amazon VPC and other networking services. For more information about AWS connectivity, see AWS Connectivity Options in the Teradata documentation.

To configure a AWS Glue Teradata NOS connection:

1. In your Teradata configuration, identify or create a *teradataUsername* and *teradataPassword* AWS Glue will connect with. For more information, see Vantage Security Overview in the Teradata documentation.
2. In AWS Secrets Manager, create a secret using your Teradata credentials. To create a secret in AWS Secrets Manager, follow the tutorial available in Create an AWS Secrets Manager secret in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
   - When selecting Key/value pairs, create a pair for the key USERNAME with the value *teradataUsername*.
   - When selecting Key/value pairs, create a pair for the key PASSWORD with the value *teradataPassword*.
3. In the AWS Glue console, create a connection by following the steps in Adding an AWS Glue connection . After creating the connection, keep the connection name, *connectionName*, for the next step.
   - When selecting a **Connection type**, select Teradata Vantage NOS.
   - When providing JDBC URL, provide the URL for your instance. You can also hardcode certain comma separated connection parameters in your JDBC URL. The URL must conform to the following format: `jdbc:teradata://teradataHostname/ParameterName=ParameterValue,ParameterName=ParameterValue` .
   - Supported URL parameters include:
     - `DATABASE`– name of database on host to access by default.
     - `DBS_PORT`– the database port, used when running on a nonstandard port.
   - When selecting a **Credential type**, select AWS Secrets Manager, then set **AWS Secret** to *secretName*.
4. In the following situations, you may require additional configuration:

- For Teradata instances hosted on AWS in an Amazon VPC, you will need to provide Amazon VPC connection information to the AWS Glue connection that defines your Teradata security credentials. When creating or updating your connection, set **VPC**, **Subnet**, and **Security groups** in **Network options**.

After creating a AWS Glue Teradata Vantage NOS connection, you will need to perform the following steps before calling your connection method.

1. Grant the IAM role associated with your AWS Glue job permission to read *secretName*.
2. In your AWS Glue job configuration, provide *connectionName* as an **Additional network connection** Under **Connections**.

Reading from Teradata tables

Prerequisites:

- A Teradata table you would like to read from. You will need the table name, *tableName*.
- The Teradata environment has write access to the Amazon S3 path specified by `staging_fs_url` option, *stagingFsUrl*.
- The IAM role associated with AWS Glue job has write access to the Amazon S3 location specified by `staging_fs_url` option.
- An AWS Glue Teradata NOS connection configured to provide auth information. Complete the steps To configure a AWS Glue Teradata NOS connection: to configure your auth information. You will need the name of the AWS Glue connection, *connectionName*.

Example:

```
teradata_read_table = glueContext.create_dynamic_frame.from_options(
    connection_type= "teradatanos",
    connection_options={
        "connectionName": "connectionName",
        "dbtable": "tableName",
        "staging_fs_url": "stagingFsUrl"
    }
)
```

You can also provide a SELECT SQL query, to filter the results returned to your DynamicFrame. You will need to configure query. If you configure both dbTable and query, the connector fails to read the data. For example:

```
teradata_read_query = glueContext.create_dynamic_frame.from_options(
    connection_type="teradatanos",
    connection_options={
        "connectionName": "connectionName",
        "query": "query",
        "staging_fs_url": "stagingFsUrl"
    }
)
```

Additionally, you can use Spark DataFrame API to read from Teradata tables. For example:

```
options = {
    "url": "JDBC_URL",
    "dbtable": "tableName",
    "user": "teradataUsername", # or use "username" as key here
    "password": "teradataPassword",
    "staging_fs_url": "stagingFsUrl"
}
teradata_read_table = spark.read.format("teradatanos").option(**options).load()
```

Writing to Teradata tables

Prerequisites

- A Teradata table you would like to write to: *tableName*.
- The Teradata environment has read access to the Amazon S3 location specified by `staging_fs_url` option, *stagingFsUrl* .
- The IAM role associated with AWS Glue job has write access to the Amazon S3 location specified by `staging_fs_url` option.
- An AWS Glue Teradata connection configured to provide auth information. Complete the steps in To configure a AWS Glue Teradata NOS connection: to configure your auth information. You will need the name of the AWS Glue connection, *connectionName*.

  For example:

  ```
  teradata_write = glueContext.write_dynamic_frame.from_options(
  ```

```
    frame=dynamicFrame,
    connection_type= "teradatanos",
    connection_options={
        "connectionName": "connectionName",
        "dbtable": "tableName",
        "staging_fs_url": "stagingFsUrl"
    }
)
```

Teradata connection option reference

Connection and Operation Options:

- `connectionName` — Required. Used for Read/Write. The name of an AWS Glue Teradata connection configured to provide auth and networking information to your connection method.
- `staging_fs_url` — Required. Used for Read/Write. A writable location in Amazon S3, to be used for unloaded data when reading from Teradata, and for Parquet data to be loaded into Redshift when writing to Teradata. The S3 bucket must be in the same region as the region of your AWS Glue jobs.
- `dbtable` — Required for writing, required for reading unless `query` is provided. Used for Read/Write. The name of a table your connection method will interact with.
- `query` — Used for Read. A SELECT SQL query defining what should be retrieved when reading from Teradata. You can not pass if `dbtable` option is provided.
- `clean_staging_s3_dir` — Optional. Used for Read/Write. If true, clean up the staging Amazon S3 objects after a read or a write. The default value is true.
- `pre_actions` — Optional. Used for Write. Semicolon-separated list of SQL commands that are executed before data is transferred between Spark and Teradata Vantage.
- `post_actions` — Optional. Used for Write. Semicolon-separated list of SQL commands that are executed after data is transferred between Spark and Teradata Vantage.
- `truncate` — Optional. Used for Write. If true, the connector truncates the table when writing in overwrite mode. If false, the connector drops the table when writing in overwrite mode. The default value is false.
- `create_table_script` — Optional. Used for Write. An SQL statement to create table when writing to Teradata Vantage. Useful when you want to create a table with custom metadata (e.g. CREATE MULTISET or SET table or change primary index). Note that the table name used in create table script should match with the table name specified in `dbtable` option.

- `partition_size_in_mb` — Optional. Used for Read. Maximum size of a Spark partition in megabytes while reading staging Amazon S3 objects. The default value is 128.

You can provide advanced options when creating a Teradata node. These options are the same as those available when programming AWS Glue for Spark scripts.

See the section called “Teradata Vantage connections”.

Authorization Options:

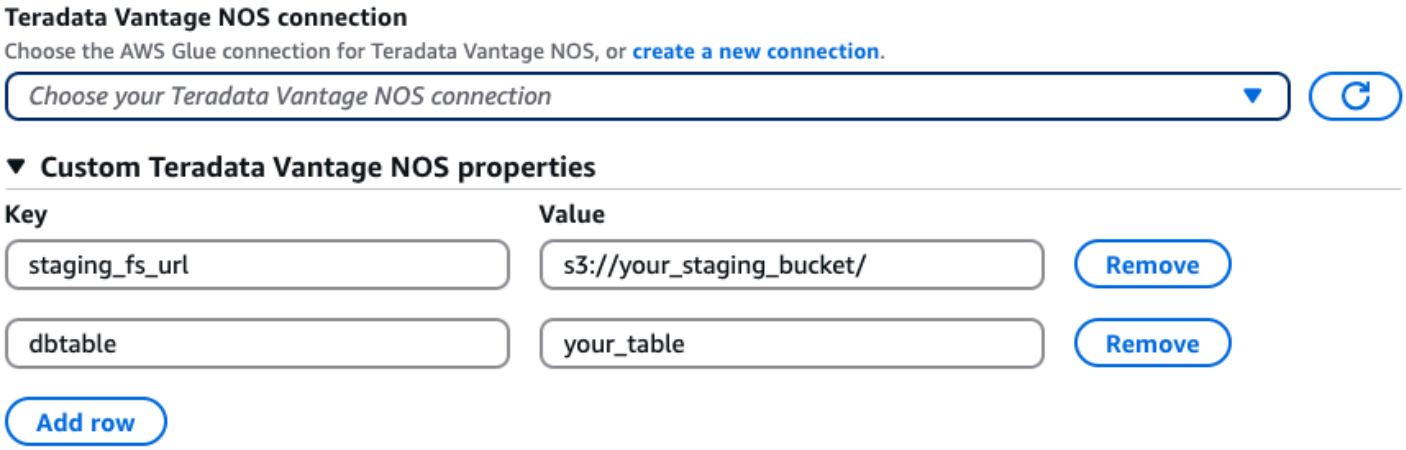
Below are options used to provide AWS account credentials that the connector uses to access the staging Amazon S3 bucket. You can choose to (1) not provide any authorization options at all, and use temporary credentials generated from your AWS Glue execution role; or (2) provide an authorization object, `auth_object` you created; or (3) provide `aws_access_key_id` and `aws_secret_access_key` if using long term credentials, or provide `aws_access_key`, `aws_secret_access_key`, and `aws_session_token` if using temporary credentials.

- `auth_object` – Optional. Used for accessing the staging Amazon S3 bucket. An authorization object string created in Teradata instance. If provided, the connector will use this authorization object to access the staging Amazon S3 bucket. If not provided, and `aws_access_key_id` and `aws_secret_access_key` are also not provided, a temporary credential will be retrieved from AWS Glue execution role and used by the connector. The AWS account associated with this authorization object must be in the same region as your AWS Glue jobs and your staging Amazon S3 bucket or configured with cross account trust.
- `aws_access_key_id` – Optional. Used for accessing the staging Amazon S3 bucket. Part of an AWS account security credential. If `auth_object` is not provided, and `aws_access_key_id` is provided with `aws_secret_access_key`, the connector will use them to access staging Amazon S3 bucket. The AWS account associated with this access key must be in the same region as your AWS Glue jobs and your staging Amazon S3 bucket or configured with cross account trust.
- `aws_secret_access_key` – Optional. Used for accessing the staging Amazon S3 bucket. Part of an AWS account security credential. If `auth_object` is not provided, and `aws_secret_access_key` is provided with `aws_access_key_id` , the connector will use them to access staging Amazon S3 bucket. The AWS account associated with this secret key must be in the same region as your AWS Glue jobs and your staging Amazon S3 bucket or configured with cross account trust.

- `aws_session_token` – Optional. Used for accessing the staging Amazon S3 bucket. Part of a temporary AWS account security credential. Should be provided with `aws_access_key_id` and `aws_secret_access_key`.

Provide Options in AWS Glue Visual ETL UI

You can provide all above options in your visual ETL job UI. For connectionName option, you should choose it from the Teradata Vantage NOS connection drop down list. For all other options, you should provide them through the Custom Teradata Vantage NOS properties as key value pairs.



Vertica connections

You can use AWS Glue for Spark to read from and write to tables in Vertica in AWS Glue 4.0 and later versions. You can define what to read from Vertica with a SQL query. You connect to Vertica using username and password credentials stored in AWS Secrets Manager through a AWS Glue connection.

For more information about Vertica, consult the Vertica documentation.

Configuring Vertica connections

To connect to Vertica from AWS Glue, you will need to create and store your Vertica credentials in a AWS Secrets Manager secret, then associate that secret with a Vertica AWS Glue connection. If your Vertica instance is in an Amazon VPC, you will also need to provide networking options to your AWS Glue Vertica connection. You will need an Amazon S3 bucket or folder to use for temporary storage when reading from and writing to the database.

To connect to Vertica from AWS Glue, you will need some prerequisites:

- An Amazon S3 bucket or folder to use for temporary storage when reading from and writing to the database, referred to by *tempS3Path*.

> **Note**
>
> When using Vertica in AWS Glue job data previews, temporary files may not be automatically removed from *tempS3Path*. To ensure the removal of temporary files, directly end the data preview session by choosing **End session** in the **Data preview** pane. If you cannot guarantee the data preview session is ended directly, consider setting Amazon S3 Lifecycle configuration to remove old data. We recommend removing data older than 49 hours, based on maximum job runtime plus a margin. For more information about configuring Amazon S3 Lifecycle, see Managing your storage lifecycle in the Amazon S3 documentation.

- An IAM policy with appropriate permissions to your Amazon S3 path you can associate with your AWS Glue job role.
- If your Vertica instance is in an Amazon VPC, configure Amazon VPC to allow your AWS Glue job to communicate with the Vertica instance without traffic traversing the public internet.

  In Amazon VPC, identify or create a **VPC**, **Subnet** and **Security group** that AWS Glue will use while executing the job. Additionally, you need to ensure Amazon VPC is configured to permit network traffic between your Vertica instance and this location. Your job will need to establish a TCP connection with your Vertica client port, (default 5433). Based on your network layout, this may require changes to security group rules, Network ACLs, NAT Gateways and Peering connections.

You can then proceed to configure AWS Glue for use with Vertica.

To configure a connection to Vertica:

1. In AWS Secrets Manager, create a secret using your Vertica credentials, *verticaUsername* and *verticaPassword*. To create a secret in Secrets Manager, follow the tutorial available in Create an AWS Secrets Manager secret in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.

   - When selecting **Key/value pairs**, create a pair for the key `user` with the value *verticaUsername*.

- When selecting **Key/value pairs**, create a pair for the key `password` with the value *`verticaPassword`*.

2. In the AWS Glue console, create a connection by following the steps in the section called "Adding an AWS Glue connection". After creating the connection, keep the connection name, *`connectionName`*, for the next step.

   - When selecting a **Connection type**, select Vertica.
   - When selecting **Vertica Host**, provide the hostname of your Vertica installation.
   - When selecting **Vertica Port**, the port your Vertica installation is available through.
   - When selecting an **AWS Secret**, provide *`secretName`*.

3. In the following situations, you may require additional configuration:

   - For Vertica instances hosted on AWS in an Amazon VPC
     - Provide Amazon VPC connection information to the AWS Glue connection that defines your Vertica security credentials. When creating or updating your connection, set **VPC**, **Subnet** and **Security groups** in **Network options**.

After creating a AWS Glue Vertica connection, you will need to perform the following steps before calling your connection method.

- Grant the IAM role associated with your AWS Glue job permissions to *`tempS3Path`*.
- Grant the IAM role associated with your AWS Glue job permission to read *`secretName`*.
- In your AWS Glue job configuration, provide *`connectionName`* as an **Additional network connection**.

Reading from Vertica

Prerequisites:

- A Vertica table you would like to read from. You will need the Vertica database name, *`dbName`* and the table name, *`tableName`*.
- A AWS Glue Vertica connection configured to provide auth information. Complete the steps in the previous procedure, *To configure a connection to Vertica* to configure your auth information. You will need the name of the AWS Glue connection, *`connectionName`*.

- A Amazon S3 bucket or folder to use for temporary storage, mentioned previously. You will need the name, *tempS3Path*. You will need to connect to this location using the s3a protocol.

For example:

```
dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type="vertica",
    connection_options={
        "connectionName": "connectionName",
        "staging_fs_url": "s3a://tempS3Path",
        "db": "dbName",
        "table": "tableName",
    }
)
```

You can also provide a SELECT SQL query, to filter the results returned to your DynamicFrame or to access a dataset from multiple tables.

For example:

```
dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type="vertica",
    connection_options={
        "connectionName": "connectionName",
        "staging_fs_url": "s3a://tempS3Path",
        "db": "dbName",
        "query": "select * FROM tableName",
    },
)
```

Writing to Vertica tables

This example writes information from an existing DynamicFrame, *dynamicFrame* to Vertica. If the table already has information, AWS Glue will append data from your DynamicFrame.

Prerequisites:

- A current or desired table name, *tableName*, you would like to write to. You will also need the corresponding Vertica database name, *dbName*.

- A AWS Glue Vertica connection configured to provide auth information. Complete the steps in the previous procedure, *To configure a connection to Vertica* to configure your auth information. You will need the name of the AWS Glue connection, *connectionName*.
- A Amazon S3 bucket or folder to use for temporary storage, mentioned previously. You will need the name, *tempS3Path*. You will need to connect to this location using the s3a protocol.

For example:

```
glueContext.write_dynamic_frame.from_options(
    frame=dynamicFrame,
    connection_type="vertica",
    connection_options={
        "connectionName": "connectionName",
        "staging_fs_url": "s3a://tempS3Path",
        "db": "dbName",
        "table": "tableName",
    }
)
```

Vertica connection option reference

- connectionName — Required. Used for Read/Write. The name of a AWS Glue Vertica connection configured to provide auth and networking information to your connection method.
- db — Required. Used for Read/Write. The name of a database in Vertica your connection method will interact with.
- dbSchema — Required if needed to identify your table. Used for Read/Write. Default: public. The name of a schema your connection method will interact with.
- table — Required for writing, required for reading unless query is provided. Used for Read/Write. The name of a table your connection method will interact with.
- query — Used for Read. A SELECT SQL query defining what should be retrieved when reading from Teradata.
- staging_fs_url — Required. Used for Read/Write. Valid Values: s3a URLs. The URL of a Amazon S3 bucket or folder to use for temporary storage.

DataFrame options for ETL in AWS Glue 5.0 for Spark

A DataFrame is a Dataset organized into named columns similar to a table and supports functional-style (map/reduce/filter/etc.) operations and SQL operations (select, project, aggregate).

To create a DataFrame for a data source supported by Glue, the following are required:

- data source connector `ClassName`
- data source connection `Options`

Similarly, to write a DataFrame to a data sink supported by Glue, the same are required:

- data sink connector `ClassName`
- data sink connection `Options`

Note that AWS Glue features such as job bookmarks and DynamicFrame options such as `connectionName` are not supported in DataFrame. For more details about DataFrame and the supported operations, see the Spark documentation for DataFrame.

Specifying the connector ClassName

To specify the `ClassName` of a data source/sink, use the `.format` option to provide the corresponding connector `ClassName` that defines the data source/sink.

JDBC connectors

For JDBC connectors, specify `jdbc` as the value of the `.format` option and provide the JDBC driver `ClassName` in the `driver` option.

```
df = spark.read.format("jdbc").option("driver", "<DATA SOURCE JDBC DRIVER
 CLASSNAME>")...

df.write.format("jdbc").option("driver", "<DATA SINK JDBC DRIVER CLASSNAME>")...
```

The following table lists the JDBC driver `ClassName` of the supported data source in AWS Glue for DataFrames.

Data source	Driver ClassName

PostgreSQL	org.postgresql.Driver
Oracle	oracle.jdbc.driver.OracleDriver
SQLServer	com.microsoft.sqlserver.jdbc.SQLServerDriver
MySQL	com.mysql.jdbc.Driver
SAPHana	com.sap.db.jdbc.Driver
Teradata	com.teradata.jdbc.TeraDriver

Spark connectors

For spark connectors, specify the `ClassName` of the connector as the value of the `.format` option.

```
df = spark.read.format("<DATA SOURCE CONNECTOR CLASSNAME>")...

df.write.format("<DATA SINK CONNECTOR CLASSNAME>")...
```

The following table lists the Spark connector `ClassName` of the supported data source in AWS Glue for DataFrames.

Data source	ClassName
MongoDB/DocumentDB	glue.spark.mongodb
Redshift	io.github.spark_redshift_community.spark.redshift
AzureCosmos	cosmos.oltp
AzureSQL	com.microsoft.sqlserver.jdbc.spark
BigQuery	com.google.cloud.spark.bigquery
OpenSearch	org.opensearch.spark.sql
Snowflake	net.snowflake.spark.snowflake

Vertica	com.vertica.spark.datasource.VerticaSource

Specifying the connection Options

To specify the `Options` of the connection to a data source/sink, use the `.option(<KEY>, <VALUE>)` to provide individual options or `.options(<MAP>)` to provide multiple options as a key-value map.

Each data source/sink supports its own set of connection `Options`. For details on the available `Options`, refer to the public documentation of the specific data source/sink Spark connector listed in the following table.

- JDBC
- MongoDB/DocumentDB
- Redshift
- AzureCosmos
- AzureSQL
- BigQuery
- OpenSearch
- Snowflake
- Vertica

Examples

The following examples read from PostgreSQL and write into SnowFlake:

Python

Example:

```
from awsglue.context import GlueContext
from pyspark.sql import SparkSession

spark = SparkSession.builder.getOrCreate()

dataSourceClassName = "jdbc"
dataSourceOptions = {
  "driver": "org.postgresql.Driver",
```

```
  "url": "<url>",
  "user": "<user>",
  "password": "<password>",
  "dbtable": "<dbtable>",
}

dataframe = spark.read.format(className).options(**options).load()

dataSinkClassName = "net.snowflake.spark.snowflake"
dataSinkOptions = {
  "sfUrl": "<url>",
  "sfUsername": "<username>",
  "sfPassword": "<password>",
  "sfDatabase" -> "<database>",
  "sfSchema" -> "<schema>",
  "sfWarehouse" -> "<warehouse>"
}

dataframe.write.format(dataSinkClassName).options(**dataSinkOptions).save()
```

Scala

Example:

```
import org.apache.spark.sql.SparkSession

val spark = SparkSession.builder().getOrCreate()

val dataSourceClassName = "jdbc"
val dataSourceOptions = Map(
  "driver" -> "org.postgresql.Driver",
  "url" -> "<url>",
  "user" -> "<user>",
  "password" -> "<password>",
  "dbtable" -> "<dbtable>"
)

val dataframe =
 spark.read.format(dataSourceClassName).options(dataSourceOptions).load()

val dataSinkClassName = "net.snowflake.spark.snowflake"
val dataSinkOptions = Map(
  "sfUrl" -> "<url>",
  "sfUsername" -> "<username>",
```

```
  "sfPassword" -> "<password>",
  "sfDatabase" -> "<database>",
  "sfSchema" -> "<schema>",
  "sfWarehouse" -> "<warehouse>"
)

dataframe.write.format(dataSinkClassName).options(dataSinkOptions).save()
```

Custom and AWS Marketplace connectionType values

These include the following:

- `"connectionType": "marketplace.athena"`: Designates a connection to an Amazon Athena data store. The connection uses a connector from AWS Marketplace.
- `"connectionType": "marketplace.spark"`: Designates a connection to an Apache Spark data store. The connection uses a connector from AWS Marketplace.
- `"connectionType": "marketplace.jdbc"`: Designates a connection to a JDBC data store. The connection uses a connector from AWS Marketplace.
- `"connectionType": "custom.athena"`: Designates a connection to an Amazon Athena data store. The connection uses a custom connector that you upload to AWS Glue Studio.
- `"connectionType": "custom.spark"`: Designates a connection to an Apache Spark data store. The connection uses a custom connector that you upload to AWS Glue Studio.
- `"connectionType": "custom.jdbc"`: Designates a connection to a JDBC data store. The connection uses a custom connector that you upload to AWS Glue Studio.

Connection options for type custom.jdbc or marketplace.jdbc

- `className` – String, required, the fully-qualified Java class name of the JDBC driver (for example, `com.mysql.cj.jdbc.Driver`). You must specify this option when using a custom or AWS Marketplace JDBC connector. If you omit this option, the job may fail with a `No suitable driver` error, particularly when using parameterized JDBC URLs.
- `connectionName` – String, required, name of the connection that is associated with the connector.
- `url` – String, required, JDBC URL with placeholders (`${}`) which are used to build the connection to the data source. The placeholder `${secretKey}` is replaced with the secret of the same name in AWS Secrets Manager. Refer to the data store documentation for more information about constructing the URL.

- `secretId` or `user/password` – String, required, used to retrieve credentials for the URL.
- `dbTable` or `query` – String, required, the table or SQL query to get the data from. You can specify either `dbTable` or `query`, but not both.
- `partitionColumn` – String, optional, the name of an integer column that is used for partitioning. This option works only when it's included with `lowerBound`, `upperBound`, and `numPartitions`. This option works the same way as in the Spark SQL JDBC reader. For more information, see JDBC To Other Databases in the *Apache Spark SQL, DataFrames and Datasets Guide*.

  The `lowerBound` and `upperBound` values are used to decide the partition stride, not for filtering the rows in table. All rows in the table are partitioned and returned.

  > **Note**
  >
  > When using a query instead of a table name, you should validate that the query works with the specified partitioning condition. For example:
  >
  > - If your query format is `"SELECT col1 FROM table1"`, then test the query by appending a `WHERE` clause at the end of the query that uses the partition column.
  > - If your query format is `"SELECT col1 FROM table1 WHERE col2=val"`, then test the query by extending the `WHERE` clause with `AND` and an expression that uses the partition column.

- `lowerBound` – Integer, optional, the minimum value of `partitionColumn` that is used to decide partition stride.
- `upperBound` – Integer, optional, the maximum value of `partitionColumn` that is used to decide partition stride.
- `numPartitions` – Integer, optional, the number of partitions. This value, along with `lowerBound` (inclusive) and `upperBound` (exclusive), form partition strides for generated `WHERE` clause expressions that are used to split the `partitionColumn`.

  > **Important**
  >
  > Be careful with the number of partitions because too many partitions might cause problems on your external database systems.

- `filterPredicate` – String, optional, extra condition clause to filter data from source. For example:

```
BillingCity='Mountain View'
```

  When using a *query* instead of a *table* name, you should validate that the query works with the specified `filterPredicate`. For example:

  - If your query format is `"SELECT col1 FROM table1"`, then test the query by appending a `WHERE` clause at the end of the query that uses the filter predicate.
  - If your query format is `"SELECT col1 FROM table1 WHERE col2=val"`, then test the query by extending the `WHERE` clause with `AND` and an expression that uses the filter predicate.

- `dataTypeMapping` – Dictionary, optional, custom data type mapping that builds a mapping from a **JDBC** data type to a **Glue** data type. For example, the option `"dataTypeMapping":{"FLOAT":"STRING"}` maps data fields of JDBC type `FLOAT` into the Java `String` type by calling the `ResultSet.getString()` method of the driver, and uses it to build AWS Glue records. The `ResultSet` object is implemented by each driver, so the behavior is specific to the driver you use. Refer to the documentation for your JDBC driver to understand how the driver performs the conversions.
- The AWS Glue data types supported currently are:
  - DATE
  - STRING
  - TIMESTAMP
  - INT
  - FLOAT
  - LONG
  - BIGDECIMAL
  - BYTE
  - SHORT
  - DOUBLE

  The JDBC data types supported are Java8 java.sql.types.

  The default data type mappings (from JDBC to AWS Glue) are:
  - DATE -> DATE

- VARCHAR -> STRING
- CHAR -> STRING
- LONGNVARCHAR -> STRING
- TIMESTAMP -> TIMESTAMP
- INTEGER -> INT
- FLOAT -> FLOAT
- REAL -> FLOAT
- BIT -> BOOLEAN
- BOOLEAN -> BOOLEAN
- BIGINT -> LONG
- DECIMAL -> BIGDECIMAL
- NUMERIC -> BIGDECIMAL
- TINYINT -> SHORT
- SMALLINT -> SHORT
- DOUBLE -> DOUBLE

If you use a custom data type mapping with the option `dataTypeMapping`, then you can override a default data type mapping. Only the JDBC data types listed in the `dataTypeMapping` option are affected; the default mapping is used for all other JDBC data types. You can add mappings for additional JDBC data types if needed. If a JDBC data type is not included in either the default mapping or a custom mapping, then the data type converts to the AWS Glue `STRING` data type by default.

The following Python code example shows how to read from JDBC databases with AWS Marketplace JDBC drivers. It demonstrates reading from a database and writing to an S3 location.

```
    import sys
    from awsglue.transforms import *
    from awsglue.utils import getResolvedOptions
    from pyspark.context import SparkContext
    from awsglue.context import GlueContext
    from awsglue.job import Job

    ## @params: [JOB_NAME]
    args = getResolvedOptions(sys.argv, ['JOB_NAME'])
```

```
    sc = SparkContext()
    glueContext = GlueContext(sc)
    spark = glueContext.spark_session
    job = Job(glueContext)
    job.init(args['JOB_NAME'], args)
    ## @type: DataSource
    ## @args: [connection_type = "marketplace.jdbc", connection_options =
     {"dataTypeMapping":{"INTEGER":"STRING"},"upperBound":"200","query":"select id,
       name, department from department where id < 200","numPartitions":"4",
       "partitionColumn":"id","lowerBound":"0","connectionName":"test-connection-
jdbc"},
        transformation_ctx = "DataSource0"]
    ## @return: DataSource0
    ## @inputs: []
    DataSource0 = glueContext.create_dynamic_frame.from_options(connection_type =
      "marketplace.jdbc", connection_options = {"dataTypeMapping":{"INTEGER":"STRING"},
      "upperBound":"200","query":"select id, name, department from department where
       id < 200","numPartitions":"4","partitionColumn":"id","lowerBound":"0",
       "connectionName":"test-connection-jdbc"}, transformation_ctx = "DataSource0")
    ## @type: ApplyMapping
    ## @args: [mappings = [("department", "string", "department", "string"), ("name",
 "string",
     "name", "string"), ("id", "int", "id", "int")], transformation_ctx =
 "Transform0"]
    ## @return: Transform0
    ## @inputs: [frame = DataSource0]
    Transform0 = ApplyMapping.apply(frame = DataSource0, mappings = [("department",
 "string",
     "department", "string"), ("name", "string", "name", "string"), ("id", "int",
 "id", "int")],
      transformation_ctx = "Transform0")
    ## @type: DataSink
    ## @args: [connection_type = "s3", format = "json", connection_options = {"path":
     "s3://<S3 path>/", "partitionKeys": []}, transformation_ctx = "DataSink0"]
    ## @return: DataSink0
    ## @inputs: [frame = Transform0]
    DataSink0 = glueContext.write_dynamic_frame.from_options(frame = Transform0,
      connection_type = "s3", format = "json", connection_options = {"path":
      "s3://<S3 path>/", "partitionKeys": []}, transformation_ctx = "DataSink0")
    job.commit()
```

Connection options for type custom.athena or marketplace.athena

- `className` – String, required, driver class name. When you're using the Athena-CloudWatch connector, this parameter value is the prefix of the class Name (for example, `"com.amazonaws.athena.connectors"`). The Athena-CloudWatch connector is composed of two classes: a metadata handler and a record handler. If you supply the common prefix here, then the API loads the correct classes based on that prefix.
- `tableName` – String, required, the name of the CloudWatch log stream to read. This code snippet uses the special view name `all_log_streams`, which means that the dynamic data frame returned will contain data from all log streams in the log group.
- `schemaName` – String, required, the name of the CloudWatch log group to read from. For example, `/aws-glue/jobs/output`.
- `connectionName` – String, required, name of the connection that is associated with the connector.

For additional options for this connector, see the Amazon Athena CloudWatch Connector README file on GitHub.

The following Python code example shows how to read from an Athena data store using an AWS Marketplace connector. It demonstrates reading from Athena and writing to an S3 location.

```
    import sys
    from awsglue.transforms import *
    from awsglue.utils import getResolvedOptions
    from pyspark.context import SparkContext
    from awsglue.context import GlueContext
    from awsglue.job import Job

    ## @params: [JOB_NAME]
    args = getResolvedOptions(sys.argv, ['JOB_NAME'])

    sc = SparkContext()
    glueContext = GlueContext(sc)
    spark = glueContext.spark_session
    job = Job(glueContext)
    job.init(args['JOB_NAME'], args)
    ## @type: DataSource
    ## @args: [connection_type = "marketplace.athena", connection_options =
     {"tableName":"all_log_streams","schemaName":"/aws-glue/jobs/output",
```

```
      "connectionName":"test-connection-athena"}, transformation_ctx = "DataSource0"]
   ## @return: DataSource0
   ## @inputs: []
   DataSource0 = glueContext.create_dynamic_frame.from_options(connection_type =
     "marketplace.athena", connection_options = {"tableName":"all_log_streams",,
     "schemaName":"/aws-glue/jobs/output","connectionName":
     "test-connection-athena"}, transformation_ctx = "DataSource0")
   ## @type: ApplyMapping
   ## @args: [mappings = [("department", "string", "department", "string"), ("name",
"string",
     "name", "string"), ("id", "int", "id", "int")], transformation_ctx =
"Transform0"]
   ## @return: Transform0
   ## @inputs: [frame = DataSource0]
   Transform0 = ApplyMapping.apply(frame = DataSource0, mappings = [("department",
"string",
     "department", "string"), ("name", "string", "name", "string"), ("id", "int",
"id", "int")],
      transformation_ctx = "Transform0")
   ## @type: DataSink
   ## @args: [connection_type = "s3", format = "json", connection_options = {"path":
    "s3://<S3 path>/", "partitionKeys": []}, transformation_ctx = "DataSink0"]
   ## @return: DataSink0
   ## @inputs: [frame = Transform0]
   DataSink0 = glueContext.write_dynamic_frame.from_options(frame = Transform0,
     connection_type = "s3", format = "json", connection_options = {"path":
     "s3://<S3 path>/", "partitionKeys": []}, transformation_ctx = "DataSink0")
   job.commit()
```

Connection options for type custom.spark or marketplace.spark

- `className` – String, required, connector class name.
- `secretId` – String, optional, used to retrieve credentials for the connector connection.
- `connectionName` – String, required, name of the connection that is associated with the connector.
- Other options depend on the data store. For example, OpenSearch configuration options start with the prefix `es`, as described in the Elasticsearch for Apache Hadoop documentation. Spark connections to Snowflake use options such as `sfUser` and `sfPassword`, as described in Using the Spark Connector in the *Connecting to Snowflake* guide.

The following Python code example shows how to read from an OpenSearch data store using a `marketplace.spark` connection.

```
   import sys
   from awsglue.transforms import *
   from awsglue.utils import getResolvedOptions
   from pyspark.context import SparkContext
   from awsglue.context import GlueContext
   from awsglue.job import Job

   ## @params: [JOB_NAME]
   args = getResolvedOptions(sys.argv, ['JOB_NAME'])

   sc = SparkContext()
   glueContext = GlueContext(sc)
   spark = glueContext.spark_session
   job = Job(glueContext)
   job.init(args['JOB_NAME'], args)
   ## @type: DataSource
   ## @args: [connection_type = "marketplace.spark", connection_options =
{"path":"test",
     "es.nodes.wan.only":"true","es.nodes":"https://<AWS endpoint>",
     "connectionName":"test-spark-es","es.port":"443"}, transformation_ctx =
"DataSource0"]
   ## @return: DataSource0
   ## @inputs: []
   DataSource0 = glueContext.create_dynamic_frame.from_options(connection_type =
     "marketplace.spark", connection_options = {"path":"test","es.nodes.wan.only":
     "true","es.nodes":"https://<AWS endpoint>","connectionName":
     "test-spark-es","es.port":"443"}, transformation_ctx = "DataSource0")
   ## @type: DataSink
   ## @args: [connection_type = "s3", format = "json", connection_options = {"path":
        "s3://<S3 path>/", "partitionKeys": []}, transformation_ctx = "DataSink0"]
   ## @return: DataSink0
   ## @inputs: [frame = DataSource0]
   DataSink0 = glueContext.write_dynamic_frame.from_options(frame = DataSource0,
      connection_type = "s3", format = "json", connection_options = {"path":
      "s3://<S3 path>/", "partitionKeys": []}, transformation_ctx = "DataSink0")
   job.commit()
```

General options

The options in this section are provided as `connection_options`, but do not specifically apply to one connector.

The following parameters are used generally when configuring bookmarks. They may apply to Amazon S3 or JDBC workflows. For more information, see the section called “Using job bookmarks”.

- `jobBookmarkKeys` — Array of column names.
- `jobBookmarkKeysSortOrder` — String defining how to compare values based on sort order. Valid values: `"asc"`, `"desc"`.
- `useS3ListImplementation` — Used to manage memory performance when listing Amazon S3 bucket contents. For more information, see Optimize memory management in AWS Glue.

Data format options for inputs and outputs in AWS Glue for Spark

These pages offer information about feature support and configuration parameters for data formats supported by AWS Glue for Spark. See the following for a description of the usage and applicablity of this information.

Feature support across data formats in AWS Glue

Each data format may support different AWS Glue features. The following common features may or may not be supported based on your format type. Refer to the documentation for your data format to understand how to leverage our features to meet your requirements.

Read	AWS Glue can recognize and interpret this data format without additional resources, such as connectors.
Write	AWS Glue can write data in this format without additional resources. You can include third-party libraries in your job and use standard Apache Spark functions to write data, as you would in other Spark environme nts. For more information about including

	libraries, see the section called "Python libraries".
Streamir read	AWS Glue can recognize and interpret this data format from an Apache Kafka, Amazon Managed Streaming for Apache Kafka or Amazon Kinesis message stream. We expect streams to present data in a consistent format, so they are read in as `DataFrames` .
Group small files	AWS Glue can group files together to batch work sent to each node when performing AWS Glue transforms. This can significantly improve performance for workloads involving large amounts of small files. For more information, see the section called "Grouping input files".
Job bookmar	AWS Glue can track the progress of transform s performing the same work on the same dataset across job runs with job bookmarks. This can improve performance for workloads involving datasets where work only needs to be done on new data since the last job run. For more information, see the section called "Tracking processed data using job bookmarks ".

Parameters used to interact with data formats in AWS Glue

Certain AWS Glue connection types support multiple `format` types, requiring you to specify information about your data format with a `format_options` object when using methods like `GlueContext.write_dynamic_frame.from_options`.

- `s3` – For more information, see Connection types and options for ETL in AWS Glue: S3 connection parameters. You can also view the documentation for the methods facilitating this connection type: the section called "create_dynamic_frame_from_options" and the section called

"write_dynamic_frame_from_options" in Python and the corresponding Scala methods the section called "getSourceWithFormat" and the section called "getSinkWithFormat".

- `kinesis` – For more information, see Connection types and options for ETL in AWS Glue: Kinesis connection parameters. You can also view the documentation for the method facilitating this connection type: the section called "create_data_frame_from_options" and the corresponding Scala method the section called "createDataFrameFromOptions".
- `kafka` – For more information, see Connection types and options for ETL in AWS Glue: Kafka connection parameters. You can also view the documentation for the method facilitating this connection type: the section called "create_data_frame_from_options" and the corresponding Scala method the section called "createDataFrameFromOptions".

Some connection types do not require `format_options`. For example, in normal use, a JDBC connection to a relational database retrieves data in a consistent, tabular data format. Therefore, reading from a JDBC connection would not require `format_options`.

Some methods to read and write data in glue do not require `format_options`. For example, using `GlueContext.create_dynamic_frame.from_catalog` with AWS Glue crawlers. Crawlers determine the shape of your data. When using crawlers, a AWS Glue classifier will examine your data to make smart decisions about how to represent your data format. It will then store a representation of your data in the AWS Glue Data Catalog, which can be used within a AWS Glue ETL script to retrieve your data with the `GlueContext.create_dynamic_frame.from_catalog` method. Crawlers remove the need to manually specify information about your data format.

For jobs that access AWS Lake Formation governed tables, AWS Glue supports reading and writing all formats supported by Lake Formation governed tables. For the current list of supported formats for AWS Lake Formation governed tables, see Notes and Restrictions for Governed Tables in the *AWS Lake Formation Developer Guide*.

> **Note**
>
> For writing Apache Parquet, AWS Glue ETL only supports writing to a governed table by specifying an option for a custom Parquet writer type optimized for Dynamic Frames. When writing to a governed table with the `parquet` format, you should add the key `useGlueParquetWriter` with a value of `true` in the table parameters.

Using the CSV format in AWS Glue

AWS Glue retrieves data from sources and writes data to targets stored and transported in various data formats. If your data is stored or transported in the CSV data format, this document introduces you available features for using your data in AWS Glue.

AWS Glue supports using the comma-separated value (CSV) format. This format is a minimal, row-based data format. CSVs often don't strictly conform to a standard, but you can refer to RFC 4180 and RFC 7111 for more information.

You can use AWS Glue to read CSVs from Amazon S3 and from streaming sources as well as write CSVs to Amazon S3. You can read and write `bzip` and `gzip` archives containing CSV files from S3. You configure compression behavior on the S3 connection parameters instead of in the configuration discussed on this page.

The following table shows which common AWS Glue features support the CSV format option.

Read	Write	Streaming read	Group small files	Job bookmarks
Supported	Supported	Supported	Supported	Supported

Example: Read CSV files or folders from S3

Prerequisites: You will need the S3 paths (`s3path`) to the CSV files or folders that you want to read.

Configuration: In your function options, specify `format="csv"`. In your `connection_options`, use the `paths` key to specify `s3path`. You can configure how the reader interacts with S3 in `connection_options`. For details, see Connection types and options for ETL in AWS Glue: S3 connection parameters. You can configure how the reader interprets CSV files in your `format_options`. For details, see CSV Configuration Reference.

The following AWS Glue ETL script shows the process of reading CSV files or folders from S3.

We provide a custom CSV reader with performance optimizations for common workflows through the `optimizePerformance` configuration key. To determine if this reader is right for your workload, see the section called "Using optimized CSV reader".

Python

For this example, use the create_dynamic_frame.from_options method.

```
# Example: Read CSV from S3
# For show, we handle a CSV with a header row.  Set the withHeader option.
# Consider whether optimizePerformance is right for your workflow.

from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type="s3",
    connection_options={"paths": ["s3://s3path"]},
    format="csv",
    format_options={
        "withHeader": True,
        # "optimizePerformance": True,
    },
)
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
dataFrame = spark.read\
    .format("csv")\
    .option("header", "true")\
    .load("s3://s3path")
```

Scala

For this example, use the getSourceWithFormat operation.

```
// Example: Read CSV from S3
// For show, we handle a CSV with a header row.  Set the withHeader option.
// Consider whether optimizePerformance is right for your workflow.

import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.{DynamicFrame, GlueContext}
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    val dynamicFrame = glueContext.getSourceWithFormat(
      formatOptions=JsonOptions("""{"withHeader": true}"""),
      connectionType="s3",
      format="csv",
      options=JsonOptions("""{"paths": ["s3://s3path"], "recurse": true}""")
    ).getDynamicFrame()
  }
}
```

You can also use DataFrames in a script (`org.apache.spark.sql.DataFrame`).

```
val dataFrame = spark.read
  .option("header","true")
  .format("csv")
  .load("s3://s3path“)
```

Example: Write CSV files and folders to S3

Prerequisites: You will need an initialized DataFrame (`dataFrame`) or a DynamicFrame (`dynamicFrame`). You will also need your expected S3 output path, `s3path`.

Configuration: In your function options, specify `format="csv"`. In your `connection_options`, use the `paths` key to specify `s3path`. You can configure how the writer interacts with S3 in `connection_options`. For details, see Connection types and options for ETL in AWS Glue: S3 connection parameters. You can configure how your operation writes the contents of your files in `format_options`. For details, see CSV Configuration Reference. The following AWS Glue ETL script shows the process of writing CSV files and folders to S3.

Python

For this example, use the write_dynamic_frame.from_options method.

```
# Example: Write CSV to S3
# For show, customize how we write string type values.  Set quoteChar to -1 so our
 values are not quoted.

from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

glueContext.write_dynamic_frame.from_options(
    frame=dynamicFrame,
    connection_type="s3",
    connection_options={"path": "s3://s3path"},
    format="csv",
    format_options={
        "quoteChar": -1,
    },
)
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
dataFrame.write\
    .format("csv")\
    .option("quote", None)\
    .mode("append")\
```

```
    .save("s3://s3path")
```

Scala

For this example, use the getSinkWithFormat method.

```
// Example: Write CSV to S3
// For show, customize how we write string type values. Set quoteChar to -1 so our
 values are not quoted.

import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.{DynamicFrame, GlueContext}
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    glueContext.getSinkWithFormat(
        connectionType="s3",
        options=JsonOptions("""{"path": "s3://s3path"}"""),
        format="csv"
    ).writeDynamicFrame(dynamicFrame)
  }
}
```

You can also use DataFrames in a script (`org.apache.spark.sql.DataFrame`).

```
dataFrame.write
    .format("csv")
    .option("quote", null)
    .mode("Append")
    .save("s3://s3path")
```

CSV configuration reference

You can use the following `format_options` wherever AWS Glue libraries specify `format="csv"`:

- `separator` –Specifies the delimiter character. The default is a comma, but any other character can be specified.

  - **Type:** Text, **Default:** `","`
- `escaper` – Specifies a character to use for escaping. This option is used only when reading CSV files, not writing. If enabled, the character that immediately follows is used as-is, except for a small set of well-known escapes (`\n`, `\r`, `\t`, and `\0`).
  - **Type:** Text, **Default:** none
- `quoteChar` – Specifies the character to use for quoting. The default is a double quote. Set this to `-1` to turn off quoting entirely.
  - **Type:** Text, **Default:** `'"'`
- `multiLine` – Specifies whether a single record can span multiple lines. This can occur when a field contains a quoted new-line character. You must set this option to `True` if any record spans multiple lines. Enabling `multiLine` might decrease performance because it requires more cautious file-splitting while parsing.
  - **Type:** Boolean, **Default:** `false`
- `withHeader` – Specifies whether to treat the first line as a header. This option can be used in the `DynamicFrameReader` class.
  - **Type:** Boolean, **Default:** `false`
- `writeHeader` – Specifies whether to write the header to output. This option can be used in the `DynamicFrameWriter` class.
  - **Type:** Boolean, **Default:** `true`
- `skipFirst` – Specifies whether to skip the first data line.
  - **Type:** Boolean, **Default:** `false`
- `optimizePerformance` – Specifies whether to use the advanced SIMD CSV reader along with Apache Arrow–based columnar memory formats. Only available in AWS Glue 3.0+.
  - **Type:** Boolean, **Default:** `false`
- `strictCheckForQuoting` – When writing CSVs, Glue may add quotes to values it interprets as strings. This is done to prevent ambiguity in what is written out. To save time when deciding what to write, Glue may quote in certain situations where quotes are not necessary. Enabling a strict check will perform a more intensive computation and will only quote when strictly necessary. Only available in AWS Glue 3.0+.
  - **Type:** Boolean, **Default:** `false`

Optimize read performance with vectorized SIMD CSV reader

AWS Glue version 3.0 adds an optimized CSV reader that can significantly speed up overall job performance compared to row-based CSV readers.

The optimized reader:

- Uses CPU SIMD instructions to read from disk
- Immediately writes records to memory in a columnar format (Apache Arrow)
- Divides the records into batches

This saves processing time when records would be batched or converted to a columnar format later on. Some examples are when changing schemas or retrieving data by column.

To use the optimized reader, set `"optimizePerformance"` to `true` in the `format_options` or table property.

```
glueContext.create_dynamic_frame.from_options(
    frame = datasource1,
    connection_type = "s3",
    connection_options = {"paths": ["s3://s3path"]},
    format = "csv",
    format_options={
        "optimizePerformance": True,
        "separator": ","
        },
    transformation_ctx = "datasink2")
```

Limitations for the vectorized CSV reader

Note the following limitations of the vectorized CSV reader:

- It doesn't support the `multiLine` and `escaper` format options. It uses the default `escaper` of double quote char `'"'`. When these options are set, AWS Glue automatically falls back to using the row-based CSV reader.
- It doesn't support creating a DynamicFrame with ChoiceType.
- It doesn't support creating a DynamicFrame with error records.
- It doesn't support reading CSV files with multibyte characters such as Japanese or Chinese characters.

Using the Parquet format in AWS Glue

AWS Glue retrieves data from sources and writes data to targets stored and transported in various data formats. If your data is stored or transported in the Parquet data format, this document introduces you available features for using your data in AWS Glue.

AWS Glue supports using the Parquet format. This format is a performance-oriented, column-based data format. For an introduction to the format by the standard authority see, Apache Parquet Documentation Overview.

You can use AWS Glue to read Parquet files from Amazon S3 and from streaming sources as well as write Parquet files to Amazon S3. You can read and write `bzip` and `gzip` archives containing Parquet files from S3. You configure compression behavior on the S3 connection parameters instead of in the configuration discussed on this page.

The following table shows which common AWS Glue features support the Parquet format option.

Read	Write	Streaming read	Group small files	Job bookmarks
Supported	Supported	Supported	Unsupported	Supported*

* Supported in AWS Glue version 1.0+

Example: Read Parquet files or folders from S3

Prerequisites: You will need the S3 paths (`s3path`) to the Parquet files or folders that you want to read.

Configuration: In your function options, specify `format="parquet"`. In your `connection_options`, use the `paths` key to specify your `s3path`.

You can configure how the reader interacts with S3 in the `connection_options`. For details, see Connection types and options for ETL in AWS Glue: S3 connection parameters.

You can configure how the reader interprets Parquet files in your `format_options`. For details, see Parquet Configuration Reference.

The following AWS Glue ETL script shows the process of reading Parquet files or folders from S3:

Python

For this example, use the create_dynamic_frame.from_options method.

```
# Example: Read Parquet from S3

from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type = "s3",
    connection_options = {"paths": ["s3://s3path/"]},
    format = "parquet"
)
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
dataFrame = spark.read.parquet("s3://s3path/")
```

Scala

For this example, use the getSourceWithFormat method.

```
// Example: Read Parquet from S3

import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.{DynamicFrame, GlueContext}
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    val dynamicFrame = glueContext.getSourceWithFormat(
      connectionType="s3",
      format="parquet",
```

```
      options=JsonOptions("""{"paths": ["s3://s3path"]}""")
    ).getDynamicFrame()
  }
}
```

You can also use DataFrames in a script (`org.apache.spark.sql.DataFrame`).

```
spark.read.parquet("s3://s3path/")
```

Example: Write Parquet files and folders to S3

Prerequisites: You will need an initialized DataFrame (`dataFrame`) or DynamicFrame (`dynamicFrame`). You will also need your expected S3 output path, `s3path`.

Configuration: In your function options, specify `format="parquet"`. In your `connection_options`, use the `paths` key to specify `s3path`.

You can further alter how the writer interacts with S3 in the `connection_options`. For details, see Connection types and options for ETL in AWS Glue: S3 connection parameters. You can configure how your operation writes the contents of your files in `format_options`. For details, see Parquet Configuration Reference.

The following AWS Glue ETL script shows the process of writing Parquet files and folders to S3.

We provide a custom Parquet writer with performance optimizations for DynamicFrames, through the `useGlueParquetWriter` configuration key. To determine if this writer is right for your workload, see Glue Parquet Writer.

Python

For this example, use the write_dynamic_frame.from_options method.

```
# Example: Write Parquet to S3
# Consider whether useGlueParquetWriter is right for your workflow.

from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)
```

```
glueContext.write_dynamic_frame.from_options(
    frame=dynamicFrame,
    connection_type="s3",
    format="parquet",
    connection_options={
        "path": "s3://s3path",
    },
    format_options={
        # "useGlueParquetWriter": True,
    },
)
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
df.write.parquet("s3://s3path/")
```

Scala

For this example, use the getSinkWithFormat method.

```
// Example: Write Parquet to S3
// Consider whether useGlueParquetWriter is right for your workflow.

import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.{DynamicFrame, GlueContext}
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    glueContext.getSinkWithFormat(
        connectionType="s3",
        options=JsonOptions("""{"path": "s3://s3path"}"""),
        format="parquet"
    ).writeDynamicFrame(dynamicFrame)
  }
}
```

You can also use DataFrames in a script (`org.apache.spark.sql.DataFrame`).

```
df.write.parquet("s3://s3path/")
```

Parquet configuration reference

You can use the following `format_options` wherever AWS Glue libraries specify `format="parquet"`:

- `useGlueParquetWriter` – Specifies the use of a custom Parquet writer that has performance optimizations for DynamicFrame workflows. For usage details, see Glue Parquet Writer.
  - **Type:** Boolean, **Default:**`false`
- `compression` – Specifies the compression codec used. Values are fully compatible with `org.apache.parquet.hadoop.metadata.CompressionCodecName`.
  - **Type:** Enumerated Text, **Default:** `"snappy"`
  - Values: `"uncompressed"`, `"snappy"`, `"gzip"`, and `"lzo"`
- `blockSize` – Specifies the size in bytes of a row group being buffered in memory. You use this for tuning performance. Size should divide exactly into a number of megabytes.
  - **Type:** Numerical, **Default:**`134217728`
  - The default value is equal to 128 MB.
- `pageSize` – Specifies the size in bytes of a page. You use this for tuning performance. A page is the smallest unit that must be read fully to access a single record.
  - **Type:** Numerical, **Default:**`1048576`
  - The default value is equal to 1 MB.

> **Note**
>
> Additionally, any options that are accepted by the underlying SparkSQL code can be passed to this format by way of the `connection_options` map parameter. For example, you can set a Spark configuration such as mergeSchema for the AWS Glue Spark reader to merge the schema for all files.

Optimize write performance with AWS Glue Parquet writer

> **Note**
>
> The AWS Glue Parquet writer has historically been accessed through the `glueparquet` format type. This access pattern is no longer advocated. Instead, use the `parquet` type with `useGlueParquetWriter` enabled.

The AWS Glue Parquet writer has performance enhancements that allow faster Parquet file writes. The traditional writer computes a schema before writing. The Parquet format doesn't store the schema in a quickly retrievable fashion, so this might take some time. With the AWS Glue Parquet writer, a pre-computed schema isn't required. The writer computes and modifies the schema dynamically, as data comes in.

Note the following limitations when you specify `useGlueParquetWriter`:

- The writer supports only schema evolution (such as adding or removing columns), but not changing column types, such as with `ResolveChoice`.
- The writer doesn't support writing empty DataFrames—for example, to write a schema-only file. When integrating with the AWS Glue Data Catalog by setting `enableUpdateCatalog=True`, attempting to write an empty DataFrame will not update the Data Catalog. This will result in creating a table in the Data Catalog without a schema.

If your transform doesn't require these limitations, turning on the AWS Glue Parquet writer should increase performance.

Using the XML format in AWS Glue

AWS Glue retrieves data from sources and writes data to targets stored and transported in various data formats. If your data is stored or transported in the XML data format, this document introduces you available features for using your data in AWS Glue.

AWS Glue supports using the XML format. This format represents highly configurable, rigidly defined data structures that aren't row or column based. XML is highly standardized. For an introduction to the format by the standard authority, see XML Essentials.

You can use AWS Glue to read XML files from Amazon S3, as well as `bzip` and `gzip` archives containing XML files. You configure compression behavior on the S3 connection parameters instead of in the configuration discussed on this page.

The following table shows which common AWS Glue features support the XML format option.

Read	Write	Streaming read	Group small files	Job bookmarks
Supported	Unsupported	Unsupported	Supported	Supported

Example: Read XML from S3

The XML reader takes an XML tag name. It examines elements with that tag within its input to infer a schema and populates a DynamicFrame with corresponding values. The AWS Glue XML functionality behaves similarly to the XML Data Source for Apache Spark. You might be able to gain insight around basic behavior by comparing this reader to that project's documentation.

Prerequisites: You will need the S3 paths (`s3path`) to the XML files or folders that you want to read, and some information about your XML file. You will also need the tag for the XML element you want to read, `xmlTag`.

Configuration: In your function options, specify `format="xml"`. In your `connection_options`, use the `paths` key to specify `s3path`. You can further configure how the reader interacts with S3 in the `connection_options`. For details, see Connection types and options for ETL in AWS Glue: S3 connection parameters. In your `format_options`, use the `rowTag` key to specify `xmlTag`. You can further configure how the reader interprets XML files in your `format_options`. For details, see XML Configuration Reference.

The following AWS Glue ETL script shows the process of reading XML files or folders from S3.

Python

For this example, use the create_dynamic_frame.from_options method.

```
# Example: Read XML from S3
# Set the rowTag option to configure the reader.

from awsglue.context import GlueContext
```

```
from pyspark.context import SparkContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type="s3",
    connection_options={"paths": ["s3://s3path"]},
    format="xml",
    format_options={"rowTag": "xmlTag"},
)
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
dataFrame = spark.read\
    .format("xml")\
    .option("rowTag", "xmlTag")\
    .load("s3://s3path")
```

Scala

For this example, use the getSourceWithFormat operation.

```
// Example: Read XML from S3
// Set the rowTag option to configure the reader.

import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.GlueContext
import org.apache.spark.sql.SparkSession

val glueContext = new GlueContext(SparkContext.getOrCreate())
val sparkSession: SparkSession = glueContext.getSparkSession

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val dynamicFrame = glueContext.getSourceWithFormat(
      formatOptions=JsonOptions("""{"rowTag": "xmlTag"}"""),
      connectionType="s3",
      format="xml",
      options=JsonOptions("""{"paths": ["s3://s3path"], "recurse": true}""")
    ).getDynamicFrame()
}
```

You can also use DataFrames in a script (`org.apache.spark.sql.DataFrame`).

```
val dataFrame = spark.read
  .option("rowTag", "xmlTag")
  .format("xml")
  .load("s3://s3path“)
```

XML configuration reference

You can use the following `format_options` wherever AWS Glue libraries specify `format="xml"`:

- `rowTag` – Specifies the XML tag in the file to treat as a row. Row tags cannot be self-closing.
  - **Type:** Text, **Required**
- `encoding` – Specifies the character encoding. It can be the name or alias of a Charset supported by our runtime environment. We don't make specific guarantees around encoding support, but major encodings should work.
  - **Type:** Text, **Default:** `"UTF-8"`
- `excludeAttribute` – Specifies whether you want to exclude attributes in elements or not.
  - **Type:** Boolean, **Default:** `false`
- `treatEmptyValuesAsNulls` – Specifies whether to treat white space as a null value.
  - **Type:** Boolean, **Default:** `false`
- `attributePrefix` – A prefix for attributes to differentiate them from child element text. This prefix is used for field names.
  - **Type:** Text, **Default:** `"_"`
- `valueTag` – The tag used for a value when there are attributes in the element that have no child.
  - **Type:** Text, **Default:** `"_VALUE"`
- `ignoreSurroundingSpaces` – Specifies whether the white space that surrounds values should be ignored.
  - **Type:** Boolean, **Default:** `false`
- `withSchema` – Contains the expected schema, in situations where you want to override the inferred schema. If you don't use this option, AWS Glue infers the schema from the XML data.
  - **Type:** Text, **Default:** Not applicable

- The value should be a JSON object that represents a `StructType`.

Manually specify the XML schema

Manual XML schema example

This is an example of using the `withSchema` format option to specify the schema for XML data.

```
from awsglue.gluetypes import *

schema = StructType([
  Field("id", IntegerType()),
  Field("name", StringType()),
  Field("nested", StructType([
    Field("x", IntegerType()),
    Field("y", StringType()),
    Field("z", ChoiceType([IntegerType(), StringType()]))
  ]))
])

datasource0 = create_dynamic_frame_from_options(
    connection_type,
    connection_options={"paths": ["s3://xml_bucket/someprefix"]},
    format="xml",
    format_options={"withSchema": json.dumps(schema.jsonValue())},
    transformation_ctx = ""
)
```

Using the Avro format in AWS Glue

AWS Glue retrieves data from sources and writes data to targets stored and transported in various data formats. If your data is stored or transported in the Avro data format, this document introduces you available features for using your data in AWS Glue.

AWS Glue supports using the Avro format. This format is a performance-oriented, row-based data format. For an introduction to the format by the standard authority see, Apache Avro 1.8.2 Documentation.

You can use AWS Glue to read Avro files from Amazon S3 and from streaming sources as well as write Avro files to Amazon S3. You can read and write `bzip2` and `gzip` archives containing Avro files from S3. Additionally, you can write `deflate`, `snappy`, and `xz` archives containing

Avro files. You configure compression behavior on the S3 connection parameters instead of in the configuration discussed on this page.

The following table shows which common AWS Glue operations support the Avro format option.

Read	Write	Streaming read	Group small files	Job bookmarks
Supported	Supported	Supported*	Unsupported	Supported

*Supported with restrictions. For more information, see the section called "Notes and restrictions for Avro streaming sources".

Example: Read Avro files or folders from S3

Prerequisites: You will need the S3 paths (`s3path`) to the Avro files or folders that you want to read.

Configuration: In your function options, specify `format="avro"`. In your `connection_options`, use the `paths` key to specify `s3path`. You can configure how the reader interacts with S3 in the `connection_options`. For details, see Data format options for ETL inputs and outputs in AWS Glue: the section called "S3 connection parameters". You can configure how the reader interprets Avro files in your `format_options`. For details, see Avro Configuration Reference.

The following AWS Glue ETL script shows the process of reading Avro files or folders from S3:

Python

For this example, use the create_dynamic_frame.from_options method.

```
from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type="s3",
    connection_options={"paths": ["s3://s3path"]},
    format="avro"
)
```

Scala

For this example, use the getSourceWithFormat operation.

```
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.GlueContext
import org.apache.spark.sql.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    val dynamicFrame = glueContext.getSourceWithFormat(
      connectionType="s3",
      format="avro",
      options=JsonOptions("""{"paths": ["s3://s3path"]}""")
    ).getDynamicFrame()
  }
```

Example: Write Avro files and folders to S3

Prerequisites: You will need an initialized DataFrame (`dataFrame`) or DynamicFrame (`dynamicFrame`). You will also need your expected S3 output path, `s3path`.

Configuration: In your function options, specify `format="avro"`. In your `connection_options`, use the `paths` key to specify your `s3path`. You can further alter how the writer interacts with S3 in the `connection_options`. For details, see Data format options for ETL inputs and outputs in AWS Glue: the section called "S3 connection parameters". You can alter how the writer interprets Avro files in your `format_options`. For details, see Avro Configuration Reference.

The following AWS Glue ETL script shows the process of writing Avro files or folders to S3.

Python

For this example, use the write_dynamic_frame.from_options method.

```
from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)
```

```
glueContext.write_dynamic_frame.from_options(
    frame=dynamicFrame,
    connection_type="s3",
    format="avro",
    connection_options={
        "path": "s3://s3path"
    }
)
```

Scala

For this example, use the getSinkWithFormat method.

```
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.{DynamicFrame, GlueContext}
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    glueContext.getSinkWithFormat(
      connectionType="s3",
      options=JsonOptions("""{"path": "s3://s3path"}"""),
      format="avro"
    ).writeDynamicFrame(dynamicFrame)
  }
}
```

Avro configuration reference

You can use the following `format_options` values wherever AWS Glue libraries specify `format="avro"`:

- `version` — Specifies the version of Apache Avro reader/writer format to support. The default is "1.7". You can specify `format_options={"version": “1.8”}` to enable Avro logical type reading and writing. For more information, see the Apache Avro 1.7.7 Specification and Apache Avro 1.8.2 Specification.

  The Apache Avro 1.8 connector supports the following logical type conversions:

For the reader: this table shows the conversion between Avro data type (logical type and Avro primitive type) and AWS Glue `DynamicFrame` data type for Avro reader 1.7 and 1.8.

Avro Data Type: Logical Type	**Avro Data Type: Avro Primitive Type**	**GlueDynamicFrame Data Type: Avro Reader 1.7**	**GlueDynamicFrame Data Type: Avro Reader 1.8**
Decimal	bytes	BINARY	Decimal
Decimal	fixed	BINARY	Decimal
Date	int	INT	Date
Time (millisecond)	int	INT	INT
Time (microsecond)	long	LONG	LONG
Timestamp (millisecond)	long	LONG	Timestamp
Timestamp (microsecond)	long	LONG	LONG
Duration (not a logical type)	fixed of 12	BINARY	BINARY

For the writer: this table shows the conversion between AWS Glue `DynamicFrame` data type and Avro data type for Avro writer 1.7 and 1.8.

AWS Glue `DynamicFrame` Data Type	**Avro Data Type: Avro Writer 1.7**	**Avro Data Type: Avro Writer 1.8**
Decimal	String	decimal
Date	String	date
Timestamp	String	timestamp-micros

Avro Spark DataFrame support

In order to use Avro from the Spark DataFrame API, you need to install the Spark Avro plugin for the corresponding Spark version. The version of Spark available in your job is determined by your AWS Glue version. For more information about Spark versions, see the section called "AWS Glue versions". This plugin is maintained by Apache, we do not make specific guarantees of support.

In AWS Glue 2.0 - use version 2.4.3 of the Spark Avro plugin. You can find this JAR on Maven Central, see org.apache.spark:spark-avro_2.12:2.4.3.

In AWS Glue 3.0 - use version 3.1.1 of the Spark Avro plugin. You can find this JAR on Maven Central, see org.apache.spark:spark-avro_2.12:3.1.1.

To include extra JARs in a AWS Glue ETL job, use the `--extra-jars` job parameter. For more information about job parameters, see the section called "Job parameters". You can also configure this parameter in the AWS Management Console.

Using the grokLog format in AWS Glue

AWS Glue retrieves data from sources and writes data to targets stored and transported in various data formats. If your data is stored or transported in a loosely structured plaintext format, this document introduces you available features for using your data in AWS Glue through Grok patterns.

AWS Glue supports using Grok patterns. Grok patterns are similar to regular expression capture groups. They recognize patterns of character sequences in a plaintext file and give them a type and purpose. In AWS Glue, their primary purpose is to read logs. For an introduction to the Grok by the authors, see Logstash Reference: Grok filter plugin.

Read	Write	Streaming read	Group small files	Job bookmarks
Supported	Not Applicable	Supported	Supported	Unsupported

grokLog configuration reference

You can use the following `format_options` values with `format="grokLog"`:

- `logFormat` — Specifies the Grok pattern that matches the log's format.

- `customPatterns` — Specifies additional Grok patterns used here.
- `MISSING` — Specifies the signal to use in identifying missing values. The default is `'-'`.
- `LineCount` — Specifies the number of lines in each log record. The default is `'1'`, and currently only single-line records are supported.
- `StrictMode` — A Boolean value that specifies whether strict mode is turned on. In strict mode, the reader doesn't do automatic type conversion or recovery. The default value is `"false"`.

Using the Ion format in AWS Glue

AWS Glue retrieves data from sources and writes data to targets stored and transported in various data formats. If your data is stored or transported in the Ion data format, this document introduces you available features for using your data in AWS Glue.

AWS Glue supports using the Ion format. This format represents data structures (that aren't row or column based) in interchangeable binary and plaintext representations. For an introduction to the format by the authors, see Amazon Ion. (For more information, see the Amazon Ion Specification.)

You can use AWS Glue to read Ion files from Amazon S3. You can read `bzip` and `gzip` archives containing Ion files from S3. You configure compression behavior on the S3 connection parameters instead of in the configuration discussed on this page.

The following table shows which common AWS Glue operations support the Ion format option.

Read	Write	Streaming read	Group small files	Job bookmarks
Supported	Unsupported	Unsupported	Supported	Unsupported

Example: Read Ion files and folders from S3

Prerequisites: You will need the S3 paths (`s3path`) to the Ion files or folders that you want to read.

Configuration: In your function options, specify `format="json"`. In your `connection_options`, use the `paths` key to specify your `s3path`. You can configure how the reader interacts with S3 in the `connection_options`. For details, see Connection types and options for ETL in AWS Glue: the section called “S3 connection parameters”.

The following AWS Glue ETL script shows the process of reading Ion files or folders from S3:

Python

For this example, use the create_dynamic_frame.from_options method.

```
# Example: Read ION from S3

from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type="s3",
    connection_options={"paths": ["s3://s3path"]},
    format="ion"
)
```

Scala

For this example, use the getSourceWithFormat operation.

```
// Example: Read ION from S3

import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.GlueContext
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    val dynamicFrame = glueContext.getSourceWithFormat(
      connectionType="s3",
      format="ion",
      options=JsonOptions("""{"paths": ["s3://s3path"], "recurse": true}""")
    ).getDynamicFrame()
  }
}
```

Ion configuration reference

There are no `format_options` values for `format="ion"`.

Using the JSON format in AWS Glue

AWS Glue retrieves data from sources and writes data to targets stored and transported in various data formats. If your data is stored or transported in the JSON data format, this document introduces you to available features for using your data in AWS Glue.

AWS Glue supports using the JSON format. This format represents data structures with consistent shape but flexible contents, that aren't row or column based. JSON is defined by parallel standards issued by several authorities, one of which is ECMA-404. For an introduction to the format by a commonly referenced source, see Introducing JSON.

You can use AWS Glue to read JSON files from Amazon S3, as well as `bzip` and `gzip` compressed JSON files. You configure compression behavior on the S3 connection parameters instead of in the configuration discussed on this page.

Read	Write	Streaming read	Group small files	Job bookmarks	
Supported	Supported	Supported	Supported	Supported	

Example: Read JSON files or folders from S3

Prerequisites: You will need the S3 paths (`s3path`) to the JSON files or folders you would like to read.

Configuration: In your function options, specify `format="json"`. In your `connection_options`, use the `paths` key to specify your `s3path`. You can further alter how your read operation will traverse s3 in the connection options, consult the section called “S3 connection parameters” for details. You can configure how the reader interprets JSON files in your `format_options`. For details, see JSON Configuration Reference.

The following AWS Glue ETL script shows the process of reading JSON files or folders from S3:

Python

For this example, use the create_dynamic_frame.from_options method.

```
# Example: Read JSON from S3
# For show, we handle a nested JSON file that we can limit with the JsonPath
 parameter
# For show, we also handle a JSON where a single entry spans multiple lines
# Consider whether optimizePerformance is right for your workflow.

from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type="s3",
    connection_options={"paths": ["s3://s3path"]},
    format="json",
    format_options={
        "jsonPath": "$.id",
        "multiline": True,
        # "optimizePerformance": True, -> not compatible with jsonPath, multiline
    }
)
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
dataFrame = spark.read\
    .option("multiline", "true")\
    .json("s3://s3path")
```

Scala

For this example, use the [getSourceWithFormat] operation.

```
// Example: Read JSON from S3
// For show, we handle a nested JSON file that we can limit with the JsonPath
 parameter
// For show, we also handle a JSON where a single entry spans multiple lines
// Consider whether optimizePerformance is right for your workflow.

import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.{DynamicFrame, GlueContext}
```

```
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    val dynamicFrame = glueContext.getSourceWithFormat(
      formatOptions=JsonOptions("""{"jsonPath": "$.id", "multiline": true,
 "optimizePerformance":false}"""),
      connectionType="s3",
      format="json",
      options=JsonOptions("""{"paths": ["s3://s3path"], "recurse": true}""")
    ).getDynamicFrame()
  }
}
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
val dataFrame = spark.read
    .option("multiline", "true")
    .json("s3://s3path")
```

Example: Write JSON files and folders to S3

Prerequisites: You will need an initialized DataFrame (`dataFrame`) or DynamicFrame (`dynamicFrame`). You will also need your expected S3 output path, `s3path`.

Configuration: In your function options, specify `format="json"`. In your `connection_options`, use the `paths` key to specify `s3path`. You can further alter how the writer interacts with S3 in the `connection_options`. For details, see Data format options for ETL inputs and outputs in AWS Glue : the section called “S3 connection parameters”. You can configure how the writer interprets JSON files in your `format_options`. For details, see JSON Configuration Reference.

The following AWS Glue ETL script shows the process of writing JSON files or folders from S3:

Python

For this example, use the write_dynamic_frame.from_options method.

```
# Example: Write JSON to S3
```

```
from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

glueContext.write_dynamic_frame.from_options(
    frame=dynamicFrame,
    connection_type="s3",
    connection_options={"path": "s3://s3path"},
    format="json"
)
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
df.write.json("s3://s3path/")
```

Scala

For this example, use the getSinkWithFormat method.

```
// Example: Write JSON to S3

import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.{DynamicFrame, GlueContext}
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    glueContext.getSinkWithFormat(
        connectionType="s3",
        options=JsonOptions("""{"path": "s3://s3path"}"""),
        format="json"
    ).writeDynamicFrame(dynamicFrame)
  }
}
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
df.write.json("s3://s3path")
```

Json configuration reference

You can use the following `format_options` values with `format="json"`:

- `jsonPath` — A JsonPath expression that identifies an object to be read into records. This is particularly useful when a file contains records nested inside an outer array. For example, the following JsonPath expression targets the `id` field of a JSON object.

  ```
  format="json", format_options={"jsonPath": "$.id"}
  ```

- `multiline` — A Boolean value that specifies whether a single record can span multiple lines. This can occur when a field contains a quoted new-line character. You must set this option to `"true"` if any record spans multiple lines. The default value is `"false"`, which allows for more aggressive file-splitting during parsing.
- `optimizePerformance` — A Boolean value that specifies whether to use the advanced SIMD JSON reader along with Apache Arrow based columnar memory formats. Only available in AWS Glue 3.0. Not compatible with `multiline` or `jsonPath`. Providing either of those options will instruct AWS Glue to fall back to the standard reader.
- `withSchema` — A String value that specifies a table schema in the format described in the section called “Specify XML schema”. Only used with `optimizePerformance` when reading from non-Catalog connections.

Using vectorized SIMD JSON reader with Apache Arrow columnar format

AWS Glue version 3.0 adds a vectorized reader for JSON data. It performs 2x faster under certain conditions, compared to the standard reader. This reader comes with certain limitations users should be aware of before use, documented in this section.

To use the optimized reader, set `"optimizePerformance"` to True in the `format_options` or table property. You will also need to provide `withSchema` unless reading from the catalog. `withSchema` expects an input as described in the the section called “Specify XML schema”

```
// Read from S3 data source
glueContext.create_dynamic_frame.from_options(
```

```
    connection_type = "s3",
    connection_options = {"paths": ["s3://s3path"]},
    format = "json",
    format_options={
        "optimizePerformance": True,
        "withSchema": SchemaString
        })

// Read from catalog table
glueContext.create_dynamic_frame.from_catalog(
    database = database,
    table_name = table,
    additional_options = {
    // The vectorized reader for JSON can read your schema from a catalog table
 property.
        "optimizePerformance": True,
        })
```

For more information about the building a *SchemaString* in the AWS Glue library, see the section called "Types".

Limitations for the vectorized CSV reader

Note the following limitations:

- JSON elements with nested objects or array values are not supported. If provided, AWS Glue will fall back to the standard reader.
- A schema must be provided, either from the Catalog or with `withSchema`.
- Not compatible with `multiline` or `jsonPath`. Providing either of those options will instruct AWS Glue to fall back to the standard reader.
- Providing input records that do not match the input schema will cause the reader to fail.
- Error records will not be created.
- JSON files with multi-byte characters (such as Japanese or Chinese characters) are not supported.

Using the ORC format in AWS Glue

AWS Glue retrieves data from sources and writes data to targets stored and transported in various data formats. If your data is stored or transported in the ORC data format, this document introduces you available features for using your data in AWS Glue.

AWS Glue supports using the ORC format. This format is a performance-oriented, column-based data format. For an introduction to the format by the standard authority see, Apache Orc.

You can use AWS Glue to read ORC files from Amazon S3 and from streaming sources as well as write ORC files to Amazon S3. You can read and write `bzip` and `gzip` archives containing ORC files from S3. You configure compression behavior on the S3 connection parameters instead of in the configuration discussed on this page.

The following table shows which common AWS Glue operations support the ORC format option.

Read	Write	Streaming read	Group small files	Job bookmarks
Supported	Supported	Supported	Unsupported	Supported*

*Supported in AWS Glue version 1.0+

Example: Read ORC files or folders from S3

Prerequisites: You will need the S3 paths (`s3path`) to the ORC files or folders that you want to read.

Configuration: In your function options, specify `format="orc"`. In your `connection_options`, use the `paths` key to specify your `s3path`. You can configure how the reader interacts with S3 in the `connection_options`. For details, see Connection types and options for ETL in AWS Glue: the section called "S3 connection parameters".

The following AWS Glue ETL script shows the process of reading ORC files or folders from S3:

Python

For this example, use the create_dynamic_frame.from_options method.

```
from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

dynamicFrame = glueContext.create_dynamic_frame.from_options(
```

```
    connection_type="s3",
    connection_options={"paths": ["s3://s3path"]},
    format="orc"
)
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
dataFrame = spark.read\
    .orc("s3://s3path")
```

Scala

For this example, use the getSourceWithFormat operation.

```
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.GlueContext
import org.apache.spark.sql.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    val dynamicFrame = glueContext.getSourceWithFormat(
      connectionType="s3",
      format="orc",
      options=JsonOptions("""{"paths": ["s3://s3path"]}""")
    ).getDynamicFrame()
  }
}
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
val dataFrame = spark.read
    .orc("s3://s3path")
```

Example: Write ORC files and folders to S3

Prerequisites: You will need an initialized DataFrame (`dataFrame`) or DynamicFrame (`dynamicFrame`). You will also need your expected S3 output path, `s3path`.

Configuration: In your function options, specify `format="orc"`. In your connection options, use the `paths` key to specify `s3path`. You can further alter how the writer interacts with S3 in the `connection_options`. For details, see Data format options for ETL inputs and outputs in AWS Glue: the section called "S3 connection parameters". The following code example shows the process:

Python

For this example, use the write_dynamic_frame.from_options method.

```
from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

glueContext.write_dynamic_frame.from_options(
    frame=dynamicFrame,
    connection_type="s3",
    format="orc",
    connection_options={
        "path": "s3://s3path"
    }
)
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
df.write.orc("s3://s3path/")
```

Scala

For this example, use the getSinkWithFormat method.

```
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.{DynamicFrame, GlueContext}
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
```

```
    glueContext.getSinkWithFormat(
      connectionType="s3",
      options=JsonOptions("""{"path": "s3://s3path"}"""),
      format="orc"
    ).writeDynamicFrame(dynamicFrame)
  }
}
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
df.write.orc("s3://s3path/")
```

ORC configuration reference

There are no `format_options` values for `format="orc"`. However, any options that are accepted by the underlying SparkSQL code can be passed to it by way of the `connection_options` map parameter.

Using data lake frameworks with AWS Glue ETL jobs

Open-source data lake frameworks simplify incremental data processing for files that you store in data lakes built on Amazon S3. AWS Glue 3.0 and later supports the following open-source data lake frameworks:

- Apache Hudi
- Linux Foundation Delta Lake
- Apache Iceberg

We provide native support for these frameworks so that you can read and write data that you store in Amazon S3 in a transactionally consistent manner. There's no need to install a separate connector or complete extra configuration steps in order to use these frameworks in AWS Glue ETL jobs.

When you manage datasets through the AWS Glue Data Catalog, you can use AWS Glue methods to read and write data lake tables with Spark DataFrames. You can also read and write Amazon S3 data using the Spark DataFrame API.

In this video, you can learn about the basics of how Apache Hudi, Apache Iceberg, and Delta Lake work. You'll see how to insert, update, and delete data in your data lake and how each of these frameworks works.

Topics

- Limitations
- Using the Hudi framework in AWS Glue
- Using the Delta Lake framework in AWS Glue
- Using the Iceberg framework in AWS Glue

Limitations

Consider the following limitations before you use data lake frameworks with AWS Glue.

- The following AWS Glue `GlueContext` methods for DynamicFrame don't support reading and writing data lake framework tables. Use the `GlueContext` methods for DataFrame or Spark DataFrame API instead.
  - `create_dynamic_frame.from_catalog`
  - `write_dynamic_frame.from_catalog`
  - `getDynamicFrame`
  - `writeDynamicFrame`
- The following `GlueContext` methods for DataFrame are supported with Lake Formation permission control:
  - `create_data_frame.from_catalog`
  - `write_data_frame.from_catalog`
  - `getDataFrame`
  - `writeDataFrame`
- Grouping small files is not supported.
- Job bookmarks are not supported.
- Apache Hudi 0.10.1 for AWS Glue 3.0 doesn't support Hudi Merge on Read (MoR) tables.
- `ALTER TABLE ... RENAME TO` is not available for Apache Iceberg 0.13.1 for AWS Glue 3.0.

Limitations for data lake format tables managed by Lake Formation permissions

The data lake formats are integrated with AWS Glue ETL via Lake Formation permissions. Creating a DynamicFrame using `create_dynamic_frame` is not supported. For more information, see the following examples:

- Example: Read and write Iceberg table with Lake Formation permission control
- Example: Read and write Hudi table with Lake Formation permission control
- Example: Read and write Delta Lake table with Lake Formation permission control

> **Note**
>
> The integration with AWS Glue ETL via Lake Formation permissions for Apache Hudi, Apache Iceberg, and Delta Lake is supported only in AWS Glue version 4.0.

Apache Iceberg has the best integration with AWS Glue ETL via Lake Formation permissions. It supports almost all operations and includes SQL support.

Hudi supports most basic operations with the exception of administrative operations. This is because these options generally are done via writing of dataframes and specified via `additional_options`. You need to use AWS Glue APIs to create DataFrames for your operations as SparkSQL is not supported.

Delta Lake only supports the reading and appending and overwriting of table data. Delta Lake requires the use of their own libraries to be able to perform various tasks such as updates.

The following features are not available for Iceberg tables managed by Lake Formation permissions.

- Compaction using AWS Glue ETL
- Spark SQL support via AWS Glue ETL

The following are limitations of Hudi tables managed by Lake Formation permissions:

- Removal of orphaned files

The following are limitations of Delta Lake tables managed by Lake Formation permissions:

- All features other than inserting and reading from Delta Lake tables.

Using the Hudi framework in AWS Glue

AWS Glue 3.0 and later supports Apache Hudi framework for data lakes. Hudi is an open-source data lake storage framework that simplifies incremental data processing and data pipeline development. This topic covers available features for using your data in AWS Glue when you transport or store your data in a Hudi table. To learn more about Hudi, see the official Apache Hudi documentation.

You can use AWS Glue to perform read and write operations on Hudi tables in Amazon S3, or work with Hudi tables using the AWS Glue Data Catalog. Additional operations including insert, update, and all of the Apache Spark operations are also supported.

> **Note**
>
> The Apache Hudi 0.15.0 implementation in AWS Glue 5.0 internally reverts HUDI-7001. It does not exhibit the regression related to Complex Key gen when the record key consists of a single field. However this behavior differs from OSS Apache Hudi 0.15.0.
> Apache Hudi 0.10.1 for AWS Glue 3.0 doesn't support Hudi Merge on Read (MoR) tables.

The following table lists the Hudi version that is included in each AWS Glue version.

AWS Glue version	Supported Hudi version
5.1	1.0.2
5.0	0.15.0
4.0	0.12.1
3.0	0.10.1

To learn more about the data lake frameworks that AWS Glue supports, see Using data lake frameworks with AWS Glue ETL jobs.

Enabling Hudi

To enable Hudi for AWS Glue, complete the following tasks:

- Specify `hudi` as a value for the `--datalake-formats` job parameter. For more information, see Using job parameters in AWS Glue jobs.
- Create a key named `--conf` for your AWS Glue job, and set it to the following value. Alternatively, you can set the following configuration using `SparkConf` in your script. These settings help Apache Spark correctly handle Hudi tables.

```
spark.serializer=org.apache.spark.serializer.KryoSerializer
```

- Lake Formation permission support for Hudi is enabled by default for AWS Glue 4.0. No additional configuration is needed for reading/writing to Lake Formation-registered Hudi tables. To read a registered Hudi table, the AWS Glue job IAM role must have the SELECT permission. To write to a registered Hudi table, the AWS Glue job IAM role must have the SUPER permission. To learn more about managing Lake Formation permissions, see Granting and revoking permissions on Data Catalog resources.

Using a different Hudi version

To use a version of Hudi that AWS Glue doesn't support, specify your own Hudi JAR files using the `--extra-jars` job parameter. Do not include `hudi` as a value for the `--datalake-formats` job parameter. If you use AWS Glue 5.0 or above, you must set `--user-jars-first true` job parameter.

Example: Write a Hudi table to Amazon S3 and register it in the AWS Glue Data Catalog

This example script demonstrates how to write a Hudi table to Amazon S3 and register the table to the AWS Glue Data Catalog. The example uses the Hudi Hive Sync tool to register the table.

> **Note**
>
> This example requires you to set the `--enable-glue-datacatalog` job parameter in order to use the AWS Glue Data Catalog as an Apache Spark Hive metastore. To learn more, see Using job parameters in AWS Glue jobs.

Python

```
# Example: Create a Hudi table from a DataFrame
# and register the table to Glue Data Catalog

additional_options={
    "hoodie.table.name": "<your_table_name>",
    "hoodie.database.name": "<your_database_name>",
    "hoodie.datasource.write.storage.type": "COPY_ON_WRITE",
    "hoodie.datasource.write.operation": "upsert",
    "hoodie.datasource.write.recordkey.field": "<your_recordkey_field>",
    "hoodie.datasource.write.precombine.field": "<your_precombine_field>",
    "hoodie.datasource.write.partitionpath.field": "<your_partitionkey_field>",
    "hoodie.datasource.write.hive_style_partitioning": "true",
    "hoodie.datasource.hive_sync.enable": "true",
    "hoodie.datasource.hive_sync.database": "<your_database_name>",
    "hoodie.datasource.hive_sync.table": "<your_table_name>",
    "hoodie.datasource.hive_sync.partition_fields": "<your_partitionkey_field>",
    "hoodie.datasource.hive_sync.partition_extractor_class":
 "org.apache.hudi.hive.MultiPartKeysValueExtractor",
    "hoodie.datasource.hive_sync.use_jdbc": "false",
    "hoodie.datasource.hive_sync.mode": "hms",
    "path": "s3://<s3Path/>"
}

dataFrame.write.format("hudi") \
    .options(**additional_options) \
    .mode("overwrite") \
    .save()
```

Scala

```
// Example: Example: Create a Hudi table from a DataFrame
// and register the table to Glue Data Catalog

val additionalOptions = Map(
  "hoodie.table.name" -> "<your_table_name>",
  "hoodie.database.name" -> "<your_database_name>",
  "hoodie.datasource.write.storage.type" -> "COPY_ON_WRITE",
  "hoodie.datasource.write.operation" -> "upsert",
  "hoodie.datasource.write.recordkey.field" -> "<your_recordkey_field>",
  "hoodie.datasource.write.precombine.field" -> "<your_precombine_field>",
  "hoodie.datasource.write.partitionpath.field" -> "<your_partitionkey_field>",
```

```
  "hoodie.datasource.write.hive_style_partitioning" -> "true",
  "hoodie.datasource.hive_sync.enable" -> "true",
  "hoodie.datasource.hive_sync.database" -> "<your_database_name>",
  "hoodie.datasource.hive_sync.table" -> "<your_table_name>",
  "hoodie.datasource.hive_sync.partition_fields" -> "<your_partitionkey_field>",
  "hoodie.datasource.hive_sync.partition_extractor_class" ->
 "org.apache.hudi.hive.MultiPartKeysValueExtractor",
  "hoodie.datasource.hive_sync.use_jdbc" -> "false",
  "hoodie.datasource.hive_sync.mode" -> "hms",
  "path" -> "s3://<s3Path/>")

dataFrame.write.format("hudi")
  .options(additionalOptions)
  .mode("append")
  .save()
```

Example: Read a Hudi table from Amazon S3 using the AWS Glue Data Catalog

This example reads the Hudi table that you created in the Example: Write a Hudi table to Amazon S3 and register it in the AWS Glue Data Catalog from Amazon S3.

> **Note**
>
> This example requires you to set the `--enable-glue-datacatalog` job parameter in order to use the AWS Glue Data Catalog as an Apache Spark Hive metastore. To learn more, see Using job parameters in AWS Glue jobs.

Python

For this example, use the `GlueContext.create_data_frame.from_catalog()` method.

```
# Example: Read a Hudi table from Glue Data Catalog

from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

dataFrame = glueContext.create_data_frame.from_catalog(
```

```
    database = "<your_database_name>",
    table_name = "<your_table_name>"
)
```

Scala

For this example, use the getCatalogSource method.

```
// Example: Read a Hudi table from Glue Data Catalog

import com.amazonaws.services.glue.GlueContext
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    val dataFrame = glueContext.getCatalogSource(
      database = "<your_database_name>",
      tableName = "<your_table_name>"
    ).getDataFrame()
  }
}
```

Example: Update and insert a `DataFrame` into a Hudi table in Amazon S3

This example uses the AWS Glue Data Catalog to insert a DataFrame into the Hudi table that you created in Example: Write a Hudi table to Amazon S3 and register it in the AWS Glue Data Catalog.

> **Note**
>
> This example requires you to set the `--enable-glue-datacatalog` job parameter in order to use the AWS Glue Data Catalog as an Apache Spark Hive metastore. To learn more, see Using job parameters in AWS Glue jobs.

Python

For this example, use the `GlueContext.write_data_frame.from_catalog()` method.

```
# Example: Upsert a Hudi table from Glue Data Catalog

from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

glueContext.write_data_frame.from_catalog(
    frame = dataFrame,
    database = "<your_database_name>",
    table_name = "<your_table_name>",
    additional_options={
        "hoodie.table.name": "<your_table_name>",
        "hoodie.database.name": "<your_database_name>",
        "hoodie.datasource.write.storage.type": "COPY_ON_WRITE",
        "hoodie.datasource.write.operation": "upsert",
        "hoodie.datasource.write.recordkey.field": "<your_recordkey_field>",
        "hoodie.datasource.write.precombine.field": "<your_precombine_field>",
        "hoodie.datasource.write.partitionpath.field": "<your_partitionkey_field>",
        "hoodie.datasource.write.hive_style_partitioning": "true",
        "hoodie.datasource.hive_sync.enable": "true",
        "hoodie.datasource.hive_sync.database": "<your_database_name>",
        "hoodie.datasource.hive_sync.table": "<your_table_name>",
        "hoodie.datasource.hive_sync.partition_fields": "<your_partitionkey_field>",
        "hoodie.datasource.hive_sync.partition_extractor_class":
 "org.apache.hudi.hive.MultiPartKeysValueExtractor",
        "hoodie.datasource.hive_sync.use_jdbc": "false",
        "hoodie.datasource.hive_sync.mode": "hms"
    }
)
```

Scala

For this example, use the getCatalogSink method.

```
// Example: Upsert a Hudi table from Glue Data Catalog

import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.util.JsonOptions
import org.apacke.spark.SparkContext

object GlueApp {
```

```
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    glueContext.getCatalogSink("<your_database_name>", "<your_table_name>",
      additionalOptions = JsonOptions(Map(
        "hoodie.table.name" -> "<your_table_name>",
        "hoodie.database.name" -> "<your_database_name>",
        "hoodie.datasource.write.storage.type" -> "COPY_ON_WRITE",
        "hoodie.datasource.write.operation" -> "upsert",
        "hoodie.datasource.write.recordkey.field" -> "<your_recordkey_field>",
        "hoodie.datasource.write.precombine.field" -> "<your_precombine_field>",
        "hoodie.datasource.write.partitionpath.field" ->
 "<your_partitionkey_field>",
        "hoodie.datasource.write.hive_style_partitioning" -> "true",
        "hoodie.datasource.hive_sync.enable" -> "true",
        "hoodie.datasource.hive_sync.database" -> "<your_database_name>",
        "hoodie.datasource.hive_sync.table" -> "<your_table_name>",
        "hoodie.datasource.hive_sync.partition_fields" ->
 "<your_partitionkey_field>",
        "hoodie.datasource.hive_sync.partition_extractor_class" ->
 "org.apache.hudi.hive.MultiPartKeysValueExtractor",
        "hoodie.datasource.hive_sync.use_jdbc" -> "false",
        "hoodie.datasource.hive_sync.mode" -> "hms"
      )))
      .writeDataFrame(dataFrame, glueContext)
  }
}
```

Example: Read a Hudi table from Amazon S3 using Spark

This example reads a Hudi table from Amazon S3 using the Spark DataFrame API.

Python

```
# Example: Read a Hudi table from S3 using a Spark DataFrame

dataFrame = spark.read.format("hudi").load("s3://<s3path/>")
```

Scala

```
// Example: Read a Hudi table from S3 using a Spark DataFrame
```

```
val dataFrame = spark.read.format("hudi").load("s3://<s3path/>")
```

Example: Write a Hudi table to Amazon S3 using Spark

This example writes a Hudi table to Amazon S3 using Spark.

Python

```
# Example: Write a Hudi table to S3 using a Spark DataFrame

dataFrame.write.format("hudi") \
    .options(**additional_options) \
    .mode("overwrite") \
    .save("s3://<s3Path/>")
```

Scala

```
// Example: Write a Hudi table to S3 using a Spark DataFrame

dataFrame.write.format("hudi")
  .options(additionalOptions)
  .mode("overwrite")
  .save("s3://<s3path/>")
```

Example: Read and write Hudi table with Lake Formation permission control

This example reads and writes a Hudi table with Lake Formation permission control.

1. Create a Hudi table and register it in Lake Formation.
   a. To enable Lake Formation permission control, you'll first need to register the table Amazon S3 path on Lake Formation. For more information, see Registering an Amazon S3 location. You can register it either from the Lake Formation console or by using the AWS CLI:

      ```
      aws lakeformation register-resource --resource-arn arn:aws:s3:::<s3-bucket>/<s3-
      folder> --use-service-linked-role --region <REGION>
      ```

      Once you register an Amazon S3 location, any AWS Glue table pointing to the location (or any of its child locations) will return the value for the `IsRegisteredWithLakeFormation` parameter as true in the `GetTable` call.

b. Create a Hudi table that points to the registered Amazon S3 path through the Spark dataframe API:

```
hudi_options = {
    'hoodie.table.name': table_name,
    'hoodie.database.name': database_name,
    'hoodie.datasource.write.storage.type': 'COPY_ON_WRITE',
    'hoodie.datasource.write.recordkey.field': 'product_id',
    'hoodie.datasource.write.table.name': table_name,
    'hoodie.datasource.write.operation': 'upsert',
    'hoodie.datasource.write.precombine.field': 'updated_at',
    'hoodie.datasource.write.hive_style_partitioning': 'true',
    'hoodie.upsert.shuffle.parallelism': 2,
    'hoodie.insert.shuffle.parallelism': 2,
    'path': <S3_TABLE_LOCATION>,
    'hoodie.datasource.hive_sync.enable': 'true',
    'hoodie.datasource.hive_sync.database': database_name,
    'hoodie.datasource.hive_sync.table': table_name,
    'hoodie.datasource.hive_sync.use_jdbc': 'false',
    'hoodie.datasource.hive_sync.mode': 'hms'
}

df_products.write.format("hudi")  \
    .options(**hudi_options)  \
    .mode("overwrite")  \
    .save()
```

2. Grant Lake Formation permission to the AWS Glue job IAM role. You can either grant permissions from the Lake Formation console, or using the AWS CLI. For more information, see Granting table permissions using the Lake Formation console and the named resource method

3. Read the Hudi table registered in Lake Formation. The code is same as reading a non-registered Hudi table. Note that the AWS Glue job IAM role needs to have the SELECT permission for the read to succeed.

```
val dataFrame = glueContext.getCatalogSource(
     database = "<your_database_name>",
     tableName = "<your_table_name>"
   ).getDataFrame()
```

4. Write to a Hudi table registered in Lake Formation. The code is same as writing to a non-registered Hudi table. Note that the AWS Glue job IAM role needs to have the SUPER permission for the write to succeed.

```
glueContext.getCatalogSink("<your_database_name>", "<your_table_name>",
      additionalOptions = JsonOptions(Map(
        "hoodie.table.name" -> "<your_table_name>",
        "hoodie.database.name" -> "<your_database_name>",
        "hoodie.datasource.write.storage.type" -> "COPY_ON_WRITE",
        "hoodie.datasource.write.operation" -> "<write_operation>",
        "hoodie.datasource.write.recordkey.field" -> "<your_recordkey_field>",
        "hoodie.datasource.write.precombine.field" -> "<your_precombine_field>",
        "hoodie.datasource.write.partitionpath.field" -> "<your_partitionkey_field>",
        "hoodie.datasource.write.hive_style_partitioning" -> "true",
        "hoodie.datasource.hive_sync.enable" -> "true",
        "hoodie.datasource.hive_sync.database" -> "<your_database_name>",
        "hoodie.datasource.hive_sync.table" -> "<your_table_name>",
        "hoodie.datasource.hive_sync.partition_fields" ->
 "<your_partitionkey_field>",
        "hoodie.datasource.hive_sync.partition_extractor_class" ->
 "org.apache.hudi.hive.MultiPartKeysValueExtractor",
        "hoodie.datasource.hive_sync.use_jdbc" -> "false",
        "hoodie.datasource.hive_sync.mode" -> "hms"
      )))
      .writeDataFrame(dataFrame, glueContext)
```

Using the Delta Lake framework in AWS Glue

AWS Glue 3.0 and later supports the Linux Foundation Delta Lake framework. Delta Lake is an open-source data lake storage framework that helps you perform ACID transactions, scale metadata handling, and unify streaming and batch data processing. This topic covers available features for using your data in AWS Glue when you transport or store your data in a Delta Lake table. To learn more about Delta Lake, see the official Delta Lake documentation.

You can use AWS Glue to perform read and write operations on Delta Lake tables in Amazon S3, or work with Delta Lake tables using the AWS Glue Data Catalog. Additional operations such as insert, update, and Table batch reads and writes are also supported. When you use Delta Lake tables, you also have the option to use methods from the Delta Lake Python library such as `DeltaTable.forPath`. For more information about the Delta Lake Python library, see Delta Lake's Python documentation.

The following table lists the version of Delta Lake included in each AWS Glue version.

AWS Glue version	Supported Delta Lake version
5.1	3.3.2
5.0	3.3.0
4.0	2.1.0
3.0	1.0.0

To learn more about the data lake frameworks that AWS Glue supports, see Using data lake frameworks with AWS Glue ETL jobs.

Enabling Delta Lake for AWS Glue

To enable Delta Lake for AWS Glue, complete the following tasks:

- Specify `delta` as a value for the `--datalake-formats` job parameter. For more information, see Using job parameters in AWS Glue jobs.
- Create a key named `--conf` for your AWS Glue job, and set it to the following value. Alternatively, you can set the following configuration using `SparkConf` in your script. These settings help Apache Spark correctly handle Delta Lake tables.

```
spark.sql.extensions=io.delta.sql.DeltaSparkSessionExtension --conf
 spark.sql.catalog.spark_catalog=org.apache.spark.sql.delta.catalog.DeltaCatalog --
conf
 spark.delta.logStore.class=org.apache.spark.sql.delta.storage.S3SingleDriverLogStore
```

- Lake Formation permission support for Delta tables is enabled by default for AWS Glue 4.0. No additional configuration is needed for reading/writing to Lake Formation-registered Delta tables. To read a registered Delta table, the AWS Glue job IAM role must have the SELECT permission. To write to a registered Delta table, the AWS Glue job IAM role must have the SUPER permission. To learn more about managing Lake Formation permissions, see Granting and revoking permissions on Data Catalog resources.

Using a different Delta Lake version

To use a version of Delta lake that AWS Glue doesn't support, specify your own Delta Lake JAR files using the `--extra-jars` job parameter. Do not include `delta` as a value for the `--datalake-formats` job parameter. If you use AWS Glue 5.0 or above, you must set `--user-jars-first true` job parameter. To use the Delta Lake Python library in this case, you must specify the library JAR files using the `--extra-py-files` job parameter. The Python library comes packaged in the Delta Lake JAR files.

Example: Write a Delta Lake table to Amazon S3 and register it to the AWS Glue Data Catalog

The following AWS Glue ETL script demonstrates how to write a Delta Lake table to Amazon S3 and register the table to the AWS Glue Data Catalog.

Python

```
# Example: Create a Delta Lake table from a DataFrame
# and register the table to Glue Data Catalog

additional_options = {
    "path": "s3://<s3Path>"
}
dataFrame.write \
    .format("delta") \
    .options(**additional_options) \
    .mode("append") \
    .partitionBy("<your_partitionkey_field>") \
    .saveAsTable("<your_database_name>.<your_table_name>")
```

Scala

```
// Example: Example: Create a Delta Lake table from a DataFrame
// and register the table to Glue Data Catalog

val additional_options = Map(
  "path" -> "s3://<s3Path>"
)
dataFrame.write.format("delta")
  .options(additional_options)
  .mode("append")
  .partitionBy("<your_partitionkey_field>")
  .saveAsTable("<your_database_name>.<your_table_name>")
```

Example: Read a Delta Lake table from Amazon S3 using the AWS Glue Data Catalog

The following AWS Glue ETL script reads the Delta Lake table that you created in Example: Write a Delta Lake table to Amazon S3 and register it to the AWS Glue Data Catalog.

Python

For this example, use the create_data_frame.from_catalog method.

```
# Example: Read a Delta Lake table from Glue Data Catalog

from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

df = glueContext.create_data_frame.from_catalog(
    database="<your_database_name>",
    table_name="<your_table_name>",
    additional_options=additional_options
)
```

Scala

For this example, use the getCatalogSource method.

```
// Example: Read a Delta Lake table from Glue Data Catalog

import com.amazonaws.services.glue.GlueContext
import org.apacke.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    val df = glueContext.getCatalogSource("<your_database_name>",
 "<your_table_name>",
      additionalOptions = additionalOptions)
      .getDataFrame()
  }
}
```

Example: Insert a `DataFrame` into a Delta Lake table in Amazon S3 using the AWS Glue Data Catalog

This example inserts data into the Delta Lake table that you created in Example: Write a Delta Lake table to Amazon S3 and register it to the AWS Glue Data Catalog.

> **Note**
>
> This example requires you to set the `--enable-glue-datacatalog` job parameter in order to use the AWS Glue Data Catalog as an Apache Spark Hive metastore. To learn more, see Using job parameters in AWS Glue jobs.

Python

For this example, use the write_data_frame.from_catalog method.

```
# Example: Insert into a Delta Lake table in S3 using Glue Data Catalog

from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

glueContext.write_data_frame.from_catalog(
    frame=dataFrame,
    database="<your_database_name>",
    table_name="<your_table_name>",
    additional_options=additional_options
)
```

Scala

For this example, use the getCatalogSink method.

```
// Example: Insert into a Delta Lake table in S3 using Glue Data Catalog

import com.amazonaws.services.glue.GlueContext
import org.apacke.spark.SparkContext
```

```
object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    glueContext.getCatalogSink("<your_database_name>", "<your_table_name>",
      additionalOptions = additionalOptions)
      .writeDataFrame(dataFrame, glueContext)
  }
}
```

Example: Read a Delta Lake table from Amazon S3 using the Spark API

This example reads a Delta Lake table from Amazon S3 using the Spark API.

Python

```
# Example: Read a Delta Lake table from S3 using a Spark DataFrame

dataFrame = spark.read.format("delta").load("s3://<s3path/>")
```

Scala

```
// Example: Read a Delta Lake table from S3 using a Spark DataFrame

val dataFrame = spark.read.format("delta").load("s3://<s3path/>")
```

Example: Write a Delta Lake table to Amazon S3 using Spark

This example writes a Delta Lake table to Amazon S3 using Spark.

Python

```
# Example: Write a Delta Lake table to S3 using a Spark DataFrame

dataFrame.write.format("delta") \
    .options(**additional_options) \
    .mode("overwrite") \
    .partitionBy("<your_partitionkey_field>")
    .save("s3://<s3Path>")
```

Scala

```
// Example: Write a Delta Lake table to S3 using a Spark DataFrame

dataFrame.write.format("delta")
  .options(additionalOptions)
  .mode("overwrite")
  .partitionBy("<your_partitionkey_field>")
  .save("s3://<s3path/>")
```

Example: Read and write Delta Lake table with Lake Formation permission control

This example reads and writes a Delta Lake table with Lake Formation permission control.

1. Create a Delta table and register it in Lake Formation

   a. To enable Lake Formation permission control, you'll first need to register the table Amazon S3 path on Lake Formation. For more information, see Registering an Amazon S3 location. You can register it either from the Lake Formation console or by using the AWS CLI:

   ```
   aws lakeformation register-resource --resource-arn arn:aws:s3:::<s3-bucket>/<s3-folder> --use-service-linked-role --region <REGION>
   ```

   Once you register an Amazon S3 location, any AWS Glue table pointing to the location (or any of its child locations) will return the value for the `IsRegisteredWithLakeFormation` parameter as true in the `GetTable` call.

   b. Create a Delta table that points to the registered Amazon S3 path through Spark:

   > **Note**
   >
   > The following are Python examples.

   ```
   dataFrame.write \
    .format("delta") \
    .mode("overwrite") \
    .partitionBy("<your_partitionkey_field>") \
    .save("s3://<the_s3_path>")
   ```

After the data has been written to Amazon S3, use the AWS Glue crawler to create a new Delta catalog table. For more information, see Introducing native Delta Lake table support with AWS Glue crawlers.

You can also create the table manually through the AWS Glue `CreateTable` API.

2. Grant Lake Formation permission to the AWS Glue job IAM role. You can either grant permissions from the Lake Formation console, or using the AWS CLI. For more information, see Granting table permissions using the Lake Formation console and the named resource method
3. Read the Delta table registered in Lake Formation. The code is same as reading a non-registered Delta table. Note that the AWS Glue job IAM role needs to have the SELECT permission for the read to succeed.

```
# Example: Read a Delta Lake table from Glue Data Catalog

df = glueContext.create_data_frame.from_catalog(
    database="<your_database_name>",
    table_name="<your_table_name>",
    additional_options=additional_options
)
```

4. Write to a Delta table registered in Lake Formation. The code is same as writing to a non-registered Delta table. Note that the AWS Glue job IAM role needs to have the SUPER permission for the write to succeed.

   By default AWS Glue uses Append as saveMode. You can change it by setting the saveMode option in `additional_options`. For information about saveMode support in Delta tables, see Write to a table.

```
glueContext.write_data_frame.from_catalog(
    frame=dataFrame,
    database="<your_database_name>",
    table_name="<your_table_name>",
    additional_options=additional_options
)
```

Using the Iceberg framework in AWS Glue

AWS Glue 3.0 and later supports the Apache Iceberg framework for data lakes. Iceberg provides a high-performance table format that works just like a SQL table. This topic covers available features for using your data in AWS Glue when you transport or store your data in an Iceberg table. To learn more about Iceberg, see the official Apache Iceberg documentation.

You can use AWS Glue to perform read and write operations on Iceberg tables in Amazon S3, or work with Iceberg tables using the AWS Glue Data Catalog. Additional operations including insert and all Spark Queries Spark Writes are also supported. Update is not supported for Iceberg tables.

> **Note**
>
> `ALTER TABLE ... RENAME TO` is not available for Apache Iceberg 0.13.1 for AWS Glue 3.0.

The following table lists the version of Iceberg included in each AWS Glue version.

AWS Glue version	Supported Iceberg version
5.1	1.10.0
5.0	1.7.1
4.0	1.0.0
3.0	0.13.1

To learn more about the data lake frameworks that AWS Glue supports, see Using data lake frameworks with AWS Glue ETL jobs.

Enabling the Iceberg framework

To enable Iceberg for AWS Glue, complete the following tasks:

- Specify `iceberg` as a value for the `--datalake-formats` job parameter. For more information, see Using job parameters in AWS Glue jobs.

- Create a key named `--conf` for your AWS Glue job, and set it to the following value. Alternatively, you can set the following configuration using `SparkConf` in your script. These settings help Apache Spark correctly handle Iceberg tables.

```
spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions
--conf spark.sql.catalog.glue_catalog=org.apache.iceberg.spark.SparkCatalog
--conf spark.sql.catalog.glue_catalog.warehouse=s3://<your-warehouse-dir>/
--conf spark.sql.catalog.glue_catalog.catalog-
impl=org.apache.iceberg.aws.glue.GlueCatalog
--conf spark.sql.catalog.glue_catalog.io-impl=org.apache.iceberg.aws.s3.S3FileIO
```

  If you are reading or writing to Iceberg tables that are registered with Lake Formation, follow the guidance in the section called "Lake Formation for FGAC" in AWS Glue 5.0 and later. In AWS Glue 4.0, add the following configuration to enable Lake Formation support.

```
--conf spark.sql.catalog.glue_catalog.glue.lakeformation-enabled=true
--conf spark.sql.catalog.glue_catalog.glue.id=<table-catalog-id>
```

  If you use AWS Glue 3.0 with Iceberg 0.13.1, you must set the following additional configurations to use Amazon DynamoDB lock manager to ensure atomic transaction. AWS Glue 4.0 or later uses optimistic locking by default. For more information, see Iceberg AWS Integrations in the official Apache Iceberg documentation.

```
--conf spark.sql.catalog.glue_catalog.lock-
impl=org.apache.iceberg.aws.glue.DynamoLockManager
--conf spark.sql.catalog.glue_catalog.lock.table=<your-dynamodb-table-name>
```

Using a different Iceberg version

To use a version of Iceberg that AWS Glue doesn't support, specify your own Iceberg JAR files using the `--extra-jars` job parameter. Do not include `iceberg` as a value for the `--datalake-formats` parameter. If you use AWS Glue 5.0 or above, you must set `--user-jars-first true` job parameter.

Enabling encryption for Iceberg tables

> **Note**
>
> Iceberg tables have their own mechanisms to enable server-side encryption. You should enable this configuration in addition to AWS Glue's security configuration.

To enable server-side encryption on Iceberg tables, review the guidance from the Iceberg documentation.

Add Spark configuration for Iceberg cross region

To add additional spark configuration for Iceberg cross-region table access with the AWS Glue Data Catalog and AWS Lake Formation, follow the steps below:

1. Create a Multi-region access point.
2. Set the following Spark properties:

```
-----
    --conf spark.sql.catalog.my_catalog.s3.use-arn-region-enabled=true \
    --conf spark.sql.catalog.{CATALOG}.s3.access-points.bucket1",
 "arn:aws:s3::<account-id>:accesspoint/<mrap-id>.mrap \
    --conf spark.sql.catalog.{CATALOG}.s3.access-points.bucket2",
 "arn:aws:s3::<account-id>:accesspoint/<mrap-id>.mrap
-----
```

Example: Write an Iceberg table to Amazon S3 and register it to the AWS Glue Data Catalog

This example script demonstrates how to write an Iceberg table to Amazon S3. The example uses Iceberg AWS Integrations to register the table to the AWS Glue Data Catalog.

Python

```
# Example: Create an Iceberg table from a DataFrame
# and register the table to Glue Data Catalog

dataFrame.createOrReplaceTempView("tmp_<your_table_name>")

query = f"""
CREATE TABLE glue_catalog.<your_database_name>.<your_table_name>
USING iceberg
```

```
TBLPROPERTIES ("format-version"="2")
AS SELECT * FROM tmp_<your_table_name>
"""
spark.sql(query)
```

Scala

```
// Example: Example: Create an Iceberg table from a DataFrame
// and register the table to Glue Data Catalog

dataFrame.createOrReplaceTempView("tmp_<your_table_name>")

val query = """CREATE TABLE glue_catalog.<your_database_name>.<your_table_name>
USING iceberg
TBLPROPERTIES ("format-version"="2")
AS SELECT * FROM tmp_<your_table_name>
"""
spark.sql(query)
```

Alternatively, you can write an Iceberg table to Amazon S3 and the Data Catalog using Spark methods.

Prerequisites: You will need to provision a catalog for the Iceberg library to use. When using the AWS Glue Data Catalog, AWS Glue makes this straightforward. The AWS Glue Data Catalog is pre-configured for use by the Spark libraries as `glue_catalog`. Data Catalog tables are identified by a *`databaseName`* and a *`tableName`*. For more information about the AWS Glue Data Catalog, see *Data discovery and cataloging*.

If you are not using the AWS Glue Data Catalog, you will need to provision a catalog through the Spark APIs. For more information, see Spark Configuration in the Iceberg documentation.

This example writes an Iceberg table to Amazon S3 and the Data Catalog using Spark.

Python

```
# Example: Write an Iceberg table to S3 on the Glue Data Catalog

# Create (equivalent to CREATE TABLE AS SELECT)
dataFrame.writeTo("glue_catalog.databaseName.tableName") \
    .tableProperty("format-version", "2") \
    .create()
```

```
# Append (equivalent to INSERT INTO)
dataFrame.writeTo("glue_catalog.databaseName.tableName") \
    .tableProperty("format-version", "2") \
    .append()
```

Scala

```
// Example: Write an Iceberg table to S3 on the Glue Data Catalog

// Create (equivalent to CREATE TABLE AS SELECT)
dataFrame.writeTo("glue_catalog.databaseName.tableName")
    .tableProperty("format-version", "2")
    .create()

// Append (equivalent to INSERT INTO)
dataFrame.writeTo("glue_catalog.databaseName.tableName")
    .tableProperty("format-version", "2")
    .append()
```

Example: Read an Iceberg table from Amazon S3 using the AWS Glue Data Catalog

This example reads the Iceberg table that you created in Example: Write an Iceberg table to Amazon S3 and register it to the AWS Glue Data Catalog.

Python

For this example, use the `GlueContext.create_data_frame.from_catalog()` method.

```
# Example: Read an Iceberg table from Glue Data Catalog

from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

df = glueContext.create_data_frame.from_catalog(
    database="<your_database_name>",
    table_name="<your_table_name>",
    additional_options=additional_options
)
```

Scala

For this example, use the getCatalogSource method.

```
// Example: Read an Iceberg table from Glue Data Catalog

import com.amazonaws.services.glue.GlueContext
import org.apacke.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    val df = glueContext.getCatalogSource("<your_database_name>",
 "<your_table_name>",
      additionalOptions = additionalOptions)
      .getDataFrame()
  }
}
```

Example: Insert a `DataFrame` into an Iceberg table in Amazon S3 using the AWS Glue Data Catalog

This example inserts data into the Iceberg table that you created in Example: Write an Iceberg table to Amazon S3 and register it to the AWS Glue Data Catalog.

> **Note**
>
> This example requires you to set the `--enable-glue-datacatalog` job parameter in order to use the AWS Glue Data Catalog as an Apache Spark Hive metastore. To learn more, see Using job parameters in AWS Glue jobs.

Python

For this example, use the `GlueContext.write_data_frame.from_catalog()` method.

```
# Example: Insert into an Iceberg table from Glue Data Catalog

from awsglue.context import GlueContext
```

```
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

glueContext.write_data_frame.from_catalog(
    frame=dataFrame,
    database="<your_database_name>",
    table_name="<your_table_name>",
    additional_options=additional_options
)
```

Scala

For this example, use the getCatalogSink method.

```
// Example: Insert into an Iceberg table from Glue Data Catalog

import com.amazonaws.services.glue.GlueContext
import org.apacke.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    glueContext.getCatalogSink("<your_database_name>", "<your_table_name>",
      additionalOptions = additionalOptions)
      .writeDataFrame(dataFrame, glueContext)
  }
}
```

Example: Read an Iceberg table from Amazon S3 using Spark

Prerequisites: You will need to provision a catalog for the Iceberg library to use. When using the AWS Glue Data Catalog, AWS Glue makes this straightforward. The AWS Glue Data Catalog is pre-configured for use by the Spark libraries as `glue_catalog`. Data Catalog tables are identified by a *`databaseName`* and a *`tableName`*. For more information about the AWS Glue Data Catalog, see *Data discovery and cataloging*.

If you are not using the AWS Glue Data Catalog, you will need to provision a catalog through the Spark APIs. For more information, see Spark Configuration in the Iceberg documentation.

This example reads an Iceberg table in Amazon S3 from the Data Catalog using Spark.

Python

```
# Example: Read an Iceberg table on S3 as a DataFrame from the Glue Data Catalog

dataFrame = spark.read.format("iceberg").load("glue_catalog.databaseName.tableName")
```

Scala

```
// Example: Read an Iceberg table on S3 as a DataFrame from the Glue Data Catalog

val dataFrame =
 spark.read.format("iceberg").load("glue_catalog.databaseName.tableName")
```

Example: Read and write Iceberg table with Lake Formation permission control

This example reads and writes an Iceberg table with Lake Formation permission control.

> **Note**
>
> This example works only in AWS Glue 4.0. In AWS Glue 5.0 and later, follow the guidance in the section called "Lake Formation for FGAC".

1. Create an Iceberg table and register it in Lake Formation:
   a. To enable Lake Formation permission control, you'll first need to register the table Amazon S3 path on Lake Formation. For more information, see Registering an Amazon S3 location. You can register it either from the Lake Formation console or by using the AWS CLI:

      ```
      aws lakeformation register-resource --resource-arn arn:aws:s3:::<s3-bucket>/<s3-
      folder> --use-service-linked-role --region <REGION>
      ```

      Once you register an Amazon S3 location, any AWS Glue table pointing to the location (or any of its child locations) will return the value for the `IsRegisteredWithLakeFormation` parameter as true in the `GetTable` call.

   b. Create an Iceberg table that points to the registered path through Spark SQL:

> **Note**
>
> The following are Python examples.

```
dataFrame.createOrReplaceTempView("tmp_<your_table_name>")

query = f"""
CREATE TABLE glue_catalog.<your_database_name>.<your_table_name>
USING iceberg
AS SELECT * FROM tmp_<your_table_name>
"""
spark.sql(query)
```

You can also create the table manually through AWS Glue `CreateTable` API. For more information, see Creating Apache Iceberg tables.

> **Note**
>
> The `UpdateTable` API does not currently support Iceberg table format as an input to the operation.

2. Grant Lake Formation permission to the job IAM role. You can either grant permissions from the Lake Formation console, or using the AWS CLI. For more information, see: https://docs.aws.amazon.com/lake-formation/latest/dg/granting-table-permissions.html
3. Read an Iceberg table registered with Lake Formation. The code is same as reading a non-registered Iceberg table. Note that your AWS Glue job IAM role needs to have the SELECT permission for the read to succeed.

```
# Example: Read an Iceberg table from the AWS Glue Data Catalog
from awsglue.context import GlueContextfrom pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

df = glueContext.create_data_frame.from_catalog(
    database="<your_database_name>",
    table_name="<your_table_name>",
```

```
    additional_options=additional_options
)
```

4. Write to an Iceberg table registered with Lake Formation. The code is same as writing to a non-registered Iceberg table. Note that your AWS Glue job IAM role needs to have the SUPER permission for the write to succeed.

```
glueContext.write_data_frame.from_catalog(
    frame=dataFrame,
    database="<your_database_name>",
    table_name="<your_table_name>",
    additional_options=additional_options
)
```

Shared configuration reference

You can use the following `format_options` values with any format type.

- `attachFilename` — A string in the appropriate format to be used as a column name. If you provide this option, the name of the source file for the record will be appended to the record. The parameter value will be used as the column name.
- `attachTimestamp` — A string in the appropriate format to be used as a column name. If you provide this option, the modification time of the source file for the record will be appended to the record. The parameter value will be used as the column name.

AWS Glue Data Catalog support for Spark SQL jobs

The AWS Glue Data Catalog is an Apache Hive metastore-compatible catalog. You can configure your AWS Glue jobs and development endpoints to use the Data Catalog as an external Apache Hive metastore. You can then directly run Apache Spark SQL queries against the tables stored in the Data Catalog. AWS Glue dynamic frames integrate with the Data Catalog by default. However, with this feature, Spark SQL jobs can start using the Data Catalog as an external Hive metastore.

This feature requires network access to the AWS Glue API endpoint. For AWS Glue jobs with connections located in private subnets, you must configure either a VPC endpoint or NAT gateway to provide the network access. For information about configuring a VPC endpoint, see Setting up network access to data stores. To create a NAT gateway, see NAT Gateways in the *Amazon VPC User Guide*.

You can configure AWS Glue jobs and development endpoints by adding the `"--enable-glue-datacatalog": ""` argument to job arguments and development endpoint arguments respectively. Passing this argument sets certain configurations in Spark that enable it to access the Data Catalog as an external Hive metastore. It also enables Hive support in the `SparkSession` object created in the AWS Glue job or development endpoint.

To enable the Data Catalog access, check the **Use AWS Glue Data Catalog as the Hive metastore** check box in the **Catalog options** group on the **Add job** or **Add endpoint** page on the console. Note that the IAM role used for the job or development endpoint should have `glue:CreateDatabase` permissions. A database called "`default`" is created in the Data Catalog if it does not exist.

Lets look at an example of how you can use this feature in your Spark SQL jobs. The following example assumes that you have crawled the US legislators dataset available at `s3://awsglue-datasets/examples/us-legislators`.

To serialize/deserialize data from the tables defined in the AWS Glue Data Catalog, Spark SQL needs the Hive SerDe class for the format defined in the AWS Glue Data Catalog in the classpath of the spark job.

SerDes for certain common formats are distributed by AWS Glue. The following are the Amazon S3 links for these:

- JSON
- XML
- Grok

Add the JSON SerDe as an extra JAR to the development endpoint. For jobs, you can add the SerDe using the `--extra-jars` argument in the arguments field. For more information, see Using job parameters in AWS Glue jobs.

Here is an example input JSON to create a development endpoint with the Data Catalog enabled for Spark SQL.

```
{
    "EndpointName": "Name",
    "RoleArn": "role_ARN",
    "PublicKey": "public_key_contents",
```

```
    "NumberOfNodes": 2,
    "Arguments": {
      "--enable-glue-datacatalog": ""
    },
    "ExtraJarsS3Path": "s3://crawler-public/json/serde/json-serde.jar"
}
```

Now query the tables created from the US legislators dataset using Spark SQL.

```
>>> spark.sql("use legislators")
DataFrame[]
>>> spark.sql("show tables").show()
+-----------+-----------------+-----------+
|   database|        tableName|isTemporary|
+-----------+-----------------+-----------+
|legislators|       areas_json|      false|
|legislators|   countries_json|      false|
|legislators|      events_json|      false|
|legislators| memberships_json|      false|
|legislators|organizations_json|      false|
|legislators|     persons_json|      false|
+-----------+-----------------+-----------+
>>> spark.sql("describe memberships_json").show()
+--------------------+---------+-----------------+
|            col_name|data_type|          comment|
+--------------------+---------+-----------------+
|             area_id|   string|from deserializer|
|     on_behalf_of_id|   string|from deserializer|
|     organization_id|   string|from deserializer|
|                role|   string|from deserializer|
|           person_id|   string|from deserializer|
|legislative_perio...|   string|from deserializer|
|          start_date|   string|from deserializer|
|            end_date|   string|from deserializer|
+--------------------+---------+-----------------+
```

If the SerDe class for the format is not available in the job's classpath, you will see an error similar to the following.

```
>>> spark.sql("describe memberships_json").show()
```

```
Caused by: MetaException(message:java.lang.ClassNotFoundException Class
 org.openx.data.jsonserde.JsonSerDe not found)
    at
 org.apache.hadoop.hive.metastore.MetaStoreUtils.getDeserializer(MetaStoreUtils.java:399)
    at
 org.apache.hadoop.hive.ql.metadata.Table.getDeserializerFromMetaStore(Table.java:276)
    ... 64 more
```

To view only the distinct `organization_ids` from the `memberships` table, run the following SQL query.

```
>>> spark.sql("select distinct organization_id from memberships_json").show()
+--------------------+
|     organization_id|
+--------------------+
|d56acebe-8fdc-47b...|
|8fa6c3d2-71dc-478...|
+--------------------+
```

If you need to do the same with dynamic frames, run the following.

```
>>> memberships = glueContext.create_dynamic_frame.from_catalog(database="legislators",
 table_name="memberships_json")
>>> memberships.toDF().createOrReplaceTempView("memberships")
>>> spark.sql("select distinct organization_id from memberships").show()
+--------------------+
|     organization_id|
+--------------------+
|d56acebe-8fdc-47b...|
|8fa6c3d2-71dc-478...|
+--------------------+
```

While DynamicFrames are optimized for ETL operations, enabling Spark SQL to access the Data Catalog directly provides a concise way to run complex SQL statements or port existing applications.

Using job bookmarks

AWS Glue for Spark uses job bookmarks to track data that has already been processed. For a summary of the job bookmarks feature and what it supports, see the section called “Tracking

processed data using job bookmarks". When programming a AWS Glue job with bookmarks, you have access to flexibility unavailable in visual jobs.

- When reading from JDBC, you can specify the column(s) to use as bookmark keys in your AWS Glue script.
- You can chose which `transformation_ctx` to apply to each method call.

Always call `job.init` in the beginning of the script and the `job.commit` in the end of the script with appropriately configured parameters. These two functions initialize the bookmark service and update the state change to the service. Bookmarks won't work without calling them.

Specify bookmark keys

For JDBC workflows, the bookmark keeps track of which rows your job has read by comparing the values of key fields to a bookmarked value. This is not necessary or applicable for Amazon S3 workflows. When writing a AWS Glue script without the visual editor, you can specify which column to track with bookmarks. You can also specify multiple columns. Gaps in the sequence of values are permitted when specifying user-defined bookmark keys.

> **Warning**
>
> If user-defined bookmarks keys are used, they must each be strictly monotonically increasing or decreasing. When selecting additional fields for a compound key, fields for concepts like "minor versions" or "revision numbers" do not meet this criteria, since their values are reused throughout your dataset.

You can specify `jobBookmarkKeys` and `jobBookmarkKeysSortOrder` in the following ways:

- `create_dynamic_frame.from_catalog` — Use `additional_options`.
- `create_dynamic_frame.from_options` — Use `connection_options`.

Transformation context

Many of the AWS Glue PySpark dynamic frame methods include an optional parameter named `transformation_ctx`, which is a unique identifier for the ETL operator instance. The `transformation_ctx` parameter is used to identify state information within a job bookmark

for the given operator. Specifically, AWS Glue uses `transformation_ctx` to index the key to the bookmark state.

> **Warning**
>
> The `transformation_ctx` serves as the key to search the bookmark state for a specific source in your script. For the bookmark to work properly, you should always keep the source and the associated `transformation_ctx` consistent. Changing the source property or renaming the `transformation_ctx` may make the previous bookmark invalid and the time stamp based filtering may not yield the correct result.

For job bookmarks to work properly, enable the job bookmark parameter and set the `transformation_ctx` parameter. If you don't pass in the `transformation_ctx` parameter, then job bookmarks are not enabled for a dynamic frame or a table used in the method. For example, if you have an ETL job that reads and joins two Amazon S3 sources, you might choose to pass the `transformation_ctx` parameter only to those methods that you want to enable bookmarks. If you reset the job bookmark for a job, it resets all transformations that are associated with the job regardless of the `transformation_ctx` used.

For more information about the `DynamicFrameReader` class, see DynamicFrameReader class. For more information about PySpark extensions, see AWS Glue PySpark extensions reference.

Examples

Example

The following is an example of a generated script for an Amazon S3 data source. The portions of the script that are required for using job bookmarks are shown in italics. For more information about these elements see the GlueContext class API, and the DynamicFrameWriter class API.

```
# Sample Script
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job

args = getResolvedOptions(sys.argv, ['JOB_NAME'])
sc = SparkContext()
```

```
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
job.init(args['JOB_NAME'], args)

datasource0 = glueContext.create_dynamic_frame.from_catalog(
    database = "database",
    table_name = "relatedqueries_csv",
    transformation_ctx = "datasource0"
)

applymapping1 = ApplyMapping.apply(
    frame = datasource0,
    mappings = [("col0", "string", "name", "string"), ("col1", "string", "number",
 "string")],
    transformation_ctx = "applymapping1"
)

datasink2 = glueContext.write_dynamic_frame.from_options(
    frame = applymapping1,
    connection_type = "s3",
    connection_options = {"path": "s3://input_path"},
    format = "json",
    transformation_ctx = "datasink2"
)

job.commit()
```

Example

The following is an example of a generated script for a JDBC source. The source table is an employee table with the empno column as the primary key. Although by default the job uses a sequential primary key as the bookmark key if no bookmark key is specified, because empno is not necessarily sequential—there could be gaps in the values—it does not qualify as a default bookmark key. Therefore, the script explicitly designates empno as the bookmark key. That portion of the code is shown in italics.

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
```

```
from awsglue.job import Job

args = getResolvedOptions(sys.argv, ['JOB_NAME'])

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
job.init(args['JOB_NAME'], args)

datasource0 = glueContext.create_dynamic_frame.from_catalog(
    database = "hr",
    table_name = "emp",
    transformation_ctx = "datasource0",
    additional_options = {"jobBookmarkKeys":["empno"],"jobBookmarkKeysSortOrder":"asc"}
)

applymapping1 = ApplyMapping.apply(
    frame = datasource0,
    mappings = [("ename", "string", "ename", "string"), ("hrly_rate", "decimal(38,0)",
 "hrly_rate", "decimal(38,0)"), ("comm", "decimal(7,2)", "comm", "decimal(7,2)"),
 ("hiredate", "timestamp", "hiredate", "timestamp"), ("empno", "decimal(5,0)", "empno",
 "decimal(5,0)"), ("mgr", "decimal(5,0)", "mgr", "decimal(5,0)"), ("photo", "string",
 "photo", "string"), ("job", "string", "job", "string"), ("deptno", "decimal(3,0)",
 "deptno", "decimal(3,0)"), ("ssn", "decimal(9,0)", "ssn", "decimal(9,0)"), ("sal",
 "decimal(7,2)", "sal", "decimal(7,2)")],
    transformation_ctx = "applymapping1"
)

datasink2 = glueContext.write_dynamic_frame.from_options(
    frame = applymapping1,
    connection_type = "s3",
    connection_options = {"path": "s3://hr/employees"},
    format = "csv",
    transformation_ctx = "datasink2"
)

job.commit()
```

Using Sensitive Data Detection outside AWS Glue Studio

AWS Glue Studio allows you to detect sensitive data, however, you can also use the Sensitive Data Detection functionality outside of AWS Glue Studio.

For a full list of managed sensitive data types, see Managed data types.

Detecting Sensitive Data Detection using AWS Managed PII types

AWS Glue provides two APIs in a AWS Glue ETL job. These are `detect()` and `classifyColumns()`:

```
 detect(frame: DynamicFrame,
     entityTypesToDetect: Seq[String],
     outputColumnName: String = "DetectedEntities",
     detectionSensitivity: String = "LOW"): DynamicFrame

detect(frame: DynamicFrame,
     detectionParameters: JsonOptions,
     outputColumnName: String = "DetectedEntities",
     detectionSensitivity: String = "LOW"): DynamicFrame

 classifyColumns(frame: DynamicFrame,
     entityTypesToDetect: Seq[String],
     sampleFraction: Double = 0.1,
     thresholdFraction: Double = 0.1,
     detectionSensitivity: String = "LOW")
```

You can use the `detect()` API to identify AWS Managed PII types and custom entity types. A new column is automatically created with the detection result. The `classifyColumns()` API returns a map where keys are column names and values are list of detected entity types. `SampleFraction` indicates the fraction of the data to sample when scanning for PII entities whereas `ThresholdFraction` indicates the fraction of the data that must be met in order for a column to be identified as PII data.

Row-level detection

In the example, the job is performing the following actions using the `detect()` and `classifyColumns()` APIs:

- reading data from an Amazon S3 bucket and turns it into a dynamicFrame
- detecting instances of "Email" and "Credit Card" in the dynamicFrame
- returning a dynamicFrame with original values plus one column which encompasses detection result for each row

- writing the returned dynamicFrame in another Amazon S3 path

```
 import com.amazonaws.services.glue.GlueContext
 import com.amazonaws.services.glue.MappingSpec
 import com.amazonaws.services.glue.errors.CallSite
 import com.amazonaws.services.glue.util.GlueArgParser
 import com.amazonaws.services.glue.util.Job
 import com.amazonaws.services.glue.util.JsonOptions
 import org.apache.spark.SparkContext
 import scala.collection.JavaConverters._
 import com.amazonaws.services.glue.ml.EntityDetector

 object GlueApp {
   def main(sysArgs: Array[String]) {
     val spark: SparkContext = new SparkContext()
     val glueContext: GlueContext = new GlueContext(spark)
     val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
     Job.init(args("JOB_NAME"), glueContext, args.asJava)
     val frame=
glueContext.getSourceWithFormat(formatOptions=JsonOptions("""{"quoteChar": "\"",
"withHeader": true, "separator": ","}"""), connectionType="s3", format="csv",
options=JsonOptions("""{"paths": ["s3://pathToSource"], "recurse": true}"""),
transformationContext="AmazonS3_node1650160158526").getDynamicFrame()

     val frameWithDetectedPII = EntityDetector.detect(frame, Seq("EMAIL",
"CREDIT_CARD"))

     glueContext.getSinkWithFormat(connectionType="s3",
options=JsonOptions("""{"path": "s3://pathToOutput/", "partitionKeys": []}"""),
transformationContext="someCtx",
format="json").writeDynamicFrame(frameWithDetectedPII)

     Job.commit()
   }
 }
```

Row-level detection with fine-grained actions

In the example, the job is performing the following actions using the `detect()` APIs:

- reading data from an Amazon S3 bucket and turns it into a dynamicFrame
- detecting sensitive data types for “USA_PTIN”, “ BANK_ACCOUNT”, “USA_SSN”, “USA_PASSPORT_NUMBER” , and “PHONE_NUMBER” in the dynamicFrame
- returning a dynamicFrame with modified masked values plus one column which encompasses detection result for each row
- writing the returned dynamicFrame in another Amazon S3 path

In contrast with the above `detect()` API, this uses fine-grained actions for entity types to detect. For more information, see Detection parameters for using `detect()`.

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.MappingSpec
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._
import com.amazonaws.services.glue.ml.EntityDetector

object GlueApp {
  def main(sysArgs: Array[String]) {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)
    val frame =
 glueContext.getSourceWithFormat(formatOptions=JsonOptions("""{"quoteChar": "\"",
 "withHeader": true, "separator": ","}"""), connectionType="s3", format="csv",
 options=JsonOptions("""{"paths": ["s3://pathToSource"], "recurse": true}"""),
 transformationContext="AmazonS3_node_source").getDynamicFrame()

    val detectionParameters = JsonOptions(
      """
        {
          "USA_DRIVING_LICENSE": [{
            "action": "PARTIAL_REDACT",
            "sourceColumns": ["Driving License"],
            "actionOptions": {
              "matchPattern": "[0-9]",
              "redactChar": "*"
```

```
            }
          }],
          "BANK_ACCOUNT": [{
            "action": "DETECT",
            "sourceColumns": ["*"]
          }],
          "USA_SSN": [{
            "action": "SHA256_HASH",
            "sourceColumns": ["SSN"]
          }],
          "IP_ADDRESS": [{
            "action": "REDACT",
            "sourceColumns": ["IP Address"],
            "actionOptions": {"redactText": "*****"}
          }],
          "PHONE_NUMBER": [{
            "action": "PARTIAL_REDACT",
            "sourceColumns": ["Phone Number"],
            "actionOptions": {
              "numLeftCharsToExclude": 1,
              "numRightCharsToExclude": 0,
              "redactChar": "*"
            }
          }]
        }
      """
    )

    val frameWithDetectedPII = EntityDetector.detect(frame, detectionParameters,
 "DetectedEntities", "HIGH")

    glueContext.getSinkWithFormat(connectionType="s3", options=JsonOptions("""{"path":
 "s3://pathToOutput/", "partitionKeys": []}"""),
 transformationContext="AmazonS3_node_target",
 format="json").writeDynamicFrame(frameWithDetectedPII)

    Job.commit()
  }
}
```

Column-level detection

In the example, the job is performing the following actions using the `classifyColumns()`APIs:

- reading data from an Amazon S3 bucket and turns it into a dynamicFrame
- detecting instances of "Email" and "Credit Card" in the dynamicFrame
- set parameters to sample 100% of the column, mark an entity as detected if it is in 10% of cells, and have “LOW” sensitivity
- returns a map where keys are column names and values are list of detected entity types
- writing the returned dynamicFrame in another Amazon S3 path

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.MappingSpec
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._
import com.amazonaws.services.glue.DynamicFrame
import com.amazonaws.services.glue.ml.EntityDetector

object GlueApp {
  def main(sysArgs: Array[String]) {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)
    val frame =
 glueContext.getSourceWithFormat(formatOptions=JsonOptions("""{"quoteChar":
 "\"", "withHeader": true, "separator": ",", "optimizePerformance": false}"""),
 connectionType="s3", format="csv", options=JsonOptions("""{"paths": ["s3://
pathToSource"], "recurse": true}"""), transformationContext="frame").getDynamicFrame()

    import glueContext.sparkSession.implicits._

    val detectedDataFrame = EntityDetector.classifyColumns(
        frame,
        entityTypesToDetect = Seq("CREDIT_CARD", "PHONE_NUMBER"),
        sampleFraction = 1.0,
        thresholdFraction = 0.1,
```

```
        detectionSensitivity = "LOW"
    )
    val detectedDF = (detectedDataFrame).toSeq.toDF("columnName", "entityTypes")
    val DetectSensitiveData_node = DynamicFrame(detectedDF, glueContext)

    glueContext.getSinkWithFormat(connectionType="s3", options=JsonOptions("""{"path":
 "s3://pathToOutput", "partitionKeys": []}"""), transformationContext="someCtx",
 format="json").writeDynamicFrame(DetectSensitiveData_node)

    Job.commit()
  }
}
```

Detecting Sensitive Data Detection using AWS CustomEntityType PII types

You can define custom entities through AWS Studio. However, to use this feature out of AWS Studio, you have to first define the custom entity types and then add the defined custom entity types to the list of `entityTypesToDetect`.

If you have specific sensitive data types in your data (such as 'Employee Id'), you can create custom entities by calling the `CreateCustomEntityType()` API. The following example defines the custom entity type 'EMPLOYEE_ID' to the `CreateCustomEntityType()` API with the request parameters:

```
{
    "name": "EMPLOYEE_ID",
    "regexString": "\d{4}-\d{3}",
    "contextWords": ["employee"]
}
```

Then, modify the job to use the new custom sensitive data type by adding the custom entity type (EMPLOYEE_ID) to the `EntityDetector()` API:

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.MappingSpec
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.util.GlueArgParser
```

```
 import com.amazonaws.services.glue.util.Job
 import com.amazonaws.services.glue.util.JsonOptions
 import org.apache.spark.SparkContext
 import scala.collection.JavaConverters._
 import com.amazonaws.services.glue.ml.EntityDetector

 object GlueApp {
   def main(sysArgs: Array[String]) {
     val spark: SparkContext = new SparkContext()
     val glueContext: GlueContext = new GlueContext(spark)
     val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
     Job.init(args("JOB_NAME"), glueContext, args.asJava)
     val frame=
glueContext.getSourceWithFormat(formatOptions=JsonOptions("""{"quoteChar": "\"",
"withHeader": true, "separator": ","}"""), connectionType="s3", format="csv",
options=JsonOptions("""{"paths": ["s3://pathToSource"], "recurse": true}"""),
transformationContext="AmazonS3_node1650160158526").getDynamicFrame()

     val frameWithDetectedPII = EntityDetector.detect(frame, Seq("EMAIL",
"CREDIT_CARD", "EMPLOYEE_ID"))

     glueContext.getSinkWithFormat(connectionType="s3",
options=JsonOptions("""{"path": "s3://pathToOutput/", "partitionKeys": []}"""),
transformationContext="someCtx",
format="json").writeDynamicFrame(frameWithDetectedPII)

     Job.commit()
   }
 }
```

Note

If a custom sensitive data type is defined with the same name as an existing managed entity type, then the custom sensitive data type will take precedent and overwrite the managed entity type's logic.

Detection parameters for using `detect()`

This method is used for detecting entities in a DynamicFrame. It returns a new DataFrame with original values and an additional column outputColumnName that has PII detection metadata.

Custom masking can be done after this DynamicFrame is returned within the AWS Glue script, or the detect() with fine-grained actions API can be used instead.

```
detect(frame: DynamicFrame,
       entityTypesToDetect: Seq[String],
       outputColumnName: String = "DetectedEntities",
       detectionSensitivity: String = "LOW"): DynamicFrame
```

Parameters:

- **frame** – (type: `DynamicFrame`) The input DynamicFrame containing the data to be processed.
- **entityTypesToDetect** – (type: `[Seq[String]`) List of entity types to detect. Can be either Managed Entity Types or Custom Entity Types.
- **outputColumnName** – (type: `String`, default: "DetectedEntities") The name of the column where detected entities will be stored. If not provided, the default column name is "DetectedEntities".
- **detectionSensitivity** – (type: `String`, options: "LOW" or "HIGH", default: "LOW") Specifies the sensitivity of the detection process. Valid options are "LOW" or "HIGH". If not provided, the default sensitivity is set to "LOW".

`outputColumnName` settings:

The name of the column where detected entities will be stored. If not provided, the default column name is "DetectedEntities". For each row in the output column, the supplementary column includes a map of the column name to the detected entity metadata with the following key-value pairs:

- **entityType** – The detected entity type.
- **start** – The starting position of the detected entity in the original data.
- **end** – The ending position of the detected entity in the original data.
- **actionUsed** – The action performed on the detected entity (e.g., "DETECT," "REDACT," "PARTIAL_REDACT," "SHA256_HASH").

Example:

```
{
```

```
   "DetectedEntities":{
      "SSN Col":[
         {
            "entityType":"USA_SSN",
            "actionUsed":"DETECT",
            "start":4,
            "end":15
         }
      ],
      "Random Data col":[
         {
            "entityType":"BANK_ACCOUNT",
            "actionUsed":"PARTIAL_REDACT",
            "start":4,
            "end":13
         },
         {
            "entityType":"IP_ADDRESS",
            "actionUsed":"REDACT",
            "start":4,
            "end":13
         }
      ]
   }
}
```

Detection Parameters for `detect()` with fine grained actions

This method is used for detecting entities in a DynamicFrame using specified parameters. It returns a new DataFrame with original values replaced with masked sensitive data and an additional column `outputColumnName` that has PII detection metadata.

```
detect(frame: DynamicFrame,
       detectionParameters: JsonOptions,
       outputColumnName: String = "DetectedEntities",
       detectionSensitivity: String = "LOW"): DynamicFrame
```

Parameters:

- **frame** – (type: `DynamicFrame`): The input DynamicFrame containing the data to be processed.

- **detectionParameters** – (type: `Json0ptions`): JSON options specifying parameters for the detection process.
- **outputColumnName** – (type: `String`, default: "DetectedEntities"): The name of the column where detected entities will be stored. If not provided, the default column name is "DetectedEntities".
- **detectionSensitivity** – (type: `String`, options: "LOW" or "HIGH", default: "LOW"): Specifies the sensitivity of the detection process. Valid options are "LOW" or "HIGH". If not provided, the default sensitivity is set to "LOW".

`detectionParameters` settings

If no settings are included, default values will be used.

- **action** – (type: `String`, options: "DETECT", "REDACT", "PARTIAL_REDACT", "SHA256_HASH") Specifies the action to be performed on the entity. Required. Note that actions that perform masking (all but "DETECT") can only perform one action per column. This is a preventative measure for masking coalesced entities.
- **sourceColumns** – (type: `List[String]`, default: [“*”]) List of source column names to perform detection on for the entity. Defaults to [“*”] if not present. Raises `IllegalArgumentException` if an invalid column name is used.
- **sourceColumnsToExclude** – (type: `List[String]`) List of source column names to to perform detection on for the entity. Use either `sourceColumns` or `sourceColumnsToExclude`. Raises `IllegalArgumentException` if an invalid column name is used.
- **actionOptions** – Additional options based on the specified action:
  - For "DETECT" and "SHA256_HASH", no options are allowed.
  - For "REDACT":
    - **redactText** – (type: `String`, default: "*****") Text to replace the detected entity.
  - For "PARTIAL_REDACT":
    - **redactChar** – (type: `String`, default: "*") Character to replace each detected character in the entity.
    - **matchPattern** – (type: `String`) Regex pattern for partial redaction. Cannot be combined with numLeftCharsToExclude or `numRightCharsToExclude`.
    - **numLeftCharsToExclude** – (type: `String, integer`) Number of left characters to exclude. Cannot be combined with matchPattern, but can be used with `numRightCharsToExclude`.

- **numRightCharsToExclude** – (type: `String, integer`) Number of right characters to exclude. Cannot be combined with matchPattern, but can be used with `numRightCharsToExclude`.

`outputColumnName` settings

See outputColumnName settings

Detection Parameters for `classifyColumns()`

This method is used for detecting entities in a DynamicFrame. It returns a map where keys are column names and values are list of detected entity types. Custom masking can be done after this is returned within the AWS Glue script.

```
classifyColumns(frame: DynamicFrame,
                entityTypesToDetect: Seq[String],
                sampleFraction: Double = 0.1,
                thresholdFraction: Double = 0.1,
                detectionSensitivity: String = "LOW")
```

Parameters:

- **frame** – (type: `DynamicFrame`) The input DynamicFrame containing the data to be processed.
- **entityTypesToDetect** – (type: `Seq[String]`) List of entity types to detect. Can be either Managed Entity Types or Custom Entity Types.
- **sampleFraction** – (type: `Double`, default: 10%) The fraction of the data to sample when scanning for PII entities.
- **thresholdFraction** – (type: `Double`, default: 10%): The fraction of the data that must be met in order for a column to be identified as PII data.
- **detectionSensitivity** – (type: `String`, options: "LOW" or "HIGH", default: "LOW") Specifies the sensitivity of the detection process. Valid options are "LOW" or "HIGH". If not provided, the default sensitivity is set to "LOW".

Managed Sensitive Data Types

Global entities

Data Type	Category	Description
PERSON_NAME	Universal	The name of the person.
EMAIL	Personal	The email address.
IP_ADDRESS	Computer	The IP address
MAC_ADDRESS	Personal	The MAC address.

US data types

Data Type	Description
BANK_ACCOUNT	The bank account number. Not specific to a country or region, however, only US and Canadian account formats are detected.
CREDIT_CARD	The credit card number.
PHONE_NUMBER	The phone number. Not specific to a country or region, however, only US and Canadian phone numbers are detected at this time.
USA_ATIN	The US Adoption Taxpayer Identification Number issued by the Internal Revenue Service.
USA_CPT_CODE	The CPT Code (US specific).
USA_DEA_NUMBER	The DEA number (US specific).
USA_DRIVING_LICENSE	The driver license number (US specific).
USA_HCPCS_CODE	The HCPCS code (US specific).
USA_HEALTH_INSURANCE_CLAIM_NUMBER	Health Insurance Claim Number (US specific).

Data Type	Description
USA_ITIN	The ITIN (for US persons or entities).
USA_MEDICARE_BENEFICIARY_IDENTIFIER	Medicare Beneficiary Identifier (US specific).
USA_NATIONAL_DRUG_CODE	The NDC code (US specific).
USA_NATIONAL_PROVIDER_IDENTIFIER	The National Provider Identifier number (US specific).
USA_PASSPORT_NUMBER	The passport number (for US persons).
USA_PTIN	The US Preparer Tax Identification Number issued by the Internal Revenue Service.
USA_SSN	The social security number (for US persons).

Argentina data types

Data Type	Description
ARGENTINA_TAX_IDENTIFICATION_NUMBER	Argentina Tax Identification Number. Also known as CUIT or CUIL.

Australian data types

Data Type	Description
AUSTRALIA_BUSINESS_NUMBER	Australia Business Number (ABN). A unique identifier issued by the Australian Business Register (ABR) to identify businesses to the government and community.
AUSTRALIA_COMPANY_NUMBER	Australia Company Number (ACN). Unique identifier issued by the Australian Securities and Investments Commission.

Data Type	Description
AUSTRALIA_DRIVING_LICENSE	A driver's license number for Australia.
AUSTRALIA_MEDICARE_NUMBER	Australian Medicare Number. Personal identifier issued by the Australian Health Insurance Commission.
AUSTRALIA_PASSPORT_NUMBER	Australian passport number.
AUSTRALIA_TAX_FILE_NUMBER	Australia Tax File Number (TFN). Issued by the Australian Taxation Office (ATO) to taxpayers (individual, company, etc) for tax dealings.

Austria data types

Data Type	Description
AUSTRIA_DRIVING_LICENSE	The driver license number (Austria specific).
AUSTRIA_PASSPORT_NUMBER	The passport number (Austria specific).
AUSTRIA_SSN	The social security number (for Austria persons).
AUSTRIA_TAX_IDENTIFICATION_NUMBER	Tax identification number (Austria specific).
AUSTRIA_VALUE_ADDED_TAX	Value-Added Tax (Austria specific).

Balkans data types

Data Type	Description
BOSNIA_UNIQUE_MASTER_CITIZEN_NUMBER	Unique master citizen number (JMBG) for Bosnia-Herzegovina citizens.

Data Type	Description
KOSOVO_UNIQUE_MASTER_CITIZEN_NUMBER	Unique master citizen number (JMBG) for Kosovo.
MACEDONIA_UNIQUE_MASTER_CIT IZEN_NUMBER	Unique master citizen number for Macedonia.
MONTENEGRO_UNIQUE_MASTER_CI TIZEN_NUMBER	Unique master citizen number (JMBG) for Montenegro.
SERBIA_UNIQUE_MASTER_CITIZEN_NUMBER	Unique master citizen number (JMBG) for Serbia.
SERBIA_VALUE_ADDED_TAX	Value-Added Tax (Serbia specific).
VOJVODINA_UNIQUE_MASTER_CIT IZEN_NUMBER	Unique master citizen number (JMBG) for Vojvodina.

Belgium data types

Data Type	Description
BELGIUM_DRIVING_LICENSE	The driver license number (Belgium specific).
BELGIUM_NATIONAL_IDENTIFICATION_NUMB ER	The Belgian National Number (BNN).
BELGIUM_PASSPORT_NUMBER	The passport number (Belgium specific).
BELGIUM_TAX_IDENTIFICATION_NUMBER	Tax identification number (Belgium specific).
BELGIUM_VALUE_ADDED_TAX	Value-Added Tax (Belgium specific).

Brazil data types

Data Type	Description
BRAZIL_BANK_ACCOUNT	The bank account number (Brazil specific).
BRAZIL_NATIONAL_IDENTIFICATION_NUMBER	The national identifier (Brazil specific).
BRAZIL_NATIONAL_REGISTRY_OF_LEGAL_ENTITIES_NUMBER	The identification number issued to companies (Brazil specific), also known as the CNPJ.
BRAZIL_NATURAL_PERSON_REGISTRY_NUMBER	Natural Person Registry Number, also known as CPF.

Bulgaria data types

Data Type	Description
BULGARIA_DRIVING_LICENSE	The driver license number (Bulgaria specific).
BULGARIA_UNIFORM_CIVIL_NUMBER	Unified Civil Number (EGN) that serves as a national identification number.
BULGARIA_VALUE_ADDED_TAX	Value-Added Tax (Bulgaria specific).

Canada data types

Data Type	Description
CANADA_DRIVING_LICENSE	The driver license number (Canada specific).
CANADA_GOVERNMENT_IDENTIFICATION_CARD_NUMBER	The national identifier (Canada specific).
CANADA_PASSPORT_NUMBER	The passport number (Canada specific).
CANADA_PERMANENT_RESIDENCE_NUMBER	Permanent residence number (PR Card number).

Data Type	Description
CANADA_PERSONAL_HEALTH_NUMBER	The unique identifier for healthcare (PHN number).
CANADA_SOCIAL_INSURANCE_NUMBER	The social insurance number (SIN) in Canada.

Chile data types

Data Type	Description
CHILE_DRIVING_LICENSE	The driver license number (Chile specific).
CHILE_NATIONAL_IDENTIFICATION_NUMBER	The Chile national identifier, also known as RUT or RUN.

China, Hong Kong, Macau, and Taiwan data types

Data Type	Description
CHINA_IDENTIFICATION	The China identifier.
CHINA_LICENSE_PLATE_NUMBER	The driver license number (China specific).
CHINA_MAINLAND_TRAVEL_PERMIT_ID_HONG_KONG_MACAU	The Mainland Travel Permit for Hong Kong and Macao Residents.
CHINA_MAINLAND_TRAVEL_PERMIT_ID_TAIWAN	The Mainland Travel Permit for Taiwan Residents issued by Government of the People's Republic of China (PRC).
CHINA_PASSPORT_NUMBER	The passport number (China specific).
CHINA_PHONE_NUMBER	The phone number (China specific).
HONG_KONG_IDENTITY_CARD	The official identity document issued by the Immigration Department of Hong Kong.

Data Type	Description
MACAU_RESIDENT_IDENTITY_CARD	The Macau Resident Identity Card or BIR is an official identity card issued by the Identific ation Services Bureau of Macau.
TAIWAN_NATIONAL_IDENTIFICATION_NUMBE R	The national identifier (Taiwan specific).
TAIWAN_PASSPORT_NUMBER	The passport number (Taiwan specific).

Colombia data types

Data Type	Description
COLOMBIA_PERSONAL_IDENTIFICATION_NUM BER	Unique identifier assigned to Colombians at birth.
COLOMBIA_TAX_IDENTIFICATION_NUMBER	Tax identification number (Colombia specific).

Croatia data types

Data Type	Description
CROATIA_DRIVING_LICENSE	The driver license number (Croatia specific).
CROATIA_IDENTITY_NUMBER	The national identifier (Croatia specific).
CROATIA_PASSPORT_NUMBER	The passport number (Croatia specific).
CROATIA_PERSONAL_IDENTIFICATION_NUMB ER	The personal identifier number (OIB).

Cyprus data types

Data Type	Description
CYPRUS_DRIVING_LICENSE	The driver license number (Cyprus specific).
CYPRUS_NATIONAL_IDENTIFICATION_NUMBER	The Cypriot identity card.
CYPRUS_PASSPORT_NUMBER	The passport number (Cyprus specific).
CYPRUS_TAX_IDENTIFICATION_NUMBER	Tax identification number (Cyprus specific).
CYPRUS_VALUE_ADDED_TAX	Value-Added Tax (Cyprus specific).

Czechia data types

Data Type	Description
CZECHIA_DRIVING_LICENSE	The driver license number (Czechia specific).
CZECHIA_PERSONAL_IDENTIFICATION_NUMBER	The personal identifier number (Czechia specific).
CZECHIA_VALUE_ADDED_TAX	Value-Added Tax (Czechia specific).

Denmark data types

Data Type	Description
DENMARK_DRIVING_LICENSE	The driver license number (Denmark specific).
DENMARK_PERSONAL_IDENTIFICATION_NUMBER	The personal identifier number (Denmark specific).
DENMARK_TAX_IDENTIFICATION_NUMBER	Tax identification number (Denmark specific).
DENMARK_VALUE_ADDED_TAX	Value-Added Tax (Denmark specific).

Estonia data types

Data Type	Description
ESTONIA_DRIVING_LICENSE	The driver license number (Estonia specific).
ESTONIA_PASSPORT_NUMBER	The passport number (Estonia specific).
ESTONIA_PERSONAL_IDENTIFICATION_CODE	The personal identifier number (Estonia specific).
ESTONIA_VALUE_ADDED_TAX	Value-Added Tax (Estonia specific).

Finland data types

Data Type	Description
FINLAND_DRIVING_LICENSE	The driver license number (Finland specific).
FINLAND_HEALTH_INSURANCE_NUMBER	The health insurance number (Finland specific) .
FINLAND_NATIONAL_IDENTIFICATION_NUMBER	The national identifier number (Finland specific).
FINLAND_PASSPORT_NUMBER	The passport number (Finland specific).
FINLAND_VALUE_ADDED_TAX	Value-Added Tax (Finland specific).

France data types

Data Type	Description
FRANCE_BANK_ACCOUNT	The bank account number (France specific).
FRANCE_DRIVING_LICENSE	The driver license number (France specific).
FRANCE_HEALTH_INSURANCE_NUMBER	France health insurance number.

Data Type	Description
FRANCE_INSEE_CODE	France social security, SSN, or NIR number.
FRANCE_NATIONAL_IDENTIFICATION_NUMBER	France national identifier number (CNI).
FRANCE_PASSPORT_NUMBER	The passport number (France specific).
FRANCE_TAX_IDENTIFICATION_NUMBER	Tax identification number (France specific).
FRANCE_VALUE_ADDED_TAX	Value-Added Tax (France specific).

Germany data types

Data Type	Description
GERMANY_BANK_ACCOUNT	The bank account number (Germany specific).
GERMANY_DRIVING_LICENSE	The driver license number (Germany specific).
GERMANY_PASSPORT_NUMBER	The passport number (Germany specific).
GERMANY_PERSONAL_IDENTIFICATION_NUMBER	The personal identification number (Germany specific).
GERMANY_TAX_IDENTIFICATION_NUMBER	Tax identification number (Germany specific).
GERMANY_VALUE_ADDED_TAX	Value-Added Tax (Germany specific).

Greece data types

Data Type	Description
GREECE_DRIVING_LICENSE	The driver license number (Greece specific).
GREECE_PASSPORT_NUMBER	The passport number (Greece specific).

Data Type	Description
