Key features of hypothesis visualizations:

- **Resource nodes** - Each AWS resource mentioned in the hypothesis appears as a distinct node, labeled with the resource type and identifier.
- **Connections** - Connections between nodes indicate the relationships that CloudWatch investigations has identified.
- **Visual context** - The layout helps you understand the scope and complexity of multi-resource issues at a glance.

This visual representation is particularly valuable for:

- Understanding distributed system failures that span multiple services
- Identifying upstream and downstream impact relationships
- Quickly assessing the scope of an issue before diving into detailed analysis

> **Note**
>
> Hypothesis visualizations are automatically generated when CloudWatch investigations identifies causal relationships between multiple resources.

How CloudWatch investigations finds data for suggestions

CloudWatch investigations uses a wide range of data sources to determine dependency relationships and plan analysis paths, including telemetry data configurations, service configurations, and observed relationships. These dependency relationships are found more easily if you use CloudWatch Application Signals and AWS X-Ray. When Application Signals and X-Ray aren't available, CloudWatch investigations will attempt to infer dependency relationships through co-occurring telemetry anomalies.

While CloudWatch investigations will continue to analyze telemetry data and provide suggestions without these features enabled, we strongly recommend that you enable the services and features listed in (Recommended) Best practices to enhance investigations for optimal quality and performance for CloudWatch investigations.

Important

To help CloudWatch investigations provide the most relevant information, we might use certain content from CloudWatch investigations, including but not limited to, questions that you ask CloudWatch investigations and its response, insights, user interactions, telemetry, and metadata for service improvements. Your trust and privacy, as well as the security of your content, is our highest priority. For more information, see **AWS Service Terms** and **AWS responsible AI policy**.

You can opt out of having your content collected to develop or improve the quality of CloudWatch investigations by creating an AI service opt-out policy for CloudWatch or AI Operations (aiops). For more information, see AI services opt-out policies in the AWS Organizations User Guide.

Costs associated with CloudWatch investigations

CloudWatch investigations might incur AWS service usage including telemetry and resource queries and other API usage. While the majority of these will not be charged to your AWS bill, there are exceptions including, but not limited to:

- CloudWatch APIs (`ListMetrics`, `GetDashboard`, `ListDashboards`, and `GetInsightRuleReport`)
- X-Ray APIs (`GetServiceGraph`, `GetTraceSummaries`, and `BatchGetTraces`)
- CloudWatch investigations also uses AWS Cloud Control APIs which might incur usage of AWS services such as Amazon Kinesis Data Streams and AWS Lambda.
- Additionally, if you choose to integrate CloudWatch investigations in chat applications you might incur usage of Amazon Simple Notification Service.

For usage of these services exceeding the AWS Free Tier, you will see charges on your AWS bill. These charges are expected to be minimal for normal usage of CloudWatch investigations. For more information, see Amazon Kinesis Data Streams pricing, AWS Lambda pricing for Automation, and Amazon Simple Notification Service pricing.

Insights that CloudWatch investigations can surface in investigations

CloudWatch investigations can surface the following types of items and add them to the **Suggestions** tab of an investigation. For hypotheses involving multiple resources, visual diagrams may also be provided to illustrate causal relationships.

- Hypotheses about root causes
- CloudWatch alarms, including both metric alarms and composite alarms
- CloudWatch metrics
- AWS Health events
- Change events logged in CloudTrail
- X-Ray trace data
- CloudWatch Logs Insights queries for log groups in the Standard log class
- CloudWatch Contributor Insights data
- CloudWatch Application Signals data
- CloudWatch Database Insights data

AWS services where investigations are supported

You can launch investigations from telemetry data (such as CloudWatch metrics, alarms, and logs), review generated anomaly signals, and explore hypotheses on investigations. CloudWatch investigations work best when helping you with automated troubleshooting guidance on the AWS services listed below:

- Amazon API Gateway
- AWS AppSync
- Amazon Data Firehose
- Amazon DynamoDB
- Amazon EBS[1]
- Amazon EC2[1]
- Amazon ECS on Amazon EC2[2]

- Amazon ECS on Fargate[2]
- Amazon EKS[3]
- Amazon Kinesis Data Streams
- AWS Lambda
- Amazon OpenSearch Service
- Amazon RDS[4]
- Amazon S3
- Amazon SNS
- Amazon SQS
- AWS Step Functions

The list of services will continue to be expanded over time. CloudWatch investigations utilizes a wide range of data sources to determine dependency relationships and plan analysis paths, including telemetry data configurations, service configurations, and observed relationships through CloudWatch Application Signals and X-Ray. Where none of the above is available, CloudWatch investigations will attempt to infer dependency relationships through co-occurring telemetry anomalies.

Best practice setup

While CloudWatch investigations will continue to analyze telemetry data and provide suggestions without the following features enabled, for optimal quality and performance for CloudWatch investigations, we recommend you complete the following steps:

- [1]For both Amazon EC2 and Amazon EBS, update your CloudWatch agent to version 1.30049.1 or later. For more information, see Collect metrics, logs, and traces using the CloudWatch agent.
- [2]For Amazon ECS, enable CloudWatch Container Insights. For more information, see Container Insights.
- [3]For Amazon EKS, enable CloudWatch Container Insights and configure Amazon EKS Access Entries. For more information, see Container Insights and Integration with Amazon EKS.
- [4]For Amazon RDS, enable CloudWatch Database Insights in the **Advanced mode**. For more information, see Turning on the Advanced mode of Database Insights for Amazon Aurora in the *Aurora User Guide*.
- Enable CloudWatch Application Signals and X-Ray. For more information, see Application Signals and What is AWS X-Ray.

Conduct an CloudWatch investigation without additional configuration

You can conduct a CloudWatch investigations AI-powered root cause analysis without any additional configuration of your AWS account using the **Investigations** feature available in **Operational troubleshooting**.

These investigations provide instant access to CloudWatch investigations capabilities from commonly used telemetry sources in the AWS console. This type of investigation is session-based, read-only, and automatically deleted after 24 hours.

The investigation pane provides you:

- **AI-generated observations** - Telemetry that fans out from your initial observation you provided to locate additional supporting data that can lead to a potential root cause.
- **Root cause hypotheses** - Potential explanations for what's causing the problem, including causal diagrams when multiple resources are involved
- **Natural language explanations** - Easy-to-understand descriptions of findings and recommendations

You can use the suggestions from the investigation pane to help accelerate your troubleshooting process.

To start an investigation

1. Navigate to any supported telemetry source showing an issue you want to investigate, such as:
   - A CloudWatch metric showing unusual patterns
   - A CloudWatch alarm in ALARM state
   - A Lambda function's monitoring tab showing performance issues
2. In **Operational troubleshooting**, choose the **Investigate** tab, then choose **Start investigation**.
3. Watch as CloudWatch investigations analyzes your telemetry and generates insights about potential root causes.
4. (Optional) To add additional telemetry sources or collaborate on the investigation with others, choose **Get started** in the information box at the bottom of the **Investigate** tab. You'll be

guided through the investigation group configuration process. For more information, see Configure CloudWatch investigations

> **Important**
>
> You must have the appropriate IAM permissions to create or access investigation groups. Users with read-only permissions will see information about requesting additional permissions from their administrators.

Configure CloudWatch investigations

Configuring CloudWatch investigations creates an investigation group that CloudWatch investigations will use to access telemetry and aggregate data related to the investigation. Before you create the investigation group, you can walk-through a sample investigation to get an overall idea of how they work.

Topics

- See a sample investigation
- Set up an investigation group
- Configure alarms to create investigations
- Integration with Amazon EKS

See a sample investigation

If you'd like to see an investigation in action before you configure an investigation group for your account, you can walk through a sample investigation. The sample investigation doesn't use your data and doesn't make data calls or start API operations in your account.

To view the sample investigation

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, choose **AI Operations**, **Overview**.
3. Choose **Try a sample investigation**.

   The console displays the sample investigation, with suggestions and findings in the right pane. In each popup, choose **Next** to advance to the next part of the sample walkthrough.

Set up an investigation group

To set up CloudWatch investigations in your account for use with an enhanced investigation, you create an *investigation group*. Creating an investigation group is a one-time setup task, after it's created it is used to conduct other investigations. Settings in the investigation group help you centrally manage the common properties of your investigations, such as the following:

- Who can access the investigations
- Cross-account investigation support to access resources in other accounts during the investigation
- Whether investigation data is encrypted with a customer managed AWS Key Management Service key.
- How long investigations and their data are retained by default.

You can have one investigation group per account. Each investigation in your account will be part of this investigation group.

To create an investigation group you must be signed in to an IAM principal that has the either the **AIOpsConsoleAdminPolicy** or the **AdministratorAccess** IAM policy attached, or to an account that has similar permissions.

> **Note**
>
> To be able to choose the recommended option of creating a new IAM role for CloudWatch investigations operational investigations, you must be signed in to an IAM principal that has the `iam:CreateRole`, `iam:AttachRolePolicy`, and `iam:PutRolePolicy` permissions.

> **Important**
>
> CloudWatch investigations uses *cross-Region inference* to distribute traffic across different AWS Regions. For more information, see Cross-Region inference.

To create an investigation group in your account

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

2. In the left navigation pane, choose **AI Operations**, **Configuration**.
3. Choose **Configure for this account**.
4. Optionally change the retention period for investigations. For more information about what the retention period governs, see CloudWatch investigations data retention.
5. (Optional) To encrypt your investigation data with a customer managed AWS KMS key, choose **Customize encryption settings** and follow the steps to create or specify a key to use. If you don't specify a customer managed key, CloudWatch investigations uses an AWS owned key for encryption. For more information, see Encryption of investigation data.
6. Choose how to give CloudWatch investigations permissions to access resources. To be able to choose either of the first two options, you must be signed in to an IAM principal that has the `iam:CreateRole`, `iam:AttachRolePolicy`, and `iam:PutRolePolicy` permissions.

   a. (Recommended) Select **Auto-create a new role with default investigation permissions**. This role will be granted permissions using the AWS managed policies for AI Operations.For more information, see User permissions for your CloudWatch investigations group.

   b. Create a new role yourself and then assign the policy templates.

   c. Choose **Assign an existing role** if you already have a role with the permissions that you want to use.

      If you choose this option, you must make sure the role includes a trust policy that names `aiops.amazonaws.com` as the service principal. For more information about using service principals in trust policies, see AWS service principals.

      We also recommend that you include a `Condition` section with the account number, to prevent a confused deputy situation. The following example trust policy illustrates both the service principal and the `Condition` section.

      JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "aiops.amazonaws.com"
```

```
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "123456789012"
                },
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:aiops:us-
east-1:123456789012:*"
                }
            }
        }
    ]
}
```

7. Choose **Create investigation group**, you can now create an investigation from an alarm, metric, or log insight.

Optionally, you can setup additional recommended configurations to enhance your experience.

1. In the left navigation pane, choose **AI Operations, Configuration**.
2. On the **Optional configuration** tab, choose the enhancements you want to add to CloudWatch investigations.
3. In **Configure cross account access** you can set this account as a monitoring account that collects data from other source accounts in your organization. For more information, see Cross-account investigations.
4. For **Enhanced integrations**, choose to allow CloudWatch investigations access to additional services in your system, to enable it to gather more data and be more useful.

    a. In the **Tags for application boundary detection** section, enter the existing custom tag keys for custom applications in your system. Resource tags help CloudWatch investigations narrow the search space when it is unable to discover definite relationships between resources. For example, to discover that an Amazon ECS service depends on an Amazon RDS database, CloudWatch investigations can discover this relationship using data sources such as X-Ray and CloudWatch Application Signals. However, if you haven't deployed these features, CloudWatch investigations will attempt to identify possible relationships. Tag boundaries can be used to narrow the resources that will be discovered by CloudWatch investigations in these cases.

You don't need to enter tags created by myApplications or CloudFormation, because CloudWatch investigations can automatically detect those tags.

b. CloudTrail records events about changes in your system including deployment events. These events can often be useful to CloudWatch investigations to create hypotheses about root causes of issues in your system. In the **CloudTrail for change event detection** section, you can give CloudWatch investigations some access to the events logged by AWS CloudTrail by enabling **Allow the assistant access to CloudTrail change events through the CloudTrail Event history**. For more information, see Working with CloudTrail Event history.

c. The **X-Ray for topology mapping** and **Application Signals for health assessment** sections point out other AWS services that can help CloudWatch investigations find information. If you have deployed them and you have granted the **AIOpsAssistantPolicy** IAM policy to CloudWatch investigations, it will be able to access X-Ray and Application Signals telemetry.

   For more information about how these services help CloudWatch investigations, see X-Ray and CloudWatch Application Signals.

d. If you use Amazon EKS, your CloudWatch investigations investigation group can utilize information directly from your Amazon EKS cluster once you set up access entries. For more information, see Integration with Amazon EKS.

e. If you use Amazon RDS, enable the Advanced mode of Database Insights on your database instances. Database Insights monitors database load and provides detailed performance analysis that helps CloudWatch investigations identify database-related issues during investigations. When Advanced Database Insights is enabled, CloudWatch investigations can automatically generate performance analysis reports that include detailed observations, metric anomalies, root cause analysis, and recommendations specific to your database workload. For more information about Database Insights and how to enable Advanced mode, see Monitoring Amazon RDS databases with CloudWatch Database Insights.

5. You can integrate CloudWatch investigations with a *chat channel*. This makes it possible to receive notifications about an investigation through the chat channel. CloudWatch investigations support chat channels in the following applications:

   - Slack
   - Microsoft Teams

If you want to integrate with a chat channel, we recommend that you complete some additional steps before enabling this enhancement in your investigation group. For more information, see Integration with third-party chat systems.

Then, perform the following steps to integrate with a chat channel in chat applications:

- In the **Chat client integration** section, choose **Select SNS topic**.
- Select the SNS topic to use for sending notifications about your investigations.

Configure alarms to create investigations

You can configure an existing CloudWatch alarm to automatically create investigations in CloudWatch investigations. When the alarm enters the ALARM state, CloudWatch automatically creates a new investigation or adds to an existing investigation based on the deduplication string.

When configuring an alarm to automatically create investigations, you'll need to specify an Amazon Resource Name (ARN) in the alarm's actionArns. This ARN identifies the investigation group where alarm-triggered investigations will be created. You can optionally include a deduplication string in the ARN to group related alarms.

ARN format and parameters

The ARN pattern for investigation group alarm actions follows this format:

```
arn:aws:aiops:region:account-id:investigation-group/investigation-group-
identifier#DEDUPE_STRING=value
```

The following table describes each ARN component:

Parameter	Description
`region` (required)	The AWS Region where your investigation group is located. For example: `us-east-1` .
`account-id` (required)	Your 12-digit AWS account ID. For example: `123456789012` .

Parameter	Description
`investigation-group-identifier` (required)	The unique identifier of your investigation group. Fore example, `sMwwg1IogXdvL7UZ`
`DEDUPE_STRING=value` (optional)	A deduplication string that groups related alarms into the same investigation. When multiple alarms use the same deduplication string, they contribute to a single investigation instead of creating separate ones.

Example without deduplication string:

```
arn:aws:aiops:us-east-1:123456789012:investigation-group/sMwwg1IogXdvL7UZ
```

Example with deduplication string:

```
arn:aws:aiops:us-east-1:123456789012:investigation-group/
sMwwg1IogXdvL7UZ#DEDUPE_STRING=performance
```

Benefits of deduplication strings

Deduplication strings help you organize related alarms and reduce investigation fragmentation. Use deduplication strings when:

- **Multiple alarms monitor the same system** - CPU, memory, and disk alarms for the same EC2 instance can share a deduplication string to create one comprehensive investigation.
- **Cascading failures occur** - When one issue triggers multiple related alarms, the same deduplication string prevents creating separate investigations for each symptom.
- **You want to categorize by problem type** - Use descriptive strings like "performance", "connectivity", or "security" to group alarms by issue category.

Effective deduplication string examples:

- `DEDUPE_STRING=webserver-performance` - Groups performance-related alarms for web servers
- `DEDUPE_STRING=database-connectivity` - Groups database connection issues

- `DEDUPE_STRING=instance-i-1234567890abcdef0` - Groups all alarms for a specific EC2 instance

> **Note**
>
> If no deduplication string is specified, the system uses a default combination of alarm name, account ID, and region to group investigations.

For more information about investigation groups, see Set up an investigation group.

Configure an alarm to create investigations

After you have an investigation group set up in your account, you can configure existing CloudWatch alarms to automatically create investigations when they enter the ALARM state. This eliminates the need to manually start investigations and ensures consistent response to operational issues. You can configure alarms using the AWS Management Console, AWS CLI, CloudFormation, or AWS SDKs.

Console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, and select an existing alarm.
3. Choose **Actions**, **Edit**.
4. In the **Alarm actions** section, choose **Add alarm action**.
5. Under the **Configure actions**, **Investigation action** section, choose the investigation group ARN.
6. (Optional) Add a deduplication string to group related alarms.
7. Choose **Update alarm**.

CLI

This command requires that you specify an ARN for the `alarm-actions` parameter. For information about how to create the ARN, see ARN format and parameters.

To configure a CloudWatch alarm with InvestigationGroup action (AWS CLI)

1. Install and configure the AWS CLI, if you haven't already. For information, see Installing or updating the latest version of the AWS CLI.
2. Run the following command to collect information about the alarm that you want to configure.

```
aws cloudwatch describe-alarms --alarm-names "alarm name"
```

3. Run the following command to update an alarm. Replace each *example resource placeholder* with your own information.

```
aws cloudwatch put-metric-alarm --alarm-name name \
--alarm-description "description" \
--metric-name name --namespace namespace \
--statistic statistic --period value --threshold value \
--comparison-operator value \
--dimensions "dimensions" --evaluation-periods value \
--alarm-actions "arn:aws:aiops:region:{account-id}:investigation-group/
{investigationGroupIdentifier}#DEDUPE_STRING={my-dedupe-string}"
```

Here's an example.

```
//Without deduplication string
aws cloudwatch put-metric-alarm --alarm-name cpu-mon \
--alarm-description "Alarm when CPU exceeds 70 percent" \
--metric-name CPUUtilization --namespace AWS/EC2 \
--statistic Average --period 300 --threshold 70 \
--comparison-operator GreaterThanThreshold \
--dimensions "Name=InstanceId,Value=i-12345678" --evaluation-periods 2 \
--alarm-actions arn:aws:aiops:us-east-1:123456789012:investigation-group/
sMwwg1IogXdvL7UZ \
--unit Percent

//With deduplication string
aws cloudwatch put-metric-alarm --alarm-name cpu-mon \
--alarm-description "Alarm when CPU exceeds 70 percent" \
--metric-name CPUUtilization --namespace AWS/EC2 \
--statistic Average --period 300 --threshold 70 \
--comparison-operator GreaterThanThreshold \
--dimensions "Name=InstanceId,Value=i-12345678" --evaluation-periods 2 \
```

```
--alarm-actions arn:aws:aiops:us-east-1:123456789012:investigation-group/
sMwwg1IogXdvL7UZ#DEDUPE_STRING=performance \
--unit Percent
```

CloudFormation

This section includes CloudFormation templates that you can use to configure CloudWatch alarms to automatically create or update investigations. Each template requires that you specify an ARN for the `AlarmActions` parameter. For information about how to create the ARN, see ARN format and parameters.

```
//Without deduplication string
Resources:
  MyAlarm:
    Type: AWS::CloudWatch::Alarm
    Properties:
      AlarmActions:
        - !Sub "arn:aws:aiops:${AWS::Region}:${AWS::AccountId}:investigation-group/
{investigationGroupIdentifier}"

//With deduplication string
Resources:
  MyAlarm:
    Type: AWS::CloudWatch::Alarm
    Properties:
      AlarmActions:
        - !Sub "arn:aws:aiops:${AWS::Region}:${AWS::AccountId}:investigation-group/
{investigationGroupIdentifier}#DEDUPE_STRING={my-dedupe-string}"
```

SDK

This section includes Java code snippets that you can use to configure CloudWatch alarms to automatically create or update investigations. Each snippet requires that you specify an ARN for the `investigationGroupArn` parameter. For information about how to create the ARN, see ARN format and parameters.

```
import com.amazonaws.services.cloudwatch.AmazonCloudWatch;
import com.amazonaws.services.cloudwatch.AmazonCloudWatchClientBuilder;
import com.amazonaws.services.cloudwatch.model.ComparisonOperator;
import com.amazonaws.services.cloudwatch.model.Dimension;
import com.amazonaws.services.cloudwatch.model.PutMetricAlarmRequest;
```

```
import com.amazonaws.services.cloudwatch.model.PutMetricAlarmResult;
import com.amazonaws.services.cloudwatch.model.StandardUnit;
import com.amazonaws.services.cloudwatch.model.Statistic;

//Without deduplication string
private void putMetricAlarmWithCloudWatchInvestigationAction() {
        final AmazonCloudWatch cloudWatchClient =
                AmazonCloudWatchClientBuilder.defaultClient();

        Dimension dimension = new Dimension()
                .withName("InstanceId")
                .withValue("i-12345678");
        String investigationGroupArn = "arn:aws:aiops:us-
east-1:123456789012:investigation-group/sMwwg1IogXdvL7UZ";

        PutMetricAlarmRequest request = new PutMetricAlarmRequest()
                    .withAlarmName("cpu-mon")
                    .withComparisonOperator(
                        ComparisonOperator.GreaterThanThreshold)
                    .withEvaluationPeriods(2)
                    .withMetricName("CPUUtilization")
                    .withNamespace("AWS/EC2")
                    .withPeriod(300)
                    .withStatistic(Statistic.Average)
                    .withThreshold(70.0)
                    .withActionsEnabled(true)
                    .withAlarmDescription("Alarm when CPU exceeds 70 percent")
                    .withUnit(StandardUnit.Percent)
                    .withDimensions(dimension)
                    .withAlarmActions(investigationGroupArn);

        PutMetricAlarmResult response = cloudWatchClient.putMetricAlarm(request);
}

//With deduplication string
private void putMetricAlarmWithCloudWatchInvestigationActionWithDedupeString() {
        final AmazonCloudWatch cloudWatchClient =
                AmazonCloudWatchClientBuilder.defaultClient();

        Dimension dimension = new Dimension()
                .withName("InstanceId")
                .withValue("i-12345678");
        String investigationGroupArn = "arn:aws:aiops:us-
east-1:123456789012:investigation-group/sMwwg1IogXdvL7UZ#DEDUPE_STRING=performance";
```

```
        PutMetricAlarmRequest request = new PutMetricAlarmRequest()
                    .withAlarmName("cpu-mon")
                    .withComparisonOperator(
                        ComparisonOperator.GreaterThanThreshold)
                    .withEvaluationPeriods(2)
                    .withMetricName("CPUUtilization")
                    .withNamespace("AWS/EC2")
                    .withPeriod(300)
                    .withStatistic(Statistic.Average)
                    .withThreshold(70.0)
                    .withActionsEnabled(true)
                    .withAlarmDescription("Alarm when CPU exceeds 70 percent")
                    .withUnit(StandardUnit.Percent)
                    .withDimensions(dimension)
                    .withAlarmActions(investigationGroupArn);

        PutMetricAlarmResult response = cloudWatchClient.putMetricAlarm(request);
}
```

Integration with Amazon EKS

CloudWatch investigations investigation groups can utilize information directly from your Amazon EKS cluster. To get started, first grant access to the `Investigation Group` IAM role. We recommend using the default AWS managed *access policy* `AmazonAIOpsAssistantPolicy` that grants CloudWatch investigations investigation groups access to resources in the cluster. By using this policy you will automatically get policy updates as needed.

> **Note**
>
> `AmazonAIOpsAssistantPolicy` is an access policy. The AWS managed identity policy that authorizes the access associated with CloudWatch investigations investigation groups is `AIOpsAssistantPolicy`.

Use the **Advanced Configuration** option to scope down the access provided by the access policy to a set of namespaces or the entire cluster. Alternatively, you can further scope access down by associating the access entry to a Kubernetes group RBAC permission. For more information, see Creating access entries.

Configuring the Amazon EKS access entry (Console)

To associate the `AmazonAIOpsAssistantPolicy` to the investigation role using the AWS Management Console, follow these steps:

1. Open the CloudWatch console and navigate to the Investigations Configuration page.
2. In the Amazon EKS Access section, select the option to associate the `AmazonAIOpsAssistantPolicy` with your investigation role.
3. Review the policy details and confirm the association.

To further customize the access scope:

1. Click **Advanced Configuration** in the Amazon EKS Access section.
2. You will be redirected to the Amazon EKS console.
3. In the Amazon EKS console, you can:
    a. Scope the policy to specific namespaces
    b. Configure the group feature for more granular access control

Configuring Amazon EKS Access Entries (CDK)

To configure Amazon EKS Access Entries using the AWS CDK, use the following code example:

```
const testAccessEntry = new AccessEntry(this, `test-access-entry`, {
    cluster: eksCluster,
    principal: investigationsIamRole.roleArn,
    accessPolicies: [
        AccessPolicy.fromAccessPolicyName('AmazonAIOpsAssistantPolicy', {
            accessScopeType: AccessScopeType.CLUSTER
        }),
    ],
});
```

AmazonAIOpsAssistantPolicy

The Amazon EKS Access Policy, `AmazonAIOpsAssistantPolicy`, provides comprehensive Read Only access to resources in the cluster. Information from each resource may not be currently utilized by CloudWatch investigations.

```

Updates to AmazonAIOpsAssistantPolicy

Change	Description	Date
Add policy for CloudWatch investigations	Initial release of `AmazonAIOpsAssistantPolicy`	August 9, 2025

(Recommended) Best practices to enhance investigations

As a best practice, we recommend that you enable several AWS services and features in your account that can help CloudWatch investigations discover more information in your topology and make better suggestions during investigations.

Topics

- CloudWatch agent
- AWS CloudTrail
- CloudWatch Application Signals
- X-Ray
- Container insights
- Database insights

CloudWatch agent

We recommend that you install the latest version of the CloudWatch agent on your servers. Using a recent version of the CloudWatch agent enhances the ability to find issues in Amazon EC2 and Amazon EBS during investigations. At a minimum, you should use Version 1.300049.1 or later of the CloudWatch agent. For more information about the CloudWatch agent and how to install it, see Collect metrics, logs, and traces using the CloudWatch agent.

AWS CloudTrail

We recommend that you configure your CloudTrail trails to send management events to CloudWatch Logs. CloudTrail records management events about control plane operations in your AWS account, such as configuring permissions policies and creating, modifying, and updating resources. When CloudTrail events are sent to CloudWatch Logs, CloudWatch investigations can analyze these events in your AWS account to detect changes in your account related to your investigation. For more information, see What is AWS CloudTrail, Creating a trail with the CloudTrail console, Working with CloudTrail trails and Sending events to CloudWatch Logs.

> **Note**
>
> CloudWatch investigations can only analyze CloudTrail events from trails that send events to CloudWatch Logs in the same AWS Region where you conduct the investigation. For cross-account investigations, it will review the CloudTrail trails in each configured account in the same region where you conduct the investigation.

CloudWatch Application Signals

CloudWatch Application Signals discovers the topology of your environment, including your applications and their dependencies. It also automatically collects standard metrics such as latency and availability. By enabling Application Signals, CloudWatch investigations can use this topology and metric information during investigations.

For more information about application signals, see Application Signals.

X-Ray

We recommend that you enable AWS X-Ray. X-Ray collects traces about requests that your applications serve. For any traced request to your application, you can see detailed information not only about the request and response, but also about calls that your application makes to downstream AWS resources, microservices, databases, and web APIs. This information can help CloudWatch investigations during investigations.

For more information, see **What is AWS X-Ray**

Container insights

If you use Amazon ECS or Amazon EKS, we recommend that you install Container insights. This improves the ability of CloudWatch investigations to find issues in your containers. For more information about the CloudWatch agent and how to install it, see Container Insights.

Database insights

If you use Amazon RDS, we recommend that you enable the Advanced mode of Database Insights on your database instances. Database Insights monitors database load and provides detailed performance analysis that helps CloudWatch investigations identify database-related issues during investigations. When Advanced Database Insights is enabled, CloudWatch investigations can automatically generate performance analysis reports that include detailed observations, metric anomalies, root cause analysis, and recommendations specific to your database workload. For more information about Database Insights and how to enable Advanced mode, see Monitoring Amazon RDS databases with CloudWatch Database Insights.

Investigate operational issues in your environment

You can create investigations in several ways depending on your workflow and the source of the issue you're investigating. Once an investigation is active, you can review AI-generated suggestions, accept or discard findings, and take remediation actions through automated runbooks.

The following procedures show you how to start investigations from different entry points and how to work with active investigations:

Contents

- Create an investigation
  - Create an investigation from Amazon Q chat
  - Create an investigation from a CloudWatch alarm action
- Create an investigation from a CloudWatch Application Signals Service Level Objective (SLO)
- View and continue an open investigation
- Reviewing and executing suggested runbook remediations for CloudWatch investigations
- Manage your current investigations
- Restart an archived investigation

Create an investigation

You can start an investigation from several AWS consoles, including (but not limited to) CloudWatch alarm pages, CloudWatch metric pages, and Lambda monitoring pages.

To start an investigation from an AWS console page

1. In **Account-level** select the graph of the metric or alarm that you want to investigate.
2. If the top of the page has an **Investigate** button, choose it and then choose **Start new investigation**.

   Otherwise, choose the vertical ellipsis menu icon

   for the metric, and choose **Investigate**, **Start a new investigation**.
3. In the **Investigation** pane, enter a name for the investigation in **New investigation title**, and optionally enter notes about the selected metric or alarm.

4. Under **Approximate impact start time** CloudWatch investigations recommends a timestamp to investigate based on the selected telemetry. To change the timestamp of the investigation, update the date and time.
5. Then choose **Start investigation**.

   The investigation starts. CloudWatch investigations scans your telemetry data to find data that might be associated with this situation.
6. To move the investigation data to the larger pane, choose **Open in full page**.
7. For detailed instructions about steps that you can take while continuing the investigation, see View and continue an open investigation.

Create an investigation from Amazon Q chat

You can ask questions about issues in your deployment in CloudWatch investigations chat. The question could be something like "Why is my Lambda function slow today?"

When you do so, CloudWatch investigations might ask follow up questions and run a health check regarding the issue. After the health check, the chat will prompt you about whether you want to start an investigation.

For more information and more sample questions, see Chatting with Amazon Q about AWS.

For detailed instructions about steps that you can take while continuing the investigation after it has been started, see View and continue an open investigation.

Create an investigation from a CloudWatch alarm action

When you create a CloudWatch alarm, you can specify for it to automatically start an investigation when it goes into ALARM state. You can do this for both metric alarms and composite alarms. For more information, see Start a CloudWatch investigations from an alarm, Create a CloudWatch alarm based on a static threshold and Create a composite alarm.

Create an investigation from a CloudWatch Application Signals Service Level Objective (SLO)

You can start an investigation from a CloudWatch Application Signals Service Level Objective (SLO) metric.

To start an investigation from a CloudWatch Application Signals Service Level Objective (SLO)

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Navigate to the **Applications Signals (APM)**, **Service Level Objectives (SLO)** console page.
3. Select an entry from the **Service Level Objectives (SLO)** list to display the metrics available for that SLO.
4. Select a metric, then choose **Investigate** from the **Action** menu.

   Alternatively, in the visualization of the metric you want to investigate, next to the more menu, select the AI icon to start an investigation.

   > **Note**
   >
   > If you have not configured operational investigations in your account, the AI icon opens the **Operation troubleshooting** pane. Select **Get started** to configure an investigation group and then continue.

5. In the **Operational troubleshooting** pane on the **Investigate**, under **Investigation title** enter a name for the investigation and optionally enter notes about the selected metric.
6. Under **Approximate impact start time** CloudWatch investigations recommends a timestamp to investigate based on the selected telemetry. To change the timestamp of the investigation, update the date and time.
7. Then choose **Start investigation**.

   The investigation starts. CloudWatch investigations scans your telemetry data to find data that might be associated with this situation.
8. To move the investigation data to the larger pane, choose **Open in full page**.
9. For detailed instructions about steps that you can take while continuing the investigation, see View and continue an open investigation.

View and continue an open investigation

Use the steps in this section to view and continue and existing investigation

To view and continue an investigation

1. If you aren't already on the page for the investigation, do the following:

   a. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

   b. In the left navigation pane, choose **AI Operations**, **Investigations**.

   c. Choose the name of the investigation.

2. The **Feed** section displays the items that have been added to the investigation findings, including the metric or alarm that was originally selected to start the investigation with.

   The pane on the right includes tabs. Choose the **Suggestions** tab.

3. The **Suggestions** tab displays *observations* of other telemetry that CloudWatch investigations has found that might be related to the investigation. It might also include *hypotheses*, which are possible reasons or root causes that CloudWatch investigations has found for the situation.

   Both observations and hypotheses are written in natural language by CloudWatch investigations.

   You have several options:

   - For each suggestion, you can choose **Accept** or **Discard**.

     When you choose **Accept**, the suggestion is added to the **Feed** section, and CloudWatch investigations uses this information to direct further scanning and suggestions.

     If you choose **Discard**, the suggestion is moved to the **Discarded** tab.

   - For each observation-type suggestion, you can choose to expand the graph in the **Suggestions** tab, or open it in the CloudWatch console to see more details about it.

   - Some of the observations might be results of CloudWatch Logs Insights queries that CloudWatch investigations ran as part of the investigation. When an observation is a CloudWatch Logs Insights query result, the query itself is displayed as part of the observation. You can edit the query and re-run it. To do so, choose the vertical ellipsis menu icon

     by the results, and then choose **Open in Logs Insights**. For more information, see Analyzing log data with CloudWatch Logs Insights.

- If you know of telemetry in an AWS service that might apply to this investigation, you can go to that service's console and add the telemetry to the investigation. For example, to add a Lambda metric to the investigation, you can do the following:

  1. Open the Lambda console.
  2. In the **Monitor** section, find the metric.
  3. Open the vertical ellipsis context menu

     for the metric, choose **Investigate**, **Add to investigation** Then, in the **Investigate** pane, select the name of the investigation.

- When you view a hypothesis in the **Suggestions** tab, you can choose **Show reasoning** to display the data that CloudWatch investigations used to generate the hypothesis. For hypotheses involving multiple resources, you may also see a visual representation showing the causal relationships between the resources as connected nodes.
- You can choose the **Discarded** tab and view the suggestions that have been previously discarded. To add one of them to the findings, choose **Restore to findings**.
- To add notes to the findings, choose **New note** in the **Feed** pane. Then enter your notes and choose **Add**.

4. When you add a hypothesis to the **Feed** area, it might display **Show suggested actions**. If so, choosing this displays possible actions that you can take, assuming that hypothesis is correct about the issue. Possible actions include the following:

   - **Documentation suggestions** are links to AWS documentation that can help you understand the issue that you are working on, and how to solve it. To view suggested documentation, choose its **Review** link
   - **Runbook suggestions** are suggestions that leverage the pre-defined *runbooks* in Systems Manager Automation. Each runbook defines a number of steps for performing a task on an AWS resource. For information about continuing with a runbook action, see Reviewing and executing suggested runbook remediations for CloudWatch investigations.

     > **Important**
     >
     > There is a charge for executing an Automation runbook. However, CloudWatch investigations provides you with a preview of actions that a suggested runbook takes, giving you an opportunity to better evaluate whether to execute the runbook.

For information about Automation pricing, see AWS Systems Manager pricing for Automation.

5. (Optional) Choose **Incident report** to create a comprehensive incident analysis document. For more information, see Generate incident reports.
6. When you are ready to end an investigation, choose **End investigation** and then optionally add final notes. The investigation status changes to **Archived**. You can restart archived investigations by opening the investigation page and choosing **Restart investigation**.

> **Note**
>
> At some point, you might see **Completed the analysis. Finished with the investigation.** displayed above the **Feed** area. If you then add more telemetry to the findings, this message changes and CloudWatch investigations begins scanning your telemetry again, based on the new data that you added to the findings.

Reviewing and executing suggested runbook remediations for CloudWatch investigations

When you add a hypothesis to the **Feed** area of an active investigation, CloudWatch investigations might display **Show suggested actions**. One suggested action might be to view documentation with information to help you remediate a problem manually.

Another suggestion might be to use an *Automation runbook* to attempt to automatically resolve the issue. Automation is a capability in Systems Manager, another AWS service. Automation runbooks define a series of steps, or actions, to be run on the resources that you select. Each runbook is designed to address a specific issue. Runbooks can address a variety of operational needs: Creating, repairing, reconfiguring, installing, troubleshooting, remediating, duplicating, and more. For more information about Automation, see Integration with AWS Systems Manager Automation.

Before you begin

Before working with Automation runbooks in an investigation, be aware of the following important considerations:

- Choosing to execute a runbook incurs charges. For information, see AWS Systems Manager pricing.
- Root causes and runbook suggestions are powered by automated reasoning and generative artificial intelligence services.

> **Important**
>
> You are responsible for actions that result from executing runbook steps and the choice of parameter values entered during runbook execution. You might need to edit the suggested runbook to make sure the runbook performs as expected. For more information, see **AWS responsible AI policy**.

- Depending on the runbook, you might need to enter values for the runbook's **Input parameters** before the execution can run.
- The runbook executes using the IAM permissions assigned to the operator. If necessary, sign in with different IAM permissions to execute the runbook. In addition to permissions for the actions being taken, you'll need additional Systems Manager permissions to execute runbook steps. For more information, see Setting up Automation in the *AWS Systems Manager User Guide*.

To review and execute suggested runbook actions for CloudWatch investigations

1. To view information about a suggested runbook, choose **Review** for information about how to execute the runbook steps.

   On the investigation details page, choose **Suggestions**.
2. In the **Suggestions** pane, review the list of hypotheses based on the system's analysis of the issue under investigation.

   For each hypothesis, you can choose from the following options:

   - **Show reasoning** – View more information about why the system has generated the hypothesis.
   - **View actions** – View the suggested actions for the issue. Not all hypotheses will include suggested actions.
   - **Accept** – Accept the hypothesis and add it to the investigation's **Feed** section.

> **Note**
>
> Accepting the hypothesis doesn't automatically run the associated runbook solution. You can view suggested runbooks before accepting a hypothesis, but you must accept the hypothesis to execute a runbook.

- **Discard** – Reject the hypothesis and don't engage with it any further.

3. After you choose **View action**, in the **Suggested actions** pane, review the list of suggested actions you can take to address the issue. Suggested actions can include one or more of the following:

   - **AWS knowledge articles** – Provides information about steps you can take to manually address the issue, plus a link to more information.
   - **AWS documentation** – Provides links to user documentation topics related to the issue.
   - **AWS-owned runbooks** – Lists one or more Automation runbooks that are managed by AWS that you can run to attempt issue resolution.
   - **Runbooks owned by you** – Lists one or more custom Automation runbooks created by you or someone else in your account or organization, which you can run to attempt issue resolution.

   > **Note**
   >
   > The system automatically generates this list of runbooks by evaluating keywords in your custom runbooks and then comparing them to terms related to the issue being investigated.
   > More keyword matches mean a particular custom runbook appears higher in the **Runbooks owned by you** list.

4. After reviewing the hypothesis, you can examine a specific suggested action further and read related documentation by choosing **Learn more**. You can also choose **Review details** to inspect suggested runbooks owned by AWS and you.

5. When choosing **Review details** for runbooks, do the following:

   a. For **Runbook description**, review the content, which provides an overview of the actions the runbook can take to remediate the issue being investigated. Choose **View steps** to visualize the runbook's workflow and drill into the details of individual steps.

b. For **Input parameters**, specify values for any parameters required by the runbook. These parameters vary from runbook to runbook.

c. For **Execution preview**, carefully review the information. This information explains what the scope and impact would be if you choose to execute the runbook.

   The **Execution preview** content provides the following information:

   - How many accounts and Regions the runbook operation would occur in.
   - The types of actions that would be taken, and how many of each type.

     Action types include the following:

     - `Mutating`: A runbook step would make changes to the targets through actions that create, modify, or delete resources.
     - `Non-Mutating`: A runbook step would retrieve data about resources but not make changes to them. This category generally includes `Describe`, `List`, `Get`, and similar read-only API actions.
     - `Undetermined`: An undetermined step invokes executions performed by another orchestration service like AWS Lambda, AWS Step Functions, or Run Command, a capability of AWS Systems Manager. An undetermined step might also call a third-party API or run a Python or PowerShell script. Systems Manager Automation can't detect what the outcome would be of the orchestration processes or third-party API executions, and therefore can't evaluate them. The results of those steps would have to be manually reviewed to determine their impact.

     For information about supported actions and their impact types, see Remediation impact types of runbook actions in the *AWS Systems Manager User Guide*.

d. Review the preview information carefully before deciding whether to proceed.

   At this point, you can choose one of the following actions:

   - Stop and do not execute the runbook.
   - Change the input parameters before executing the runbook.
   - Execute the runbook with the options you have already selected.

> **Important**
>
> Choosing to execute the runbook incurs charges. For information, see AWS Systems Manager pricing.

6. If you want to execute the runbook, choose **Execute**.

   If you already accepted the hypothesis, the execution runs.

   If you have not already accepted the hypothesis, a dialog box prompts you to accept it before the execution runs.

After you choose **Execute** for a runbook, that action is added to the **Feed** pane of the investigation. From the investigation, you can monitor new data in the metrics in the findings to see if the runbook actions are correcting the issue.

Manage your current investigations

You can view a list of your current investigations, end active investigations, re-open archived investigations, rename, and delete investigations. You can take these actions on individual investigations, or in bulk.

To manage your current investigations

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, choose **AI Operations**, **Investigations**.
3. (Optional) Filter the investigations displayed in the list by name or investigation state.
4. Select the checkboxes for the investigation or investigations that you want to take action on.
5. Choose **End investigation**, **Rename**, or **Delete**.

   You will be prompted to confirm your action or to input a new investigation title.

Restart an archived investigation

You can restart archived investigations.

To restart an archived investigation

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, choose **AI Operations**, **Investigations**.
3. Choose the name of an archived investigation.
4. Choose **Restart investigation**.
5. (Optional)Update incident reports.

   Any incident reports generated from the original investigation remain available in the investigation history. You can access these reports from the investigation details page. If the restarted investigation discovers more facts, you can regenerate the incident report using the following steps:

   a. Choose **Incident report** to regenerate your incident report with new or updated facts.
   b. From the **Incident report** page, review updated facts.
   c. Choose **Regenerate** to update your incident report. If the **Regenerate** button is disabled, no new facts are present.

   We recommend that you don't leave investigations open indefinitely, because alarm state transitions related to the investigation will keep being added to the investigation as long as it is open.

Cross-account investigations

Cross-account CloudWatch investigations enables you to investigate application issues that span multiple AWS accounts from a centralized monitoring account. This feature allows you to correlate telemetry data, metrics, and logs across up to 25 accounts, in addition to the monitoring account, to gain comprehensive visibility into distributed applications and troubleshoot complex multi-account scenarios.

Topics

- Prerequisites
- Setup your monitoring account for cross-account access
- Setup your source account(s) for cross-account access
- Investigating multi-account issues

Prerequisites

- Multi-account investigation requires you to already have cross-account observability set up in order to view cross-account telemetries. To complete the prerequisite, set up either cross-account observability or the cross-account dashboard.
- Setup an investigation group. For cross-account observability, this should be in the monitoring account. You can also set them up in the source accounts and run single account investigations there.

Setup your monitoring account for cross-account access

Setup your monitoring account for cross-account access

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, choose **AI Operations**, **Configuration**.
3. Under **Configure Cross-account access**, select **Configure**.
4. Add the Account ID for up to 25 accounts under the **List source accounts** section.
5. Update your IAM role.

   a. Automatically

   - If you choose **Automatically update the assistant role (recommended)** , this creates a customer managed policy named `AIOpsAssistantCrossAccountPolicy-${guid}` that includes the `sts:AssumeRole` statements needed to assume the assistant role in the specified source accounts. Choosing the automatic update option defaults the IAM role name to `AIOps-CrossAccountInvestigationRole` in the source accounts .

     JSON

```
{
    "Version":"2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Action": "sts:AssumeRole",
        "Resource": [
            "arn:aws:iam::777777777777:role/AIOps-
CrossAccountInvestigationRole",
```

```
            "arn:aws:iam::555555555555:role/AIOps-
CrossAccountInvestigationRole",
            "arn:aws:iam::666666666666:role/AIOps-
CrossAccountInvestigationRole"
        ]
    }
}
```

- If the monitoring account owner removes a source account from the cross-account configuration, the IAM policy will not update automatically. You must manually update the IAM role and policy to ensure it always has the minimum permissions possible.
- You might reach the limit of managed policies per role if the permissions are not manually updated when a source account is removed. You must delete any unused managed policies attached to your investigation role.

b. Manually

- The following example shows the trust policy required for the assistant role:

  JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowAIOpsAssumeRole",
            "Effect": "Allow",
            "Principal": {
                "Service": "aiops.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {
                    "sts:ExternalId": "arn:aws:aiops:us-
east-1:123456789012:investigation-group/AaBbcCDde1EfFG2g"
                }
            }
        }
    ]
}
```

You can use the AWS CLI to create the custom source account role and then attach the `AIOpsAssistantPolicy` to the role using the following commands, replacing the placeholder values with the appropriate values for your environment:

```
aws iam create-role
 --role-name custom-role-name
 --assume-role-policy-document
    '{
       "Version": "2012-10-17",
       "Statement": [
                 {
                      "Effect": "Allow",
                      "Principal": { "AWS": "investigation-group-role-arn"
                          },
                      "Action": "sts:AssumeRole",
                      "Condition": {
                                "StringEquals": {
                                        "sts:ExternalId": "investigation-
group-arn"
                                          } } } ] }'

aws iam attach-role-policy
 --role-name custom-role-name
 --policy-arn arn:aws:iam::aws:policy/AIOpsAssistantPolicy
```

- To grant cross-account access, the permission policy of the assistant role in the monitoring account must contain the following. If you are configuring the monitoring account manually, the role name can be whatever you choose. It does not default to `AIOps-CrossAccountInvestigationRole`, make sure to specify the name of the assistant role for each of the source accounts.

  JSON

```
{
    "Version":"2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Action": "sts:AssumeRole",
        "Resource": [

 "arn:aws:iam::777777777777:role/custom_source_account_role_name",
```

```
 "arn:aws:iam::555555555555:role/custom_source_account_role_name",

 "arn:aws:iam::666666666666:role/custom_source_account_role_name"
        ]
    }
}
```

- Use the AWS CLI to update the monitoring account investigation group with the custom source account role ARN using the following command, replacing the placeholder values with the appropriate values for your environment:

```
aws aiops update-investigation-group
 --identifier investigation-group-id
 --cross-account-configurations sourceRoleArn=sourceRoleArn1
 sourceRoleArn=sourceRoleArn2
```

For more details on this command, see the AWS CLI Command Reference.

Setup your source account(s) for cross-account access

1. Provision an IAM role with the name `AIOps-CrossAccountInvestigationRole` if you selected the **Automatically update the assistant role** option to set up the monitoring account. If you used the manual setup option, provision the IAM role with your customized source account role name.

   a. Attach the AWS managed policy `AIOpsAssistantPolicy` to the role in the IAM console.

   b. The trust policy of the role on the source account looks like this. `ExternalID` must be specified on the policy. Use the monitoring account investigation group ARN.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
```

```
                "AWS": "arn:aws:iam::123456789012:role/investigation-
role-name"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {
                    "sts:ExternalId": "investigation-group-arn"
                }
            }
        }
    ]
}
```

2. This must be done in each of the source accounts.
3. If you set up the monitoring account role through the console, the role name of the source account defaults to `AIOps-CrossAccountInvestionRole`.
4. Confirm access by logging into the monitoring account, navigating to **Investigation Group**, then **Configuration**, and then choosing **Cross-account setup**.

   Make sure the source account shows up in the cross-account configuration, and the status is **Linked to monitoring account**.

Investigating multi-account issues

After you set up CloudWatch cross-account observability dashboard, you can view and investigate from a cross-account telemetry in your monitoring account. You must add a cross-account telemetry from the source account in order to run an investigation into that source account.

For detailed information about how to create an investigation, see Investigate operational issues in your environment.

Generate incident reports

Incident reports help you more quickly and easily write a report about your incident investigation. You can use this report to provide details to management or to help your team learn from the incident and take actions to prevent future such occurrences. The structure of the report is based on industry standards for these types of reports and can be copied into other repositories for long-term retention.

When you use the AWS Management Console to create an *investigation group* resource in CloudWatch investigations, an IAM role is created for the group to give it access to resources during the investigation. Generating CloudWatch investigations incident reports requires additional permissions be granted to your investigation group. The new managed policy `AIOpsAssistantIncidentReportPolicy` provides the required permissions and is automatically added to investigation groups created using the AWS Management Console after October 10, 2025. For more information, see AIOpsAssistantIncidentReportPolicy.

> **Note**
>
> If you are using the CDK or SDK, you must explicitly add the investigation group role and specify the role policy or equivalent inline permissions on the role. For more details about permissions, see Security in CloudWatch investigations

These reports capture investigation findings, root causes, timeline events, and recommended corrective actions in a structured format that can be easily shared with stakeholders and used for organizational learning.

Incident report generation is included at no additional charge for all CloudWatch investigations users and integrates seamlessly with your investigation workflow.

How incident reports work

1. Run an investigation on your incident.
2. Accept at least one hypothesis. Each hypothesis you accept is considered for the report. The hypothesis doesn't need to be 100% accurate.
3. Choose **Incident report**. During the investigation the AI parsed the data collected for your investigation and derived facts. Facts are atomic pieces of information about your incident that form the basis of generating the report. Fact extraction can take a few minutes.
4. When fact extraction is finished, you can review the facts available in the following areas:
   a. **Incident Overview** – High-level overview of the incident including its severity, duration, and operational hypothesis.
   b. **Impact Assessment** – Metrics and analysis related to the impact of the incident on customers, service function, and business operations.
   c. **Detection and Response** – Metrics and analysis related to how and when the incident was detected and how you responded to the incident.

d. **Root Cause Analysis** – Detailed analysis of underlying causes based on investigation hypotheses.

e. **Mitigation and Resolution** – Metrics and analysis related to mitigation steps and resolution measures, along with the time measurement for incident mitigation and resolution.

f. **Learning and Next Steps** – A list of recommended actions for your team to consider, automatically generated from the investigation findings. These recommendations may include preventive measures against similar incidents, as well as suggested improvements to your monitoring and response processes.

5. After reviewing the facts, choose **Generate report** to create a comprehensive analysis of the incident. While the selected facts serve as key reference points, the report draws from all available information gathered during the investigation. This process can take a few minutes.
6. After generating the report, you can then either:
   - Use the report as is:
     - Copy it to edit in your external editor if needed
     - Save it for later reference
   - Enhance the report by adding more data:
     - Choose **Add facts** (recommended method) to input additional text-based content such as incident tickets or custom narratives. The AI will analyze this content to augment existing facts or infer new ones.
     - Edit facts directly (use sparingly) - Manually edited facts may create inconsistencies with the investigation timeline. This should be used only as a last resort when **Add facts** doesn't achieve the desired result.
   - Choose **Regenerate report** to produce a new report using the updated information.

- Generate a report from an investigation
- Using 5 Whys analysis in incident reports

Understanding AI-derived facts in incident reports

AI-derived facts form the foundation of CloudWatch investigations incident reports, representing information that the AI system considers objectively true or highly probable based on comprehensive analysis of your AWS environment. These facts emerge through a sophisticated process that combines machine learning pattern recognition with systematic verification methods, creating a robust framework for incident analysis that maintains the operational rigor required for production environments.

Understanding how AI-derived facts are developed helps you evaluate their reliability and make informed decisions during incident response. The process represents a hybrid approach where artificial intelligence augments human expertise rather than replacing it, ensuring that the insights generated are both comprehensive and trustworthy.

The development process of AI-derived facts

The journey from raw telemetry data to actionable AI-derived facts begins with pattern observation, where the CloudWatch investigations AI analyzes vast amounts of AWS telemetry using sophisticated machine learning algorithms. The AI examines your CloudWatch metrics, logs, and traces across multiple dimensions simultaneously, identifying recurring patterns and relationships that might not be immediately apparent to human operators. The analysis encompasses temporal patterns that reveal when incidents typically occur and their duration characteristics, service correlations that show how different AWS services interact during failure scenarios, metric anomalies that precede or accompany incidents, and log event sequences that indicate specific failure modes.

Consider, for example, how the AI might observe that in your environment, Amazon EC2 instance CPU utilization consistently spikes to above 90% approximately 15 minutes before application response times exceed acceptable thresholds. This temporal relationship, when observed across multiple incidents, becomes a significant pattern worthy of further investigation. The AI doesn't simply note the correlation; it measures the statistical significance of the relationship and considers various confounding factors that might influence the pattern.

From these observed patterns, the AI moves into hypothesis generation, formulating potential explanations for the relationships it has discovered. This process involves creating multiple competing hypotheses and ranking them by probability based on the strength of supporting evidence. When the AI observes that CPU spikes precede response time degradation, it might generate several hypotheses: resource exhaustion due to insufficient compute capacity, memory

leaks causing increased CPU overhead, or inefficient algorithms triggered by specific input patterns. Each hypothesis receives a preliminary confidence level based on how well it explains the observed data and aligns with known AWS service behaviors.

The human verification and validation of these hypotheses ensures that these AI-generated insights meet operational standards before becoming facts in your incident reports. This process involves correlating AI-derived patterns with established AWS service behavior models, checking consistency with industry best practices for incident response, and validating against historical incident data from similar environments. The AI must demonstrate that its findings are reproducible across different analysis methods and time periods, meet statistical significance requirements for operational decision-making, align with empirical observations of AWS service behavior, and provide actionable insights for incident resolution or prevention.

Throughout this process, the AI faces several inherent challenges that you should understand when interpreting AI-derived facts. The distinction between correlation and causation remains a fundamental challenge; while the AI might identify strong correlations between network traffic spikes and incident occurrence, establishing direct causation requires additional investigation and domain expertise. Hidden variables that exist outside the scope of AWS telemetry, such as third-party service dependencies or external network provider issues, may influence incidents without being captured in the AI analysis. The quality of AI-derived facts depends entirely on the completeness and accuracy of the underlying CloudWatch data, making comprehensive monitoring coverage essential for reliable insights.

Novel incident patterns present another challenge, as those are not present in AI training data, and AIs often struggle to interpret unfamiliar failure modes. This limitation underscores the importance of human expertise in interpreting AI-derived facts and supplementing them with domain knowledge and contextual understanding.

Applying AI-derived facts in incident response

AI excels at identifying patterns across large datasets that would be impractical for humans to analyze manually, providing insights that can significantly accelerate incident diagnosis and resolution. AI works best when combined with human expertise that can provide context, validate conclusions, and identify factors that may not be captured in telemetry data.

The most effective approach involves treating AI-derived facts as highly informed starting points for investigation rather than definitive conclusions. When the AI identifies a fact such as "Database connection pool exhaustion preceded the incident by 8 minutes," this provides a valuable lead that

can be quickly verified through targeted analysis of database metrics and application logs. The fact gives you a specific timeframe and potential root cause to investigate, dramatically reducing the time needed to identify the issue compared to manually searching through all available telemetry.

Data quality plays a crucial role in the reliability of AI-derived facts. Comprehensive CloudWatch monitoring coverage provides the AI access to complete and accurate information for analysis. Gaps in monitoring can lead to incomplete or misleading facts, as the AI can only work with the data available to it. Organizations that use thorough observability practices that include detailed metrics collection, comprehensive logging, and distributed tracing are more likely to have accurate and actionable AI-derived facts in their incident reports.

Incident report terminology

The following terms are used in CloudWatch investigations incident reports:

AI-derived fact

A piece of information or observation that the AI system considers to be objectively true or highly probable based on the available data, telemetry, logs, and historical patterns within AWS services. These facts are derived through algorithmic analysis and machine learning models, and while they are treated as reliable by the system, they should be subject to human verification, especially in critical decision-making contexts. AI-derived facts may include correlations between events, anomaly detections, or inferences about system behavior that might not be immediately apparent to human operators.

Corrective actions

Specific, actionable steps recommended by CloudWatch investigations to address the root cause of an incident and prevent its recurrence, based on AWS best practices and the specific context of the affected resources.

Fact categories

Structured groupings of incident-related information, such as impact metrics, detection details, and mitigation steps, used to organize data for report generation.

Impact assessment

A quantitative and qualitative evaluation of an incident's effects on system performance, user experience, and business operations, derived from CloudWatch metrics and other AWS service data added to the investigation.

Incident report generation

An automated process that creates comprehensive documentation of an operational incident, including its timeline, impact, root cause, and resolution steps, based on data collected during a CloudWatch investigations investigation.

Investigation Feed

A chronological display of accepted observations, hypotheses, and user-added notes within a CloudWatch investigations investigation, serving as the primary record of the investigation's progress and findings.

Lessons learned

Automatically generated insights and improvement opportunities identified through the incident investigation process, aimed at enhancing system reliability, operational efficiency, and incident response capabilities across the organization.

Report assessment

An automated evaluation of the generated incident report, identifying potential data gaps or areas requiring additional information to improve report completeness and quality.

Root cause analysis

A systematic process of identifying the fundamental reason for an operational issue, leveraging CloudWatch investigations AI-driven hypotheses and correlations across multiple AWS services.

Suggestions tab

A feature in CloudWatch investigations that presents AI-generated observations and hypotheses about potential causes or related issues, based on analysis of system telemetry and logs.

Timeline events

A chronological sequence of significant occurrences during an incident, automatically extracted from CloudWatch logs, metrics, and other AWS service data to provide a clear overview of incident progression.

Generate a report from an investigation

You can generate incident reports from in-progress or completed investigations. Incident reports generated early in an investigation may not include key facts such as root causes and

recommended actions. When the investigation is active you can edit the facts available to supplement the investigation with additional information. After the investigation is ended, you can't edit or add facts to the investigation.

Prerequisites

Before generating an incident confirm the following requirements are met:

- Ensure the investigation group uses the required KMS key and has appropriate IAM policies attached to its role for decrypting data from AWS services. If your AWS resources are encrypted with customer-managed KMS keys, you must add IAM policy statements to the investigation group role to grant CloudWatch Investigations the permissions needed to decrypt and access this data.
- Investigation group role has been granted the following permissions:
  - `aiops:GetInvestigation`
  - `aiops:ListInvestigationEvents`
  - `aiops:GetInvestigationEvent`
  - `aiops:PutFact`
  - `aiops:UpdateReport`
  - `aiops:CreateReport`
  - `aiops:GetReport`
  - `aiops:ListFacts`
  - `aiops:GetFact`
  - `aiops:GetFactVersions`

> **Note**
>
> You can add these permissions as an inline policy to the investigation group role, or attach an additional permissions policy to investigation group role. For more information see, Permissions for incident report generation.
> The new managed policy `AIOpsAssistantIncidentReportPolicy` provides the required permissions and is automatically added to investigation groups created after October 10, 2025. For more information, see AIOpsAssistantIncidentReportPolicy.

To generate an incident report

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, choose **AI Operations**, **Investigations**.
3. Choose the name of an investigation.
4. On the investigation page, under **Feed** accept any additional relevant hypotheses and add any additional notes to the investigation.

   > **Note**
   >
   > Report generation requires an investigation with at least one accepted hypothesis.

5. On the top of the investigation page, choose **Incident report**. Wait while the relevant facts of the investigation are collected and synced.
6. On the **Incident Report** page review the facts being used to generate the report. The facts are available in the right pane. Navigate through the fact category tab using the left and right arrows, or expand the pane to see all of the categories.

   a. Choose **Edit** on a fact panel to manually add or edit the data in that category.

   b. Choose **View details** on a fact panel to see the supporting evidence and fact history gathered by the AI assistant. You can also choose **Edit** within the fact detail window.

   c. Choose **Add facts** if you want to provide additional context to the investigation, such as external events or extenuating circumstances.

7. Choose **Generate report**.

   CloudWatch investigations will analyze the investigation data and generate a structured report. This process might take some time.

8. Review the generated report in the preview pane. The report will include:

   - Automatically extracted timeline events
   - Root cause analysis based on accepted hypotheses
   - Impact assessment derived from investigation telemetry
   - Recommended corrective actions and lessons learned following AWS best practices

9. To retain a copy of the report in a different location, you can choose to copy the text of the report and paste it into your desired location.

10. Choose **Report assessment** to review a list of data gaps in the report. You can use this information to gather additional data for the report and then update the facts accordingly and regenerate the report.

Using 5 Whys analysis in incident reports

When generating incident reports, CloudWatch investigations can perform a 5 Whys root cause analysis to systematically identify the underlying causes of operational issues. This structured approach enhances your incident reports with deeper insights and actionable remediation steps.

This feature uses Amazon Q to provide a conversational chat. The user signed into the AWS Management Console must have the following permissions:

```
{
    "Sid" : "AmazonQAccess",
    "Effect" : "Allow",
    "Action" : [
       "q:StartConversation",
       "q:SendMessage",
       "q:GetConversation",
       "q:ListConversations",
       "q:UpdateConversation",
       "q:DeleteConversation",
       "q:PassRequest"
     ],
    "Resource" : "*"
 }
```

You can add these permissions directly, or by attaching either the AIOpsConsoleAdminPolicy or AIOpsOperatorAccess managed policy to the user or role.

What is 5 Whys analysis?

The 5 Whys is a root cause analysis technique that asks "why" repeatedly to drill down from incident symptoms to fundamental causes. Each answer becomes the basis for the next question, creating a logical chain that reveals the true root cause rather than just surface-level symptoms.

During incident report generation, CloudWatch investigations uses this method to analyze investigation findings and provide structured root cause analysis that goes beyond immediate technical failures to identify process, configuration, or systemic issues.

Benefits for incident reporting

Including 5 Whys analysis in incident reports provides several advantages:

- **Comprehensive root cause identification** - Moves beyond immediate technical causes to identify underlying process or system issues
- **Actionable remediation plans** - Provides specific, targeted actions to prevent recurrence rather than temporary fixes
- **Organizational learning** - Documents the complete causal chain for future reference and team knowledge sharing
- **Structured analysis** - Ensures systematic investigation rather than ad-hoc problem solving

Example scenarios in incident reports

Database connection failure incident

Initial incident: E-commerce application experiencing widespread 500 errors

1. **Why 1:** Why are users getting 500 errors? The application cannot connect to the primary database.
2. **Why 2:** Why can't the application connect to the database? The database instance ran out of available connections.
3. **Why 3:** Why did the database run out of connections? A batch processing job opened many connections without properly closing them.
4. **Why 4:** Why didn't the batch job close connections properly? The job's error handling doesn't include connection cleanup in failure scenarios.
5. **Why 5:** Why wasn't proper error handling implemented? Code review process doesn't include specific checks for resource management patterns.

Root cause: Inadequate code review standards for resource management

Recommended actions: Update code review checklist, implement connection pooling monitoring, add automated resource leak detection

Performance degradation incident

Initial incident: API response times increased from 200ms to 5000ms during traffic spike

1. **Why 1:** Why did response times increase? CPU utilization reached 100% on all application instances.
2. **Why 2:** Why didn't auto scaling add more instances? Auto scaling was triggered but new instances failed health checks.
3. **Why 3:** Why did new instances fail health checks? The application startup process takes 8 minutes, longer than the health check timeout.
4. **Why 4:** Why does startup take so long? The application downloads large configuration files from S3 on every startup.
5. **Why 5:** Why wasn't this startup delay considered in auto scaling configuration? Performance testing was done with pre-warmed instances, not cold starts.

Root cause: Performance testing methodology doesn't reflect production auto scaling scenarios

Recommended actions: Include cold start testing, optimize application startup, adjust health check timeouts, implement configuration caching

Complex incident with branch analysis

Initial incident: OpenSearch Serverless customers experienced 48.3% availability degradation for 11 hours

Main analysis chain:

1. **Why 1:** Why did customers experience service degradation? Service availability dropped to 48.3% due to incorrect ingester scaling.
2. **Why 2:** Why was ingester scaling incorrect? CortexOperator reduced ingesters from 223 to 174 due to AZ balance miscalculation.
3. **Why 3:** Why did CortexOperator miscalculate AZ balance? The code couldn't process new Kubernetes label formats after version 1.17 upgrade.
4. **Why 4 (Branch A - Technical):** Why didn't the code handle new label formats? The code expected 'failure-domain.beta.kubernetes.io/zone' labels but Kubernetes 1.17 changed to 'topology.kubernetes.io/zone'.
5. **Why 5 (Branch A):** Why wasn't backward compatibility implemented? The label format change wasn't documented in the upgrade notes reviewed during deployment planning.

Branch B - Process Analysis:

1. **Why 4 (Branch B - Process):** Why wasn't this caught in testing? Integration tests used pre-configured clusters with old label formats.
2. **Why 5 (Branch B):** Why didn't testing include label format validation? Test environment setup didn't mirror production Kubernetes version upgrade sequence.

Root causes identified:

- Technical: Missing backward compatibility for Kubernetes label format changes
- Process: Testing methodology doesn't validate version upgrade impacts

Integrated remediation plan: Implement label format detection logic, enhance upgrade testing procedures, add automated compatibility validation, and establish version change impact assessment process.

Using the guided 5 Whys workflow

CloudWatch investigations provides a guided 5 Whys analysis workflow to help you address missing facts and strengthen your incident reports. This feature appears as a suggested workflow when the system identifies opportunities to enhance root cause analysis.

Interactive analysis experience

The 5 Whys analysis in CloudWatch investigations uses an interactive, chat-based approach that guides you through the investigation process. This conversational method helps ensure comprehensive analysis while maintaining logical flow between questions.

Key features of the interactive experience:

- **Fact-based initialization** - The system presents relevant facts from your investigation upfront, using them to pre-populate obvious answers and clearly indicating fact-based versus inference-based suggestions
- **Guided probing** - For each "why" question, the system suggests answers based on available facts, requests specific additional context, and guides you to consider important aspects before proceeding
- **Branch management** - When multiple contributing factors are identified, the system clearly presents branch options, explains relationships between branches, and helps prioritize parallel investigations

- **Progressive validation** - For each response, the system reformulates answers for clarity, seeks confirmation, highlights key insights, and connects findings to broader context

This approach ensures that you capture all relevant information while maintaining focus on the most critical causal relationships.

Accessing the guided workflow:

1. During incident report generation, review the **Facts need attention** section in the right panel.
2. Look for the **Guided 5-Whys analysis** suggestion under **Suggested workflow**.
3. Choose **Guide me** to start the interactive 5 Whys process.
4. Follow the guided prompts to systematically work through each "why" question, building a complete causal chain from symptoms to root cause.

The guided workflow helps ensure you capture comprehensive root cause information by walking you through each step of the 5 Whys methodology. The analysis results are automatically incorporated into your incident report, providing structured documentation for post-incident reviews and organizational learning.

You can also request a 5 Whys analysis through the chat interface by asking questions such as "Perform a 5 Whys analysis for this incident" or "What is the root cause using 5 Whys methodology?"

Handling complex incidents with multiple causes

Some incidents involve multiple contributing factors that require parallel analysis paths. CloudWatch investigations supports branch analysis to ensure all significant causes are identified and addressed.

When branch analysis is needed:

- Multiple independent failures occurred simultaneously
- Different system components contributed to the same customer impact
- Both technical and process failures played significant roles
- Cascading failures created multiple causal chains

Branch analysis process:

1. **Branch identification** - The system identifies points where multiple causes converge or diverge
2. **Parallel investigation** - Each branch is analyzed using the complete 5 Whys methodology
3. **Connection mapping** - Relationships between branches are documented to show how they interact
4. **Integrated resolution** - Remediation plans address all identified root causes and their interactions

This comprehensive approach ensures that complex incidents receive thorough analysis and that all contributing factors are addressed in the final remediation plan.

Best practices for effective 5 Whys analysis

To maximize the effectiveness of 5 Whys analysis in your incident reports, follow these best practices derived from operational experience:

Question formulation guidelines

- **Start with customer impact** - Begin each analysis with the customer-facing problem to maintain focus on business impact
- **Increase technical depth progressively** - Move from business impact to technical details as you progress through the questions
- **Maintain logical continuity** - Ensure each answer naturally leads to the next question without logical gaps
- **Include supporting evidence** - Reference specific metrics, logs, or timeline events to validate each answer

Analysis validation

Validate your 5 Whys analysis using these criteria:

- **Logical flow** - Clear progression from symptoms to root cause with no missing steps
- **Technical accuracy** - Correct terminology, accurate system behavior descriptions, and valid component interactions
- **Completeness** - The analysis explains all observed symptoms and reaches a fundamental cause that, if addressed, would prevent recurrence

- **Actionability** - The root cause identified leads to specific, implementable remediation actions

Common pitfalls to avoid

- **Stopping at symptoms** - Don't conclude the analysis at the first technical failure; continue until you reach systemic or process causes
- **Blame-focused analysis** - Focus on system and process failures rather than individual actions
- **Single-path thinking** - Consider multiple contributing factors and use branch analysis when appropriate
- **Insufficient evidence** - Ensure each answer is supported by concrete data from your investigation

Integration with incident report sections

The 5 Whys analysis integrates with other sections of your incident report to provide comprehensive documentation:

- **Timeline correlation** - Each "why" question can reference specific timeline events, providing temporal context for causal relationships
- **Metrics validation** - Answers are supported by metrics and graphs that demonstrate the technical behaviors described
- **Impact assessment alignment** - The first "why" directly connects to customer impact metrics documented in the impact assessment section
- **Lessons learned foundation** - Root causes identified through 5 Whys analysis directly inform the lessons learned and corrective actions sections

This integration ensures consistency across your incident report and provides stakeholders with a complete, coherent narrative from initial symptoms through root cause to remediation plans.

Integrations with other systems

Topics

- Integration with AWS Systems Manager Automation
- Integration with third-party chat systems

Integration with AWS Systems Manager Automation

CloudWatch investigations is integrated with Automation, a capability of AWS Systems Manager. You don't need to configure integration, but you might need to update AWS Identity and Access Management (IAM) permissions so you can use Automation runbooks.

What is AWS Systems Manager?

Systems Manager helps you centrally view, manage, and operate *managed nodes* at scale in AWS, on-premises, and multicloud environments. In Systems Manager, a managed node is any machine configured for use with Systems Manager. For information, see the *AWS Systems Manager User Guide*.

What is Systems Manager Automation?

Automation performs common maintenance, deployment, troubleshooting, and remediation tasks through the use of *runbooks*. Each runbook defines a number of steps for performing tasks. Each step is associated with a particular *action*. The action determines the inputs, behavior, and outputs of the step. For descriptions of the nearly two dozen actions that are supported for runbooks, see the Systems Manager Automation actions reference in the *AWS Systems Manager User Guide*.

Automation provides over 400 AWS managed runbooks. For details about each runbook, including a step-by-step description of the actions performed when executed, see the Systems Manager Automation runbook reference. Customers can also design their own runbooks to address specific scenarios in their environments. For information, see Creating your own runbooks in the *AWS Systems Manager User Guide*.

For information about working with runbooks in an investigation, see Reviewing and executing suggested runbook remediations for CloudWatch investigations.

Integration with third-party chat systems

By integrating CloudWatch investigations with CloudWatch investigations in chat applications, you can have updates from investigations sent to third-party chat services, including Slack, and Microsoft Teams. The integration is facilitated by Amazon Simple Notification Service.

The following topics describe the required steps in the recommended order:

Topics

- Create and configure the Amazon SNS topic and access policy
- Configure CloudWatch investigations in your chat applications
- Add Amazon SNS topics to CloudWatch AI Operations

Create and configure the Amazon SNS topic and access policy

Create an Amazon SNS topic in the same region as your investigation. For more information, see Creating an Amazon Simple Notification Service topic.

To enable CloudWatch investigations to send notifications, you must add an the following access policy to the Amazon SNS topic

```
{
    "Sid": "AIOPS-CHAT-PUBLISH",
    "Effect": "Allow",
    "Principal": {
        "Service": "aiops.amazonaws.com"
    },
    "Action": "sns:Publish",
    "Resource": "SNS-TOPIC-ARN",
    "Condition": {
        "StringEquals": {
            "aws:SourceAccount": "account-Id"
        }
    }
}
```

Configure CloudWatch investigations in your chat applications

To configure CloudWatch investigations in chat applications for communication with a third-party chat service, use the following tutorials:

- Tutorial: Get started with Slack.
- Tutorial: Get started with Microsoft Teams.

Then, to support using AI assistant actions within chat channels you must provide the CloudWatch investigations in chat applications role with appropriate permissions. When you create a new IAM channel role for the channel, select the **Notifications** and **Amazon Q operations assistant permissions** policy templates.

Attach the **AIOpsOperatorAccess** managed IAM policy to the guardrail policies in CloudWatch investigations in chat applications. This grants permissions to CloudWatch investigations in chat applications to interact with CloudWatch investigations and perform required actions on your behalf.

In the channel configuration, you must also subscribe to the Amazon SNS topic that you created in the previous procedure.

Add Amazon SNS topics to CloudWatch AI Operations

You must use the CloudWatch console to configure CloudWatch investigations to integrate with Amazon SNS. You can do this while you create the investigation group in your account, or later.

If you have already created an investigation group and want to add chat integration, follow these steps.

To add chat integration to an existing investigation group

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **AI Operations**, **Configuration**.
3. On the **Optional configuration** tab, in the **Chat integration** section, do the following:
   - If you have already integrated CloudWatch investigations in chat applications with a third-party chat system, you can choose **Select SNS topic** to choose the Amazon SNS topic to use to send updates to about investigations. This Amazon SNS topic will relay those updates to the chat client.
   - If you want to integrate CloudWatch investigations in chat applications with a third-party chat system, choose **Configure new chat client**. For more information about setting up this configuration, see Getting started with CloudWatch investigations in chat applications.

When incident reports are generated, notifications can be sent to configured chat channels to alert team members that new documentation is available. These notifications include links to the generated reports and can be customized to include key findings or action items.

Security in CloudWatch investigations

This section includes topics about how CloudWatch investigations integrate with AWS security and permissions features.

Topics

- Default CloudWatch investigations permissions, retention, and encryption
- User permissions for your CloudWatch investigations group
- Additional permissions for Database Insights
- How to control what data CloudWatch investigations has access to during investigations
- Encryption of investigation data
- Cross-Region inference

Default CloudWatch investigations permissions, retention, and encryption

When you run investigations using default settings without additional configuration in your account the investigation uses the permissions available to your current console session and only accesses telemetry data using Read-only permissions. No investigation group IAM role configuration or permission policy is needed. However, that means the investigation's access to data is limited by the signed in user's permissions.

This investigation is only available to the same user that started the investigation. The investigation is available to view only for a 24 hour period, after which the investigation is deleted with no recovery option available.

The investigation data is encrypted at rest with an AWS owned key. You can't view or manage AWS owned keys, and you can't use them for other purposes or audit their use. However, you don't have to take any action or change any settings to use these keys. For more information, see AWS KMS keys.

User permissions for your CloudWatch investigations group

AWS has created three managed IAM policies that you can use for your users who will be working with your CloudWatch investigations group.

- AIOpsConsoleAdminPolicy– grants an administrator the ability to set up CloudWatch investigations in the account, access to CloudWatch investigations actions, the management of trusted identity propagation, and the management of integration with IAM Identity Center and organizational access.

- AIOpsOperatorAccess– grants a user access to investigation actions including starting an investigation. It also grants additional permissions that are necessary for accessing investigation events.
- AIOpsReadOnlyAccess– grants read-only permissions for CloudWatch investigations and other related services.

We recommend that you use three IAM principals, granting one of them the **AIOpsConsoleAdminPolicy** IAM policy, granting another the **AIOpsOperatorAccess** policy, and granting the third the **AIOpsReadOnlyAccess** policy. These principals could be either IAM roles (recommended) or IAM users. Then your users who work with CloudWatch investigations would sign on using one of these principals.

Permissions for incident report generation

Incident report generation requires additional permissions to allow the AI to collect events, facts, and then create reports.

Users with **AIOpsConsoleAdminPolicy** can generate, edit, and copy incident reports. By default, your investigation group is assigned the **AIOpsAssistantPolicy** to give it access to resource. However, it does not have the permissions required to generate an investigation report. To give permissions to your investigation group to collate the investigation data into an incident report you must add a policy similar to the following example that includes additional permissions or add the additional actions as an inline policy to the group:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "IncidentReportOperations",
            "Effect": "Allow",
            "Action": [
                "aiops:GetInvestigation",
                "aiops:ListInvestigationEvents",
                "aiops:GetInvestigationEvent",

                "aiops:CreateReport",
                "aiops:UpdateReport",
```

```
                "aiops:GetReport",

                "aiops:PutFact",
                "aiops:ListFacts",
                "aiops:GetFact",
                "aiops:GetFactVersions"
            ],
            "Resource": [
                "arn:aws:aiops:*:*:investigation-group/*"
            ]
        }
    ]
}
```

The new managed policy `AIOpsAssistantIncidentReportPolicy` provides the required permissions and is automatically added to investigation groups created after October 10, 2025. For more information, see AIOpsAssistantIncidentReportPolicy.

Additional permissions for Database Insights

To use Database Insights capabilities during investigations, you must attach the `AmazonRDSPerformanceInsightsFullAccess` managed policy to the IAM role or user that you use to perform investigations. CloudWatch investigations requires these permissions to create and access performance analysis reports for your Amazon RDS database instances.

To attach this policy, use the IAM console to add the `AmazonRDSPerformanceInsightsFullAccess` managed policy to your investigation principal. For more information about this managed policy and its permissions, see AmazonRDSPerformanceInsightsFullAccess.

How to control what data CloudWatch investigations has access to during investigations

When you configure an investigation group in your account, you specify what permissions that CloudWatch investigations has to access your resources during investigations. You do this by assigning an IAM role to the investigation group.

To enable CloudWatch investigations to access resources and be able to make suggestions and hypotheses, the recommended method is to attach the **AIOpsAssistantPolicy** to the investigation

group role. This grants the investigation group permissions to analyze your AWS resources during your investigations. For information about the complete contents of this policy, see AIOpsAssistantPolicy.

You can also choose to attach the general AWS **ReadOnlyAccess** to the investigation group role, in addition to attaching **AIOpsAssistantPolicy**. The reason to do this is that AWS updates **ReadOnlyAccess** more frequently with permissions for new AWS services and actions that are released. The **AIOpsAssistantPolicy** will also be updated for new actions, but not as frequently.

If you want to scope down the permissions granted to CloudWatch investigations, you can attach a custom IAM policy to the investigation group IAM role instead of attaching the **AIOpsAssistantPolicy** policy. To do this, start your custom policy with the contents of AIOpsAssistantPolicy and then remove permissions that you don't want to grant to CloudWatch investigations. This will prevent CloudWatch investigations from making suggestions based on the AWS services or actions that you don't grant access to.

> **Note**
>
> Anything that CloudWatch investigations can access can be added to the investigation and seen by your investigation operators. We recommend that you align CloudWatch investigations permissions with the permissions that your investigation group operators have.

Allowing CloudWatch investigations to decrypt encrypted data during investigations

If you encrypt your data in any of the following services with a customer managed key in AWS KMS, and you want CloudWatch investigations to be able to decrypt the data from these services and include them in investigations, you'll need to attach one or more additional IAM policies to the investigation group IAM role.

- AWS Step Functions

The policy statement should include a context key for encryption context to help scope down the permissions. For example, the following policy would enable CloudWatch investigations to decrypt data for a Step Functions state machine.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
        {
            "Sid": "AIOPSKMSAccessForStepFunctions",
            "Effect": "Allow",
            "Principal": {
                "Service": "aiops.amazonaws.com"
            },
            "Action":
            [
                "kms:Decrypt"
            ],
            "Resource": "*",
            "Condition":
            {
                "StringEquals":
                {
                     "kms:ViaService": "states.*.amazonaws.com",
                     "kms:EncryptionContext:aws:states:stateMachineArn":
 "arn:aws:states:region:accountId:stateMachine:*"
                }
            }
        }
    ]
}
```

For more information about these types of policies and using these context keys, see kms:ViaService and kms:EncryptionContext:*context-key* in the AWS Key Management Service Developer Guide, and aws:SourceArn in the IAM User Guide.

Encryption of investigation data

For the encryption of your investigation data, AWS offers two options:

- **AWS owned keys**– By default, CloudWatch investigations encrypts investigation data at rest with an AWS owned key. You can't view or manage AWS owned keys, and you can't use them for other

purposes or audit their use. However, you don't have to take any action or change any settings to use these keys. For more information about AWS owned keys, see AWS owned keys.

- **Customer managed keys**– These are keys that you create and manage yourself. You can choose to use a customer managed key instead of an AWS owned key for your investigation data. For more information about customer managed keys, see Customer managed keys.

Incident reports generated from investigations use the same encryption settings as the parent investigation. This maintains a consistent security posture across your investigation data and documentation

> **Note**
>
> CloudWatch investigations automatically enables encryption at rest using AWS owned keys at no charge. If you use a customer managed key, AWS KMS charges apply. For more information about pricing, see AWS Key Management Service pricing.

For more information about AWS KMS, see AWS Key Management Service.

Using a customer managed key for your investigation group

You can associate an investigation group with a customer managed key, and then all investigations created in that group will use the customer managed key to encrypt your investigation data at rest.

CloudWatch investigations customer managed key usage has the following conditions:

- CloudWatch investigations supports only symmetric encryption AWS KMS keys with the default key spec, `SYMMETRIC_DEFAULT`, and that have usage defined as `ENCRYPT_DECRYPT`.
- For a user to create or update an investigation group with a customer managed key, that user must have the `kms:DescribeKey`, `kms:GenerateDataKey`, and `kms:Decrypt` permissions.
- For a user to create or update an investigation in an investigation group that uses a customer managed key, that user must have the `kms:GenerateDataKey` and `kms:Decrypt` permissions.
- For a user to view investigation data in an investigation group that uses a customer managed key, that user must have the `kms:Decrypt` permission.

Setting up investigations to use a AWS KMS customer managed key

First, if you don't already have a symmetric key that you want to use, create a new key with the following command.

```
aws kms create-key
```

The command output includes the key ID and the Amazon Resource Name (ARN) of the key. You will need those in later steps in this section. The following is an example of this output.

```
{
"KeyMetadata": {
"Origin": "AWS_KMS",
        "KeyId": "1234abcd-12ab-34cd-56ef-1234567890ab",
        "Description": "",
        "KeyManager": "CUSTOMER",
        "Enabled": true,
        "CustomerMasterKeySpec": "SYMMETRIC_DEFAULT",
        "KeyUsage": "ENCRYPT_DECRYPT",
        "KeyState": "Enabled",
        "CreationDate": 1478910250.94,
        "Arn": "arn:aws:kms:us-west-2:111122223333:key/6f815f63-e628-448c-8251-
e4EXAMPLE",
        "AWSAccountId": "111122223333",
        "EncryptionAlgorithms": [
            "SYMMETRIC_DEFAULT"
        ]
    }
}
```

Set permissions on the key

Next, set permissions on the key. By default, all AWS KMS keys are private. Only the resource owner can use it to encrypt and decrypt data. However, the resource owner can grant permissions to access the key to other users and resources. With this step, you give the AI Operations service principal permission to use the key. This service principal must be in the same AWS Region where the KMS key is stored.

As a best practice, we recommend that you restrict the use of the KMS key to only those AWS accounts or resources that you specify.

The first step to set the permissions is to save the default policy for your key as `policy.json`. Use the following command to do so. Replace *`key-id`* with the ID of your key.

```
aws kms get-key-policy --key-id key-id --policy-name default --output text > ./
policy.json
```

Open the `policy.json` file in a text editor and add the following policy sections into that policy. Separate the existing statement from the new sections with a comma. These new sections use `Condition` sections to enhance the security of the AWS KMS key. For more information, see AWS KMS keys and encryption context.

This policy provides permissions for service principals for the following reasons:

- The `aiops` service needs `GenerateDataKey` permissions to get the data key and use that data key to encrypt your data while it is stored in rest. The `Decrypt` permission is needed to decrypt your data while reading from the data store. The decryption happens when you read the data using `aiops` APIs or when you update the investigation or investigation event. The update operation fetches the existing data after decrypting it, updates the data, and stores the updated data in the data store after encrypting
- The CloudWatch alarms service can create investigations or investigation events. These create operations verify that the caller has access to the AWS KMS key defined for the investigation group. The policy statement gives the `GenerateDataKey` and `Decrypt` permissions to the CloudWatch alarms service to create investigations on behalf of you.

Note

The following policy assumes that you follow the recommendation of using three IAM principals, and granting one of them the **AIOpsConsoleAdminPolicy** IAM policy, granting another the **AIOpsOperatorAccess** policy, and granting the third the **AIOpsReadOnlyAccess** policy. These principals could be either IAM roles (recommended) or IAM users. Then your users who work with CloudWatch investigations would sign on with one of these principals.
For the following policy, you'll need the ARNs of those three principals.

```
{
    "Sid": "Enable AI Operations Admin for the DescribeKey permissions",
```

```
    "Effect": "Allow",
    "Principal": {
        "AWS": "arn:aws:iam::{account-id}:role/{AIOpsConsoleAdmin}"
    },
    "Action": [
        "kms:DescribeKey"
    ],
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "kms:ViaService": "aiops.{region}.amazonaws.com"
        }
    }
},
{
   "Sid": "Enable AI Operations Admin and Operator for the Decrypt and GenerateDataKey
 permissions",
   "Effect": "Allow",
    "Principal": {
        "AWS": [
            "arn:aws:iam::{account-id}:role/{AIOpsConsoleAdmin}",
            "arn:aws:iam::{account-id}:role/{AIOpsOperator}"
         ]
    },
    "Action": [
        "kms:Decrypt",
        "kms:GenerateDataKey"
    ],
    "Resource": "*",
    "Condition": {

            "kms:ViaService": "aiops.{region}.amazonaws.com"
        },
        "ArnLike": {
            "kms:EncryptionContext:aws:aiops:investigation-group-arn": "arn:aws:aiops:
{region}:{account-id}:investigation-group/*"
        }
    }
 },
 {
   "Sid": "Enable the AI Operations service to have the DescribeKey permission",
   "Effect": "Allow",
    "Principal": {
        "Service": "aiops.amazonaws.com"
    },
    "Action": [
        "kms:DescribeKey"
    ],
    "Resource": "*",
    "Condition": {
       "StringEquals": {
            "aws:SourceAccount": "{account-id}"
        },
        "StringLike": {
            "aws:SourceArn": "arn:aws:aiops:{region}:{account-id}:investigation-group/
*"
        }
    }
 },
 {
   "Sid": "Enable the AI Operations service to have the Decrypt and GenerateDataKey
 permissions",
   "Effect": "Allow",
    "Principal": {
        "Service": "aiops.amazonaws.com"
    },
    "Action": [
        "kms:Decrypt",
```

```
        "kms:GenerateDataKey"
    ],
    "Resource": "*",
    "Condition": {
       "StringEquals": {
            "aws:SourceAccount": "{account-id}"
        },
        "StringLike": {
            "aws:SourceArn": "arn:aws:aiops:{region}:{account-id}:investigation-group/
*"
        },
        "ArnLike": {
            "kms:EncryptionContext:aws:aiops:investigation-group-arn": "arn:aws:aiops:
{region}:{account-id}:investigation-group/*"
        }
    }
 },
 {
    "Sid": "Enable CloudWatch to have the Decrypt and GenerateDataKey permissions",
    "Effect": "Allow",
    "Principal": {
        "Service": "aiops.alarms.cloudwatch.amazonaws.com"
    },
    "Action": [
        "kms:GenerateDataKey",
        "kms:Decrypt"
    ],
    "Resource": "*",
    "Condition": {
        "ArnLike": {
            "kms:EncryptionContext:aws:aiops:investigation-group-arn": "arn:aws:aiops:
{region}:{account-id}:investigation-group/*"
        },
        "StringEquals": {
            "aws:SourceAccount": "{account-id}",
            "kms:ViaService": "aiops.{region}.amazonaws.com"
        },
        "StringLike": {
            "aws:SourceArn": "arn:aws:cloudwatch:{region}:{account-id}:alarm:*"
        }
    }
  }
```

After you've updated the policy, assign it to the key by entering the following command.

```
aws kms put-key-policy --key-id key-id --policy-name default --policy file://
policy.json
```

Associate the key with the investigation group

When you use the CloudWatch console to create an investigation group, you can choose to associate the AWS KMS key with the investigation group. For more information, see Set up an investigation group.

You can also associate a customer managed key with an existing investigation group.

Changing your encryption configuration

You can update an investigation group to change between using a customer managed key or a service owned key. You can also change from using one customer managed key to using another. When you make such a change, the change applies to new investigations created after the change. Previous investigations are still associated with the old encryption configuration. Current ongoing investigations also continue using the original key for new data.

As long as a previously-used key is active and Amazon Q has access to it for investigations, you can retrieve the older investigations encrypted with that method, as well as data in current investigations that was encrypted with the previous key. If you delete a previously-used key or revoke access to it, the investigation data encrypted with that key can't be retrieved.

Cross-Region inference

CloudWatch investigations uses *cross-Region inference* to distribute traffic across different AWS Region. Although the data remains stored only in the primary Region, when using cross-Region inference, your investigation data might move outside of your primary Region. All data will be transmitted encrypted across Amazon's secure network.

For details about where cross-Region inference distribution occurs for each Region, see the following table.

Supported CloudWatch investigations geography	Investigation Region	Possible inference Regions
United States (US)	US East (N. Virginia)	US East (N. Virginia), US East (Ohio), US West (Oregon)
	US East (Ohio)	US East (N. Virginia), US East (Ohio), US West (Oregon)
	US West (Oregon)	US East (N. Virginia), US East (Ohio), US West (Oregon)
Europe (EU)	Europe (Frankfurt)	Europe (Frankfurt), Europe (Ireland), Europe (Paris), Europe (Stockholm)
	Europe (Ireland)	Europe (Frankfurt), Europe (Ireland), Europe (Paris), Europe (Stockholm)
	Europe (Spain)	Europe (Frankfurt), Europe (Ireland), Europe (Paris), Europe (Stockholm)
	Europe (Stockholm)	Europe (Frankfurt), Europe (Ireland), Europe (Paris), Europe (Stockholm)
Asia-Pacific (AP)	Asia Pacific (Hong Kong)	US East (N. Virginia), US East (Ohio), US West (Oregon)
	Asia Pacific (Mumbai)	US East (N. Virginia), US East (Ohio), US West (Oregon)
	Asia Pacific (Singapore)	US East (N. Virginia), US East (Ohio), US West (Oregon)
	Asia Pacific (Sydney)	US East (N. Virginia), US East (Ohio), US West (Oregon)

Supported CloudWatch investigations geography	Investigation Region	Possible inference Regions
	Asia Pacific (Tokyo)	US East (N. Virginia), US East (Ohio), US West (Oregon)
	Asia Pacific (Malaysia)	US East (N. Virginia), US East (Ohio), US West (Oregon)
	Asia Pacific (Thailand)	US East (N. Virginia), US East (Ohio), US West (Oregon)

CloudWatch investigations data retention

The retention period that you set for an investigation group determines how long that investigation data is kept. Valid values are seven days to 90 days.

After you first create an investigation, if you don't end it manually, it moves to a CLOSED state automatically after seven days. Then, the retention period determines how long the data is kept after the investigation moves to the CLOSED state. The data that is kept during the retention period includes the data in the investigation, accepted and discarded findings, and AI assistant audit log messages.

When this retention period expires, the investigation data is deleted.

If you manually end an investigation, that also moves the investigation to the CLOSED state and the retention period time begins to be in effect.

> **Note**
>
> Investigations conducted without configuring your CloudWatch investigations settings are linked to individual user sessions and are deleted after 24 hours, with no recovery option available.

Incident report retention

Incident reports generated from investigations follow the same retention policy as their parent investigations.

We recommend copying important incident reports to external systems if you need to retain them beyond the investigation retention period.

For more information, see Generate incident reports.

Troubleshooting

Topics

- CloudWatch investigations cannot assume the necessary IAM roles or permissions. Please verify required roles and permissions are correctly configured
- Unable to identify event source. Verify that the resource exists in your application topology and the resource type is supported.
- Analysis complete. Submit additional findings to receive updated suggestions
- Source account status shows "Pending link to monitoring account"
- Incident report generation issues

CloudWatch investigations cannot assume the necessary IAM roles or permissions. Please verify required roles and permissions are correctly configured

CloudWatch investigations use an IAM role to be able to access information in your topology. This IAM role must be configured with adequate permissions. For more information about the necessary permissions, see How to control what data CloudWatch investigations has access to during investigations.

Unable to identify event source. Verify that the resource exists in your application topology and the resource type is supported.

There are several AWS services and features that we recommend you to enable to provide additional valuable information to CloudWatch investigations. These services and features can help

CloudWatch investigations identify event sources. For more information, see (Recommended) Best practices to enhance investigations.

Analysis complete. Submit additional findings to receive updated suggestions

When you see this message, CloudWatch investigations has finished analyzing your topology and telemetry based on the findings that it has found so far. If you think that the root cause hasn't been found, you can manually add more telemetry to the investigation, and this might cause CloudWatch investigations to scan your system again based on the new information.

To add new telemetry, navigate to that service's console and add the telemetry to the investigation. For example, to add a Lambda metric to the investigation, you can do the following:

1. Open the Lambda console.
2. In the **Monitor** section, find the metric.
3. Open the vertical ellipsis context menu

   for the metric, choose **Investigate**, **Add to investigation** Then, in the **Investigate** pane, select the name of the investigation.

Source account status shows "Pending link to monitoring account"

Check that both your monitoring account and source account are set up correctly.

1. Check that the source account ID and the source account role name are correct.
2. The monitoring account role needs to have `sts:AssumeRole` permission to assume the source account role.
3. The source account role needs to have a trust policy for the monitoring account role to assume.
4. The trust policy in the source account role must be properly scoped to have the Investigation Group arn in the `sts:ExternalId` context key:

```
        "Condition": {
            "StringEquals": {
                "sts:ExternalId": "investigation-group-arn"
            }
```

```
        }
```

Incident report generation issues

This section describes common issues you might encounter when generating incident reports and how to resolve them.

Report generation fails or produces incomplete content

If incident report generation fails, verify the following:

- The investigation has at least one accepted hypothesis in the **Feed**
- Your user and your investigation group have the necessary permissions, see User permissions for your CloudWatch investigations group.

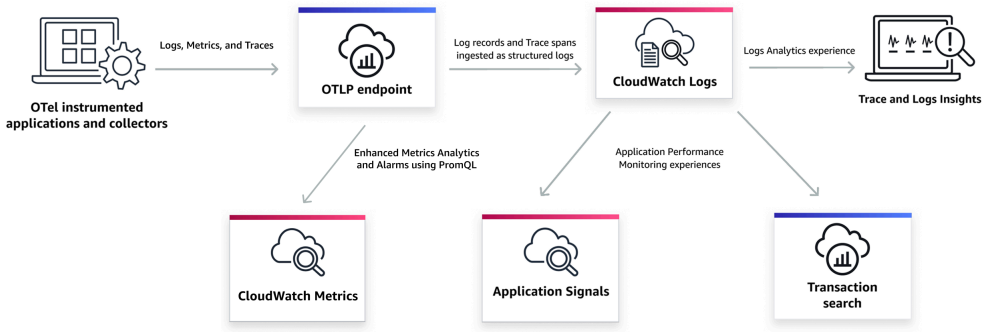
OpenTelemetry

> **Tip**
>
> To learn more about OpenTelemetry on CloudWatch, check out the Cloud Operations Enablement workshop and event series.

OpenTelemetry is an open-source observability framework that provides vendor-agnostic instrumentation for collecting metrics, logs, and traces from your applications. Amazon CloudWatch supports OpenTelemetry natively across all three signal types: metrics queryable with PromQL for flexible and scalable analytics, logs searchable with Logs Insights, and traces explorable with Transaction Search. Because all three signals share a common data model with consistent attributes, you can correlate across metrics, logs, and traces to move from detection to root cause faster. OpenTelemetry metrics carry rich semantic labels and support higher granularity than traditional CloudWatch metrics, enabling precise filtering, aggregation, and analysis across your applications and infrastructure.

CloudWatch supports OpenTelemetry metrics, allowing you to send custom OTel metrics directly to CloudWatch and query them using PromQL alongside AWS vended metrics from over 70 services. You can use PromQL to build dashboards, set CloudWatch Alarms, and explore metrics in Query Studio, the native PromQL console experience. OTel logs sent to CloudWatch are available in Logs Insights for interactive querying and in LiveTail for real-time streaming.

For application performance monitoring, CloudWatch Application Signals provides a unified, application-centric view of your services and dependencies. Application Signals uses OTLP traces to help you monitor application health, triage issues, and identify the impact on end users. With Transaction Search, you can explore OTLP spans interactively, find transactions using attributes such as customer identifiers or order numbers, correlate transactions to business events such as failed payments, and trace interactions between application components to establish root cause.



Topics

- OTLP Endpoints

- Setting up bearer token authentication for Metrics
- Troubleshooting

OTLP Endpoints

OpenTelemetry Protocol (OTLP) is a general-purpose telemetry data delivery protocol designed for the OpenTelemetry. CloudWatch OpenTelemetry endpoints are HTTP 1.1 endpoints. You need to configure your OpenTelemetry collector to start sending open telemetry data to CloudWatch. For more information, see Getting started.

Logs endpoint

The logs endpoint follows the pattern `https://logs.AWS Region.amazonaws.com/v1/logs`. For example, for the `US West (Oregon) (us-west-2) Region`, the endpoint will be `https://logs.us-west-2.amazonaws.com/v1/logs`. You can use the above endpoint to forward logs to an existing `LogGroup` and `LogStream`. For more information on setting up `LogGroup` to ingest log data, see Amazon CloudWatch Logs concepts.

You must configure `LogGroup` and `LogStream` when you invoke CloudWatch Logs OpenTelemetry endpoint by setting `x-aws-log-group` and `x-aws-log-stream` HTTP headers to `LogGroup` and `LogStream` name respectively. For more information, see Getting started.

The endpoint supports the following authentication methods:

- **AWS Signature Version 4 (SigV4)** – Recommended for workloads running on AWS. Uses short-term credentials via IAM roles. For more information, see AWS Signature Version 4 for API requests.
- **Bearer token (API key)** – For workloads running outside AWS or environments that do not support the AWS SDK. Requires bearer token authentication to be enabled on the target log group. For more information, see Setting up bearer token authentication for Logs.

When log event size exceed 1MB, CloudWatch Logs automatically truncates up to 10 fields, starting with the largest fields. Each field is truncated as needed to keep the total event size as close to 1MB as possible. The excess portions are stored as Large Log Objects (LLOs) and LLO reference system fields are added. Optionally, you can specify the field paths that need to be truncated by setting the `x-aws-truncatable-fields` HTTP header. The LLOs can be retrieved and streamed back using the `GetLogObject` API. For more information, see GetLogObject. Support of log events larger than 1MB and LLO experience is available in US East (N. Virginia) US West (Oregon), Europe (Frankfurt), Asia Pacific (Sydney), Asia Pacific (Mumbai), US East (Ohio), Europe (Ireland), Asia Pacific (Tokyo), and Asia Pacific (Singapore).

Metrics endpoint

The metrics endpoint follows the pattern `https://monitoring.`*`AWS Region`*`.amazonaws.com/v1/metrics`. For example, for the US West (Oregon) (us-west-2) Region, the endpoint will be `https://monitoring.us-west-2.amazonaws.com/v1/metrics`.

You need to configure your OpenTelemetry collector to start sending metrics to CloudWatch. The endpoint supports two authentication methods:

- **AWS Signature Version 4 (SigV4)**– The recommended authentication method using short-term credentials. For more information, see AWS Signature Version 4 for API requests.
- **Bearer token (API key)**– For workloads running outside AWS or environments that do not support the AWS SDK. Uses a long-lived API key passed in the `Authorization` header. For more information, see Setting up bearer token authentication for Metrics.

Traces endpoint

The traces endpoint follows the pattern `https://xray.AWS Region.amazonaws.com/v1/traces`. For example, for the US West (Oregon) (us-west-2) Region, the endpoint will be `https://xray.us-west-2.amazonaws.com/v1/traces`.

You need to configure your OpenTelemetry collector to start sending traces to CloudWatch. The endpoint authenticates callers using Signature 4 authentication. For more information, see AWS Signature Version 4 for API requests.

RUM endpoint

The RUM endpoint follows the pattern `https://dataplane.rum.{AWS Region}.amazonaws.com/v1/rum`. For example, for the US West (Oregon) Region, the endpoint is `https://dataplane.rum.us-west-2.amazonaws.com/v1/rum`. This endpoint handles *client-side telemetry data* (only traces and log records with `eventName`) for CloudWatch RUM applications.

To use this endpoint, you must create a RUM app monitor with Mobile platform (Android/ iOS) and use the code snippet generated to instrument your applications. The snippet will pull the RUM Mobile SDKs which are configured with this endpoint. You can configure the SDKs further for RUM to collect telemetry accordingly.

The endpoint supports both authenticated and unauthenticated requests. You can use AWS Signature Version 4 (SigV4) for authenticated requests, or resource-based policies to allow unauthenticated access from mobile applications.

To learn more about the authentication models as defined in their SDKs, see the following:

- iOS applications - AWS Distro for OpenTelemetry (ADOT) iOS SDK.
- Android applications - AWS Distro for OpenTelemetry (ADOT) Android SDK.

Endpoint limits and restrictions

The table lists the common endpoint limits and restrictions for metrics, traces, and logs.

Limit	Endpoint	Additional information
Required collector extension	sigv4authextension	To send metrics, logs, or traces to the OTLP endpoints you must use sigv4auth extension. For the metrics and logs endpoints, you can alternatively authenticate with a bearer token using the bearertokenauth extension. See Setting up bearer token authentication for Metrics or Setting up bearer token authentication for Logs.
Supported protocol	HTTP	The endpoint supports only HTTP and doesn't support gRPC
Supported OTLP versions	OTLP 1.x	
Payload format	binary, json	The endpoint accepts requests using binary and json formats
Compression methods	gzip, none	The endpoint only supports gzip and none compression methods

The table lists the endpoint limits and restrictions for traces.

Limit	Traces endpoint	Additional information
Maximum uncompressed bytes / request	5 MB	The OTLP endpoint will reject requests larger than 5MB when payload is uncompressed.
Maximum events / request	10,000 spans	The maximum number of spans in a batch is 10,000. Exceeding this limit will cause rejection of the API call.
Single resource and scope size	16 KB	Each unique resource and corresponding scope should not exceed 16 KB of size. Exceeding this limit for any resource will cause rejection of the entire API call.
Single span maximum size	200 KB	Spans more than 200KB will be rejected by the endpoint.
Span created timestamps	2 hours in the future and 14 days in the past	None of the spans in the batch can be more than two hours in the future or more than 14 days in the past.

Limit	Traces endpoint	Additional information
Maximum time gap in events / request	24 hours	

The table lists the endpoint limits and restrictions for metrics.

Limit	Metrics endpoint	Additional information	Error code
Maximum TPS	500	The maximum number of requests per second allowed per account.	429
Maximum new series creation rate	1,000,000	Maximum number of new series that can be created in a 10-minute window. This limit applies only to creating new metric names, not to ingesting data points for existing metrics.	429 - all metrics in the requests are throttled ; 200 - metrics in the requests are partially throttled
Maximum request size	1 MB	The maximum uncompressed size of the request.	400
Maximum datapoint count	1,000	The maximum number of datapoints sent in a single request. This number is a sum across ResourceMetrics, ScopeMetrics and Metrics.	400
Maximum metadata size	40 KB	The maximum combined size of all labels and label values accepted for a series per datapoint.	400 - all metrics in the requests are invalid; 200

Limit	Metrics endpoint	Additional information	Error code
			- metrics in the requests are partially invalid
Maximum label count	150	Maximum number of labels across Resource/Scope/ Datapoint attributes per datapoint.	400 - all metrics in the requests are invalid; 200 - metrics in the requests are partially invalid
Metrics created timestamps	10 minutes in the future and 14 days in the past	Metrics can be created with a timestamp that is at most 10 minutes in the future and at most 14 days in the past.	400

The table lists the endpoint limits and restrictions for logs.

Limit	Logs endpoint	Additional information
Maximum uncompressed bytes / request	1 MB	The OTLP endpoint will reject requests larger than 1MB when payload is uncompressed. The maximum request size is 1,048,576 bytes after decompression and

Limit	Logs endpoint	Additional information
		deserialization of binary data serialized by Protocol buffers. This size is calculated as the sum of all event messages in UTF-8, plus 26 bytes for each log record.
	20 MB Available only in US East (N. Virginia) US West (Oregon), Europe (Frankfurt), Asia Pacific (Sydney), Asia Pacific (Mumbai), US East (Ohio), Europe (Ireland), Asia Pacific (Tokyo), and Asia Pacific (Singapore).	The maximum request size is 20MB (20,971,520 bytes) after the OTLP payload is decompressed and decoded from JSON format. For logs up to 1MB – These logs have full access to all CloudWatch Logs features including queries and live tail. For logs larger than 1MB – The excess portion is processed as Large Log Objects (LLOs).

Limit	Logs endpoint	Additional information
Request per second	5000	5000 transactions per second per account per Region You can request an increase to the per-second throttling quota by using the Service Quotas service.
Single resource and scope size	16 KB	Each unique resource and corresponding scope should not exceed 16 KB of size. Exceeding this limit for any resource will cause rejection of the entire API call.
Single LogEvent size	1 MB	LogEvent size is calculated as sum of sizes for each LogRecord, Scope and Resource. This quota can't be changed.

Limit	Logs endpoint	Additional information
Logs created timestamps	2 hours in future and 14 days old	The log records in the batch does not have to be in a chronological order. However, the log records in the batch cannot be more than 2 hours in the future and cannot be more than 14 days in the past. Also, none of the log records can be earlier than the retention period of the log group.
Maximum time gap in events / request	24 hours	
Maximum events / request	10,000 logs	The maximum number of log events in a batch is 10,000. Exceeding this limit will cause rejection of the API call.

Limit	Logs endpoint	Additional information
Maximum large log objects / request	1 log record Available in US East (N. Virginia) US West (Oregon), Europe (Frankfurt), Asia Pacific (Sydney), Asia Pacific (Mumbai), US East (Ohio), Europe (Ireland), Asia Pacific (Tokyo), and Asia Pacific (Singapore).	For content exceeding 1MB in a log event, the excess content is stored as LLOs. Limited to 1 log record per request.
Maximum large log objects / record	10 LLOs Available in US East (N. Virginia) US West (Oregon), Europe (Frankfurt), Asia Pacific (Sydney), Asia Pacific (Mumbai), US East (Ohio), Europe (Ireland), Asia Pacific (Tokyo), and Asia Pacific (Singapore).	A single log record can contain up to 10 LLOs.

Note

The account limits for Logs are shared across the SDK and the new Logs endpoint.

Getting started

To get started with OpenTelemetry in CloudWatch, you can choose from several options to send telemetry to the CloudWatch OTLP endpoints. For most customers, the CloudWatch agent is the recommended path. The CloudWatch agent is an AWS-managed OpenTelemetry Collector with CloudWatch components pre-built, and it provides the most integrated monitoring experience in CloudWatch.

You also have the flexibility to use an upstream OpenTelemetry Collector, build your own custom OpenTelemetry Collector, or send telemetry directly to the OTLP endpoint without a collector agent using the AWS Distro for OpenTelemetry (ADOT) SDK. Make an informed choice based on the feature support:

Feature	CloudWatch agent (recommended)	Upstream OpenTelemetry Collector	Custom OpenTelemetry Collector	Collectorless with AWS Distro for OpenTelemetry (ADOT) SDK
Search and analyze spans and trace summaries	Yes	Yes	Yes	Yes
Search and analyze logs summaries	Yes	Yes	Yes	No
CloudWatch entity correlation (resource linkage in the console and service map)	Yes	No	Yes	No
Runtime metrics correlated with your application. For example, JVM metrics	Yes	No	Yes	No
CloudWatch Enhanced Container Insights	Yes	No	No	No
CloudWatch Application Signals (Application	Yes	No	Yes	Yes

Feature	CloudWatch agent (recommended)	Upstream OpenTelemetry Collector	Custom OpenTelemetry Collector	Collectorless with AWS Distro for OpenTelemetry (ADOT) SDK
performance metrics, service discovery, and application map)				
Telemetry supported	Logs, Metrics, Traces	Logs, Metrics, Traces	Logs, Metrics, Traces	Metrics, Traces

> **Note**
>
> Make sure Transaction Search is enabled before you use the OTLP Endpoint for traces.

> **Note**
>
> AWS supports telemetry that you send to AWS destinations through the CloudWatch OTLP endpoints.

Topics

- Amazon CloudWatch agent
- OpenTelemetry Collector
- Build your own custom OpenTelemetry Collector
- Exporting collector-less telemetry using AWS Distro for OpenTelemetry (ADOT) SDK
- AWS vended metrics in OpenTelemetry format

Amazon CloudWatch agent

The CloudWatch agent is built on the OpenTelemetry Collector, so you can use it to receive OpenTelemetry data and send it to the CloudWatch OTLP endpoints. For most customers, this is the recommended way to send OpenTelemetry telemetry to CloudWatch, because a single agent can also power curated experiences such as CloudWatch Application Signals and CloudWatch Enhanced Container Insights.

To send OpenTelemetry data through the agent today, you supply an OpenTelemetry collector configuration in YAML and append it to the agent's own configuration. Start the agent with your CloudWatch agent configuration file, then append the OpenTelemetry YAML file:

```
/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -c
 file:/tmp/agent.json -s
/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a append-config -c
 file:/tmp/otel.yaml -s
```

The agent merges the two configurations on startup and logs the resolved configuration. To avoid merge conflicts with pipelines that the agent creates automatically, add a custom suffix to each component and pipeline name in your OpenTelemetry YAML (for example, `otlphttp/cwagent`).

Supported OpenTelemetry components

The following OpenTelemetry components are available for you to configure in your appended YAML configuration. Use the component type name shown here as the key in your YAML.

Component type	Available components
Receivers	`otlp`, `prometheus` , `statsd`, `collectd`, `jmx`, `hostmetrics` , `filelog`, `tcplog`, `udplog`, `jaeger`, `zipkin`, `kafka`, `kubeletstats`
Processors	`batch`, `memory_limiter` , `filter`, `attributes` , `resource`, `resourcedetection` , `metricstransform` , `transform` , `cumulativetodelta` , `deltatocumulative` , `deltatorate` , `groupbyattrs` , `groupbytrace` , `k8sattributes` , `metricsgeneration` , `metricstarttime` , `probabilistic_sampler` , `span`, `tail_sampling`

Component type	Available components
Exporters	`otlphttp`, `awsemf`, `awscloudwatchlogs` , `awsxray`, `prometheusremotewrite` , `debug`
Extensions	`sigv4auth` , `headers_setter` , `file_storage` , `health_check` , `pprof`, `zpages`

The CloudWatch agent only supports writing telemetry to AWS destinations.

Configuration examples

The following examples send each signal to the corresponding CloudWatch OTLP endpoint using the `otlphttp` exporter and the `sigv4auth` extension. Each component and pipeline name uses a `/cwagent` suffix to avoid conflicts with pipelines that the agent creates automatically. Replace *`region`* with your AWS Region.

Metrics

```
receivers:
  otlp/cwagent:
    protocols:
      http:
        endpoint: 0.0.0.0:4318
processors:
  batch/cwagent: {}
exporters:
  otlphttp/cwagent:
    metrics_endpoint: https://monitoring.region.amazonaws.com/v1/metrics
    auth:
      authenticator: sigv4auth/cwagent
extensions:
  sigv4auth/cwagent:
    region: "region"
    service: "monitoring"
service:
  extensions: [sigv4auth/cwagent]
  pipelines:
    metrics/cwagent:
      receivers: [otlp/cwagent]
      processors: [batch/cwagent]
```

```
      exporters: [otlphttp/cwagent]
```

Logs

```
receivers:
  otlp/cwagent:
    protocols:
      http:
        endpoint: 0.0.0.0:4318
exporters:
  otlphttp/cwagent:
    logs_endpoint: https://logs.region.amazonaws.com/v1/logs
    headers:
      x-aws-log-group: my-log-group
      x-aws-log-stream: default
    auth:
      authenticator: sigv4auth/cwagent
extensions:
  sigv4auth/cwagent:
    region: "region"
    service: "logs"
service:
  extensions: [sigv4auth/cwagent]
  pipelines:
    logs/cwagent:
      receivers: [otlp/cwagent]
      exporters: [otlphttp/cwagent]
```

Traces

```
receivers:
  otlp/cwagent:
    protocols:
      http:
        endpoint: 0.0.0.0:4318
exporters:
  otlphttp/cwagent:
    traces_endpoint: https://xray.region.amazonaws.com/v1/traces
    auth:
      authenticator: sigv4auth/cwagent
extensions:
  sigv4auth/cwagent:
    region: "region"
```

```
    service: "xray"
service:
  extensions: [sigv4auth/cwagent]
  pipelines:
    traces/cwagent:
      receivers: [otlp/cwagent]
      exporters: [otlphttp/cwagent]
```

Note

Make sure Transaction Search is enabled before you send traces to the OTLP traces endpoint.

OpenTelemetry Collector

The OpenTelemetry Collector is an open source, vendor-agnostic agent that receives, processes, and exports telemetry data. It acts as a central pipeline between your applications and Amazon CloudWatch, collecting metrics, logs, and traces from multiple sources and sending them to CloudWatch using the OpenTelemetry Protocol (OTLP).

Using the OpenTelemetry Collector with CloudWatch provides the following benefits:

- Collect telemetry from multiple applications and hosts through a single agent, reducing the number of connections to CloudWatch.
- Process and filter telemetry before sending it to CloudWatch, including adding or removing attributes, batching data, and sampling traces.
- Use the same collector configuration across AWS, on-premises, and other cloud environments, providing a consistent telemetry pipeline regardless of where your applications run.
- Send metrics to CloudWatch with rich labels that are available to query using the Prometheus Query Language (PromQL) in CloudWatch Query Studio.

Supported receivers

The OpenTelemetry Collector supports a wide range of receivers for ingesting telemetry data. You can use OpenTelemetry receivers such as the OTLP receiver for applications instrumented with OpenTelemetry SDKs, or Prometheus receivers to scrape metrics from existing Prometheus exporters. Common Prometheus receivers used with CloudWatch include:

- Prometheus receiver, for scraping any Prometheus-compatible endpoint
- Host Metrics receiver, for collecting system-level metrics from the host
- Kubernetes Cluster receiver, for collecting cluster-level metrics from the Kubernetes API server

You can configure multiple receivers in a single collector, allowing you to collect both OpenTelemetry and Prometheus metrics and send them to CloudWatch through the same pipeline. For the full list of available receivers, see the OpenTelemetry Collector repository.

Getting started

Prerequisite – If using the OTLP endpoint for tracing, ensure that Transaction Search is enabled.

Steps:

1. Download the latest release of the OpenTelemetry Collector distribution. For more information, see the OpenTelemetry Collector releases.
2. Install the OpenTelemetry Collector on your host. The collector runs on any operating system and platform. For more information, see Install the Collector.
3. Configure AWS credentials on your Amazon EC2 or on-premises host. The collector uses these credentials to authenticate with CloudWatch when sending telemetry data. See below for details.

   Setup IAM permissions for Amazon EC2

   Follow the below procedure to attach the `CloudWatchAgentServerPolicy` IAM policy to the IAM role of your Amazon EC2 instance.

   1. Open the IAM console at https://console.aws.amazon.com/iam/.
   2. Choose **Roles** and find and select the role used by your Amazon EC2 instance.
   3. Under the **Permissions** tab, choose **Add permissions**, **Attach policies**.
   4. Using the search box, search for `CloudWatchAgentServerPolicy` policy.
   5. Select the **CloudWatchAgentServerPolicy** policy and choose **Add permissions**.

Setup IAM permissions for on-premise hosts

You can create an IAM user that can be used to provide permissions to your on-premise hosts.

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose **Users**, **Create User**.
3. Under **User details**,for **User name**, enter a name for the new IAM user. This is the sign-in name for AWS that will be used to authenticate your host.
4. Choose **Next**.
5. On the **Set permissions** page, under **Permissions options**, select **Attach policies directly**.
6. From the **Permissions policies** list, select the **CloudWatchAgentServerPolicy** policy to add to your user.
7. Choose **Next**.
8. On the **Review and create** page, ensure that you are satisfied with the user name and that the **CloudWatchAgentServerPolicy** policy is under the **Permissions summary**.
9. Choose **Create user**.
10. **Create and retrieve your AWS access key and secret key** – In the navigation pane in the IAM console, choose **Users** and then select the user name of the user that you created in the previous step.
11. On the user's page, choose the **Security credentials** tab.
12. Under the **Access keys** section, choose **Create access key**.
13. For **Create access key Step 1**, choose **Command Line Interface (CLI)**.
14. For **Create access key Step 2**, optionally enter a tag and then choose **Next**.
15. For **Create access key Step 3,** select **Download .csv file** to save a .csv file with your IAM user's access key and secret access key. You need this information for the next steps.
16. Choose **Done**.
17. Configure your AWS credentials in your on-premises host by entering the following command. Replace *ACCESS_KEY_ID* and *SECRET_ACCESS_ID* with your newly generated access key and secret access key from the .csv file that you downloaded in the previous step.

```
$ aws configure
AWS Access Key ID [None]: ACCESS_KEY_ID
AWS Secret Access Key [None]: SECRET_ACCESS_ID
Default region name [None]: MY_REGION
Default output format [None]: json
```

> **Tip**
>
> For on-premises hosts that only need to send metrics or logs, you can use bearer token authentication as a simpler alternative to configuring AWS access keys. Bearer tokens don't require the `aws configure` step or credential files on the host. For more information, see Setting up bearer token authentication for Metrics.

4. Setup AWS credentials for your Amazon EKS or Kubernetes clusters. The easiest way to get started with Amazon EKS is to use the EKS OTel Container Insights add-on. If you prefer to use the OpenTelemetry Collector directly, follow the procedure below to set up AWS credentials for your Amazon EKS or Kubernetes clusters to send telemetry to CloudWatch.

   Setup IAM permissions for Amazon EKS

   1. Create an IAM OIDC identity provider for your cluster using the following command.

      ```
      eksctl utils associate-iam-oidc-provider --cluster ${CLUSTER_NAME} --region
       ${REGION} --approve
      ```

   2. Assign IAM roles to Kubernetes service account for OTel Collector using the following command.

      ```
      eksctl create iamserviceaccount \
      --name ${COLLECTOR_SERVICE_ACCOUNT}\
      --namespace ${NAMESPACE} \
      --cluster ${CLUSTER_NAME} \
      --region ${REGION} \
      --attach-policy-arn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy \
      --approve \
      --override-existing-serviceaccounts
      ```

Setup IAM permissions for Kubernetes

1. Configure your AWS credentials in your on-premises host by entering the following command. Replace *ACCESS_KEY_ID* and *SECRET_ACCESS_ID* with your newly generated access key and secret access key from the .csv file that you downloaded in the previous step. By default, the credential file is saved under */home/user/.aws/credentials.*.

```
aws configure
AWS Access Key ID [None]: ACCESS_KEY_ID
AWS Secret Access Key [None]: SECRET_ACCESS_ID
Default region name [None]: MY_REGION
Default output format [None]: json
```

2. Edit OpenTelemetry Collector resource to add the newly created AWS credentials secret by using the command: `kubectl edit OpenTelemetryCollector otel_collector`
3. Using the file editor, add the AWS credentials into the OpenTelemetryCollector container by adding the following configuration to the top of the deployment. Replace the path */home/user/.aws/credentials* with the location of your local AWS credentials file.

```
 spec:
volumeMounts:
- mountPath: /rootfs
volumeMounts:
- name: aws-credentials
mountPath: /root/.aws
readOnly: true
volumes:
- hostPath:
path: /home/user/.aws/credentials
name: aws-credentials
```

5. Configure the OTLP exporter in your collector configuration to send telemetry to the CloudWatch endpoint. See examples below.

Authenticate with a bearer token (API key)

If you don't need to configure AWS credentials on the host – for example, when running on non-AWS infrastructure, other cloud providers, or CI/CD pipelines – you can use bearer token authentication instead of SigV4. Bearer tokens are supported for the metrics and logs endpoints (separate API keys are required for each service). Bearer token authentication is not supported for traces.

For setup instructions, see Setting up bearer token authentication for Metrics. For logs, see Setting up bearer token authentication for Logs.

For a collector configuration example using bearer tokens, see the bearer token metrics example in the collector configuration examples below.

Collector configuration examples

Copy and paste the content below to configure your collector to send logs and traces to the OTLP endpoints.

```
receivers:
  otlp:
    protocols:
      grpc:
        endpoint: 0.0.0.0:4317
      http:
        endpoint: 0.0.0.0:4318

exporters:
  otlphttp/logs:
    compression: gzip
    logs_endpoint: logs_otlp_endpoint
    headers:
      x-aws-log-group: ency_log_group
      x-aws-log-stream: default
    auth:
      authenticator: sigv4auth/logs

  otlphttp/traces:
    compression: gzip
    traces_endpoint: traces_otlp_endpoint
    auth:
      authenticator: sigv4auth/traces
```

```
extensions:
  sigv4auth/logs:
    region: "region"
    service: "logs"
  sigv4auth/traces:
    region: "region"
    service: "xray"

service:
  telemetry:
  extensions: [sigv4auth/logs, sigv4auth/traces]
  pipelines:
    logs:
      receivers: [otlp]
      exporters: [otlphttp/logs]
    traces:
      receivers: [otlp]
      exporters: [otlphttp/traces]
```

The following is an example to send logs and traces using sigv4 to us-east-1.

```
receivers:
  otlp:
    protocols:
      grpc:
        endpoint: 0.0.0.0:4317
      http:
        endpoint: 0.0.0.0:4318

exporters:
  otlphttp/logs:
    compression: gzip
    logs_endpoint: https://logs.us-east-1.amazonaws.com/v1/logs
    headers:
      x-aws-log-group: MyApplicationLogs
      x-aws-log-stream: default
    auth:
      authenticator: sigv4auth/logs

  otlphttp/traces:
```

```
    compression: gzip
    traces_endpoint: https://xray.us-east-1.amazonaws.com/v1/traces
    auth:
      authenticator: sigv4auth/traces

extensions:
  sigv4auth/logs:
    region: "us-east-1"
    service: "logs"
  sigv4auth/traces:
    region: "us-east-1"
    service: "xray"

service:
  telemetry:
  extensions: [sigv4auth/logs, sigv4auth/traces]
  pipelines:
    logs:
     receivers: [otlp]
      exporters: [otlphttp/logs]
    traces:
      receivers: [otlp]
      exporters: [otlphttp/traces]
```

Note

Configure your OpenTelemetry SDKs to *always_on* sampling configuration to reliably record 100% spans and get full visibility into your critical applications with CloudWatch Application Signals. For more information, see an OpenTelemetry Java SDK sampler configuration example. For an example on setting up OpenTelemetry Collector with X-Ray OTLP endpoint, see the application signals demo repository.

Copy and paste the content below to configure your collector to send metrics to the OTLP endpoints.

```
receivers:
  otlp:
    protocols:
```

```
      http:
        endpoint: "0.0.0.0:4318"

processors:
  batch:
    send_batch_size: 200
    timeout: 10s

exporters:
  otlphttp:
    tls:
      insecure: false
    endpoint: metrics_otlp_endpoint
    auth:
      authenticator: sigv4auth

extensions:
  sigv4auth:
    service: "monitoring"
    region: "region"

service:
  extensions: [sigv4auth]
  pipelines:
    metrics:
      receivers: [otlp]
      processors: [batch]
      exporters: [otlphttp]
```

The following is an example to send metrics using sigv4 to us-east-1.

```
receivers:
  otlp:
    protocols:
      http:
        endpoint: "0.0.0.0:4318"

processors:
  batch:
    send_batch_size: 200
    timeout: 10s
```

```
exporters:
  otlphttp:
    tls:
      insecure: false
    endpoint: "https://monitoring.us-east-1.amazonaws.com/v1/metrics:443"
    auth:
      authenticator: sigv4auth

extensions:
  sigv4auth:
    service: "monitoring"
    region: "us-east-1"

service:
  extensions: [sigv4auth]
  pipelines:
    metrics:
      receivers: [otlp]
      processors: [batch]
      exporters: [otlphttp]
```

Metrics with bearer token authentication

The following is an example to send metrics using a bearer token to us-east-1. For setup instructions and security best practices, see Setting up bearer token authentication for Metrics.

```
extensions:
  bearertokenauth:
    filename: "/etc/otel/cw-api-key"

receivers:
  otlp:
    protocols:
      http:
        endpoint: "0.0.0.0:4318"

processors:
  batch:
    send_batch_size: 200
    timeout: 10s

exporters:
```

```
  otlphttp:
    tls:
      insecure: false
    endpoint: "https://monitoring.us-east-1.amazonaws.com/v1/metrics"
    auth:
      authenticator: bearertokenauth

service:
  extensions: [bearertokenauth]
  pipelines:
    metrics:
      receivers: [otlp]
      processors: [batch]
      exporters: [otlphttp]
```

Important

Never hardcode API keys directly in collector configuration files. Use `filename` to read from a mounted secret, or `${env:VAR}` to read from an environment variable injected by your secrets manager.

Note

Unlike SigV4, bearer tokens don't require AWS credentials files, IAM roles, or IRSA configuration. The collector can run on any platform without AWS SDK dependencies.

Build your own custom OpenTelemetry Collector

You can build your own custom OpenTelemetry Collector to get the best application observability experience in CloudWatch with OpenTelemetry. In this setup, you need to build your own OpenTelemetry Collector with open source CloudWatch components.

Prerequisite

Make sure *Transaction Search* is enabled in CloudWatch. For more information, see Transaction Search.

Build your own collector

You can build your own collector with the following configuration to monitor your application in CloudWatch with OpenTelemetry. For more information, see Building a custom collector.

The common configuration for CloudWatch.

```
dist:
  name: otelcol-dev
  description: OTel Collector for sending telemetry to CloudWatch.
  output_path: ./otelcol-dev
extensions:
  - gomod: github.com/open-telemetry/opentelemetry-collector-contrib/extension/
sigv4authextension v0.111.0
  - gomod: github.com/open-telemetry/opentelemetry-collector-contrib/extension/awsproxy
 v0.113.0
exporters:
  - gomod: go.opentelemetry.io/collector/exporter/otlpexporter v0.111.0
  - gomod: go.opentelemetry.io/collector/exporter/otlphttpexporter v0.111.0
receivers:
  - gomod: go.opentelemetry.io/collector/receiver/otlpreceiver v0.111.0
```

Additional configuration for traces.

```
# Enable Tracing
dist:
  name: otelcol-dev
  description: OTel Collector for sending telemetry to CloudWatch.
  output_path: ./otelcol-dev
extensions:
    #Include common configurations and your custom extensions

exporters:
    #Include common configurations and your custom extensions

receivers:
  - gomod: go.opentelemetry.io/collector/receiver/otlpreceiver v0.111.0
processors:
  - gomod: github.com/amazon-contributing/opentelemetry-collector-contrib/processor/
awsapplicationsignalsprocessor v0.113.0
```

```
  - gomod: github.com/open-telemetry/opentelemetry-collector-contrib/processor/
resourcedetectionprocessor v0.113.0
  - gomod: github.com/open-telemetry/opentelemetry-collector-contrib/processor/
metricstransformprocessor v0.113.0
replaces:
  - github.com/open-telemetry/opentelemetry-collector-contrib/internal/aws/awsutil
 v0.113.0 => github.com/amazon-contributing/opentelemetry-collector-contrib/internal/
aws/awsutil v0.113.0
  - github.com/open-telemetry/opentelemetry-collector-contrib/internal/aws/cwlogs
 v0.113.0 => github.com/amazon-contributing/opentelemetry-collector-contrib/internal/
aws/cwlogs v0.113.0
  - github.com/open-telemetry/opentelemetry-collector-contrib/exporter/awsemfexporter
 v0.113.0 => github.com/amazon-contributing/opentelemetry-collector-contrib/exporter/
awsemfexporter v0.113.0
  - github.com/openshift/api v3.9.0+incompatible => github.com/openshift/api
 v0.0.0-20180801171038-322a19404e37
```

Note

Note the following:

- After the collector is built, deploy and configure the custom collector in a host or kubernetes environment by following the procedure under OpenTelemetry Collector.
- For information on setting up custom OpenTelemetry collector with Application Signals Processor, see an Application Signals custom configurationexample. Application Signals Processor only supports the latest versions of the OpenTelemetry Collectors for custom builds. For information on the supported versions, see opentelemetry-collector-contrib repository.

Exporting collector-less telemetry using AWS Distro for OpenTelemetry (ADOT) SDK

You can use the ADOT SDKs to go collector-less and to send metrics, traces and logs directly to the OTLP endpoints.

> **Note**
>
> Application Signals includes Transaction Search capabilities. To avoid duplicate costs, disable Application Signals in the ADOT SDK and keep `OTEL_AWS_APPLICATION_SIGNALS_ENABLED` set to false (default setting).

Topics

- Prerequisite
- Set up IAM permissions for your role
- Configure your credentials providers
- Enabling ADOT SDKs

Prerequisite

If you are using traces, make sure Transaction Search is enabled to send spans to the X-Ray OTLP endpoint. For more information, see Getting started with Transaction Search.

Set up IAM permissions for your role

Follow these steps to attach the necessary IAM policies to your role:

Traces:

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose **Roles** and find and select your configured role.
3. Under the **Permissions** tab, choose **Add permissions**, then **Attach policies**.
4. Using the search box, search for the `AWSXrayWriteOnlyPolicy`.
5. Select the `AWSXrayWriteOnlyPolicy` policy and choose **Add permissions**.

Logs:

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose **Roles** and find and select your configured role.
3. Under the **Permissions** tab, choose **Add permissions**, then **Create inline policy**.

4. Select **CloudWatch Logs** for the service and under **Actions allowed**, filter and select:

```
logs:PutLogEvents
logs:DescribeLogGroups
logs:DescribeLogStreams
```

5. The following is an example IAM policy that grants the required permissions:

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "CloudWatchLogsAccess",
            "Effect": "Allow",
            "Action": [
                "logs:PutLogEvents",
                "logs:DescribeLogGroups",
                "logs:DescribeLogStreams"

            ],
            "Resource": [
                "arn:aws:logs:*:*:log-group:*"
            ]
        }
    ]
}
```

Configure your credentials providers

ADOT uses the AWS SDKs to automatically discover valid credentials required to export your telemetry data to AWS. For guidance on configuring credentials for your specific environment, refer to the documentation on how the AWS SDKS retrieves credentials.

Setting up IAM credentials for on-premise hosts:

Configure your AWS credentials in your on-premises host by entering the following command. Replace **ACCESS_KEY_ID** and **SECRET_ACCESS_KEY** with the credentials for your configured IAM role or user.

```
$ aws configure
AWS Access Key ID [None]: ACCESS_KEY_ID
AWS Secret Access Key [None]: SECRET_ACCESS_ID
Default region name [None]: MY_REGION
Default output format [None]: json
```

Enabling ADOT SDKs

You can enable logs and traces for your application to be sent directly to the OTLP endpoints from AWS Distro for OpenTelemetry (ADOT) SDK on Java, Node.js, Python, and .Net.

Note

When you send traces directly to the OTLP endpoint without using a collector, the SDK defaults to `parentbased_always_on`, which samples 100% of traces. This can result in up to 20x higher ingestion volume and costs compared to the recommended 5% sampling rate.
If you plan to use Transaction Search for 100% trace visibility, no action is needed. If you want to moderate trace ingestion, configure a local sampler by setting the following environment variables before starting your application:

```
export OTEL_TRACES_SAMPLER="parentbased_traceidratio"
export OTEL_TRACES_SAMPLER_ARG="0.05"
```

The example above samples 5% of traces. Adjust the value of `OTEL_TRACES_SAMPLER_ARG` between `0` and `1` to set the sampling rate appropriate for your workload.
For more information about sampler configuration options, see OTEL_TRACES_SAMPLER in the OpenTelemetry documentation.

Java

Note

You must use **ADOT Java Agent version 2.11.2 or later** for these features to be available.

1. Download the latest version of the AWS Distro for OpenTelemetry Java auto-instrumentation agent. You can download the latest version by using this command:

   ```
   curl -L -O https://github.com/aws-observability/aws-otel-java-instrumentation/
   releases/latest/download/aws-opentelemetry-agent.jar
   ```

   You can view information about all released versions at aws-otel-java-instrumentation Releases.

2. To enable the different exporter that directly sends telemetry to the OTLP endpoints and to optimize benefits, use the following environment variables before you start your application:

   Traces:

   - Set `OTEL_EXPORTER_OTLP_TRACES_ENDPOINT` to specify the X-Ray OTLP traces endpoint: `https://xray.[`*`AWSRegion`*`].amazonaws.com/v1/traces`

     For example:

     ```
     export OTEL_EXPORTER_OTLP_TRACES_ENDPOINT="https://xray.us-
     west-2.amazonaws.com/v1/traces"
     ```

   - Set `OTEL_TRACES_EXPORTER` to `otlp` (this is optional and is the default value if this environment variable is not set).
   - Set `OTEL_EXPORTER_OTLP_TRACES_PROTOCOL` variable to `http/protobuf` (this is optional and is the default value if this environment variable is not set).
   - Set `OTEL_RESOURCE_ATTRIBUTES` variable to specify the following information as key-value pairs. These environment variables are used by Application Signals, and is converted into X-Ray trace annotations and CloudWatch metric dimensions.:
     - (Optional) `service.name` sets the name of the service. This will be displayed as the service name for your application in Application Signals dashboards. If you don't provide a value for this key, the default of `UnknownService` is used.
     - (Optional) `deployment.environment` sets the environment that the application runs in. This will be displayed as the **Hosted In** environment of your application.
     - (Optional) To enable log correlation, in `OTEL_RESOURCE_ATTRIBUTES`, set an additional environment variable `aws.log.group.names` for the log groups of your application. By doing so, the traces and metrics from your application can be

correlated with the relevant log entries from these log groups. For this variable, replace `$YOUR_APPLICATION_LOG_GROUP` with the log group names for your application. If you have multiple log groups, you can use an ampersand (&) to separate them as in this example: `aws.log.group.names=log-group-1&log-group-2`. To enable metric to log correlation, setting this current environmental variable is enough. For more information, see Enable metric to log correlation. To enable trace to log correlation, you'll also need to change the logging configuration in your application. For more information, see Enable trace to log correlation.

Logs:

- Set `OTEL_EXPORTER_OTLP_LOGS_ENDPOINT` to specify the CloudWatch OTLP logs endpoint: `https://logs.[AWSRegion].amazonaws.com/v1/logs`

  For example:

  ```
  export OTEL_EXPORTER_OTLP_LOGS_ENDPOINT="https://logs.us-west-2.amazonaws.com/v1/logs"
  ```

- Set `OTEL_EXPORTER_OTLP_LOGS_HEADERS` to specify the log group and log stream (note: these must created **before** running ADOT) you want to export your logs to: `x-aws-log-group=[CW-LOG-GROUP-NAME],x-aws-log-stream=[CW-LOG-STREAM-NAME]`

  For example:

  ```
  export OTEL_EXPORTER_OTLP_LOGS_HEADERS=x-aws-log-group=MyLogGroup,x-aws-log-stream=default
  ```

- Set `OTEL_LOGS_EXPORTER` to `otlp` (this is optional and is the default value if this environment variable is not set).
- Set `OTEL_EXPORTER_OTLP_LOGS_PROTOCOL` variable to `http/protobuf` (this is optional and is the default value if this environment variable is not set).

3. Set `JAVA_TOOL_OPTIONS` to specify the path where the AWS Distro for OpenTelemetry Java auto-instrumentation agent is stored. For example:

```
export JAVA_TOOL_OPTIONS=" -javaagent:$AWS_ADOT_JAVA_INSTRUMENTATION_PATH"
export AWS_ADOT_JAVA_INSTRUMENTATION_PATH="./aws-opentelemetry-agent.jar"
```

4. Your application should now be running with ADOT Java instrumentation and will generate spans and logs. Spans will be stored in the `aws/spans` CloudWatch log group, while logs will be stored in the log group specified in the `OTEL_EXPORTER_OTLP_LOGS_HEADERS` header. You can also view the logs and metrics correlated with your spans in the CloudWatch Traces and Metrics Console.
5. Start your application with the environment variables listed in the previous step. The following is an example of a starting script.

```
JAVA_TOOL_OPTIONS=" -javaagent:$AWS_ADOT_JAVA_INSTRUMENTATION_PATH" \
OTEL_METRICS_EXPORTER=none \
OTEL_TRACES_EXPORTER=otlp \
OTEL_EXPORTER_OTLP_TRACES_PROTOCOL=http/protobuf \
OTEL_EXPORTER_OTLP_TRACES_ENDPOINT=https://xray.us-east-1.amazonaws.com/v1/
traces \
OTEL_LOGS_EXPORTER=otlp \
OTEL_EXPORTER_OTLP_LOGS_PROTOCOL=http/protobuf \
OTEL_EXPORTER_OTLP_LOGS_ENDPOINT=https://logs.us-east-1.amazonaws.com/v1/logs \
OTEL_EXPORTER_OTLP_LOGS_HEADERS=x-aws-log-group=MyLogGroup,x-aws-log-
stream=default
OTEL_RESOURCE_ATTRIBUTES="service.name=$YOUR_SVC_NAME" \
java -jar $MY_JAVA_APP.jar
```

Node.js

> **Note**
>
> You must use **ADOT JavaScript version 0.7.0 or later** for these features to be available.

1. Download the latest version of the AWS Distro for OpenTelemetry JavaScript auto-instrumentation. Install it by running the following command.

```
npm install @aws/aws-distro-opentelemetry-node-autoinstrumentation
```

You can view information about all released versions at aws-otel-js-instrumentation Releases.

2. To enable the different exporter that directly sends telemetry to the OTLP endpoints and to optimize benefits, use the following environment variables before you start your application:

   Traces:

   - Set `OTEL_EXPORTER_OTLP_TRACES_ENDPOINT` to specify the X-Ray OTLP traces endpoint: `https://xray.[AWSRegion].amazonaws.com/v1/traces`

     For example:

     ```
     export OTEL_EXPORTER_OTLP_TRACES_ENDPOINT="https://xray.us-
     west-2.amazonaws.com/v1/traces"
     ```

   - Set `OTEL_TRACES_EXPORTER` to `otlp` (this is optional and is the default value if this environment variable is not set).
   - Set `OTEL_EXPORTER_OTLP_TRACES_PROTOCOL` variable to `http/protobuf` (this is optional and is the default value if this environment variable is not set).
   - Set `OTEL_RESOURCE_ATTRIBUTES` variable to specify the following information as key-value pairs. These environment variables are used by Application Signals, and is converted into X-Ray trace annotations and CloudWatch metric dimensions.:
     - (Optional) `service.name` sets the name of the service. This will be displayed as the service name for your application in Application Signals dashboards. If you don't provide a value for this key, the default of `UnknownService` is used.
     - (Optional) `deployment.environment` sets the environment that the application runs in. This will be diplayed as the **Hosted In** environment of your application.
     - (Optional) To enable log correlation, in `OTEL_RESOURCE_ATTRIBUTES`, set an additional environment variable `aws.log.group.names` for the log groups of your application. By doing so, the traces and metrics from your application can be correlated with the relevant log entries from these log groups. For this variable, replace `$YOUR_APPLICATION_LOG_GROUP` with the log group names for your application. If you have multiple log groups, you can use an ampersand (&) to separate them as in this example: `aws.log.group.names=log-group-1&log-group-2`. To enable metric to log correlation, setting this current environmental variable is enough. For more information, see Enable metric to log correlation. To enable trace to log correlation, you'll also need to change the logging configuration in your application. For more information, see Enable trace to log correlation.

Logs:

- Set `OTEL_EXPORTER_OTLP_LOGS_ENDPOINT` to specify the CloudWatch OTLP logs endpoint: `https://logs.[AWSRegion].amazonaws.com/v1/logs`

  For example:

  ```
  export OTEL_EXPORTER_OTLP_LOGS_ENDPOINT="https://logs.us-west-2.amazonaws.com/v1/logs"
  ```

- Set `OTEL_EXPORTER_OTLP_LOGS_HEADERS` to specify the log group and log stream (note: these must created **before** running ADOT) you want to export your logs to: `x-aws-log-group=[CW-LOG-GROUP-NAME],x-aws-log-stream=[CW-LOG-STREAM-NAME]`

  For example:

  ```
  export OTEL_EXPORTER_OTLP_LOGS_HEADERS=x-aws-log-group=MyLogGroup,x-aws-log-stream=default
  ```

- Set `OTEL_LOGS_EXPORTER` to `otlp` (this is optional and is the default value if this environment variable is not set).
- Set `OTEL_EXPORTER_OTLP_LOGS_PROTOCOL` variable to `http/protobuf` (this is optional and is the default value if this environment variable is not set).

3. Your application should now be running with ADOT JavaScript instrumentation and will generate spans and logs. Spans will be stored in the `aws/spans` CloudWatch log group, while logs will be stored in the log group specified in the `OTEL_EXPORTER_OTLP_LOGS_HEADERS` header. You can also view the logs and metrics correlated with your spans in the CloudWatch Traces and Metrics Console.
4. Start your application with the environment variables listed in the previous step. The following is an example of a starting script.

   Replace `$SVC_NAME` with your application name. This will be displayed as the name of the application.

   ```
   OTEL_METRICS_EXPORTER=none \
   OTEL_TRACES_EXPORTER=otlp \
   OTEL_EXPORTER_OTLP_TRACES_PROTOCOL=http/protobuf \
   ```

```
OTEL_EXPORTER_OTLP_TRACES_ENDPOINT=https://xray.us-east-1.amazonaws.com/v1/
traces \
OTEL_LOGS_EXPORTER=otlp \
OTEL_EXPORTER_OTLP_LOGS_PROTOCOL=http/protobuf \
OTEL_EXPORTER_OTLP_LOGS_ENDPOINT=https://logs.us-east-1.amazonaws.com/v1/logs \
OTEL_EXPORTER_OTLP_LOGS_HEADERS=x-aws-log-group=MyLogGroup,x-aws-log-
stream=default
OTEL_RESOURCE_ATTRIBUTES="service.name=$YOUR_SVC_NAME" \
node --require '@aws/aws-distro-opentelemetry-node-autoinstrumentation/register'
 your-application.js
```

Python

> **Note**
>
> You must use **ADOT Python version 0.10.0 or later** and have **`botocore`** installed for these features to be available.

1. Download the latest version of the AWS Distro for OpenTelemetry Python auto-instrumentation. Install it by running the following command.

   ```
   pip install aws-opentelemetry-distro
   ```

   You can view information about all released versions at aws-otel-python-instrumentation Releases.

2. To enable the different exporter that directly sends telemetry to the OTLP endpoints and to optimize benefits, use the following environment variables before you start your application:

   For both traces and logs configurations, you must set the following environment variables:

   - `OTEL_PYTHON_DISTRO` to `aws_distro`
   - `OTEL_PYTHON_CONFIGURATOR` to `aws_configurator`

   Traces:

- Set `OTEL_EXPORTER_OTLP_TRACES_ENDPOINT` to specify the X-Ray OTLP traces endpoint: `https://xray.[AWSRegion].amazonaws.com/v1/traces`

  For example:

  ```
  export OTEL_EXPORTER_OTLP_TRACES_ENDPOINT="https://xray.us-
  west-2.amazonaws.com/v1/traces"
  ```

- Set `OTEL_TRACES_EXPORTER` to `otlp` (this is optional and is the default value if this environment variable is not set).
- Set `OTEL_EXPORTER_OTLP_TRACES_PROTOCOL` variable to `http/protobuf` (this is optional and is the default value if this environment variable is not set).
- Set `OTEL_RESOURCE_ATTRIBUTES` variable to specify the following information as key-value pairs. These environment variables are used by Application Signals, and is converted into X-Ray trace annotations and CloudWatch metric dimensions.:
  - (Optional) `service.name` sets the name of the service. This will be displayed as the service name for your application in Application Signals dashboards. If you don't provide a value for this key, the default of `UnknownService` is used.
  - (Optional) `deployment.environment` sets the environment that the application runs in. This will be diplayed as the **Hosted In** environment of your application.
  - (Optional) To enable log correlation, in `OTEL_RESOURCE_ATTRIBUTES`, set an additional environment variable `aws.log.group.names` for the log groups of your application. By doing so, the traces and metrics from your application can be correlated with the relevant log entries from these log groups. For this variable, replace `$YOUR_APPLICATION_LOG_GROUP` with the log group names for your application. If you have multiple log groups, you can use an ampersand (&) to separate them as in this example: `aws.log.group.names=log-group-1&log-group-2`. To enable metric to log correlation, setting this current environmental variable is enough. For more information, see Enable metric to log correlation. To enable trace to log correlation, you'll also need to change the logging configuration in your application. For more information, see Enable trace to log correlation.

Logs:

- Set `OTEL_PYTHON_LOGGING_AUTO_INSTRUMENTATION_ENABLED` to `true`

- Set `OTEL_EXPORTER_OTLP_LOGS_ENDPOINT` to specify the CloudWatch OTLP logs endpoint: `https://logs.[AWSRegion].amazonaws.com/v1/logs`

  For example:

  ```
  export OTEL_EXPORTER_OTLP_LOGS_ENDPOINT="https://logs.us-west-2.amazonaws.com/v1/logs"
  ```

- Set `OTEL_EXPORTER_OTLP_LOGS_HEADERS` to specify the log group and log stream (note: these must created **before** running ADOT) you want to export your logs to: `x-aws-log-group=[CW-LOG-GROUP-NAME],x-aws-log-stream=[CW-LOG-STREAM-NAME]`

  For example:

  ```
  export OTEL_EXPORTER_OTLP_LOGS_HEADERS=x-aws-log-group=MyLogGroup,x-aws-log-stream=default
  ```

- Set `OTEL_LOGS_EXPORTER` to `otlp` (this is optional and is the default value if this environment variable is not set).
- Set `OTEL_EXPORTER_OTLP_LOGS_PROTOCOL` variable to `http/protobuf` (this is optional and is the default value if this environment variable is not set).

3. Your application should now be running with ADOT Python instrumentation and will generate spans and logs. Spans will be stored in the `aws/spans` CloudWatch log group, while logs will be stored in the log group specified in the `OTEL_EXPORTER_OTLP_LOGS_HEADERS` header. You can also view the logs and metrics correlated with your spans in the CloudWatch Traces and Metrics Console.
4. Start your application with the environment variables listed in the previous step. The following is an example of a starting script.

   Replace `$SVC_NAME` with your application name. This will be displayed as the name of the application.

   Replace `$PYTHON_APP` with the location and name of your application.

   ```
   OTEL_METRICS_EXPORTER=none \
   OTEL_TRACES_EXPORTER=otlp \
   OTEL_EXPORTER_OTLP_TRACES_PROTOCOL=http/protobuf \
   ```

```
OTEL_EXPORTER_OTLP_TRACES_ENDPOINT=https://xray.us-east-1.amazonaws.com/v1/
traces \
OTEL_LOGS_EXPORTER=otlp \
OTEL_EXPORTER_OTLP_LOGS_PROTOCOL=http/protobuf \
OTEL_EXPORTER_OTLP_LOGS_ENDPOINT=https://logs.us-east-1.amazonaws.com/v1/logs \
OTEL_EXPORTER_OTLP_LOGS_HEADERS=x-aws-log-group=MyLogGroup,x-aws-log-
stream=default
OTEL_PYTHON_LOGGING_AUTO_INSTRUMENTATION_ENABLED=true
OTEL_RESOURCE_ATTRIBUTES="service.name=$YOUR_SVC_NAME" \
opentelemetry-instrument python $MY_PYTHON_APP.py
```

.Net

> **Note**
>
> - **ADOT .NET version 1.8.0 or later** is required for these features to be available.
> - Compression is currently not supported.
> - Logs is currently not supported.

Download the latest version of the AWS Distro for OpenTelemetry .NET auto-instrumentation package. You can view information about all released versions at aws-otel-dotnet-instrumentation Releases.

To enable the different exporters that directly sends telemetry to the OTLP endpoints and to optimize benefits, use the following environment variables before you start your application (replace `dotnet-service-name` in the `OTEL_RESOURCE_ATTRIBUTES` environment variable with the service name of your choice):

Traces:

- You **MUST** set `OTEL_TRACES_EXPORTER` to none
- You **MUST** set `OTEL_AWS_SIG_V4_ENABLED` to `true`

  This feature is **not enabled automatically in .NET**. The environment variable is required specifically to identify this use case within the .NET instrumentation. This requirement is unique to .NET and does **not apply to other supported languages**.

The following is an example setup for Linux.

```
export INSTALL_DIR=OpenTelemetryDistribution
export CORECLR_ENABLE_PROFILING=1
export CORECLR_PROFILER={918728DD-259F-4A6A-AC2B-B85E1B658318}
export CORECLR_PROFILER_PATH=${INSTALL_DIR}/linux-x64/
OpenTelemetry.AutoInstrumentation.Native.so
export DOTNET_ADDITIONAL_DEPS=${INSTALL_DIR}/AdditionalDeps
export DOTNET_SHARED_STORE=${INSTALL_DIR}/store
export DOTNET_STARTUP_HOOKS=${INSTALL_DIR}/net/
OpenTelemetry.AutoInstrumentation.StartupHook.dll
export OTEL_DOTNET_AUTO_HOME=${INSTALL_DIR}

export
 OTEL_DOTNET_AUTO_PLUGINS="AWS.Distro.OpenTelemetry.AutoInstrumentation.Plugin,
 AWS.Distro.OpenTelemetry.AutoInstrumentation"
export OTEL_TRACES_EXPORTER=none
export OTEL_AWS_SIG_V4_ENABLED=true

export OTEL_RESOURCE_ATTRIBUTES=service.name=dotnet-service-name
export OTEL_METRICS_EXPORTER=none
export OTEL_LOGS_EXPORTER=none
export OTEL_EXPORTER_OTLP_TRACES_PROTOCOL=http/protobuf
export OTEL_EXPORTER_OTLP_TRACES_ENDPOINT=https://xray.us-east-1.amazonaws.com/v1/
traces
```

The following is an example setup for Windows Server:

```
$env:INSTALL_DIR = "OpenTelemetryDistribution"
$env:CORECLR_ENABLE_PROFILING = 1
$env:CORECLR_PROFILER = "{918728DD-259F-4A6A-AC2B-B85E1B658318}"
$env:CORECLR_PROFILER_PATH = Join-Path $env:INSTALL_DIR "win-x64/
OpenTelemetry.AutoInstrumentation.Native.dll"
$env:DOTNET_ADDITIONAL_DEPS = Join-Path $env:INSTALL_DIR "AdditionalDeps"
$env:DOTNET_SHARED_STORE = Join-Path $env:INSTALL_DIR "store"
$env:DOTNET_STARTUP_HOOKS = Join-Path $env:INSTALL_DIR "net/
OpenTelemetry.AutoInstrumentation.StartupHook.dll"
$env:OTEL_DOTNET_AUTO_HOME = $env:INSTALL_DIR
$env:OTEL_DOTNET_AUTO_PLUGINS =
 "AWS.Distro.OpenTelemetry.AutoInstrumentation.Plugin,
 AWS.Distro.OpenTelemetry.AutoInstrumentation"

$env:OTEL_TRACES_EXPORTER=none
```

```
$env:OTEL_AWS_SIG_V4_ENABLED=true

$env:OTEL_RESOURCE_ATTRIBUTES=service.name=dotnet-service-name
$env:OTEL_METRICS_EXPORTER=none
$env:OTEL_LOGS_EXPORTER=none
$env:OTEL_EXPORTER_OTLP_TRACES_PROTOCOL=http/protobuf
$env:OTEL_EXPORTER_OTLP_TRACES_ENDPOINT=https://xray.us-east-1.amazonaws.com/v1/
traces
```

1. Start your application with the environment variables listed in the previous step.
2. (Optional) Alternatively, you can use the installation scripts provided to help installation and setup of AWS Distro for OpenTelemetry .NET auto-instrumentation package.

   For Linux, download and install the Bash installation script from the GitHub releases page:

   ```
   # Download and Install
   curl -L -O https://github.com/aws-observability/aws-otel-dotnet-instrumentation/
   releases/latest/download/aws-otel-dotnet-install.sh
   chmod +x ./aws-otel-dotnet-install.sh
   ./aws-otel-dotnet-install.sh
   # Instrument
   . $HOME/.otel-dotnet-auto/instrument.shexport
    OTEL_RESOURCE_ATTRIBUTES=service.name=dotnet-service-name
   ```

   For Windows Server, download and install the PowerShell installation script from the GitHub releases page:

   ```
   # Download and Install
   $module_url = "https://github.com/aws-observability/aws-otel-dotnet-
   instrumentation/releases/latest/download/AWS.Otel.DotNet.Auto.psm1"
   $download_path = Join-Path $env:temp "AWS.Otel.DotNet.Auto.psm1"
   Invoke-WebRequest -Uri $module_url -OutFile $download_path
   Import-Module $download_path
   Install-OpenTelemetryCore
   # Instrument
   Import-Module $download_path
   Register-OpenTelemetryForCurrentSession -OTelServiceName "dotnet-service-name"
   Register-OpenTelemetryForIIS
   ```

You can find the NuGet package of the AWS Distro for OpenTelemetry .NET auto-instrumentation package in the official NuGet repository. Be sure to check the README file for instructions.

AWS vended metrics in OpenTelemetry format

> **Tip**
>
> To learn more about OpenTelemetry on CloudWatch, check out the Cloud Operations Enablement workshop and event series.

You can enable OTel enrichment to make vended metrics for supported AWS resources queryable via PromQL. Once enabled, metrics that contain a resource identifier dimension (for example, EC2 CPUUtilization with an InstanceId dimension) are enriched with resource ARN and resource tag labels and become queryable using PromQL.

The enriched metric preserves the original metric name and CloudWatch dimensions, and adds:

- **Resource attributes** – the resource ARN (`cloud.resource_id`), cloud provider, region, and account ID.
- **Instrumentation scope** – identifies the source service and marks the metric as OTel-enriched.
- **Resource tags** – any AWS resource tags associated with the resource, queryable as PromQL labels.

The original classic CloudWatch metric is not modified and remains available through existing CloudWatch APIs.

Enabling OpenTelemetry enrichment for vended metrics

Before you start OTel enrichment, you must enable resource tags on telemetry for your account.

You can enable OTel enrichment for your account in a specific region using the CloudWatch console, AWS CLI, CloudFormation, Terraform, or AWS SDK.

You will need permissions for the following operation: `cloudwatch:StartOTelEnrichment`

To enable OTel enrichment for AWS metrics (CloudWatch Console)

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **CloudWatch**, then choose **Settings**.
3. In the **Enable OTel Enrichment for AWS Metrics** pane, toggle the feature On.

AWS CLI

```
aws cloudwatch start-otel-enrichment
```

CloudFormation

> **Note**
>
> The `AWS::CloudWatch::OTelEnrichment` resource requires the `AWS::ObservabilityAdmin::TelemetryEnrichment` resource to be configured first. For more information, see enable resource tags on telemetry.

```
Resources:
  TelemetryEnrichmentExample:
    Type: AWS::ObservabilityAdmin::TelemetryEnrichment
  OTelEnrichmentExample:
    Type: AWS::CloudWatch::OTelEnrichment
    DependsOn: TelemetryEnrichmentExample
```

Terraform

> **Note**
>
> The `aws_cloudwatch_otel_enrichment` Terraform resource requires the `aws_observabilityadmin_telemetry_enrichment` resource to be configured first.

```
resource "aws_observabilityadmin_telemetry_enrichment" "example" {
}
```

```
resource "aws_cloudwatch_otel_enrichment" "example" {
  depends_on = [aws_observabilityadmin_telemetry_enrichment.example]
}
```

For more information, see aws_cloudwatch_otel_enrichment in the Terraform Registry.

To enable across multiple regions, create the same resource in each regional stack or invoke the API in each region of interest.

Once enrichment is enabled, you can start querying vended metrics via PromQL. See: Querying vended AWS metrics with PromQL.

Setting up bearer token authentication for Metrics

Note

This page covers bearer token authentication for the CloudWatch Metrics OTLP endpoint. For CloudWatch Logs bearer token authentication, see Setting up bearer token authentication for Logs in the *CloudWatch Logs User Guide*.

Before you can send metrics using bearer token authentication with the CloudWatch OTLP endpoint, you need to:

- Create an IAM user with CloudWatch Metrics permissions
- Generate service-specific credentials (API key)

Important

We recommend using SigV4 authentication with short-term credentials for all workloads where this is possible. SigV4 provides the strongest security posture. Restrict the use of API keys (bearer tokens) to scenarios where short-term credential-based authentication is not feasible, such as sending metrics from non-AWS environments, third-party vendors, or platforms that do not support the AWS SDK. When you are ready to incorporate CloudWatch Metrics into applications with greater security requirements, switch to short-term credentials. For more information, see Alternatives to long-term access keys in the *IAM User Guide*.

> **Important**
>
> The CloudWatch OTLP endpoint requires TLS (HTTPS). Bearer token requests sent over plain HTTP are rejected. Always use `https://monitoring.AWS Region.amazonaws.com/v1/metrics` when configuring your client.

Option 1: Quick start using the AWS console

The AWS Management Console provides a streamlined workflow to generate API keys for OTLP endpoint access.

To set up OTLP endpoint access using the console

1. Sign in to the AWS Management Console.
2. Navigate to **CloudWatch** > **Settings** > **Global**.
3. In the API Keys section, choose **Generate API key**.
4. For **API key expiration**, do one of the following:
   - Select an API key expiration duration of **1**, **5**, **30**, **90**, or **365** days.
   - Choose **Custom duration** to specify a custom API key expiration date.
   - Select **Never expires** (not recommended).
5. Choose **Generate API key**.

The console automatically:

- Creates a new IAM user with appropriate permissions
- Attaches the CloudWatchAPIKeyAccess managed policy (includes `cloudwatch:PutMetricData` and `cloudwatch:CallWithBearerToken` permissions)
- Generates service-specific credentials (API key)

To save and verify your API key

1. Copy and securely save the displayed credentials:
   - **API Key ID** (Service-specific credential ID)

- **API Key Secret** (Bearer token)

The console also offers the option to store your API key directly in AWS Secrets Manager during generation. If you choose to store in Secrets Manager, the key is automatically updated on reset and deleted on key deletion.

> **Important**
>
> Save the API Key Secret immediately. You can't retrieve it later. If you lose it, you must generate a new API key.

2. Send a test metric to verify your setup:

```
curl -X POST "https://monitoring.us-east-1.amazonaws.com/v1/metrics" \
     -H "Content-Type: application/json" \
     -H "Authorization: Bearer YOUR_API_KEY" \
     -d '{"resourceMetrics":[]}'
```

Option 2: Manual setup

If you prefer more control over the IAM configuration or need to customize permissions, you can set up the OTLP endpoint access manually.

Step 1: Create an IAM user

Create an IAM user for metric ingestion:

To create an IAM user for metric ingestion

1. Sign in to the AWS Management Console and navigate to IAM.
2. In the left navigation pane, choose **Users**.
3. Choose **Create user**.
4. Enter a user name (for example, **`cloudwatch-metrics-api-key-user`**).
5. Choose **Next**.
6. Attach one of the following IAM policies:

Option A: Use the managed policy (recommended)

Attach the CloudWatchAPIKeyAccess managed policy.

Option B: Create a custom policy

Create and attach the following IAM policy:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "CloudWatchMetricsAPIs",
            "Effect": "Allow",
            "Action": [
                "cloudwatch:CallWithBearerToken",
                "cloudwatch:PutMetricData"
            ],
            "Resource": "*"
        },
        {
            "Sid": "KMSDecryptForCMKDatasets",
            "Effect": "Allow",
            "Action": [
                "kms:Decrypt"
            ],
            "Condition": {
                "StringLike": {
                    "kms:ViaService": "cloudwatch.*.amazonaws.com",
                    "kms:EncryptionContext:aws:cloudwatch:arn":
 "arn:aws:cloudwatch:*:*:dataset/*"
                }
            },
            "Resource": "arn:aws:kms:*:*:key/*"
        }
    ]
}
```

7. Choose **Next** and then choose **Create user**.

> **Note**
>
> The KMS permissions are required if you plan to send metrics to datasets that use customer-managed KMS keys (CMK). The conditions restrict KMS access to only keys used through the CloudWatch service for dataset resources.

Step 2: Generate service-specific credentials (API key)

Generate the CloudWatch Metrics API key using the CreateServiceSpecificCredential API. You can also use the create-service-specific-credential AWS CLI command. For the credential age, you can specify a value between 1–36600 days. If you don't specify a credential age, the API key won't expire.

To generate an API key with an expiration of 30 days:

```
aws iam create-service-specific-credential \
    --user-name cloudwatch-metrics-api-key-user \
    --service-name cloudwatch.amazonaws.com \
    --credential-age-days 30
```

The response is a ServiceSpecificCredential object. The `ServiceCredentialSecret` value is your CloudWatch Metrics API key (bearer token).

> **Important**
>
> Store the `ServiceCredentialSecret` value securely. You can't retrieve it later. If you lose it, you must generate a new API key.

Step 3: Send metrics

You can immediately send metrics to the OTLP endpoint using your bearer token:

```
curl -X POST "https://monitoring.us-east-1.amazonaws.com/v1/metrics" \
     -H "Content-Type: application/json" \
     -H "Authorization: Bearer YOUR_API_KEY" \
     -d '{"resourceMetrics":[]}'
```

The endpoint accepts both `application/json` and `application/x-protobuf` content types.

Control permissions for generating and using CloudWatch Metrics API keys

Controlling the generation of CloudWatch Metrics API keys

The `iam:CreateServiceSpecificCredential` action controls the generation of a service-specific key (such as a CloudWatch Metrics API key). You can scope this action to IAM users as a resource to limit the users for which a key can be generated.

You can use the following condition keys to impose conditions on the permission for the `iam:CreateServiceSpecificCredential` action:

- `iam:ServiceSpecificCredentialAgeDays` — Lets you specify, in the condition, the key's expiration time in days.
- `iam:ServiceSpecificCredentialServiceName` — Lets you specify, in the condition, the name of a service.

Controlling the usage of CloudWatch Metrics API keys

The `cloudwatch:CallWithBearerToken` action controls the use of a CloudWatch Metrics API key. To prevent an identity from using CloudWatch Metrics API keys, attach a policy that denies the `cloudwatch:CallWithBearerToken` action to the IAM user associated with the key.

> **Note**
>
> Bearer tokens for CloudWatch Metrics can only be used with the OTLP metrics ingestion endpoint (`https://monitoring.`*`AWS Region`*`.amazonaws.com/v1/metrics`). They cannot be used to call any other CloudWatch API or endpoint, including query APIs (`GetMetricData`, `ListMetrics`, `DescribeAlarms`), the PromQL query endpoint, the OTLP traces endpoint, or the OTLP logs endpoint.

Example policies

Prevent an identity from generating and using CloudWatch Metrics API keys:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DenyCWMetricsAPIKeys",
            "Effect": "Deny",
            "Action": [
                "iam:CreateServiceSpecificCredential",
                "cloudwatch:CallWithBearerToken"
            ],
            "Resource": "*"
        }
    ]
}
```

Warning

This policy prevents the creation of credentials for all AWS services that support creating service-specific credentials. For more information, see Service-specific credentials for IAM users in the *IAM User Guide*.

Prevent an identity from using CloudWatch Metrics API keys:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": "cloudwatch:CallWithBearerToken",
            "Resource": "*"
        }
    ]
}
```

Allow the creation of CloudWatch Metrics keys only if they expire within 90 days:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
```

```
            "Effect": "Allow",
            "Action": "iam:CreateServiceSpecificCredential",
            "Resource": "arn:aws:iam::123456789012:user/username",
            "Condition": {
                "StringEquals": {
                    "iam:ServiceSpecificCredentialServiceName":
 "cloudwatch.amazonaws.com"
                },
                "NumericLessThanEquals": {
                    "iam:ServiceSpecificCredentialAgeDays": "90"
                }
            }
        }
    ]
}
```

Using bearer tokens with the OpenTelemetry Collector

When using bearer tokens, you do not need the `sigv4auth` extension. Use the bearertokenauth extension to securely provide your API key from a file or environment variable:

```
extensions:
  bearertokenauth:
    filename: "/etc/otel/cw-api-key"

exporters:
  otlphttp:
    tls:
      insecure: false
    endpoint: https://monitoring.us-east-1.amazonaws.com/v1/metrics
    auth:
      authenticator: bearertokenauth

receivers:
  otlp:
    protocols:
      http:
        endpoint: 0.0.0.0:4318

processors:
  batch:
    send_batch_size: 200
    timeout: 10s
```

```
service:
  extensions: [bearertokenauth]
  pipelines:
    metrics:
      receivers: [otlp]
      processors: [batch]
      exporters: [otlphttp]
```

Alternatively, you can reference an environment variable instead of a file:

```
extensions:
  bearertokenauth:
    token: "${env:CW_API_KEY}"
```

Important

Never hardcode API keys directly in collector configuration files. Configuration files are often committed to version control or stored in deployment manifests. Use `filename` to read from a mounted secret, or `${env:VAR}` to read from an environment variable injected by your secrets manager.

Note

With bearer token authentication, you do not need the `sigv4auth` extension, AWS credentials files, IAM roles, or IRSA configuration. This makes the collector configuration portable across any environment — AWS, on-premises, or other cloud providers.

Rotating API keys

Regularly rotating your API keys reduces the risk of unauthorized access. We recommend establishing a rotation schedule that aligns with your organization's security policies.

Rotation process

To rotate an API key without interrupting metric delivery, follow this procedure:

To rotate an API key

1. Create a new (secondary) credential for the IAM user:

```
aws iam create-service-specific-credential \
    --user-name cloudwatch-metrics-api-key-user \
    --service-name cloudwatch.amazonaws.com \
    --credential-age-days 90
```

> **Note**
>
> IAM allows a maximum of 2 service-specific credentials per IAM user per service. Delete or deactivate old credentials before creating new ones if you have reached this limit.

2. (Optional) Store the new credential in AWS Secrets Manager for secure retrieval and automated rotation.
3. Update your OpenTelemetry Collector configuration or application to use the new API key.
4. Set the original credential to inactive:

```
aws iam update-service-specific-credential \
    --user-name cloudwatch-metrics-api-key-user \
    --service-specific-credential-id ACCA1234EXAMPLE1234 \
    --status Inactive
```

5. Verify that metric delivery is not impacted. Send a test request using the new key and confirm you receive an HTTP 200 response. You can also monitor your application's existing CloudWatch metrics to confirm data continues to arrive.
6. After confirming successful delivery with the new key, delete the previous credential:

```
aws iam delete-service-specific-credential \
    --service-specific-credential-id ACCA1234EXAMPLE1234
```

Monitoring key expiration

To check the creation date and status of your existing API keys, use the list-service-specific-credentials command:

```
aws iam list-service-specific-credentials \
```

```
    --user-name cloudwatch-metrics-api-key-user \
    --service-name cloudwatch.amazonaws.com
```

The response includes `CreateDate` and `Status` for each credential. Use this information to identify keys that are approaching expiration or have been active longer than your rotation policy allows.

Responding to a compromised API key

If you suspect that an API key has been compromised, take the following steps immediately:

To respond to a compromised API key

1. **Deactivate the key immediately** to prevent further unauthorized use:

   ```
   aws iam update-service-specific-credential \
       --user-name cloudwatch-metrics-api-key-user \
       --service-specific-credential-id ACCA1234EXAMPLE1234 \
       --status Inactive
   ```

2. **Review CloudTrail logs** to determine the scope of unauthorized access. See the section called "Logging API key usage with CloudTrail" for how to enable auditing of API key usage.
3. **Create a replacement key** following the rotation process described in the section called "Rotation process".
4. **Delete the compromised key** after the replacement is in place:

   ```
   aws iam delete-service-specific-credential \
       --service-specific-credential-id ACCA1234EXAMPLE1234
   ```

5. **Attach a deny policy** if you need to immediately block all bearer token access for the IAM user while you investigate:

   ```
   {
       "Version": "2012-10-17",
       "Statement": {
           "Effect": "Deny",
           "Action": "cloudwatch:CallWithBearerToken",
           "Resource": "*"
       }
   }
   ```

> **Note**
>
> To carry out these actions through the API, you must authenticate with AWS credentials and not with a CloudWatch Metrics API key. Bearer tokens can only be used for metric ingestion, not for IAM management operations.

You can also use the following IAM API operations to manage compromised keys:

- ResetServiceSpecificCredential — Reset the key to generate a new password without deleting the credential. The key must not have expired.

Security best practices for API keys

Follow these best practices to protect your CloudWatch Metrics API keys:

- **Never embed API keys in source code.** Do not hard-code API keys in application code, collector configuration files, or version control systems. Use the `bearertokenauth` extension with `filename` or `${env:VAR}` to inject secrets at runtime.
- **Use a secrets manager.** Store API keys in AWS Secrets Manager or an equivalent secrets management solution. This enables centralized access control, audit logging, and automated rotation.
- **Set an expiration on all keys.** Always specify a `--credential-age-days` value when creating API keys. To enforce a maximum key lifetime across your organization, use the `iam:ServiceSpecificCredentialAgeDays` IAM condition key.
- **Apply least-privilege permissions.** Use the managed CloudWatchAPIKeyAccess policy as a starting point and restrict further as needed.
- **Enable CloudTrail logging.** Audit API key usage by enabling CloudTrail data events for `AWS::CloudWatch::Metric`. See the section called “Logging API key usage with CloudTrail”.
- **Monitor with IAM Access Analyzer.** Use IAM Access Analyzer to identify unused credentials and overly permissive policies associated with your API key IAM users.
- **Rotate keys regularly.** Establish a rotation schedule and follow the process described in the section called “Rotating API keys”.

Logging API key usage with CloudTrail

You can use AWS CloudTrail to log data events for CloudWatch Metrics OTLP ingestion. CloudWatch emits `AWS::CloudWatch::Metric` data events for calls to the OTLP endpoint, enabling you to audit metric ingestion activity including API key usage.

> **Note**
>
> The S3 bucket that you specify for the trail must have a bucket policy that allows CloudTrail to write log files to it. For more information, see Amazon S3 bucket policy for CloudTrail in the *AWS CloudTrail User Guide*.

To enable CloudTrail logging for CloudWatch Metrics API key usage

1. Create a trail:

```
aws cloudtrail create-trail \
    --name cloudwatch-metrics-api-key-audit \
    --s3-bucket-name my-cloudtrail-bucket \
    --region us-east-1
```

2. Configure advanced event selectors to capture CloudWatch Metrics write (ingestion) data events:

```
aws cloudtrail put-event-selectors \
    --region us-east-1 \
    --trail-name cloudwatch-metrics-api-key-audit \
    --advanced-event-selectors '[{
        "Name": "CloudWatch Metrics write data events",
        "FieldSelectors": [
            { "Field": "eventCategory", "Equals": ["Data"] },
            { "Field": "resources.type", "Equals": ["AWS::CloudWatch::Metric"] },
            { "Field": "readOnly", "Equals": ["false"] }
        ]
    }]'
```

3. Start trail logging:

```
aws cloudtrail start-logging \
    --name cloudwatch-metrics-api-key-audit \
```

```
    --region us-east-1
```

The `readOnly: false` filter limits logging to write operations (PutMetricData), which includes all OTLP ingestion calls. To identify bearer token usage among these events, query your trail logs (via Athena or CloudTrail Lake) and filter by the IAM user name associated with your API key (for example, `cloudwatch-metrics-api-key-user`). Events from OTLP ingestion include `AdditionalEventData.protocol` set to `OTLP` in the event payload, which you can use in post-hoc queries to distinguish them from classic PutMetricData SDK calls.

Troubleshooting

The following are the common troubleshooting scenarios and solutions for OTLP endpoint.

Issue	Description	Solution
Non-existing AWS credentials when launching OCB collector	Collector throws the following error when starting. *Error: invalid configuration: extensions::sigv4auth: could not retrieve credential provider: failed to refresh cached credentials, no EC2 IMDS role found, operation error ec2imds: GetMetadata, request canceled, context deadline exceeded*.	Enter the correct credentials.
Invalid AWS credentials	Collector throws HTTP Status Code 403, Message=The security token	Refresh the AWS credentials on the collector server.

Issue	Description	Solution
	included in the request is invalid., Details=[]“ when sending requests though OTLP endpoint.	
Transactions Search disabled	Collector throws Message=The OTLP API is supported with CloudWatch Logs as a Trace Segment Destination.	Make sure Transaction Search is enabled in CloudWatch before using the OTLP endpoint for traces. For more information, see Transaction Search.

Issue	Description	Solution
Batching and timeout issues	Collector throws one of these issues: • max elapsed time expired failed to make an HTTP request • io.opentelemetry.exporter.internal.http.HttpExporter - Failed to export spans. The request could not be executed. Full error message: timeout • io.opentelemetry.exporter.internal.grpc.GrpcExporter - Failed to export spans. Server responded with gRPC status code 2. Error message: timeout • rpc error: code = DeadlineExceeded desc = context deadline exceeded • rpc error: code = ResourceExhausted desc = Too many requests", "dropped_items": 1024	Tune batching and timeout policies using batchprocessor.

Issue	Description	Solution
Retry issues	Transient network issues between the collector and OTLP endpoint. • rpc error: code = Unavailable desc = error reading from server: read tcp • rpc error: code = Unavailable desc = unexpected HTTP status code received from server: 502 (Bad Gateway); • rpc error: code = Unavailable desc = unexpected HTTP status code received from server: 503 (Service Unavailable)	Tune retry policy using exporter.
Payload rejected	NA	Make sure the payload sent to the trace endpoint is within the limits and restrictions. For more information, see Endpoint limits and restrictions.

Issue	Description	Solution
No auth header injected to outgoing export requests in ADOT	Generic 403 error, "Missing Authentication Token": Example: `ERROR:opentelemetry.exporter.otlp.proto.http.trace_exporter:Failed to export batch code: 403, reason: Missing Authentication Token`	• Verify that you're using the correct supported version of ADOT. • Make sure your credentials are set up correctly by following the standard AWS SDK credential provider chain
Logs or spans not appearing in CloudWatch log groups	No logs or spans are appearing in the expected CloudWatch log groups (`aws/spans` for spans and your specified custom log group for logs).	Make sure that the library to be instrumented is supported by auto-instrumentation. See supported libraries for Java, Python, JavaScript and .NET.

Network Monitoring

The topics in this section describe CloudWatch network and internet monitoring capabilities provided by Network Flow Monitor, Internet Monitor and Network Synthetic Monitor. These services help you to gain operational visibility into the network and internet performance and availability of your applications hosted on AWS.

- Network Flow Monitor provides near real-time visibility into network performance, such as packet loss and latency, for traffic between Amazon EC2 instances, as well as traffic toward other AWS services, such as Amazon S3 and Amazon DynamoDB. Network Flow Monitor works by using data from lightweight software agents that you install to run on your instances. These fully-managed agents gather performance statistics from TCP connections and send them to the Network Flow Monitor backend. By creating monitors for specific agents and then using Network Flow Monitor dashboards, you can quickly visualize packet loss and latency of your network connections, and use attribution information to determine where to focus your troubleshooting efforts to improve your end users' experience.
- Internet Monitor uses the connectivity data that AWS captures from its global networking footprint to calculate a baseline of performance and availability for internet-facing traffic. You can see a global view of traffic patterns and health events, and easily drill down into information about events. You can also get alerts for internet health events that affect your application clients. In addition, you can use insights that Internet Monitor provides to explore potential improvements to your client experience, by using Amazon CloudFront or routing through different AWS Regions.
- Network Synthetic Monitor uses fully-managed agents to enable you to track and visualize latency and packet loss for hybrid network connections. To gather measurements and enable Network Synthetic Monitor to create health event alerts for your application, you create probes that are sent from your resources hosted on AWS to on-premises destination IP addresses. You don't need to install additional agents to monitor your network performance. As with Internet Monitor, you can set alerts and thresholds, get information to help you quickly troubleshoot issues, and then take action to improve your end user experience.

Topics

- Using Network Flow Monitor
- Using Internet Monitor
- Using Network Synthetic Monitor

Using Network Flow Monitor

Network Flow Monitor gives you near real-time visibility into network performance for traffic between compute resources (Amazon EC2 and Amazon Elastic Kubernetes Service), traffic to other AWS services (Amazon S3 and Amazon DynamoDB), and traffic to the edge of another AWS Region. Network Flow Monitor collects data from lightweight software agents that you install on your instances. These agents gather performance statistics from TCP connections and send this data to the Network Flow Monitor backend service, which calculates the top contributors for each metric type.

Network Flow Monitor also determines if AWS is the cause of a detected network issue, and reports that information for network flows that you choose to monitor details for.

You can view network performance information for network flows for resources in a single account, or you can configure Network Flow Monitor with AWS Organizations to view performance information for multiple accounts in an organization, by signing in with a management or delegated administrator account.

Network Flow Monitor is intended for network operators and application developers who want near real-time insights into network performance. In the Network Flow Monitor console in CloudWatch, you can see performance data for your resources' network traffic that has been aggregated from agents and grouped into different categories. For example, you can see data for flows between Availability Zones or between VPCs. Then, you can create monitors for specific flows that you want to see more details for or track more closely over time.

Using a monitor, you can quickly visualize packet loss and latency of your network connections over a time frame that you specify. For each monitor, Network Flow Monitor also generates a network health indicator (NHI). The NHI value informs you whether there were AWS network issues for the network flows tracked by your monitor during the time period that you're evaluating. Using the NHI information, you can quickly decide whether to focus troubleshooting efforts on an AWS network issue or network problems originating with your workloads.

To see an example of configuring and using Network Flow Monitor, see the following blog post: Visualizing network performance of your AWS Cloud workloads with Network Flow Monitor.

What is Network Flow Monitor?

Network Flow Monitor is a feature of Amazon CloudWatch Network Monitoring. Network Flow Monitor uses fully-managed agents that you install in your AWS workloads to return performance

and availability metrics about network flows. Using Network Flow Monitor, you can access near real-time metrics, including retransmissions and data transferred, for your actual workloads. You can also identify whether an underlying AWS network issue occurred for the network flows tracked by a monitor, by checking network health indicator (NHI) values.

Key features of Network Flow Monitor

- With Network Flow Monitor, you receive near real-time metrics for the latency and packet-loss experienced by TCP-based traffic within your VPC network, so that you can track and investigate network issues for your workload traffic.
- When your AWS workloads experience network degradation, Network Flow Monitor helps you to determine if the problem is caused by your application workload or the underlying AWS infrastructure. Then, you can quickly focus troubleshooting on the area where the issue is occurring.

How to use Network Flow Monitor

With Network Flow Monitor, you install lightweight agents on your instances, which collect and aggregate performance metrics. Network Flow Monitor agents analyze TCP traffic, and then export performance metrics to the Network Flow Monitor service backend.

Agents gather the following metrics for your workloads: TCP round-trip time (RTT), TCP retransmission timeouts, TCP retransmissions, and data (bytes) transferred. After you install agents on your instances, the agents detect the corresponding workloads that are hosted by the instances. The agents then generate network performance metrics and send the metrics to the Network Flow Monitor backend. Metrics are aggregated into categories such as subnets, Availability Zones, VPCs, and AWS services.

Performance metrics for top contributors (by metric type) from all network flows that are in your Network Flow Monitor scope are shown on the **Workload insights** tab in the AWS Management Console. By reviewing the tables and graphs of top contributors, you can determine where there might be impairments that you want to troubleshoot and which workloads you want to monitor on an ongoing basis, by creating a monitor.

With a monitor, you can monitor specific workloads more closely over time and see detailed information about specific network flows. In addition to viewing performance metrics for the top contributors for the network flows that you've selected, you can view network path information with the network hops that a network flow has traversed, to help you troubleshoot issues. In

addition, Network Flow Monitor generates a network health indicator (NHI) for monitors. An NHI value of **Degraded** indicates that there were AWS network issues for at least one of the network flows tracked by your monitor, during the time period that you've selected.

In addition to reviewing the information in monitors that you create, we recommend that you also check back regularly to review metrics on the **Workload insights** page, to see the latest top contributors for performance metrics for your network flows. As you review the latest information, consider if it would be helpful to add or remove workloads from your current monitors, or create new monitors.

Supported AWS Regions for Network Flow Monitor

Network Flow Monitor is currently available in the following AWS Regions:

Region name	Region
Asia Pacific (Mumbai)	ap-south-1
Asia Pacific (Osaka)	ap-northeast-3
Asia Pacific (Seoul)	ap-northeast-2
Asia Pacific (Singapore)	ap-southeast-1
Asia Pacific (Sydney)	ap-southeast-2
Asia Pacific (Tokyo)	ap-northeast-1
Canada (Central)	ca-central-1
Europe (Frankfurt)	eu-central-1
Europe (Ireland)	eu-west-1

Region name	Region
Europe (London)	eu-west-2
Europe (Paris)	eu-west-3
Europe (Stockholm)	eu-north-1
South America (São Paulo)	sa-east-1
US East (N. Virginia)	us-east-1
US East (Ohio)	us-east-2
US West (N. California)	us-west-1
US West (Oregon)	us-west-2

Components and features of Network Flow Monitor

Network Flow Monitor uses or references the following concepts.

Agents

An *agent* in Network Flow Monitor is a software application that you install on your AWS compute resources (Amazon EC2 and Amazon EKS). The application has two parts:

- The first part receives events related to TCP connections and is registered within the Linux kernel using eBPF. eBPF is the Linux extended Berkley Packet Filter (eBPF) capability that allows a designated program to receive certain events raised by the Linux kernel.
- The second part aggregates the statistics collected by the eBPF portion. The agent sends the aggregated metrics to the Network Flow Monitor backend about every 30 seconds, with a 5 second potential jitter (in other words, 25 to 35 seconds).

For more information about agents, see How it works.

Top contributors

Top contributors are the network flows that have the highest values for a specific metric (such as retransmissions) in your Network Flow Monitor scope or among the network flows you're tracking in a monitor. Reviewing the flows with the highest reported numbers for performance

metric measurements can help you see where there might be impairments to investigate. Network Flow Monitor returns performance metrics for top contributors in your monitoring scope for *workload insights*. In addition, if you create a monitor, Network Flow Monitor returns performance metrics for top contributors for the network flows that you choose for the monitor.

Local and remote resources

A *local resource* is the host location—or a location of multiple hosts—where a Network Flow Monitor agent is installed. It can be a subnet, a VPC, an Availability Zone, an Amazon EKS cluster, or an AWS Region. For example, consider a workload that consists of an interaction between a web service and a backend database, for example, DynamoDB. In this scenario, the local resource is the subnet of the EC2 instance hosting the web service, which also runs the agent. A network flow is typically directional, though it can be configured to be bi-directional.

A *remote resource* is the other end of a network flow. In this example of a web service with a backend database, DynamoDB is the remote resource. A remote resource can be a subnet, a VPC, an Availability Zone, an AWS service, or an AWS Region. If you specify a Region as a remote resource, Network Flow Monitor measures performance for the network flow up to the edge of the Region. It does not measure performance to specific endpoints within the Region.

A resource is identified by the ARN of the resource, the name of the AWS service, or, for an Availability Zone or Region, by the name of the zone or Region.

Workload insights

Workload insights includes the performance metrics returned for all the network flows in your scope. In the AWS Management Console, the **Workload insights** page provides performance data about workloads where you've installed Network Flow Monitor agents on workload instances. The **Workload insights** page provides a view into your applications that includes the amount of data transferred and several other metrics, grouped into categories of workloads. For example, you can see all the metrics for workloads with traffic between Availability Zones (AZs) or within an AZ. By using these insights, you can select workloads for which you want to create a monitor to see more details and to track network performance on an ongoing basis.

Monitors

You create a *monitor* so that you can monitor, on an ongoing basis, the network performance for one or several specific workloads, and see more detailed information about the network flows. For each monitor, Network Flow Monitor publishes end-to-end performance metrics, and a network health indicator (NHI), which you can use to help determine attribution for

impairments. We recommend that you review information on the **Workload insights** page to see which network flows you want to focus on, and then create a monitor for those flows. Then, by regularly reviewing **Workload insights**, you can decide if you have the monitors that you need, or if creating new monitors would be helpful.

Network health indicator (NHI)

The *network health indicator* (NHI) is a binary value that informs you whether there were AWS network issues for one or more of the network flows tracked by a monitor, during a time period that you choose. When the NHI value is 1, or **Degraded**, there was an AWS network issue for at least one network flow. With the NHI indicator, you can quickly decide whether to focus troubleshooting efforts on an AWS network issue or network problems originating with your workloads.

For more information, see View Network Flow Monitor metrics in CloudWatch.

Scope

In Network Flow Monitor, the *scope* is the account or accounts that you have observability for when you look at network performance indicators. If you sign in as a management account and configure AWS Organizations with CloudWatch, you can set your scope to more than one account in your organization (up to 100 accounts total). Otherwise, if you sign in with an AWS account that does not have management permissions in Organizations, or if you have not configured Organizations with CloudWatch, Network Flow Monitor sets your scope to the account that you're signed in with.

After you have configured Organizations, you can change your scope by adding or removing accounts. However, whenever you change the scope, Network Flow Monitor must create a new topology of the resources in the scope. For more information, see Add multiple accounts to your scope.

Network Flow Monitor generates a unique **scope ID** for the scope. Queries for metrics data use the scope ID to determine the resources that the Network Flow Monitor generates metrics for. (You must install agents to gather and submit metrics data before you can view the performance metrics for an account with Network Flow Monitor.)

Query ID

Network Flow Monitor generates a unique *query ID* for each query that is created to retrieve performance metrics data, such as a query for top contributors for a monitor. By using a query ID with an API call in Network Flow Monitor, you can check the status of a query, stop a query, run the query again, or work with the query in other ways.

Performance metrics

Network Flow Monitor gathers and calculates end-to-end *performance metrics*, including TCP round-trip time (RTT), TCP retransmissions, TCP retransmission time outs, and bytes transferred for each flow that is in your Network Flow Monitor scope. The service aggregates these metrics and returns them to the service backend. You can view top contributors by metric type. When you see an anomaly in Network Flow Monitor, you can also check the network health indicator (NHI) to see if there is an underlying AWS network issue.

Be aware that RTT data can be sparse because RTT is not always calculated.

You can also use Amazon CloudWatch features to create dashboards, alarms, and notifications based on these metrics. For example, you can learn about setting up alarms with Network Flow Monitor metrics by reviewing the information in Create alarms with Network Flow Monitor.

How it works

This section provides information about several aspects of how Network Flow Monitor works.

How Network Flow Monitor agents gather statistics

Agents in Network Flow Monitor are installed on AWS compute resources (Amazon EC2 and Amazon EKS), where they gather performance metrics and send them to the Network Flow Monitor backend. Agents do not have access to the payload of your TCP connections. Agents receive only what is called the "bpf_sock_ops" structure from the Linux kernel. This structure provides the local and remote IP address and the source and destination TCP port, as well as counters and round-trip times. For list of the TCP statistics collected and published by the agent, see View Network Flow Monitor metrics in CloudWatch.

The agent uses the Network Flow Monitor `Publish` API to send metrics to the Network Flow Monitor backend server.

Note: Network Flow Monitor supports up to approximately 5 million flows per minute. This is approximately 5,000 instances (Amazon EC2 and Amazon EKS nodes) with NFM agent installed. Installing agents on more than 5000 instances may affect monitoring performance until additional capacity is available.

How network flows are categorized in Network Flow Monitor

Network Flow Monitor categorizes network flows into classifications depending on where the flows originate and terminate.

Pricing for Network Flow Monitor

With Network Flow Monitor, there are no upfront costs or long-term commitments. Pricing for Network Flow Monitor has two components: resources monitored (agents installed and actively sending data) and CloudWatch metrics vended. Note that you are also charged standard CloudWatch prices for any additional metrics, dashboards, alarms, or insights that you create.

For more information about Network Flow Monitor and Amazon CloudWatch pricing, see Network Monitoring on the Amazon CloudWatch pricing page.

Get started with Network Flow Monitor

To help you get started, the section provides a high level overview of the steps to configure, and then gain insights, with Network Flow Monitor. For details, see the additional sections in this guide about initializing Network Flow Monitor, deploying agents, and creating monitors.

- Initialize Network Flow Monitor, to accept service-linked role permissions, create a *scope* for monitoring in Network Flow Monitor, and create an initial topology. If you want to observe network performance for network flows for instances in multiple accounts, you must integrate with AWS Organizations, and then add the accounts to your scope. To learn more, see Initialize Network Flow Monitor.
- Deploy *agents* on your instances, by using AWS Systems Manager or by configuring Kubernetes, depending on how your resources are deployed. If you install agents on VPC EC2 instances, make sure that you enable permissions for agents on each instance to send metrics to the Network Flow Monitor backend. To learn more, see Install Network Flow Monitor agents on EC2 and self-managed Kubernetes instances.
- Review top contributor metrics for network flows returned by the agents, to gain *workload insights*. Workload insights provide a high-level view of the performance for network flows in the scope you're monitoring.
- Based on the network flows that you want to see detailed network information about, create one or more *monitors*. For each monitor, specify the local and remote resources that you want to monitor network flows between. Using a monitor, you can see detailed metrics and information, including the network health indicator, as well as view network paths for specific network flows, over time periods that you select.
- On a regular basis:
  - Review network flow information in the monitors that you've created, to learn about and help troubleshoot network impairments in your workloads.

- Review workload insights for the network flows that you're monitoring, to determine if the monitors that you've created are covering the most relevant network flows or if it would be helpful to create new monitors.

Network Flow Monitor API operations

The following table lists Network Flow Monitor API operations that you can use with Network Flow Monitor. The table also includes links to relevant documentation.

Action	API operation	More information
Create a flow monitor.	See CreateMonitor	See Create a monitor in Network Flow Monitor
Generate metrics for a scope of resources.	See CreateScope	See Evaluate network flows with workload insights
Remove a monitor.	See DeleteMonitor	See Delete a monitor in Network Flow Monitor
Delete a defined scope.	See DeleteScope	See Delete a monitor in Network Flow Monitor
Get information about a monitor.	See GetMonitor	See Monitor and analyze network flows with a Network Flow Monitor monitor
Get query data for the top contributors in a specific monitor.	See GetQueryResultsMonitorTopContributors	See Monitor and analyze network flows with a Network Flow Monitor monitor
Query the top contributors for a defined scope for workload insights.	See GetQueryResultsWorkloadInsightsTopContributors	See Evaluate network flows with workload insights
Query workload insights data for the top contributors in a specific scope.	See GetQueryResultsWorkloadInsightsTopContributorsData	See Evaluate network flows with workload insights

Action	API operation	More information
Check the status of a query for top contributors in a monitor to ensure that it has succeeded before reviewing the results.	See GetQueryStatusMonitorTopContributors	N/A
Check the status of a query on workload insights for top contributors to ensure that it has succeeded before reviewing the results.	See GetQueryStatusWorkloadInsightsTopContributors	N/A
Check the status of a query on workload insights data for top contributors to ensure that it has succeeded before reviewing the results.	See GetQueryStatusWorkloadInsightsTopContributorsData	N/A
Get information about an account, or scope, including name, status, tags, and target details.	See GetScope	See Monitor and analyze network flows with a Network Flow Monitor monitor
List all monitors in an account.	See ListMonitors	Monitor and analyze network flows with a Network Flow Monitor monitor
List all scopes for an account.	See ListScopes	N/A
List all tags for a specific resource.	See ListTagsForResource	See Monitor and analyze network flows with a Network Flow Monitor monitor
See query data for top contributors in a monitor.	See StartQueryMonitorTopContributors	See Monitor and analyze network flows with a Network Flow Monitor monitor

Action	API operation	More information
Start a query to gather workload insights data for top contributors.	See StartQueryWorkloadInsightsTopContributors	See Evaluate network flows with workload insights
Stop a query for top contributors in a monitor.	See StopQueryMonitorTopContributors	N/A
Stop a query on workload insights data for top contributors.	See StopQueryWorkloadInsightsTopContributors	N/A
Stop a query on workload insights data for top contributors.	See StopQueryWorkloadInsightsTopContributorsData	N/A
Add a tag to a resource.	See TagResource	See Edit a monitor in Network Flow Monitor
Remove a tag from a resource.	See UntagResource	See Edit a monitor in Network Flow Monitor
Update a monitor to add or remove local or remote resources.	See UpdateMonitor	See Edit a monitor in Network Flow Monitor
Modify a scope to add or remove resources that Network Flow Monitor will generate metrics on.	See UpdateScope	N/A

Examples of using the CLI with Network Flow Monitor

This section includes examples for using the AWS Command Line Interface with Network Flow Monitor operations.

Before you begin, make sure that you log in to use the AWS CLI with the AWS account that provides the scope that you want to use to monitor network flows. For more information about using API actions with Network Flow Monitor, see the Network Flow Monitor API Reference Guide.

Topics

- Create a monitor
- View monitor details
- Create a scope
- Delete a monitor
- Delete a scope
- Get information about a monitor
- Retrieve data on a specific queries
- See scope information
- See a list of monitors for an account
- See a list of scopes for an account
- See the list of tags for a monitor
- Starting and stopping queries
- Tag a monitor
- Remove a tag from a monitor
- Update an existing monitor

Create a monitor

To create a monitor with the AWS CLI, use the `create-monitor` command. The following example creates a monitor named demo in the specified account.

```
aws networkflowmonitor create-monitor \
        --monitor-name demo \
        --local-resources type="AWS::EC2::VPC",identifier="arn:aws:ec2:us-
east-1:111122223333:vpc/vpc-11223344556677889"  \
        --scope-arn arn:aws:networkflowmonitor:us-east-1:111122223333:scope/sample-
aaaa-bbbb-cccc-44556677889
```

Output:

```
{
        "monitorArn": "arn:aws:networkflowmonitor:us-east-1:111122223333:monitor/demo",
        "monitorName": "demo",
        "monitorStatus": "ACTIVE",
        "tags": {}
    }
```

For more information, see Create a monitor in Network Flow Monitor.

View monitor details

To view information about a monitor with the AWS CLI, use the `get-monitor` command.

```
aws networkflowmonitor get-monitor --monitor-name "TestMonitor"
```

Output:

```
{
    "ClientLocationType": "city",
    "CreatedAt": "2022-09-22T19:27:47Z",
    "ModifiedAt": "2022-09-22T19:28:30Z",
    "MonitorArn": "arn:aws:networkflowmonitor:us-east-1:111122223333:monitor/
TestMonitor",
    "MonitorName": "TestMonitor",
    "ProcessingStatus": "OK",
    "ProcessingStatusInfo": "The monitor is actively processing data",
    "Resources": [
        "arn:aws:ec2:us-east-1:111122223333:vpc/vpc-11223344556677889"
    ],
    "MaxCityNetworksToMonitor": 10000,
    "Status": "ACTIVE"
}
```

Create a scope

The following `create-scope` example creates a scope that is the set of resources for which Network Flow Monitor will generate network traffic metrics.

```
aws networkflowmonitor create-scope \
        --targets '[{"targetIdentifier":{"targetId":
{"accountId":"111122223333"},"targetType":"ACCOUNT"},"region":"us-east-1"}]'
```

Output:

```
    {
        "scopeId": "sample-aaaa-bbbb-cccc-11112222333",
        "status": "IN_PROGRESS",
        "tags": {}
    }
```

For more information, see Components and features of Network Flow Monitor.

Delete a monitor

The following `delete-monitor` example deletes a monitor named `Demo` in your account.

```
aws networkflowmonitor delete-monitor \
        --monitor-name Demo
```

This command produces no output.

For more information, see Delete a monitor in Network Flow Monitor.

Delete a scope

The following `delete-scope` example deletes the specified scope.

```
aws networkflowmonitor delete-scope \
        --scope-id sample-aaaa-bbbb-cccc-44556677889
```

This command produces no output.

For more information, see Components and features of Network Flow Monitor.

Get information about a monitor

The following `get-monitor` example displays information about the monitor named `demo` in the specified account.

```
aws networkflowmonitor get-monitor \
```

```
        --monitor-name Demo
```

Output:

```
{
        "monitorArn": "arn:aws:networkflowmonitor:us-east-1:111122223333:monitor/Demo",
        "monitorName": "Demo",
        "monitorStatus": "ACTIVE",
        "localResources": [
            {
                "type": "AWS::EC2::VPC",
                "identifier": "arn:aws:ec2:us-east-1:111122223333:vpc/
vpc-11223344556677889"
            }
        ],
        "remoteResources": [],
        "createdAt": "2024-12-09T12:21:51.616000-06:00",
        "modifiedAt": "2024-12-09T12:21:55.412000-06:00",
        "tags": {}
    }
```

For more information, see Components and features of Network Flow Monitor.

Retrieve data on a specific queries

The following sections provide example CLI commands to retrieve query statuses.

get-query-results-workload-insights-top-contributors-data

The `get-query-results-workload-insights-top-contributors-data` example returns the data for the specified query.

```
aws networkflowmonitor get-query-results-workload-insights-top-contributors-data \
        --scope-id sample-aaaa-bbbb-cccc-11112222333 \
        --query-id sample-dddd-eeee-ffff-44556677889
```

Output:

```
{
        "datapoints": [
            {
```

```
                "timestamps": [
                    "2024-12-09T19:00:00+00:00",
                    "2024-12-09T19:05:00+00:00",
                    "2024-12-09T19:10:00+00:00"
                ],
                "values": [
                    259943.0,
                    194856.0,
                    216432.0
                ],
                "label": "use1-az6"
            }
        ],
        "unit": "Bytes"
    }
```

get-query-results-workload-insights-top-contributors

The following `get-query-results-workload-insights-top-contributors` example returns the data for the specified query.

```
aws networkflowmonitor get-query-results-workload-insights-top-contributors \
        --scope-id sample-aaaa-bbbb-cccc-11112222333 \
        --query-id sample-dddd-eeee-ffff-44556677889
```

Output:

```
{
        "topContributors": [
            {
                "accountId": "111122223333",
                "localSubnetId": "subnet-SAMPLE1111",
                "localAz": "use1-az6",
                "localVpcId": "vpc-SAMPLE2222",
                "localRegion": "us-east-1",
                "remoteIdentifier": "",
                "value": 333333,
                "localSubnetArn": "arn:aws:ec2:us-east-1:111122223333:subnet/
subnet-2222444455556666",
                "localVpcArn": "arn:aws:ec2:us-east-1:111122223333:vpc/
vpc-11223344556677889"
            }
        ]
```

```
    }
```

get-query-status-monitor-top-contributors

The following `get-query-status-monitor-top-contributors` example displays the current status of the query in the specified account.

```
aws networkflowmonitor get-query-status-monitor-top-contributors \
        --monitor-name Demo \
        --query-id sample-dddd-eeee-ffff-44556677889
```

Output:

```
{
        "status": "SUCCEEDED"
    }
```

get-query-status-workload-insights-top-contributors-data

The following `get-query-status-workload-insights-top-contributors-data` example displays the current status of the query in the specified account.

```
aws networkflowmonitor get-query-status-workload-insights-top-contributors-data \
        --scope-id sample-aaaa-bbbb-cccc-11112222333 \
        --query-id sample-dddd-eeee-ffff-44556677889
```

Output:

```
{
        "status": "SUCCEEDED"
    }
```

get-query-results-workload-insights-top-contributors

The following `get-query-results-workload-insights-top-contributors` example displays the current status of the query in the specified account.

```
aws networkflowmonitor get-query-status-workload-insights-top-contributors \
        --scope-id sample-aaaa-bbbb-cccc-11112222333 \
```

```
        --query-id sample-dddd-eeee-ffff-44556677889
```

Output:

```
{
        "status": "SUCCEEDED"
    }
```

For more information, see Evaluate network flows with workload insights.

See scope information

The following `get-scope` example displays information about a scope, such as status, tags, name, and target details.

```
aws networkflowmonitor get-scope \
        --scope-id sample-aaaa-bbbb-cccc-11112222333
```

Output:

```
{
        "scopeId": "sample-aaaa-bbbb-cccc-11112222333",
        "status": "SUCCEEDED",
        "scopeArn": "arn:aws:networkflowmonitor:us-east-1:111122223333:scope/sample-
aaaa-bbbb-cccc-11112222333",
        "targets": [
            {
                "targetIdentifier": {
                    "targetId": {
                        "accountId": "111122223333"
                    },
                    "targetType": "ACCOUNT"
                },
                "region": "us-east-1"
            }
        ],
        "tags": {}
    }
```

For more information, see Components and features of Network Flow Monitor.

See a list of monitors for an account

The following `list-monitors` example returns all the monitors in the specified account.

```
aws networkflowmonitor list-monitors
```

Output:

```
{
        "monitors": [
            {
                "monitorArn": "arn:aws:networkflowmonitor:us-
east-1:111122223333:monitor/Demo",
                "monitorName": "Demo",
                "monitorStatus": "ACTIVE"
            }
        ]
    }
```

For more information, see Components and features of Network Flow Monitor.

See a list of scopes for an account

The following `list-scopes` example lists all the scopes in the specified account.

```
aws networkflowmonitor list-scopes
```

Output:

```
{
        "scopes": [
            {
                "scopeId": "sample-aaaa-bbbb-cccc-11112222333",
                "status": "SUCCEEDED",
                "scopeArn": "arn:aws:networkflowmonitor:us-east-1:111122223333:scope/
sample-aaaa-bbbb-cccc-11112222333"
            }
        ]
    }
```

For more information, see Components and features of Network Flow Monitor.

See the list of tags for a monitor

The following `list-tags-for-resource` example returns all the tags associated with the specified resource.

```
aws networkflowmonitor list-tags-for-resource \
        --resource-arn arn:aws:networkflowmonitor:us-east-1:111122223333:monitor/Demo
```

Output:

```
{
        "tags": {
            "Value": "Production",
            "Key": "stack"
        }
    }
```

For more information, see Tagging your Amazon CloudWatch resources.

Starting and stopping queries

The following sections provide example CLI commands for starting and stopping queries in Network Flow Monitor.

start-query-monitor-top-contributors

The following `start-query-monitor-top-contributors` example starts the query which returns a queryId to retrieve the top contributors.

```
aws networkflowmonitor start-query-monitor-top-contributors \
        --monitor-name Demo \
        --start-time 2024-12-09T19:00:00Z \
        --end-time 2024-12-09T19:15:00Z \
        --metric-name DATA_TRANSFERRED \
        --destination-category UNCLASSIFIED
```

Output:

```
{
        "queryId": "sample-dddd-eeee-ffff-44556677889"
```

```
    }
```

For more information, see Evaluate network flows with workload insights.

start-query-workload-insights-top-contributors-data

The following `start-query-workload-insights-top-contributors-data` example starts the query which returns a queryId to retrieve the top contributors.

```
aws networkflowmonitor start-query-workload-insights-top-contributors-data \
        --scope-id sample-aaaa-bbbb-cccc-11112222333 \
        --start-time 2024-12-09T19:00:00Z \
        --end-time 2024-12-09T19:15:00Z \
        --metric-name DATA_TRANSFERRED \
        --destination-category UNCLASSIFIED
```

Output:

```
{
        "queryId": "sample-dddd-eeee-ffff-44556677889"
    }
```

For more information, see Evaluate network flows with workload insights.

start-query-workload-insights-top-contributors

The following `start-query-workload-insights-top-contributors` example starts the query which returns a queryId to retrieve the top contributors.

```
aws networkflowmonitor start-query-workload-insights-top-contributors \
        --scope-id sample-aaaa-bbbb-cccc-11112222333 \
        --start-time 2024-12-09T19:00:00Z \
        --end-time 2024-12-09T19:15:00Z \
        --metric-name DATA_TRANSFERRED \
        --destination-category UNCLASSIFIED
```

Output:

```
{
        "queryId": "sample-dddd-eeee-ffff-44556677889"
```

```
    }
```

For more information, see Evaluate network flows with workload insights.

stop-query-monitor-top-contributors

The following `stop-query-monitor-top-contributors` example stops the query in the specified account.

```
aws networkflowmonitor stop-query-monitor-top-contributors \
        --monitor-name Demo \
        --query-id sample-dddd-eeee-ffff-44556677889
```

This command produces no output.

For more information, see Evaluate network flows with workload insights.

stop-query-workload-insights-top-contributors-data

The following `stop-query-workload-insights-top-contributors-data` stops the query in the specified account.

```
aws networkflowmonitor stop-query-workload-insights-top-contributors-data \
        --scope-id sample-aaaa-bbbb-cccc-11112222333 \
        --query-id sample-dddd-eeee-ffff-44556677889
```

This command produces no output.

For more information, see Evaluate network flows with workload insights.

stop-query-workload-insights-top-contributors

The following `stop-query-workload-insights-top-contributors` example stops the query in the specified account.

```
aws networkflowmonitor stop-query-workload-insights-top-contributors \
        --scope-id sample-aaaa-bbbb-cccc-11112222333 \
        --query-id sample-dddd-eeee-ffff-44556677889
```

This command produces no output.

For more information, see Evaluate network flows with workload insights.

Tag a monitor

The following `tag-resource` adds a tag to the monitor in the specified account.

```
aws networkflowmonitor tag-resource \
        --resource-arn arn:aws:networkflowmonitor:us-east-1:111122223333:monitor/Demo \
        --tags Key=stack,Value=Production
```

This command produces no output.

For more information, see Tagging your Amazon CloudWatch resources.

Remove a tag from a monitor

The following `untag-resource` example removes a tag to the monitor in the specified account.

```
aws networkflowmonitor untag-resource \
        --resource-arn arn:aws:networkflowmonitor:us-east-1:111122223333:monitor/Demo \
        --tag-keys stack
```

This command produces no output.

For more information, see Tagging your Amazon CloudWatch resources.

Update an existing monitor

The following `update-monitor` example updates the monitor named ``Demo`` in the specified account.

```
aws networkflowmonitor update-monitor \
        --monitor-name Demo \
        --local-resources-to-add type="AWS::EC2::VPC",identifier="arn:aws:ec2:us-
east-1:111122223333:vpc/vpc-11223344556677889"
```

Output:

```
{
        "monitorArn": "arn:aws:networkflowmonitor:us-east-1:111122223333:monitor/Demo",
```

```
        "monitorName": "Demo",
        "monitorStatus": "ACTIVE",
        "tags": {
            "Value": "Production",
            "Key": "stack"
        }
    }
```

For more information, see Components and features of Network Flow Monitor.

Work with EKS

Using Network Flow Monitor, you can collect performance metrics for workloads that use Amazon Elastic Kubernetes Service (Amazon EKS). This chapter shows you how to install the agent step-by-step and describes the different EKS scenarios you can monitor. You'll also find detailed descriptions of the metadata that Network Flow Monitor provides for Amazon EKS in the console to help you understand network performance.

To gain the benefits of Network Flow Monitor performance monitoring, you must first install the AWS Network Flow Monitor Agent add-on for Amazon EKS. For more information, see Install the EKS AWS Network Flow Monitor Agent add-on.

If you want to monitor a single EKS cluster with enhanced visibility of workload traffic and performance insights within the cluster and with external destinations, see Amazon EKS Network Observability.

Contents

- Install the EKS AWS Network Flow Monitor Agent add-on
- Additional network path metadata included for Amazon EKS

Install the EKS AWS Network Flow Monitor Agent add-on

Follow the steps in this section to install the AWS Network Flow Monitor Agent add-on for Amazon Elastic Kubernetes Service (Amazon EKS), to send Network Flow Monitor metrics to the Network Flow Monitor backend from Kubernetes clusters. After you complete the steps, AWS Network Flow Monitor Agent pods will be running on all of your Kubernetes cluster nodes.

If you use self-managed Kubernetes clusters, the installation steps to follow are in the previous section: Install agents for self-managed Kubernetes instances.

You can install the add-on by using the console or by using API commands with the AWS Command Line Interface.

Contents

- Prerequisites for installing the add-on
- Install the AWS Network Flow Monitor Agent add-on by using the console
- Install the AWS Network Flow Monitor Agent add-on by using the AWS Command Line Interface
- Configure add-on for third party monitoring tools

Prerequisites for installing the add-on

Regardless of whether you use the console or the CLI to install the AWS Network Flow Monitor Agent add-on, there are several requirements for installing the add-on with Kubernetes.

Ensure that your version of Kubernetes is supported

Network Flow Monitor agent installation requires Kubernetes Version 1.25, or a more recent version.

Amazon EKS Pod Identity Agent add-on installation

You can install the Amazon EKS Pod Identity Agent add-on in the console or by using the CLI.

Amazon EKS Pod Identity associations provide the ability to manage credentials for your applications, similar to the way that Amazon EC2 instance profiles provide credentials to Amazon EC2 instances. Amazon EKS Pod Identity provides credentials to your workloads with an additional Amazon EKS Auth API and an agent pod that runs on each node.

To learn more and see the steps for installing the Amazon EKS Pod Identity add-on, see Set up the Amazon EKS Pod Identity Agent in the Amazon EKS User Guide.

Install the AWS Network Flow Monitor Agent add-on by using the console

Follow the steps in this section to install and configure the AWS Network Flow Monitor Agent add-on in the Amazon EKS console.

If you have already installed the add-on and have issues upgrading to a new version, see Troubleshoot issues in EKS agents installation.

Before you begin, make sure that you have installed the Amazon EKS Pod Identity Agent add-on. For more information, see the previous section.

To install the add-on using the console

1. In the AWS Management Console, navigate to the Amazon EKS console.
2. On the page for installing add-ons, in the list of add-ons, choose **AWS Network Flow Monitor Agent**.
3. Configure the add-on settings.
    1. For **Add-on access**, choose **EKS Pod Identity**.
    2. For the IAM role to use with the add-on, use a role that has the following AWS managed policy attached: CloudWatchNetworkFlowMonitorAgentPublishPolicy. This policy gives permission for an agent to send telemetry reports to the Network Flow Monitor endpoint. If you don't already have a role with the policy attached, create a role by choosing **Create recommended role**, and following the steps in the IAM console.
    3. Choose **Next**.
4. On the **Review and add** page, make sure that the add-on configuration looks correct, and then choose **Create**.

Install the AWS Network Flow Monitor Agent add-on by using the AWS Command Line Interface

Follow the steps in this section to install the AWS Network Flow Monitor Agent add-on for Amazon EKS by using the AWS Command Line Interface.

1. Install the EKS Pod Identity Agent add-on

Before you begin, make sure that you have installed the Amazon EKS Pod Identity Agent add-on. For more information, see the earlier section.

2. Create the required IAM role

The AWS Network Flow Monitor Agent add-on must have permission to send metrics to the Network Flow Monitor backend. You must attach a role with the required permissions when you create the add-on. Create a role that has the following AWS managed policy attached: CloudWatchNetworkFlowMonitorAgentPublishPolicy. You need the ARN of this IAM role to install the add-on.

3. Install the AWS Network Flow Monitor Agent add-on

To install the AWS Network Flow Monitor Agent add-on for your cluster, run the following command:

```
aws eks create-addon --cluster-name CLUSTER NAME --addon-name aws-network-flow-monitoring-agent --region AWS REGION --pod-identity-associations serviceAccount=aws-network-flow-monitor-agent-service-account,roleArn=IAM ROLE ARN
```

The result should be similar to the following:

```
{
    "addon": {
        "addonName": "aws-network-flow-monitoring-agent",
        "clusterName": "ExampleClusterName",
        "status": "CREATING",
        "addonVersion": "v1.0.0-eksbuild.1",
        "health": {
            "issues": []
        },
        "addonArn": "arn:aws:eks:us-west-2:000000000000:addon/ExampleClusterName/aws-network-flow-monitoring-agent/eec11111-bbbb-EXAMPLE",
        "createdAt": "2024-10-25T16:38:07.213000+00:00",
        "modifiedAt": "2024-10-25T16:38:07.240000+00:00",
        "tags": {},
         "podIdentityAssociations": [
            "arn:aws:eks:us-west-2:000000000000:podidentityassociation/ExampleClusterName/a-3EXAMPLE5555555"
         ]
    }
  }
```

4. Make sure that the add-on is active

Review the installed AWS Network Flow Monitor Agent add-on to ensure that it's active for your cluster. Run the following command to verify that the status is `ACTIVE`:

```
aws eks describe-addon --cluster-name CLUSTER NAME --addon-name aws-network-flow-monitoring-agent --region AWS REGION
```

The result should be similar to the following:

```
{
    "addon": {
        "addonName": "aws-network-flow-monitoring-agent",
        "clusterName": "ExampleClusterName",
        "status": "ACTIVE",
        "addonVersion": "v1.0.0-eksbuild.1",
        "health": {
            "issues": []
        },
        "addonArn": "arn:aws:eks:us-west-2:000000000000:addon/ExampleClusterName/
aws-network-flow-monitoring-agent/eec11111-bbbb-EXAMPLE",
        "createdAt": "2024-10-25T16:38:07.213000+00:00",
        "modifiedAt": "2024-10-25T16:38:07.240000+00:00",
        "tags": {},
         "podIdentityAssociations": [
            "arn:aws:eks:us-west-2:000000000000:podidentityassociation/
ExampleClusterName/a-3EXAMPLE5555555"
         ]
    }
  }
```

Configure add-on for third party monitoring tools

You can configure the Network Flow Monitor add-on to expose an OpenMetrics server during installation. This enables integration with third-party monitoring tools such as Prometheus, allowing you to collect and analyze network flow metrics alongside your existing monitoring infrastructure. Learn more about about OpenMetrics. This feature is available from add-on version v1.1.0.

To enable the OpenMetrics server, add OPEN_METRICS, OPEN_METRICS_ADDRESS, and OPEN_METRICS_PORT to the configuration values of the EKS Network Flow Monitor add-on. This guide will explain how to do this using both CLI and Console. See Amazon EKS add-ons advanced configuration for additional details about adding configuration values.

CLI Configuration

When using AWS Command Line Interface, you can provide the configuration values as a parameter:

```
aws eks create-addon \
  --cluster-name my-cluster-name \
```

```
  --addon-name aws-network-flow-monitoring-agent \
  --addon-version v1.1.0-eksbuild.1 \
  --configuration-values '{"env":
{"OPEN_METRICS":"on","OPEN_METRICS_ADDRESS":"0.0.0.0","OPEN_METRICS_PORT":9109}}'
```

Console Configuration

When using the Amazon EKS Console, these values can be added under Optional configuration settings, as part of the Configuration values.

Sample JSON:

```
{
    "env": {
        "OPEN_METRICS": "on",
        "OPEN_METRICS_ADDRESS": "0.0.0.0",
        "OPEN_METRICS_PORT": 9109
    }
}
```

Sample YAML:

```
env:
  OPEN_METRICS: "on"
  OPEN_METRICS_ADDRESS: "0.0.0.0"
  OPEN_METRICS_PORT: 9109
```

EKS Network Flow Monitor add-on OpenMetric Parameters

- **OPEN_METRICS:**
  - Enable or disable open metrics. Disabled if not supplied
  - Type: String
  - Values: ["on", "off"]
- **OPEN_METRICS_ADDRESS:**
  - Listening IP address for open metrics endpoint. Defaults to 127.0.0.1 if not supplied
  - Type: String
- **OPEN_METRICS_PORT:**
  - Listening port for open metrics endpoint. Defaults to 80 if not supplied

- Type: Integer
- Range: [0..65535]

Important: When setting OPEN_METRICS_ADDRESS to 0.0.0.0, the metrics endpoint will be accessible from any network interface. Consider using 127.0.0.1 for localhost-only access or implement appropriate network security controls to restrict access to authorized monitoring systems only.

Troubleshooting

If you encounter issues with the OpenMetrics server configuration, use the following information to diagnose and resolve common problems.

Metrics not displaying

Problem: The OpenMetrics server is configured, but metrics are not appearing in your monitoring tool.

Troubleshooting Steps:

1. Verify that the OpenMetrics server is enabled in your add-on configuration:
   - Check that OPEN_METRICS is set to "on" in your configuration values. See describe-addon.
   - Confirm that the add-on version is v1.1.0 or later in the *Configure selected add-ons settings*.
2. Test the metrics endpoint directly:
   - Access the metrics at http://*pod-ip:port*/metrics (replace pod-ip with the actual pod IP address and port with your configured port).
   - If you can't access the endpoint, verify your network configuration and security group settings.
3. Validate your monitoring tool configuration. Consult you monitoring tools user guide for details on how to do the following:
   - Ensure your monitoring tool (such as Prometheus) is configured to scrape the correct endpoint.
   - Check that the scraping interval and timeout settings are appropriate.
   - Verify that your monitoring tool has network access to the pod IP address.

Metrics missing from specific pods

Problem: Metrics are available from some pods but not others in your cluster.

Troubleshooting Steps:

The Network Flow Monitor add-on doesn't support pods that use hostNetwork: true. If your pod specification includes this setting, metrics won't be available from those pods.

Workaround: Remove the hostNetwork: true setting from your pod specification if possible. If you require host networking for your application, consider using alternative monitoring approaches for those specific pods.

Connection refused errors

Problem: You receive "connection refused" errors when trying to access the metrics endpoint.

Troubleshooting Steps:

1. Verify the OPEN_METRICS_ADDRESS configuration:
   - If set to 127.0.0.1, the endpoint is only accessible from within the pod.
   - If set to 0.0.0.0, the endpoint should be accessible from other pods in the cluster.
   - Ensure your monitoring tool can reach the configured address.
2. Check the OPEN_METRICS_PORT configuration:
   - Verify that the port number is not already in use by another service.
   - Ensure the port is within the valid range (1-65535).
   - Confirm that any security groups or network policies allow traffic on this port.

Verification steps

To confirm your OpenMetrics configuration is working correctly:

1. Check the add-on status:

```
aws eks describe-addon --cluster-name your-cluster-name --addon-name aws-network-flow-monitoring-agent
```

2. Verify pod status:

```
kubectl get pods app.kubernetes.io/name=aws-network-flow-monitoring-agent
```

3. Test the metrics endpoint from within the cluster:

```
kubectl exec add-on-pod-name -- curl localhost:9109/metrics
```

Replace 9109 with your configured port number, and the pod name with an AddOn pod name.

Additional network path metadata included for Amazon EKS

When Network Flow Monitor gathers performance metrics for network flows between Amazon EKS components, it includes additional metadata information about the network path, to help you better understand how the network paths for your workload are performing.

You can view detailed information about Amazon EKS network flow performance by creating a monitor for the network flows that you're interested in, and then viewing details on the **Historical explorer** tab.

With Network Flow Monitor, you can measure network performance between the following Amazon EKS components, to better understand how your workload is performing with your Amazon EKS configuration and determine where there are bottlenecks or impairments.

- Pod to pod on the same node
- Node to node on the same cluster
- Pod to pod on a different cluster
- Node to node on different clusters
- With and without Network Load Balancer

The following table lists the information that Network Flow Monitor returns for each network flow scenario.

Connection information				Metadata information					
				Local			Remote		
Scenario	Initiated by	Local	Remote	Pod name	Service	Namesp	Pod name	Service	Namespace
Local pod connecting to cluster IP of another internal cluster service	Local	Local pod IP address	Remote pod IP address (through cluster IP address)	✓	✓	✓	✓ [1]	✓	✓
Local pod in a node network namespa connecting to cluster IP of another internal cluster service	Local	Local node IP address	Remote pod IP address (through cluster IP address)	✓ [2]	✓ [2]	✓ [2]	✓ [1]	✓	✓
Local pod connecting to individua	Local	Local pod IP address	Remote pod IP address	✓	✓	✓	✓	✓	✓

Connection information				Metadata information					
				Local			Remote		
Scenario	Initiated by	Local	Remote	Pod name	Service	Namespa	Pod name	Service	Namespace
l pod IP address of another pod (headless service)									
Local pod connecting to individual pod IP address of another pod in node network namespace (headless service)	Local	Local pod IP address	Remote node IP address	✓	✓	✓	✓	✓	✓

Connection information				Metadata information					
				Local			Remote		
Scenario	Initiated by	Local	Remote	Pod name	Service	Namespace	Pod name	Service	Namespace
Local pod connecting to remote pod in another cluster	Local	Local pod IP address	Remote pod IP address (another cluster)	✓	✓	✓	✗	✗	✗
Local pod connecting to an external network address	Local	Local pod IP address	External IP address	✓	✓	✓	N/A	N/A	N/A
Local pod operating in a node network namespace connecting to an external network IP address	Local	Local node IP address	External IP address	✓ [2]	✓ [2]	✓ [2]	N/A	N/A	N/A

Connection information				Metadata information					
				Local			Remote		
Scenario	Initiated by	Local	Remote	Pod name	Service	Namespace	Pod name	Service	Namespace
Remote pod connecting to local pod through cluster IP address	Remote	Local pod IP address (through cluster IP address)	Remote pod IP address	✓	✓	✓	✓	✓	✓
Remote pod in a node network namespace connecting to local pod	Remote	Local pod IP address (through cluster IP address)	Remote node IP address	✓	✓	✓	✓ [3]	✓ [3]	✓ [3]
Remote pod connecting to local pod (headless service)	Remote	Local pod IP address	Remote pod IP address	✓	✓	✓	✓	✓	✓

Connection information				Metadata information					
				Local			Remote		
Scenario	Initiated by	Local	Remote	Pod name	Service	Namesp	Pod name	Service	Namespace
External pod connecting to a local pod	Remote	Local pod IP address	Remote pod IP address	✓	✓	✓	✗	✗	✗
External resource connecting through NodePort or a Load Balancer to a local pod	Remote	Local pod IP address	External IP address [4]	✓	✓	✓	N/A	N/A	N/A

Connection information				Metadata information					
				Local			Remote		
Scenario	Initiated by	Local	Remote	Pod name	Service	Namespace	Pod name	Service	Namespace
External resource connecting through NodePort or a Load Balancer to a local pod operating in a node network namespace	Remote	Local node IP address	External IP address [4]	✓	✓	✓	N/A	N/A	N/A

Be aware of the following additional information corresponding to the items marked with footnotes in the preceding table.

1. Pod name is not visible in this scenario for pods with other owners, such as a Kubernetes service managed by the EKS control plane.
2. Local pod name, service, and namespace are not resolved if other pods are present in node network namespace.
3. Remote pod name, service, and namespace are not resolved if other pods are present in node network namespace.

4. If service is using NodePort or LoadBalancer in instance mode, and `ExternalTrafficPolicy` is set to `Cluster`, then this IP address will be reported as the IP address of the node that receives the NodePort connection.

Install Network Flow Monitor agents on EC2 and self-managed Kubernetes instances

To provide performance metrics for network flows in your AWS workloads, Network Flow Monitor relies on *agents* that you install, which send the metrics to Network Flow Monitor. You install Network Flow Monitor agents on your instances, and then set the correct permissions for the agents so that they can send metrics to the Network Flow Monitor backend.

An agent is a lightweight software application that you install on your resources, such as your VPC EC2 instances. Agents send performance metrics to the Network Flow Monitor backend on an ongoing basis. Then, you can view the metrics on the **Workload insights** page in the Network Flow Monitor console. You can also track detailed metrics for a specific network flow, or set of flows, by creating a monitor.

The steps that you follow to deploy agents in your instances depend on the type of instance: Amazon EKS Kubernetes instances, VPC EC2 instances, or self-managed (non-EKS) Kubernetes instances.

- For information about working with Amazon EKS, including installing agents on EKS, see Work with EKS.
- For information about installing agents on VPC EC2 instances and self-managed Kubernetes instances, see the sections in this chapter.

You can establish a private connection between your VPC and Network Flow Monitor agents by using AWS PrivateLink. For more information, see Using CloudWatch, CloudWatch Synthetics, and CloudWatch Network Monitoring with interface VPC endpoints.

Contents

- Linux versions supported for Network Flow Monitor agents
- Install and manage agents for EC2 instances
- Install agents for self-managed Kubernetes instances
- Using AI agents to install and troubleshoot Network Flow Monitor agents

Linux versions supported for Network Flow Monitor agents

The instances that you install agents on must be running supported versions and distributions of Linux. Network Flow Monitor supports agents to run only on Linux, and the Linux kernel version must be 5.8 or later. The following Linux distributions are supported. Note that agents are tested to run on the latest versions of these distributions.

- Amazon Linux
- Ubuntu
- Red Hat
- Suse Linux
- Debian distributions for both x86 and aarch64

Install and manage agents for EC2 instances

Follow the steps in this section to install Network Flow Monitor agents for workloads on Amazon EC2 instances. You can install agents by using SSM or by downloading and installing prebuilt packages for the Network Flow Monitor agent by using the command line.

Regardless of the method that you use to install agents on EC2 instances, you must configure permissions for the agents to enable them to send performance metrics to the Network Flow Monitor backend.

Contents

- Configure permissions for agents
- Install agents on EC2 instances with SSM
- Download prebuilt packages of the Network Flow Monitor agent by using the command line

Configure permissions for agents

To enable agents to send metrics to the Network Flow Monitor ingestion backend, the EC2 instances that the agents run in must use a role that has a policy attached with the correct permissions. To provide the required permissions, use a role that has the following AWS managed policy attached: CloudWatchNetworkFlowMonitorAgentPublishPolicy. Attach this policy to the IAM roles of the EC2 instances where you plan to install Network Flow Monitor agents.

We recommend that you add the permissions before you install agents on the EC2 instances. You can choose to wait until after you install agents, but the agents won't be able to send metrics to the service until the permissions are in place.

To add permissions for Network Flow Monitor agents

1. In the AWS Management Console, in the Amazon EC2 console, locate the EC2 instances that you plan to install Network Flow Monitor agents on.
2. Attach the CloudWatchNetworkFlowMonitorAgentPublishPolicy to the IAM role for each instance.

   If an instance doesn't have an IAM role attached, choose a role by doing the following:

   1. Under **Actions**, choose **Security**.
   2. Choose **Modify IAM role**, or create a new role by choosing **Create new IAM role**.
   3. Choose a role for the instance, and attach the CloudWatchNetworkFlowMonitorAgentPublishPolicy policy.

Install agents on EC2 instances with SSM

Network Flow Monitor agents provide performance metrics about network flows. Follow the steps in this section to install and work with Network Flow Monitor agents on EC2 instances, by using AWS Systems Manager. If you use Kubernetes, skip to the next sections for information about installing agents with Amazon EKS clusters or self-managed Kubernetes clusters.

Network Flow Monitor provides a Distributor package for you in Systems Manager to use to install or uninstall agents. In addition, Network Flow Monitor provides a document to activate or deactivate agents, by using the Document Type command. Use standard Systems Manager procedures to use the package and the document, or follow the steps provided here for detailed guidance.

For more information in general about using Systems Manager, see the following documentation:

- AWS Systems Manager Run Command
- AWS Systems Manager Distributor

Complete the steps in the following sections to configure permissions, install, and work with Network Flow Monitor agents.

Contents

- Install or uninstall agents
- Activate or deactivate agents

Install or uninstall agents by using Systems Manager

Network Flow Monitor provides a distributor package in AWS Systems Manager for you to install Network Flow Monitor agents: **AmazonCloudWatchNetworkFlowMonitorAgent**. To access and run the package to install agents, follow the steps provided here.

To install agents in EC2 instances

1. In the AWS Management Console, in AWS Systems Manager, under **Node Tools**, choose **Distributor**.
2. Under **Owned by Amazon**, locate the Network Flow Monitor package, **AmazonCloudWatchNetworkFlowMonitorAgent**, and select it.
3. In the **Run command** flow, choose **Install one time** or **Install on schedule**.
4. In the **Target selection** section, choose how you want to select your EC2 instances to install agents on. You can select instances based on tags, choose instances manually, or base the choice on resource groups.
5. In the **Commmand parameters** section, under **Action**, choose **Install**.
6. Scroll down, if necessary, and then choose **Run** to start the installation.

If the installation is successful and the instances have permissions to access Network Flow Monitor endpoints, the agent will start collecting metrics and send reports to the Network Flow Monitor backend.

Agents that are active (sending metrics data) incur billing costs. For more information about Network Flow Monitor and Amazon CloudWatch pricing, see Network Monitoring on the Amazon CloudWatch pricing page. If you don't need metrics data temporarily, you can deactivate an agent. For more information, see Activate or deactivate agents. If you no longer need Network Flow Monitor agents, you can uninstall them from the EC2 instances.

To uninstall agents from EC2 instances

1. In the AWS Management Console, in AWS Systems Manager, under **Node Tools**, choose **Distributor**.
2. Under **Owned by Amazon**, locate the Network Flow Monitor package, **AmazonCloudWatchNetworkFlowMonitorAgent**, and select it.
3. In the **Commmand parameters** section, under **Action**, choose **Uninstall**.
4. Select the EC2 instances to uninstall agents from.
5. Scroll down, if necessary, and then choose **Run** to start the installation.

Activate or deactivate agents by using Systems Manager

After you install a Network Flow Monitor agent with SSM, you must activate it to receive network flow metrics from the instance where it's installed. Agents that are active (sending metrics data) incur billing costs. For more information about Network Flow Monitor and Amazon CloudWatch pricing, see Network Monitoring on the Amazon CloudWatch pricing page. If you don't need metrics data temporarily, you can deactivate an agent to prevent ongoing billing for the agent.

Network Flow Monitor provides a document in AWS Systems Manager that you can use activate or deactivate agents that you've installed on your EC2 instances. By running this document to manage the agents, you can activate them to begin receiving performance metrics. Or, you can deactivate them to temporarily stop metrics from being sent,without uninstalling the agents.

The document in SSM that you can use to activate or deactivate agents is called **AmazonCloudWatch-NetworkFlowMonitorManageAgent**. To access and run the document, follow the steps in the procedure.

To activate or deactivate Network Flow Monitor agents

1. In the AWS Management Console, in AWS Systems Manager, under **Change Management Tools**, choose **Documents**.
2. Under **Owned by Amazon**, locate the Network Flow Monitor document, **AmazonCloudWatch-NetworkFlowMonitorManageAgent**, and select the document.
3. In the **Target selection** section, choose how you want to select your EC2 instances to install agents on. You can select instances based on tags, choose instances manually, or base the choice on resource groups.

4. In the **Command parameters** section, under **Action**, choose **Activate** or **Deactivate**, depending on the action that you want to take for the agents.
5. Scroll down, if necessary, and then choose **Run** to start the installation.

Download prebuilt packages of the Network Flow Monitor agent by using the command line

You can use the command line to install the Network Flow Monitor agent as a package in Amazon Linux 2023, or download and install prebuilt packages of the Network Flow Monitor agent.

Before or after you download a prebuilt package, you can optionally verify the package signature. For more information, see Verify the signature of the Network Flow Monitor agent package.

Choose from the following instructions, depending on the Linux operating system that you're using and the type of installation that you want.

Amazon Linux AMIs

The Network Flow Monitor agent is available as a package in Amazon Linux 2023. If you're using this operating system, you can install the package by entering the following command:

```
sudo yum install network-flow-monitor-agent
```

You must also make sure that the IAM role attached to the instance has the CloudWatchNetworkFlowMonitorAgentPublishPolicy policy attached. For more information, see Configure permissions for agents.

Amazon Linux 2023

Install the package for your architecture by using one of the following commands:

- **x86_64**: `sudo yum install https://networkflowmonitoragent.awsstatic.com/latest/x86_64/network-flow-monitor-agent.rpm`
- **ARM64 (Graviton)**: `sudo yum install https://networkflowmonitoragent.awsstatic.com/latest/arm64/network-flow-monitor-agent.rpm`

Verify that Network Flow Monitor agent is successfully installed by running the following command and verifying that the response shows that the agent is enabled and active:

```
service network-flow-monitor status
network-flow-monitor.service - Network Flow Monitor Agent
```

```
     Loaded: loaded (/usr/lib/systemd/system/network-flow-monitor.service; enabled;
 preset: enabled)
     Active: active (running) since Wed 2025-04-23 19:17:16 UTC; 1min 9s ago
```

DEB-based distributions (Debian, Ubuntu)

Install the package for your architecture by using one of the following commands:

- **x86_64**: `wget https://networkflowmonitoragent.awsstatic.com/latest/x86_64/network-flow-monitor-agent.deb`
- **ARM64 (Graviton)**: `wget https://networkflowmonitoragent.awsstatic.com/latest/arm64/network-flow-monitor-agent.deb`

Install the package by using the following command: `$ sudo apt-get install ./network-flow-monitor-agent.deb`

Verify that Network Flow Monitor agent is successfully installed by running the following command and verifying that the response shows that the agent is enabled and active:

```
service network-flow-monitor status
network-flow-monitor.service - Network Flow Monitor Agent
     Loaded: loaded (/usr/lib/systemd/system/network-flow-monitor.service; enabled;
 preset: enabled)
     Active: active (running) since Wed 2025-04-23 19:17:16 UTC; 1min 9s ago
```

Verify the signature of the Network Flow Monitor agent package

The Network Flow Monitor agent rpm and deb installer packages for Linux instances are cryptographically signed. You can use a public key to verify that the agent package is original and unmodified. If the files are damaged or have been altered, the verification fails. You can verify the signature of the installer package using either RPM or GPG. The following information is for Network Flow Monitor agent versions 0.1.3 or later.

To find the correct signature file for each architecture and operating system, use the following table.

Architecture	Platform	Download link	Signature file link
x86-64	Amazon Linux 2023	https://networkflowmonitoragent.awsstatic.com/latest/	https://networkflowmonitoragent.awsstatic.com/latest/

Architecture	Platform	Download link	Signature file link
		x86_64/network-flow-monitor-agent.rpm	x86_64/network-flow-monitor-agent.rpm.sig
ARM64	Amazon Linux 2023	https://networkflowmonitoragent.awsstatic.com/latest/arm64/network-flow-monitor-agent.rpm	https://networkflowmonitoragent.awsstatic.com/latest/arm64/network-flow-monitor-agent.rpm.sig
x86-64	Debian/Ubuntu	https://networkflowmonitoragent.awsstatic.com/latest/x86_64/network-flow-monitor-agent.deb	https://networkflowmonitoragent.awsstatic.com/latest/x86_64/network-flow-monitor-agent.deb.sig
ARM64	Debian/Ubuntu	https://networkflowmonitoragent.awsstatic.com/latest/arm64/network-flow-monitor-agent.deb	https://networkflowmonitoragent.awsstatic.com/latest/arm64/network-flow-monitor-agent.deb.sig

Follow the steps here to verify the signature of the Network Flow Monitor agent.

To verify the signature of the Network Flow Monitor agent for Amazon S3 package

1. Install GnuPG so that you can run the gpg command. GnuPG is required to verify the authenticity and integrity of a downloaded Network Flow Monitor agent for an Amazon S3 package. GnuPG is installed by default on Amazon Linux Amazon Machine Images (AMIs).
2. Copy the following public key and save it to a file named `nfm-agent.gpg`.

```
-----BEGIN PGP PUBLIC KEY BLOCK-----

=INr5
-----END PGP PUBLIC KEY BLOCK-----
```

3. Import the public key into your keyring and note the returned value.

```
PS>  rpm --import nfm-agent.gpg
gpg: key 3B789C72: public key "Network Flow Monitor Agent" imported
gpg: Total number processed: 1
gpg: imported: 1 (RSA: 1)
```

Make a note of the key value because you need it in the next step. In this example, the key value is 3B789C72.

4. Verify the fingerprint by running the following command. Be sure to replace *key-value* with the value from the preceding step. We recommend that you use GPG to verify the fingerprint even if you use RPM to verify the installer package.

```
PS>  gpg --fingerprint key-value
pub   rsa4096 2025-04-08 [SC] [expires: 2028-04-07]
      7673 6CA9 97AD D3E9 D277  26A8 EFBD A4CC BC95 FAD1
uid   Network Flow Monitor Agent <network-flow-monitor-agent@amazon.com>
```

The fingerprint string should be equal to the following:

```
7673 6CA9 97AD D3E9 D277 26A8 EFBD A4CC BC95 FAD1
```

If the fingerprint string doesn't match, don't install the agent. Contact Amazon Web Services.

After you have verified the fingerprint, you can use it to verify the signature of the Network Flow Monitor agent package.

5. Download the package signature file, if you haven't already done so, based on your instance's architecture and operating system.
6. Verify the installer package signature. Be sure to replace the `signature-filename` and `agent-download-filename` with the values that you specified when you downloaded the signature file and agent, as shown in the table earlier in this topic.

```
PS> gpg --verify sig-filename agent-download-filename
gpg: Signature made Tue Apr  8 00:40:02 2025 UTC
gpg:                using RSA key 77777777EXAMPLEKEY
gpg:                issuer "network-flow-monitor-agent@amazon.com"
gpg: Good signature from "Network Flow Monitor Agent <network-flow-monitor-
agent@amazon.com>" [unknown]
gpg: WARNING: Using untrusted key!
```

If the output includes the phrase BAD `signature`, check to make sure that you performed the procedure correctly. If you continue to get this response, contact AWS Support and avoid using the downloaded file.

Note the warning about trust. A key is trusted only if you or someone who you trust has signed it. This doesn't mean that the signature is invalid, only that you have not verified the public key.

Next, follow the steps here to verify the RPM package.

To verify the signature of the RPM package

1. Copy the following public key and save it to a file named `nfm-agent.gpg`.

```
-----BEGIN PGP PUBLIC KEY BLOCK-----

mQINBGf0b5IBEAC6YQc0aYrTbcHNWWMbLuqsqfspzWrtCvoU0yQ62ld7nvCGBha9

=INr5
-----END PGP PUBLIC KEY BLOCK-----
```

2. Import the public key into your keyring.

```
PS>  rpm --import nfm-agent.gpg
```

3. Verify the installer package signature. Be sure to replace the `agent-download-filename` with the value that you specified when you downloaded the agent, as shown in the table earlier in this topic.

```
PS>  rpm --checksig agent-download-filename
```

For example, for the x86_64 architecture on Amazon Linux 2023, use the following command:

```
PS>  rpm --checksig network-flow-monitor-agent.rpm
```

This command returns output similar to the following.

```
network-flow-monitor-agent.rpm: digests signatures OK
```

If the output contains the phrase `NOT OK (MISSING KEYS: (MD5) key-id)`, check to make sure that you performed the procedure correctly. If you continue to get this response, contact AWS Support and don't install the agent.

Install agents for self-managed Kubernetes instances

Follow the steps in this section to install Network Flow Monitor agents for workloads on self-managed Kubernetes clusters. After you complete the steps, Network Flow Monitor agent pods will be running on all of your self-managed Kubernetes cluster nodes.

If you use Amazon Elastic Kubernetes Service (Amazon EKS), the installation steps to follow are in the following section: Install the EKS AWS Network Flow Monitor Agent add-on.

Contents

- Before you begin
- Download Helm charts and install agents
- Configure permissions for agents to deliver metrics

Before you begin

Before you start the installation process, follow the steps in this section to make sure that your environment is set up to successfully install agents on the right Kubernetes clusters.

Ensure that your version of Kubernetes is supported

Network Flow Monitor agent installation requires Kubernetes Version 1.25, or a more recent version.

Ensure that you have installed required tools

The scripts that you use for this installation process require that you install the following tools. If you don’t have the tools installed already, see the provided links for more information.

- The AWS Command Line Interface (CLI). For more information, see Installing or updating to the latest version of the AWS Command Line Interface in the AWS Command Line Interface Reference Guide.
- The Helm package manager. For more information, see Installing Helm on the Helm website.
- The `kubectl` command line tool. For more information, see Install kubectl on the Kubernetes website.

- The `make` Linux command dependency. For more information, see the following blog post: Intro to make Linux Command: Installation and Usage. For example, do one of the following:
  - For Debian based distributions, such as Ubuntu, use the following command: `sudo apt-get install make`
  - For RPM-based distributions, such as CentOS, use the following command: `sudo yum install make`

Ensure that you have valid, correctly configured KubeConfig environment variables

Network Flow Monitor agent installation uses the Helm package manager tool, which uses the kubeconfig variable, `$HELM_KUBECONTEXT`, to determine the target Kubernetes clusters to work with. Also, be aware that when Helm runs installation scripts, by default, it references the standard `~/.kube/config` file. You can change the configuration environment variables, to use a different config file (by updating `$KUBECONFIG`) or to define the target cluster you want to work with (by updating `$HELM_KUBECONTEXT`).

Create a Network Flow Monitor Kubernetes namespace

The Network Flow Monitor agent's Kubernetes application installs its resources into a specific namespace. The namespace must exist for the installation to succeed. To ensure that the required namespace is in place, you can do one of the following:

- Create the default namespace, `amazon-network-flow-monitor`, before you begin.
- Create a different namespace, and then define it in the `$NAMESPACE` environment variable when you run the installation to make targets.

Download Helm charts and install agents

You can download the Network Flow Monitor agent Helm charts from the AWS public repository by using the following command. Make sure that you first authenticate with your GitHub account.

```
git clone https://github.com/aws/network-flow-monitor-agent.git
```

In the `./charts/amazon-network-flow-monitor-agent` directory, you can find the Network Flow Monitor agent Helm charts and Makefile that contain the installation make targets that you use for installing agents. You install agents for Network Flow Monitor by using the following Makefile target: `helm/install/customer`

You can customize the installation if you like, for example, by doing the following:

```
# Overwrite the kubeconfig files to use
```

```
KUBECONFIG=<MY_KUBECONFIG_ABS_PATH> make helm/install/customer

# Overwrite the Kubernetes namespace to use
NAMESPACE=<MY_K8S_NAMESPACE> make helm/install/customer
```

To verify that the Kubernetes application pods for the Network Flow Monitor agents have been created and deployed successfully, check to be sure that their state is `Running`. You can check state of the agents by running the following command: `kubectl get pods -o wide -A | grep amazon-network-flow-monitor`

Configure permissions for agents to deliver metrics

After you install agents for Network Flow Monitor, you must enable the agents to send network metrics to the Network Flow Monitor ingestion APIs. Agents in Network Flow Monitor must have permission to access the Network Flow Monitor ingestion APIs so that they can deliver network flow metrics that they've collected for each instance. You grant this access by implementing IAM roles for service accounts (IRSA).

To enable agents to deliver network metrics to Network Flow Monitor, follow the steps in this section.

1. **Implement IAM roles for service accounts**

   IAM roles for service accounts provides the ability to manage credentials for your applications, similar to the way that Amazon EC2 instance profiles provide credentials to Amazon EC2 instances. Implementing IRSA is the recommended way to provide all permissions required by Network Flow Monitor agents to successfully access Network Flow Monitor ingestion APIs. For more information, see IAM roles for service accounts in the Amazon EKS User Guide.

   When you set up IRSA for Network Flow Monitor agents, use the following information:

   - **ServiceAccount:** When you define your IAM role trust policy, for `ServiceAccount`, specify `aws-network-flow-monitor-agent-service-account`.
   - **Namespace:** For the `namespace`, specify `amazon-network-flow-monitor`.
   - **Temporary credentials deployment:** When you configure permissions after you have deployed Network Flow Monitor agent pods, updating the `ServiceAccount` with your IAM role, Kubernetes does not deploy the IAM role credentials. To ensure that the Network Flow Monitor agents acquire the IAM role credentials that you've specified, you must rolling out a restart of `DaemonSet`. For example, use a command like the following:

```
kubectl rollout restart daemonset -n amazon-network-flow-monitor aws-
network-flow-monitor-agent
```

2. **Confirm that the Network Flow Monitor agent is successfully accessing the Network Flow Monitor ingestion APIs**

   You can check to make sure that your configuration for agents is working correctly by using the HTTP 200 logs for Network Flow Monitor agent pods. First, search for a Network Flow Monitor agent pod, and then search through the log files to find successful HTTP 200 requests. For example, you can do the following:

   a. Locate a Network Flow Monitor agent pod name. For example, you can use the following command:

   ```
   RANDOM_AGENT_POD_NAME=$(kubectl get pods -o wide -A | grep amazon-network-flow-
   monitor | grep Running | head -n 1 | tr -s ' ' | cut -d " " -f 2)
   ```

   b. Grep all the HTTP logs for the pod name that you've located. If you've changed the NAMESPACE, make sure that you use the new one.

   ```
   NAMESPACE=amazon-network-flow-monitor
   kubectl logs $RANDOM_AGENT_POD_NAME -\-namespace ${NAMESPACE} | grep HTTP
   ```

   If access has been granted successfully, you should see log entries similar to the following:

   ```
   ...
   {"level":"INFO","message":"HTTP request
    complete","status":200,"target":"amzn_nefmon::reports::publisher_endpoint","timestamp":17370
   {"level":"INFO","message":"HTTP request
    complete","status":200,"target":"amzn_nefmon::reports::publisher_endpoint","timestamp":17370
   ```

   Note that the Network Flow Monitor agent publishes network flow reports every 30 seconds, by calling the Network Flow Monitor ingestion APIs.

Using AI agents to install and troubleshoot Network Flow Monitor agents

You can use Model Context Protocol (MCP)-compatible AI agents to install, configure, and troubleshoot Network Flow Monitor agents on your workloads. The `aws-network-monitoring` skill from the Agent Toolkit for AWS can help with the following:

- **Agent installation** – Install Network Flow Monitor agents using AWS Systems Manager Distributor or command-line install. The skill guides the assistant through attaching the `CloudWatchNetworkFlowMonitorAgentPublishPolicy` managed policy to the instance role, running the install document, and activating the agents.
- **Troubleshooting** – Diagnose common issues, including HTTP 403 errors from missing IAM permissions, missing performance metrics after installation (activation not run), and connectivity failures from private subnets that lack the required virtual private cloud (VPC) endpoints.

Prerequisites

Before you start, make sure you have the following:

- **An AI agent** – An AI coding agent that supports MCP, such as Kiro CLI. For a list of supported AI coding agents, see What is the Agent Toolkit for AWS? in the *AWS Agent Toolkit User Guide*.
- **AWS MCP server** – Configure the AWS MCP server in your agent so it can make AWS API calls. For more information, see Setting up the AWS MCP Server in the *AWS Agent Toolkit User Guide*.
- **AWS credentials** – An AWS account with IAM credentials set up on your local machine. Credentials are required for tools that execute AWS API calls and run scripts, but not for searching documentation or discovering skills.

Install the aws-network-monitoring skill

A skill is a curated package of instructions and reference materials that helps your AI agent complete Network Flow Monitor tasks. The `aws-network-monitoring` skill contains install procedures, IAM policy attachment, activation steps, and troubleshooting patterns. For more information, see Skills in the *AWS Agent Toolkit User Guide*.

Use the AWS CLI to install the skill for your agent. For more information about the install command, see Using the AWS CLI in the *AWS Agent Toolkit User Guide*.

```
aws agent-toolkit add-skill --skill-name aws-network-monitoring
```

After the skill is installed, your agent can load it on demand when you ask about installing, configuring, or troubleshooting Network Flow Monitor agents.

Example prompts

The following prompts show common Network Flow Monitor workflows you can run through an AI agent after installing the skill.

Install agents on EC2 instances

Provide an Amazon EC2 tag key and value, or one or more instance IDs, and the AWS Region. The agent resolves the target instances, runs the Systems Manager install document, attaches the required IAM policy to each instance role, and activates the agents.

```
Install Network Flow Monitor agents on my EC2 instances tagged Environment=Sandbox in
 us-east-1.
```

```
Install the Network Flow Monitor agent on my EC2 instance i-abc123 in us-east-1.
```

Verify that agents are publishing performance metrics

Ask the agent to check whether a running Network Flow Monitor agent is successfully publishing reports to the Network Flow Monitor ingestion endpoint.

```
Verify that the Network Flow Monitor agent on i-abc123 in us-east-1 is publishing
 performance metrics.
```

Troubleshoot agents that are not sending performance metrics

The agent checks the IAM policy attachment, activation status, and endpoint reachability.

```
My Network Flow Monitor agent on i-abc123 in us-east-1 is installed but not sending
 performance metrics. What's wrong?
```

Initialize Network Flow Monitor

Before you can view performance metrics for network flows, you must initialize Network Flow Monitor, which grants required permissions and creates an initial topology for your account or accounts. If you plan to monitor resources for multiple accounts, you must also configure AWS Organizations with Amazon CloudWatch. Then, you specify accounts for your Network Flow

Monitor scope, so that Network Flow Monitor can create an initial topology for all the accounts that you'll be tracking performance metrics for.

In addition, you must install agents on your instances, to send performance metrics to the Network Flow Monitor ingestion server. For more information, see Install Network Flow Monitor agents on EC2 and self-managed Kubernetes instances.

The steps that you take to initialize Network Flow Monitor vary depending on whether you are measuring performance metrics for resources in a single account, or you want to monitor metrics from resources that are owned by multiple accounts in your organization.

- Single account monitoring initialization
- Multi-account monitoring initialization

Initialize Network Flow Monitor for single account monitoring

To initialize Network Flow Monitor to monitor network performance metrics, you must grant permissions and Network Flow Monitor must create the initial topology for your account. When you monitor resources in just one account, Network Flow Monitor sets your account as the scope for network monitoring and creates a topology for that scope.

Initializing Network Flow Monitor does the following:

- Grants permissions for Network Flow Monitor to use required service-linked roles with your account. Network Flow Monitor requires you to grant it specific permissions so that the feature can send metrics to Amazon CloudWatch on your behalf, as well as create topologies of network flows. For more information, see Service-linked roles for Network Flow Monitor.
- Sets your monitoring scope for Network Flow Monitor to the AWS account that you're signed in with. For more information, see **Scope** in Components and features of Network Flow Monitor.
- Creates an initial topology for your scope.

To initialize Network Flow Monitor by setting up the service-linked roles that provide the required permissions, setting the scope to your account, and creating a topology for network flow performance monitoring, follow these steps.

To initialize Network Flow Monitor

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

2. In the left navigation pane, under **Network Monitoring**, choose **Flow monitors**.
3. In the **Getting started with Network Flow Monitor** section, under Step 1, choose **Start initialization**.
4. On the **Configure Network Flow Monitor** page, scroll down, and then choose **Initialize Network Flow Monitor**.

Completing the initialization can take 20-30 minutes.

After you initialize Network Flow Monitor for your account, before you can view network flow performance metrics, you must also install Network Flow Monitor agents for your resources that send performance metrics to the Network Flow Monitor backed ingestion server. For more information, see Install Network Flow Monitor agents on EC2 and self-managed Kubernetes instances.

Initialize Network Flow Monitor for multi-account monitoring

If you want to monitor network flows in Network Flow Monitor for resources that are owned by different accounts, you must first configure Amazon CloudWatch with AWS Organizations. To use multiple accounts in Network Flow Monitor, you're required to turn on trusted access for CloudWatch, and it's a best practice to also register a delegated administrator.

In addition, if you plan to create monitors for network flows from the console, you must add a Network Flow Monitor policy to the role that is attached to your resources. The policy enables you to view resources from other accounts in the console, so that you can add the resources in multiple accounts to a monitor.

To monitor network flows for resources that are owned by different accounts, there are additional configuration steps to take. First, as the management account, you must configure CloudWatch with AWS Organizations to turn on trusted access, and, typically, you'll also register a delegated administrator account. Then, using the delegated administrator account, you can add more accounts in your organization, to set the scope for your network observability to include resources in those accounts. (You can also add multiple accounts with a management account, but it's a best practice in Organizations to use the delegated administrator account when you work with resources in a service. We provide steps that follow that guidance in the instructions here for Network Flow Monitor.)

Note that if you don't need to monitor network flows for instances from multiple accounts, you can use Network Flow Monitor with a single account. The scope for Network Flow Monitor is automatically set to the AWS account that you sign in with.

Use the guidance in the following sections to complete these steps.

> **⚠ Shared VPC with Amazon EKS clusters**
>
> If your Amazon EKS cluster runs in a member account that uses a shared subnet (a subnet owned by another account), you must create the monitor in the account that owns the subnet (typically the delegated admin or management account), not in the member account where the Amazon EKS cluster resides. A monitor created in the member account cannot match network flow data because the member account does not own the subnet resources. To monitor flows for the Amazon EKS cluster, create the monitor in the subnet-owning account and specify the Amazon EKS cluster as the local resource.

- Overview of steps for using multiple accounts in Network Flow Monitor
- Configure AWS Organizations in CloudWatch
- Add multiple accounts to your scope
- Set up permissions for multi-account resource access (console only)

Overview of steps for using multiple accounts in Network Flow Monitor

To get started with Network Flow Monitor, any account that has not used Network Flow Monitor before must initialize Network Flow Monitor. When you initialize Network Flow Monitor for an account, Network Flow Monitor adds the required service-linked role permissions and creates a scope of the account or accounts to be included in network observability. To work with multiple accounts in Network Flow Monitor, there are additional steps, to integrate with AWS Organizations, and then add the accounts to work with.

In summary, you take the following steps:

1. Sign in to the AWS Management Console as the management account, and then do the following:
   - Complete the required steps for integrating with AWS Organizations in CloudWatch.

2. Sign in to the AWS Management Console as the delegated administrator account, and then do the following:
   - Initialize Network Flow Monitor, including adding accounts to include in your scope.
   - Add the required permissions for accessing resources that are in other accounts from the console.

If you're setting up Network Flow Monitor to work with multiple accounts and you're not familiar with AWS Organizations, review the following resources to learn about concepts such as the management account, trusted access, and the delegated administrator account, and to learn how to integrate Organizations with CloudWatch.

- Managing accounts in an organization with AWS Organizations in the AWS Organizations User Guide.
- Amazon CloudWatch and AWS Organizations in the AWS Organizations User Guide.

Follow the steps in the following sections for specific guidance in configuring Network Flow Monitor for multiple accounts.

Configure AWS Organizations in CloudWatch

To configure Network Flow Monitor with AWS Organizations, sign in to the management account, and turn on trusted access for CloudWatch. Then, register a delegated administrator account to use for initializing Network Flow Monitor and adding multiple accounts.

If you've already configured Organizations in CloudWatch to turn on trusted access for Organizations in CloudWatch and register a delegated administrator account, you don't need to configure anything more for Organizations that is specific to Network Flow Monitor. You can sign in with the delegated administrator account for CloudWatch, and then initialize Network Flow Monitor, including adding multiple accounts for your network observability scope.

If you haven't yet configured Organizations in CloudWatch, follow the steps here to turn on trusted access and register a delegated administrator account.

Turn on trusted access in CloudWatch

Before you can use Network Flow Monitor with more than one account in your organization, you must turn on trusted access for AWS Organizations in Amazon CloudWatch. Use the following steps to turn on trusted access in the CloudWatch console.

To turn on trusted access

1. Sign in to the console with your organization's management account.
2. In the CloudWatch console, in the navigation pane, choose **Settings**.
3. Choose the **Organizations** tab.
4. In **Organizational Management Settings**, choose **Turn on**. The **Enable trusted access** page appears.
5. To review the role policy, choose **View permission** details to see the role policy.
6. Choose **Enable trusted access**.

Now, as CloudWatch discovers resources, it automatically updates information about accounts that you have permission to access the resources for in Network Flow Monitor.

Register a delegated administrator account

As a best practice with AWS Organizations, the management account for your organization should register a member account as a delegated administrator account for CloudWatch. After you register a delegated administrator account in CloudWatch, members of your organization can sign in with the delegated administrator account to monitor the network performance for resources in multiple accounts in Network Flow Monitor.

Using the delegated administrator account, you can add multiple accounts for your network observability scope in Network Flow Monitor. Although the management account can also create a scope that includes multiple accounts, we recommend that you follow the best practices for AWS Organizations and use a delegated administrator account for adding multiple accounts in Network Flow Monitor. For member accounts that are not the delegated administrator account, the scope is limited to the signed-in account, which is automatically set for the scope.

A delegated administrator account for Organizations is a member account that shares administrator access for service-managed permissions. The account that you choose to register as a delegated administrator account must be a member account in your organization. A delegated administrator account for your organization can be used outside of CloudWatch, so make sure that you understand this account type before following this procedure. For more information, see Amazon CloudWatch and AWS Organizations in the AWS Organizations User Guide.

To register a delegated administrator account

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

2. In the navigation pane, choose **Settings**.
3. Choose the **Organization** tab.
4. Choose **Register delegated administrator**.
5. In the **Register delegated administrator** window, in the **Delegated administrator account ID** field, enter the 12-digit Organization member account ID.
6. Choose **Register delegated administrator**. A confirmation message appears indicating the account was registered successfully. The **Organization Settings** page appears. To see information about the delegated administrator account, hover over the number next to **Delegated administrators**.

To remove or change the delegated administrator account, deregister the account first. For more information, see Deregistering a delegated administrator account.

Add multiple accounts to your scope

To add accounts to your Network Flow Monitor scope, sign in with the delegated administrator account. (You can add accounts to a scope if you're signed in with the management account, but it's a best practice in AWS Organizations to use the delegated administrator account to work with resources.)

After you sign in, follow the steps to initialize Network Flow Monitor, a process which authorizes the required service-linked role permissions, lets you set the scope for your network observability by adding accounts, and then creates an initial topology for the accounts in the scope you've set. The account that you sign in with—in this case, the delegated administrator account—is automatically included in your Network Flow Monitor scope.

To initialize Network Flow Monitor with multiple accounts in your scope

1. Sign in to the console with your organization's delegated administrator account.
2. In the navigation pane for the CloudWatch console, under **Network Monitoring**, choose **Flow monitors**.
3. Under **Getting started with Network Flow Monitor**, in Step 1, choose **Start initialization**.
4. On the **Network Flow Monitor** page, under **Add accounts**, choose **Add**. The account that you're signed in with is automatically included in the scope and already appears in the **Accounts in scope** table as **(this account)**.
5. On the **Add accounts** dialog page, optionally filter the accounts, and then select up to 99 additional accounts to add to your scope. The maximum number of accounts in a scope is 100.

6. Choose **Add**.
7. Choose **Initialize Network Flow Monitor**. Network Flow Monitor adds the required service-linked role permissions, creates a scope that includes all the accounts you specified, and then creates an initial topology of the resources in the accounts in your scope.

To add or remove accounts for your scope after you've already initialized Network Flow Monitor, follow the steps here.

Be aware that after you make a change to your scope, either to add or delete accounts, you must wait about 20 minutes before you can make another change to the scope. This delay is because Network Flow Monitor requires a brief period of time to update its topology information.

To add or remove accounts for your scope

1. Sign in to the console with your organization's delegated administrator account.
2. In the navigation pane for the CloudWatch console, under **Network Monitoring**, choose **Flow monitors**.
3. Under **Monitors**, select a monitor.
4. On the **Monitor details** tab, under **Accounts in scope**, choose **Add** or **Delete**.
5. Select accounts to add to your scope, up to a total of 100 accounts, or select accounts to delete.
6. Complete the steps in the confirmation dialog.

Set up permissions for multi-account resource access (console only)

If you plan to create monitors for network flows from the console, a specific policy is required for each member account in your scope. This policy enables you to view resources from other accounts when you add local and remote resources to a monitor.

For each of the account in your scope, create a role, **NetworkFlowMonitorAccountResourceAccess**, and attach the **AmazonEC2ReadOnlyAccess** policy. To see permission details for the policy, see AmazonEC2ReadOnlyAccess in the AWS Managed Policy Reference Guide.

If you want to view Amazon EKS cluster resources from other accounts in the console, you must also add the following permissions to the **NetworkFlowMonitorAccountResourceAccess** role:

```
{
    "Version": "2012-10-17",
```

```
    "Statement": [
        {
            "Sid": "EKSReadAccess",
            "Effect": "Allow",
            "Action": [
                "eks:ListClusters",
                "eks:DescribeCluster",
                "eks:ListNodegroups",
                "eks:DescribeNodegroup",
                "eks:ListFargateProfiles",
                "eks:DescribeFargateProfile",
                "eks:ListAddons",
                "eks:DescribeAddon",
                "eks:AccessKubernetesApi"
            ],
            "Resource": "*"
        }
    ]
}
```

This policy is in addition to the policy that you must add to each instance so that the Network Flow Monitor agent can send performance metrics from the instance to the Network Flow Monitor ingestion backend server. For more information about requirements for agents, see Install Network Flow Monitor agents on EC2 and self-managed Kubernetes instances.

The following procedure provides a summary of the steps to create the required role for accessing resources in your scope in the Network Flow Monitor console. For general guidance on how to create a role in IAM, see Create a role to give permissions to an IAM user in the AWS Identity and Access Management User Guide.

To create a role for resource access in the Network Flow Monitor console

1. Sign in to the AWS Management Console and open the IAM console.
2. In the navigation pane of the console, choose **Roles**, and then choose **Create role**.
3. Specify the **AWS account** trusted entity. This trusted entity type enables principals in other AWS accounts to assume the role and access resources in other accounts.
4. Choose **Next**.
5. In the list of AWS managed policies, choose the **AmazonEC2ReadOnlyAccess** policy.
6. Choose **Next**.
7. For role name, enter **NetworkFlowMonitorAccountResourceAccess**.

8. Review the role, and then choose **Create role**.

Install agents on instances

To track network performance with Network Flow Monitor, you must initialize the service, but you must also install Network Flow Monitor agents on your workload's EC2 instances and add permissions for the agents to send networking performance metrics to Network Flow Monitor. After you install the agents, wait a short period of time (about 20 minutes), for data to begin being sent to the Network Flow Monitor backend. Then, you can view network performance metrics, on the **Workload insights** tab, and also create monitors, to view detailed information.

For example, you can view the top contributor performance metrics for data transferred and retransmission timeouts, for network flows between your local and remote resources, collected by Network Flow Monitor agents. By viewing and analyzing these metrics, you can choose specific flows that you want to see more details for and track more closely with a monitor. By creating a monitor for specific flows, you can see detailed information about them, including metrics, sorted by the top contributors for each metric type and network paths for each network flow.

With a monitor, Network Flow Monitor also provides a network health indicator (NHI), which you can use to see if there have been AWS network impairments for network flows that you're tracking in the monitor, during a time period that you've selected. That information can help you decide where to focus your network troubleshooting efforts.

For more information, and instructions for how to install agents, see Install Network Flow Monitor agents on EC2 and self-managed Kubernetes instances.

Monitor and analyze network flows in Network Flow Monitor

With Network Flow Monitor, you can learn about network flows and performance for traffic that you're monitoring with your scope. Start by reviewing top contributors information, by each metric type, in the **Workload insights** tab. Then, create monitors so that you can explore network performance in detail, over different time frames, for network flows that you select in **Workload insights**.

After you initialize Network Flow Monitor and install agents on your instances, Network Flow Monitor generates performance metrics for the network flows from those instances. Review the sections in this chapter to learn more about how to use Network Flow Monitor to evaluate network performance in Network Flow Monitor, create monitors for more in-depth information, and learn about the specific metrics provided by Network Flow Monitor.

The steps provided in these sections use the AWS Management Console. You can also use Network Flow Monitor API operations with the AWS Command Line Interface (AWS CLI) or AWS SDKs to review workload insights and top contributors metrics, and to create and configure a monitor. For more information, see the following resources:

- If you plan to work with Network Flow Monitor with the CLI, see Examples of using the CLI with Network Flow Monitor.
- For detailed information about working with Network Flow Monitor API operations, see the Network Flow Monitor API Reference Guide.

Contents

- Evaluate network flows with workload insights
- Create and work with monitors in Network Flow Monitor
- Monitor and analyze network flows with a Network Flow Monitor monitor
- Delete scope for Network Flow Monitor

Evaluate network flows with workload insights

Network Flow Monitor provides workload insights about the network flows in the scope that you enable monitoring for. By surfacing top contributor network flows for each metric type, you can see which flows are potentially experiencing issues. You can view these top contributor metrics in the console on the **Workload insights** tab. In Network Flow Monitor, top contributors are network flows that have the highest values for each network performance metric.

Top contributors

On the **Workload insights** page in the Network Flow Monitor console, Network Flow Monitor displays the top contributor network performance statistics for the network flows between all the resources in your monitoring scope where you've deployed agents.

To compile lists of top contributors, Network Flow Monitor determines the network flows in your scope that have the highest values for retransmissions, retransmission timeouts, and data transferred. These network flows are the *top contributors* for each metric type.

For workload insights, the top contributors are determined for all the network flows that you're receiving performance information for; that is, network flows for all of the resources in your scope with Network Flow Monitor agents installed.

Network flow classifications

Network Flow Monitor classifies metrics into designated local-remote categories. Metrics are grouped into two types of flows:

- **Network Health Indicator (NHI) Flows:** Flows which contribute to Network Health Indicator (NHI) calculations:
  - Between AZs (`INTER_AZ`). Always within the same VPC.
  - Within AZs (`INTRA_AZ`). Always within the same VPC.
  - Between VPCs (`INTER_VPC`). Crosses the boundary between VPCs.
  - Between Regions (`INTER_REGION`). This means performance for network flows between resources in your Region and the edge of another Region.
  - Toward Amazon S3 buckets (`AMAZON_S3`)
  - Toward Amazon DynamoDB (`AMAZON_DYNAMODB`)
- **Non Network Health Indicator (NHI) Flows:** Flows which do not contribute to Network Health Indicator (NHI) calcuations:
  - Toward the Internet (`INTERNET`). Flows that traverse an Internet Gateway and end on the public Internet.
  - Towards AWS Services (`AWS_SERVICE`). Flows that end at an AWS service that is not fully monitored (like CloudFront or API Gateway).
  - Towards a Transit Gateway (`TRANSIT_GATEWAY`). Flows in this classification are flows that arrive at a Transit Gateway, but the final destination of the flow is unknown.
  - Towards a local zone (`LOCAL_ZONE`). Flows that start or end in a local zone
  - Any other flow that cannot be otherwise classified (`UNCLASSIFIED`).

Performance metrics

Performance metrics on **Workload insights** are shown in separate tables for the following metric type: Retransmissions, retransmission timeouts, and data transferred. The data provided is for the top contributors for each type. Note that after you first install Network Flow Monitor agents, there is a waiting period (about 20 minutes) before you can view performance metrics, while agents gather and send data to the Network Flow Monitor backend.

Monitor specific network flows

As you review performance metrics, when you see specific resources or network flows that you want to explore more details for, you can create a monitor that includes just those flows.

With a monitor, you can track specific groups of network flows over a period of time, to gain insights into one aspect of your workload. You can also get helpful troubleshooting information, such as checking the network health indicator (NHI) to see if issues you see are caused by AWS impairments.

For more information, see Create and work with monitors in Network Flow Monitor

Multi-account coverage

To work with multiple accounts in Network Flow Monitor, you must configure AWS Organizations integration with CloudWatch. By configuring Organizations, you can add accounts to the scope for your Network Flow Monitor coverage. Then, if you have multiple accounts in your scope that each have resources that you want to monitor network flows between, you can specify a scope that includes all of the accounts, and then view performance metrics gathered by the Network Flow Monitor agents that you've installed on your resources. For more information, see Initialize Network Flow Monitor for multi-account monitoring.

Create and work with monitors in Network Flow Monitor

You create a monitor to see details about the network performance for one or several network flows for a workload. For each monitor, Network Flow Monitor publishes end-to-end performance metrics and a network health indicator (NHI), and generates network paths of individual network flows. After you create a monitor, you can view information provided by the monitor in the console on the **Monitors** tab.

Flow monitors can help you to assess network performance issues that are impacting your workloads, including impairments within an AWS Region and issues on the AWS global network between a local and a remote Region. The network health indicator (NHI) provided by the monitor also captures the health of the AWS global network on your workload's network paths between Regions. This helps you to quickly identify whether impairments in a local Region, in the AWS global network, or in the remote Region are affecting your workloads.

For remote Regions, monitors can provide network visibility for flows to the Region's public IP address, and for private traffic flowing to a remote Region over VPC peering or Transit Gateway peering.

After you create a monitor, you can edit the monitor to make changes (except change the monitor name) or delete the monitor, at any time.

The following sections includes procedures for creating, editing, and deleting monitors in the Network Flow Monitor console.

Contents

- Create a monitor in Network Flow Monitor
- Edit a monitor in Network Flow Monitor
- Delete a monitor in Network Flow Monitor

Create a monitor in Network Flow Monitor

As you review top contributors in the **Workload insights** tab, if you see one or several network flows that you want to follow over time, or that you want more details about, you can create a monitor directly from **Workload insights**. This simplifies the process for creating a monitor for specific network flows.

Or, if you know specific network flows that you want to track with a monitor, such as looking at performance information for all network flows to another AWS Region, you can use the **Create monitor** wizard to create a monitor from scratch. When you create a monitor this way, you specify all of the local and remote resources that define the network flows that you want to monitor.

For specific procedures, see the following sections:

- Create a monitor by specifying network flows
- Create a monitor by specifying local and remote resources

Create a monitor by specifying network flows

To create a monitor by selecting network flows, start on the **Workload insights** tab. Select one or more network flows in one of the tables, in a single Region, and then, choose to create a monitor with those flows.

When you create a monitor in this way, the **Create monitor** wizard pre-populates local and remote resources for you and displays them in a modal dialog. You can choose to create a monitor with those resources, or edit the selection of local or remote resources to add or remove resources to include.

By reviewing the top contributors on **Workload insights** on an ongoing basis, you can regularly evaluate if you have the monitors that you need, or if creating new monitors would be helpful.

> **Important**
>
> These steps are designed to be completed all at once. You won't be able to save any in-process work to continue later.

To create a monitor from Workload insights

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Flow monitors**.
3. Choose **Workload insights**.
4. In one of the **Top contributors** tables, select one or more network flows and then choose **Create monitor**.
5. In the modal window that opens, you can edit the resources that define the network flows that you chose, or choose **Create monitor**.

Create a monitor by specifying local and remote resources

You can create a monitor at any time for specific local and remote resources that define network flows that you want to see details for.

For example, you might want to create a monitor for one of the following scenarios:

- A monitor that includes network flows for a specific VPC in a local Region to another VPC in the same Region. (Note that you can't select a specific resource, such as a VPC, as a network flow endpoint - that is, the remote resource - in another Region.)
  - For local resource, choose **Specific resources in *Region***. Then, choose **VPC and subnets**, and then, in the table, select a specific VPC.
  - For remote resource, do the same: choose **Specific resources in *Region***, then, choose **VPC and subnets**, and finally, select a specific VPC.
- A monitor that includes all network flows from your workload in a local Region to a specific Availability Zone.
  - For local resource, choose **Everywhere in *Region***
  - For remote resource, choose **Availability Zone**, and then choose a specific AZ
- A monitor that includes all network flows for your workload within a local Region.
  - For local resource, choose **Everywhere in *Region***

  - For remote resource, choose **Everywhere in *Region***
- A monitor that includes all network flows for your workload from a local Region to the edge of another Region.
  - For local resource, choose **Everywhere in *Region***
  - For remote resource, choose **Another Region**, and then choose the remote Region

> **Important**
>
> These steps are designed to be completed all at once. You won't be able to save any in-process work to continue later.

To create a monitor using the console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Flow monitors**.
3. From the Network Flow Monitor page, select the **Monitors** tab, and then choose **Create monitor**.
4. For **Monitor name**, enter the name that you want to use for the monitor. You can't change this name later.
5. Choose **Next**.
6. Select the local resources (one or more) for the network flows that you want to monitor.
   - To monitor network flows from all resources in your Region, choose **Everywhere in *Region***.
   - To choose specific local resources to monitor flows from, choose **Specific resources in *Region***. Then, under **Add resources**, choose **Availability Zones**, **EKS clusters**, or **VPCs and subnets**, and then choose resources to add.
7. Choose **Next**.
8. Select the remote resources (one or more) for the network flows that you want to monitor.
   - To monitor network flows to all resources in your Region, choose **Everywhere in *Region***.
   - To monitor flows from specific remote resources, choose **Specific resources in *Region***. Under **Add resources**, select **VPCs and subnets**, **Availability Zones**, or **AWS services**, and then choose the resources to add.

- To monitor network flows to the edge of another Region, choose **Another Region**.

9. Choose **Next**.
10. Review your choices to confirm the network flows to monitor, or edit the options to make changes.
11. Choose **Create monitor**.

After you create a monitor, you can edit or delete the monitor at any time to add or remove network flows. Select a monitor, and then choose **Edit** or **Delete**. Note that you can't change the name of a monitor.

To view the Network Flow Monitor dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Network monitoring**, then **Flow monitors**.

   The **Monitors** tab displays a list of the monitors that you have created.

To see more information about a specific monitor, choose a monitor.

Edit a monitor in Network Flow Monitor

You can edit a monitor at any time, to add or remove network flows.

Note that you can't change the name of a monitor after you create it.

> **Important**
>
> These steps are designed to be completed all at once. You won't be able to save any in-process work to continue later.

To edit a monitor using the console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Flow monitors**.
3. On the **Monitors** tab, select a monitor, and then under the **Actions** menu, choose **Edit**.

4. Select the local or remote resources that you want add or remove for the monitor. If you have multiple accounts in your scope, specify the account where the resources are located, and then choose resources.
5. When you're finished updating the monitor, choose **Next**, to review and confirm the network flows to monitor.
6. Choose **Save monitor**.

Delete a monitor in Network Flow Monitor

To delete a monitor in Network Flow Monitor, follow the steps here.

To delete a monitor

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Flow monitors**.
3. On the **Monitors** tab, select a monitor, and then under the **Actions** menu, choose **Delete**.
4. In the dialog that appears, enter confirmation text, and then choose **Delete**.

Monitor and analyze network flows with a Network Flow Monitor monitor

Network Flow Monitor data and graphs help you to visualize and track network issues. You can create monitors to see detailed information about specific network segments for your AWS workloads, including a view of the network path for individual network flows. After you create one or more monitors in Network Flow Monitor, you can observe performance and metrics, and explore historical data, to find anomalies.

To see the information provided by a monitor, on the **Monitors** tab, choose a monitor in the **Monitors** table. Then, choose one of the following tabs for more information: **Overview**, **Historical explorer**, or **Monitor details**.

Overview tab

On the **Overview** tab, you can review the following, for time periods that you specify. To see a broader or narrower range of historical information, including the NHI and traffic summary data, adjust the time period selection at the top of the page.

- **Network health indicator (NHI):** NHI alerts you to whether there there were AWS network issues for one or more of the network flows tracked by your monitor, during the time frame

that you've selected for viewing performance metrics. NHI is a binary value, that is, 1 or 0, which is shown in the console as **Degraded** or **Healthy**.

- NHI is shown as **Degraded** if there were issues with the portion of the AWS network that any network flow in the monitor traversed, at any time during the time frame that you select.
- Otherwise, NHI is shown as **Healthy**.

If the NHI is **Degraded**, you can view the **Network health indicator** bar graph for more information. The graph shows you when, during the selected time frame, there were AWS network issues for the network flows tracked by your monitor.

- **Traffic summary:** Observe overall metrics for the flows tracked by this monitor, for the time period that you've selected. You can see average round-trip time, sums (totals) of transmission timeouts and retransmissions, and the average amount of data transferred for the flows in the monitor. Be aware that RTT data can be sparse because RTT is not always calculated.

Historical explorer tab

On the **Historical explorer** tab, you can dive deep into information about specific flows. You can review metrics and network paths for top contributor network flows for specified time frames. In the tables of metrics, you can filter the data by different categories of flows, such as flows between Availability Zones (`INTER_AZ`).

- **Metrics:** View detailed information for the top contributors for each metric type that Network Flow Monitor aggregates data for. Separate tables of top contributors are provided for retransmission timeouts, retransmissions, and data transferred.
- **Network paths:** To get an idea about where anomalies are occurring, you can view the network path of a network flow. When you choose a specific metric in a metrics table, the network path for that flow is displayed below the table.

Monitor details tab

On the **Monitor details** tab, you can see details about the monitor, including the monitor state, the ARN, when it was created and last updated, and the flows that are included.

You can choose to edit or delete a monitor from any page on the **Monitors** tab.

As part of your regular use of Network Flow Monitor, we recommend that you periodically review the data on the **Workload insights** page to determine if there are new flows that show metrics

anomalies that you want to track more closely over time. When you see a set of flows on the **Workload insights** page that you want to see details about, select the flows and create a monitor for them.

Delete scope for Network Flow Monitor

If you decide that you no longer want to monitor network flows using Network Flow Monitor, you can delete your Network Flow Monitor scope. When you delete your scope, you can no longer see network performance information.

Before you can delete your scope, you must delete all monitors. Be aware that it can take about 15 minutes to complete removing monitors after you request to delete them. For more information, see Delete a monitor in Network Flow Monitor.

To delete your scope

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Flow monitors**.
3. On the **Settings** tab, choose **Delete scope**.
4. In the dialog box, enter confirmation text, and then choose **Delete scope**.

View Network Flow Monitor metrics in CloudWatch

Network Flow Monitor publishes the following network flow performance metrics to your account: round-trip time, TCP retransmissions, TCP retransmission timeouts, data transferred, and network health indicator. You can view these metrics in CloudWatch Metrics in the Amazon CloudWatch console.

To find all metrics for your monitor, in the CloudWatch Metrics dashboard, see the custom namespace `AWS/NetworkFlowMonitor`. Metrics are aggregated for each monitor that is deployed and active.

Network Flow Monitor provides the following metrics. Be aware that RoundTripTime data can be sparse, as this metric is not always calculated.

Metric	Description
DataTransferred	The number of bytes transferred for all flows for a monitor.
Retransmissions	Total number of retransmissions for a monitor. Retransmissions occur when the sender needs to resend packets that have been either damaged or lost.
Timeouts	Total retransmission timeouts for a monitor. This occurs when the sender is missing too many acknowledgments, and therefore decides to take a time out and stop sending altogether.
RoundTripTime	Average round-trip time for network flows for a monitor. This metric, measured in microseconds, is a measure of performance. It records the time it takes for traffic to be transmitted from a local resource to a remote IP address, and for the associated response to be received. The time is an average over the aggregation period. Data can be sparse, as this metric is not always calculated.
HealthIndicator	Network health indicator (NHI) for a monitor overall. Network health indicator (NHI) is a value that surfaces an AWS network impairment. The NHI value is 1 (degraded) if there was an AWS network issue during a specified time frame. It's set to 0 (healthy) if no AWS network issues were detected. Observing the NHI can help you to prioritize troubleshooting for either your workload or the AWS network.

Create alarms with Network Flow Monitor

You can create Amazon CloudWatch alarms based on Network Flow Monitor metrics, just as you can for other CloudWatch metrics.

For example, you can create an alarm based on the Network Flow Monitor metric `Retransmissions`, and configure it to send a notification when the metric is higher than a value that you choose. You configure alarms for Network Flow Monitor metrics following the same guidelines as for other CloudWatch metrics.

Following are example Network Flow Monitor metrics that you might choose to create an alarm for:

- **Retransmissions**
- **Timeouts**
- **RoundTripTime**

To see all the metrics available for Network Flow Monitor see Create a CloudWatch alarm based on a static threshold.

The following procedure provides an example of setting an alarm on **Retransmissions** by navigating to the metric in the CloudWatch dashboard. Then, you follow the standard CloudWatch steps to create an alarm based on a threshold that you choose, and set up a notification or choose other options.

To create an alarm for Retransmissions in CloudWatch Metrics

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Choose **Metrics**, and then choose **Classic metrics**.
3. Filter for Network Flow Monitor by choosing `AWS/NetworkFlowMonitor`.
4. Choose **MeasurementSource, MonitorName**.
5. In the list, select **Retransmissions**.
6. On the **GraphedMetrics** tab, under **Actions**, choose the bell icon to create an alarm based on a static threshold.

Now, follow the standard CloudWatch steps to choose options for the alarm. For example, you can choose to be notified by an Amazon SNS message if **Retransmissions** is below a specific threshold number. Alternatively, or in addition, you can add the alarm to a dashboard.

Keep in mind the following:

- Network Flow Monitor metrics are typically aggregated and sent to the Network Flow Monitor backend every 30 seconds, with a 5 second potential jitter (in other words, 25 to 35 seconds).
- When you create an alarm based on Network Flow Monitor metrics, make sure that you take into account the short delay before publication when you set an alarm's lookback period. We recommend that you configure **Evaluation Periods** with lookback period that is a minimum of 25 minutes.

For more information about options when you create a CloudWatch alarm, see Create a CloudWatch alarm based on a static threshold.

AWS CloudTrail for Network Flow Monitor

Monitoring a service is an important part of maintaining reliability, availability, and performance. of Network Flow Monitor and your other AWS solutions. *AWS CloudTrail* captures API calls and related events made by or on behalf of your AWS account and delivers the log files to an Amazon S3 bucket that you specify. You can identify which users and accounts called AWS, the source IP address from which the calls were made, and when the calls occurred. For more information, see the AWS CloudTrail User Guide.

For more information about Network Flow Monitor CloudTrail logging, see Network Flow Monitor in CloudTrail.

Troubleshoot issues in Network Flow Monitor

This section provides guidance for troubleshooting errors with Network Flow Monitor, including solving issues with installing agents.

Troubleshoot issues in EKS agents installation

When you try to upgrade the AWS Network Flow Monitor Agent add-on for EKS from v1.0.0 to v1.0.1 in AWS Management Console, you might receive the following error message:

"Service account `aws-network-flow-monitoring-agent-service-account` in pod identity configuration is not supported for addon `aws-network-flow-monitoring-agent`."

This error is returned because a resource was renamed. The EKS add-on v1.0.1 changes the service account name from `aws-network-flow-monitoring-agent-service-account` to `aws-network-flow-monitor-agent-service-account`.

Then, if **Not set** is not selected in the console, the pod identity association is not reset to the new resource name.

To fix this issue, do the following when you upgrade to the new version by using the console:

1. Under **Pod Identity IAM role for service account**, select **Not set**.
2. Select **New version (v1.0.1)**.
3. Select **Upgrade**.
4. Choose **Save changes**.

Data security and data protection in Network Flow Monitor

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from data centers and network architectures that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security *of* the cloud and security *in* the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS Compliance Programs. To learn about the compliance programs that apply to Network Flow Monitor, see AWS Services in Scope by Compliance Program.
- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your company's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Network Flow Monitor. The following topics show you how to configure Network Flow Monitor to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your Network Flow Monitor resources.

Topics

- Data protection in Network Flow Monitor
- Infrastructure Security in Network Flow Monitor
- Identity and Access Management for Network Flow Monitor

Data protection in Network Flow Monitor

The AWS shared responsibility model applies to data protection in Network Flow Monitor. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see Data Privacy FAQ. For information about data protection in Europe, see the General Data Protection Regulation (GDPR) Center.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual users with AWS IAM Identity Center or AWS Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with AWS CloudTrail. For information about using CloudTrail trails to capture AWS activities, see Working with CloudTrail trails in the *AWS CloudTrail User Guide*.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-3 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-3.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a **Name** field. This includes when you work with Network Flow Monitor or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form text fields used for names may

be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Infrastructure Security in Network Flow Monitor

As a managed service, Network Flow Monitor is protected by the AWS global network security procedures that are described in the Amazon Web Services: Overview of Security Processes whitepaper.

You use AWS published API calls to access Network Flow Monitor through the network. Clients must support Transport Layer Security (TLS) 1.0 or later. We recommend TLS 1.2 or later. Clients must also support cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

Identity and Access Management for Network Flow Monitor

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Network Flow Monitor resources. IAM is an AWS service that you can use with no additional charge.

Contents

- How Network Flow Monitor works with IAM
- AWS managed policies for Network Flow Monitor
- Service-linked roles for Network Flow Monitor

How Network Flow Monitor works with IAM

Before you use IAM to manage access to Network Flow Monitor, learn what IAM features are available to use with Network Flow Monitor.

To see tables showing a similar high-level view of how AWS services work with most IAM features, see AWS services that work with IAM in the *IAM User Guide*.

IAM features you can use with Network Flow Monitor

IAM feature	Network Flow Monitor support
Identity-based policies	Yes
Resource-based policies	No
Policy actions	Yes
Policy resources	Yes
Policy condition keys (service-specific)	Yes
ACLs	No
ABAC (tags in policies)	Yes
Temporary credentials	Yes
Principal permissions	Yes
Service roles	No
Service-linked roles	Yes

Identity-based policies for Network Flow Monitor

Supports identity-based policies: Yes

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Define custom IAM permissions with customer managed policies in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. To learn about all of the elements that you can use in a JSON policy, see IAM JSON policy elements reference in the *IAM User Guide*.

Resource-based policies within Network Flow Monitor

Supports resource-based policies: No

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM role trust policies and Amazon S3 bucket policies. In services that support resource-based policies, service administrators can use them to control access to a specific resource.

Policy actions for Network Flow Monitor

Supports policy actions: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Action` element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Include actions in a policy to grant permissions to perform the associated operation.

To see a list of Network Flow Monitor actions, see Actions defined by Network Flow Monitor in the *Service Authorization Reference*.

Policy actions in Network Flow Monitor use the following prefix before the action:

```
networkflowmonitor
```

To specify multiple actions in a single statement, separate them with commas.

```
"Action": [
      "networkflowmonitor:action1",
      "networkflowmonitor:action2"
         ]
```

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word `Describe`, include the following action:

```
"Action": "networkflowmonitor:Describe*"
```

Policy resources for Network Flow Monitor

Supports policy resources: Yes

In the *Service Authorization Reference*, you can see the following information related to Network Flow Monitor:

- To see a list of Network Flow Monitor resource types and their ARNs, see Resources defined by Network Flow Monitor.
- To learn the actions that you can specify with the ARN of each resource, see Actions defined by Network Flow Monitor.

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Resource` JSON policy element specifies the object or objects to which the action applies. As a best practice, specify a resource using its Amazon Resource Name (ARN). For actions that don't support resource-level permissions, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

Policy condition keys for Network Flow Monitor

Supports service-specific policy condition keys: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Condition` element specifies when statements execute based on defined criteria. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request. To see all AWS global condition keys, see AWS global condition context keys in the *IAM User Guide*.

To see a list of Network Flow Monitor condition keys, see Condition keys for Network Flow Monitor in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see Actions defined by Network Flow Monitor.

ACLs in Network Flow Monitor

Supports ACLs: No

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

ABAC with Network Flow Monitor

Supports ABAC (tags in policies): Yes

Network Flow Monitor has *partial* support for tags in policies. It supports tagging for one resource, monitors.

To use tags with Network Flow Monitor, use the AWS Command Line Interface or an AWS SDK. Tagging for Network Flow Monitor is not supported with the AWS Management Console.

To learn more about using tags in policies in general, review the following information.

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes called tags. You can attach tags to IAM entities and AWS resources, then design ABAC policies to allow operations when the principal's tag matches the tag on the resource.

To control access based on tags, you provide tag information in the condition element of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see Define permissions with ABAC authorization in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see Use attribute-based access control (ABAC) in the *IAM User Guide*.

Using temporary credentials with Network Flow Monitor

Supports temporary credentials: Yes

Temporary credentials provide short-term access to AWS resources and are automatically created when you use federation or switch roles. AWS recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see Temporary security credentials in IAM and AWS services that work with IAM in the *IAM User Guide*.

Cross-service principal permissions for Network Flow Monitor

Supports forward access sessions (FAS): Yes

Forward access sessions (FAS) use the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. For policy details when making FAS requests, see Forward access sessions.

Service roles for Network Flow Monitor

Supports service roles: No

A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Create a role to delegate permissions to an AWS service in the *IAM User Guide*.

Service-linked role for Network Flow Monitor

Supports service-linked roles: Yes

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

For more information about the service-linked role for Network Flow Monitor, see Service-linked roles for Network Flow Monitor.

For details about creating or managing service-linked roles in general in AWS, see AWS services that work with IAM. Find a service in the table that includes a Yes in the **Service-linked role** column. Choose the **Yes** link to view the service-linked role documentation for that service.

AWS managed policies for Network Flow Monitor

An AWS managed policy is a standalone policy that is created and administered by AWS. AWS managed policies are designed to provide permissions for many common use cases so that you can start assigning permissions to users, groups, and roles.

Keep in mind that AWS managed policies might not grant least-privilege permissions for your specific use cases because they're available for all AWS customers to use. We recommend that you reduce permissions further by defining customer managed policies that are specific to your use cases.

You cannot change the permissions defined in AWS managed policies. If AWS updates the permissions defined in an AWS managed policy, the update affects all principal identities (users,

groups, and roles) that the policy is attached to. AWS is most likely to update an AWS managed policy when a new AWS service is launched or new API operations become available for existing services.

For more information, see AWS managed policies in the *IAM User Guide*.

AWS managed policy: CloudWatchNetworkFlowMonitorServiceRolePolicy

You can't attach `CloudWatchNetworkFlowMonitorServiceRolePolicy` to your IAM entities. This policy is attached to a service-linked role named **AWSServiceRoleForNetworkFlowMonitor**, which publishes network telemetry aggregation results, collected by Network Flow Monitor agents, to CloudWatch. It also allows the service to use AWS Organizations to get information for multi-account scenarios.

To view the permissions for this policy, see CloudWatchNetworkFlowMonitorServiceRolePolicy in the *AWS Managed Policy Reference*.

For more information, see Service-linked roles for Network Flow Monitor.

AWS managed policy: CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy

You can't attach `CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy` to your IAM entities. This policy is attached to a service-linked role named **AWSServiceRoleForNetworkFlowMonitor_Topology**. Using these permissions, as well as internal meta data information gathering (for performance efficiencies), this service-linked role gathers meta data about resource network configurations, such as describing route tables and gateways, for resources that this service monitors network traffic for. This meta data enables Network Flow Monitor to generate topology snapshots of the resources. When there is network degradation, Network Flow Monitor uses the topologies to provide insights into the location of issues in the network and to help determine attribution for issues.

To view the permissions for this policy, see CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy in the *AWS Managed Policy Reference*.

For more information, see Service-linked roles for Network Flow Monitor.

AWS managed policy: CloudWatchNetworkFlowMonitorAgentPublishPolicy

You can use this policy in IAM roles that are attached to Amazon EC2 and Amazon EKS instance resources to send telemetry reports (metrics) to a Network Flow Monitor endpoint.

To view the permissions for this policy, see CloudWatchNetworkFlowMonitorAgentPublishPolicy in the *AWS Managed Policy Reference*.

Updates to the Network Flow Monitor service-linked roles

For updates to the AWS managed policies for the Network Flow Monitor service-linked roles, see the AWS managed policies updates table for CloudWatch. You can also subscribe to automatic RSS alerts on the CloudWatch Document history page.

Service-linked roles for Network Flow Monitor

Network Flow Monitor uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Network Flow Monitor. The service-linked role is predefined by Network Flow Monitor and includes all the permissions that the service requires to call other AWS services on your behalf.

Network Flow Monitor defines the permissions of the service-linked roles, and unless defined otherwise, only Network Flow Monitor can assume the roles. The defined permissions include the trust policies and the permissions policies, and the permissions policies cannot be attached to any other IAM entity.

You can delete the roles only after first deleting their related resources. This restriction protects your Network Flow Monitor resources because you can't inadvertently remove permissions to access the resources.

For information about other services that support service-linked roles, see AWS services that work with IAM and look for the services that have **Yes** in the **Service-linked role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Network Flow Monitor

Network Flow Monitor uses the following service-linked roles:

- **AWSServiceRoleForNetworkFlowMonitor**
- **AWSServiceRoleForNetworkFlowMonitor_Topology**

Service-linked role permissions for AWSServiceRoleForNetworkFlowMonitor

Network Flow Monitor uses the service-linked role named **AWSServiceRoleForNetworkFlowMonitor**. This role allows Network Flow Monitor to publish

CloudWatch aggregated telemetry metrics gathered for network traffic between instances, and between instances and AWS locations. It also allows the service to use AWS Organizations to get information for multi-account scenarios.

This service-linked role uses the managed policy `CloudWatchNetworkFlowMonitorServiceRolePolicy`.

To view the permissions for this policy, see CloudWatchNetworkFlowMonitorServiceRolePolicy in the *AWS Managed Policy Reference*.

The **AWSServiceRoleForNetworkFlowMonitor** service-linked role trusts the following service to assume the role:

- `networkflowmonitor.amazonaws.com`

Service-linked role permissions for AWSServiceRoleForNetworkFlowMonitor_Topology

Network Flow Monitor uses the service-linked role named **AWSServiceRoleForNetworkFlowMonitor_Topology**. This role allows Network Flow Monitor to generate a topology snapshot of the resources that you use with Network Flow Monitor.

This service-linked role uses the managed policy `CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy`.

To view the permissions for this policy, see CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy in the *AWS Managed Policy Reference*.

The **AWSServiceRoleForNetworkFlowMonitor_Topology** service-linked role trusts the following service to assume the role:

- `topology.networkflowmonitor.amazonaws.com`

Creating a service-linked role for Network Flow Monitor

You do not need to manually create the service-linked roles for Network Flow Monitor. The first time that you initialize Network Flow Monitor, Network Flow Monitor creates **AWSServiceRoleForNetworkFlowMonitor** and **AWSServiceRoleForNetworkFlowMonitor_Topology** for you.

For more information, see Creating a service-linked role in the *IAM User Guide*.

Editing a service-linked role for Network Flow Monitor

After Network Flow Monitor creates a service-linked role in your account, you cannot change the name of the role because various entities might reference the role. You can edit the description of the role using IAM. For more information, see Editing a service-linked role in the *IAM User Guide*.

Deleting a service-linked role for Network Flow Monitor

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete the role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up the resources for the service-linked role before you can manually delete it.

> **Note**
>
> If the Network Flow Monitor service is using the role when you try to delete it, then the deletion might fail. If that happens, wait for a few minutes and then try again.

To manually delete the service-linked role using IAM

Use the IAM console, the AWS CLI, or the AWS API to delete the **AWSServiceRoleForNetworkFlowMonitor** or the **AWSServiceRoleForNetworkFlowMonitor_Topology** service-linked role. For more information, see Deleting a service-linked role in the *IAM User Guide*.

Updates to the Network Flow Monitor service-linked role

For updates to `CloudWatchNetworkFlowMonitorServiceRolePolicy` or `CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy`, the AWS managed policies for the Network Flow Monitor service-linked roles, see CloudWatch updates to AWS managed policies. For automatic alerts about managed policy changes in CloudWatch, subscribe to the RSS feed on the CloudWatch Document history page.

Using Internet Monitor

Internet Monitor provides visibility into how internet issues impact the performance and availability between your applications hosted on AWS and your end users. It can reduce the

time it takes for you to diagnose internet issues from days to minutes. Internet Monitor uses the connectivity data that AWS captures from its global networking footprint to calculate a baseline of performance and availability for internet-facing traffic. This is the same data that AWS uses to monitor internet uptime and availability. With those measurements as a baseline, Internet Monitor raises awareness for you when there are significant problems for your end users (clients) in the different geographic locations where your application runs.

In the Amazon CloudWatch console, you can see a global view of traffic patterns and health events, and easily drill down into information about events, at different geographic granularities (locations). You can clearly visualize impact, and pinpoint the client locations and networks (ASNs, typically internet service providers or ISPs) that are affected. If Internet Monitor determines that an internet availability or performance issue is caused by a specific ASN or by the AWS network, it provides that information.

To get started, create a monitor that includes one or more resources, so Internet Monitor can create a traffic profile for your AWS application. Then, view information in the Internet Monitor dashboard to visualize data and get insights and suggestions about your application's internet traffic.

For information about Regional support, pricing, how Internet Monitor works, and other overview content, see What is Internet Monitor?. To begin working with Internet Monitor, see Getting started with Internet Monitor using the console.

What is Internet Monitor?

With Internet Monitor, you can monitor your application's internet performance and availability, so that you can visualize data and get insights and suggestions about your AWS application's internet traffic. You can also get suggestions for ways to reduce latency for your application, by using different Regions or AWS services, like Amazon CloudFront.

Key features of Internet Monitor

- Internet Monitor suggests insights and recommendations that can help you improve your end users' experience. You can explore, in near real-time, how to improve the projected latency of your application by switching to use other services, or by rerouting traffic to your workload through different AWS Regions.
- Internet Monitor stores internet measurements for pairs of your client locations and ASNs, or *city-networks*. Internet Monitor also creates aggregated CloudWatch metrics for traffic to your application, and to each AWS Region and edge location. With the Internet Monitor dashboard,

you can quickly identify what's impacting your application's performance and availability, so that you can track down and address issues.

- Internet Monitor also publishes internet measurements to CloudWatch Logs and CloudWatch Metrics, to support using CloudWatch tools to explore data for city-networks that are specific to your monitored application traffic. Optionally, you can also publish internet measurements to Amazon S3.
- Internet Monitor sends health events to Amazon EventBridge so that you can set up notifications. Both overall (global) health events and local health events are published to EventBridge. If an issue is caused by the AWS network, you also automatically receive an AWS Health Dashboard notification with the steps that AWS is taking to mitigate the problem.

How to use Internet Monitor

To use Internet Monitor, you create a *monitor* and associate your application's resources with it—VPCs, Network Load Balancers, CloudFront distributions, or WorkSpaces directories—to enable Internet Monitor to know where your application's internet-facing traffic is. Internet Monitor then publishes internet measurements from AWS that are specific to the *city-networks*, that is, the client locations and ASNs (typically internet service providers or ISPs), where clients access your application. For more information, see How Internet Monitor works. To begin working with Internet Monitor, see Getting started with Internet Monitor using the console.

Supported AWS Regions for Internet Monitor

The AWS Regions and AWS Local Zones where Amazon CloudWatch Internet Monitor is supported are listed in this section. For more information about Regions that Internet Monitor is supported in,

including opt-in Regions, see Amazon CloudWatch Internet Monitor endpoints and quotas in the *Amazon Web Services General Reference*.

Note that Internet Monitor stores data for a monitor in only the AWS Region in which you create the monitor, although a monitor can include resources in multiple Regions.

Region name (Opt-in support)	Region
Africa (Cape Town)	af-south-1
Asia Pacific (Hong Kong)	ap-east-1
Asia Pacific (Hyderabad)	ap-south-2
Asia Pacific (Jakarta)	ap-southeast-3
Asia Pacific (Melbourne)	ap-southeast-4
Europe (Milan)	eu-south-1
Europe (Spain)	eu-south-2
Europe (Zurich)	eu-central-2
Middle East (Bahrain)	me-south-1
Middle East (UAE)	me-central-1

Region name (Default support)	Region
US East (Ohio)	us-east-2
US East (N. Virginia)	us-east-1
US West (N. California)	us-west-1
US West (Oregon)	us-west-2
Asia Pacific (Mumbai)	ap-south-1

Region name (Default support)	Region
Asia Pacific (Osaka)	ap-northeast-3
Asia Pacific (Seoul)	ap-northeast-2
Asia Pacific (Singapore)	ap-southeast-1
Asia Pacific (Sydney)	ap-southeast-2
Asia Pacific (Tokyo)	ap-northeast-1
Canada (Central)	ca-central-1
Europe (Frankfurt)	eu-central-1
Europe (Ireland)	eu-west-1
Europe (London)	eu-west-2
Europe (Paris)	eu-west-3
Europe (Stockholm)	eu-north-1
South America (São Paulo)	sa-east-1

For Local Zones support, you must enable the Local Zone and attach it to the VPC that you want to monitor internet traffic for. Internet Monitor does not support Local Zones for other resources types. The Local Zones that are supported are listed in the following table.

Local Zone	Parent Region	Type
us-east-1-dfw-2a	us-east-1	Availability Zone
us-east-1-mia-2a	us-east-1	Availability Zone
us-east-1-qro-1a	us-east-1	Frontier Zone
us-east-1-lim-1a	us-east-1	Frontier Zone

Local Zone	Parent Region	Type
us-east-1-atl-2a	us-east-1	Availability Zone
us-east-1-bue-1a	us-east-1	Frontier Zone
us-east-1-mci-1a	us-east-1	Frontier Zone
us-west-2-lax-1a	us-west-2	Availability Zone
us-west-2-lax-1b	us-west-2	Availability Zone
af-south-1-los-1a	af-south-1	Frontier Zone

Components and terms for Internet Monitor

Internet Monitor uses or references the following concepts.

Monitor

A monitor includes the resources for a single application that you want to view internet performance and availability measurements for, and that you want to get health event alerts about. When you create a monitor for an application, you add resources for the application to define the cities (locations) for Internet Monitor to monitor. Internet Monitor uses the traffic patterns from the application resources that you add so that it can publish internet performance and availability measurements specific to just the locations and ASNs (typically, internet service providers or ISPs) that communicate with your application. In other words, the resources that you add create a scope of the *city-networks* that you want Internet Monitor to monitor and that you want it to publish measurements for.

Resource added to monitor ("monitored resource")

A resource that you add to a monitor is a "monitored resource" in Internet Monitor. That is:

- Each VPC that you add in a Region is a monitored resource. When you add a VPC, Internet Monitor monitors the traffic for any internet-facing application in the VPC, for example, an application hosted on an Amazon EC2 instance, behind a Network Load Balancer, or an AWS Fargate container.
- Each Network Load Balancer that you add in a Region is a monitored resource.
- Each WorkSpaces directory that you add in a Region is a monitored resource.

- Each CloudFront distribution that you add is a monitored resource.

Autonomous System Number (ASN)

In Internet Monitor, an ASN typically refers to an internet service provider (ISP), such as Verizon or Comcast. An ASN is a network provider that a client uses to access your internet application. An Autonomous System (AS) is a set of internet routable internet protocol (IP) prefixes that belong to a network or a collection of networks that are all managed, controlled, and supervised by one organization.

City-network (location and ASN)

A city-network is the location (such as a city) that clients access your application resources from and the ASN, typically an internet service provider (ISP), that clients access the resources through. To help control your bill, you can set a limit for the maximum number of city-networks for Internet Monitor to monitor for each monitor. You pay only for the actual number of city-networks that you monitor, up to the maximum number. For more information, see Choosing a city-network maximum limit.

Internet measurements

Internet Monitor also publishes internet measurements to log files in CloudWatch Logs every five minutes for the top 500 city-networks for your monitored application traffic.

These measurements quantify the performance score, availability score, bytes transferred (bytes in and bytes out), and round-trip time for your application's city-networks. These are measurements for the city-networks specific to your VPCs, Network Load Balancers, CloudFront distributions, or WorkSpaces directories. Optionally, you can choose to publish internet measurements and events for all monitored city-networks (up to the 500,000 city-networks service limit) to an Amazon S3 bucket.

Metrics

Internet Monitor generates aggregated metrics for CloudWatch metrics, for global traffic to your application and global traffic to each AWS Region. For more information, see View Internet Monitor metrics or set alarms in CloudWatch Metrics.

Health event

Internet Monitor creates a health event to alert you to a specific problem that affects your application. Internet Monitor detects internet issues, such as increased network latency, across the world. It then uses its historical internet measurements from across the AWS global

infrastructure footprint to calculate the impact of current issues on your application, and creates health events. Internet Monitor, by default, creates health events based on both overall impact and local impact thresholds. To learn more about health events, see When Internet Monitor creates and resolves health events.

The default health event threshold, for both performance scores and availability scores, is 95%. If you like, you can specify your own custom thresholds for when Internet Monitor creates health events. For more information about configuring thresholds, see Change health event thresholds.

Each health event includes information about the impacted city-networks. You can view health events in the CloudWatch console, or by using an AWS SDK or AWS CLI with Internet Monitor API actions. Internet Monitor also sends Amazon EventBridge notifications for health events. For more information, see When Internet Monitor creates and resolves health events.

Internet event

Internet Monitor displays information about recent global health events, called internet events, on an internet weather map that is available to all AWS customers. You don't need to create a monitor in Internet Monitor to view the internet weather map. Unlike health events, internet events are not specific to individual customers or their application traffic. For more information, see Global internet weather map in Internet Monitor.

Thresholds

Internet Monitor creates health events based on both overall thresholds and local thresholds. You can change the default thresholds and configure other options, such as turning off local thresholds. For more information about configuring thresholds, see Change health event thresholds.

Performance and availability scores

By analyzing the data that AWS collects, Internet Monitor can detect when the performance and availability for your application has dropped, compared to estimated baselines that Internet Monitor calculates. To make it easier to see those drops, Internet Monitor reports the information to you as scores. A performance score represents the estimated percentage of traffic that is **not** seeing a performance drop. Similarly, an availability score represents the estimated percentage of traffic that is **not** seeing a availability drop. For more information, see How AWS calculates performance and availability scores.

Bytes transferred and monitored bytes transferred

Bytes transferred is the total number of bytes of ingress and egress traffic between an application in AWS and the city-network (that is, the location and the ASN, typically the internet service provider) where clients access an application. Monitored bytes transferred is a similar metric, but includes only bytes for monitored traffic.

Round-trip time

Round-trip time (RTT) is how long it takes for a request from a client user to return a response to the user. When RTT is aggregated across client locations (cities or other geographies), the value is weighted by how much of your application traffic is driven by each client location.

How Internet Monitor works

This section provides information about how Internet Monitor works. This includes descriptions of how AWS collects the data that it uses to help detect connectivity issues across the internet, and how performance and availability scores are calculated.

Contents

- How Internet Monitor focuses on just your application traffic footprint
- How AWS measures connectivity issues and calculates measurements
- Geolocation accuracy in Internet Monitor
- When Internet Monitor creates and resolves health events
- Health event report timing
- How Internet Monitor works with IPv4 and IPv6 traffic
- How Internet Monitor selects the subset of city-networks to include
- How the global internet weather map is created (Frequently Asked Questions)

How Internet Monitor focuses on just your application traffic footprint

Internet Monitor focuses monitoring on just the subset of the internet that's accessed by the users of your AWS resources, instead of broadly monitoring your website from every Region in the world as other tools do. It’s also a cost effective solution, affordable for large and small companies.

Internet Monitor uses the same powerful probes and issue-detection algorithms that AWS takes advantage of internally and alerts you to connectivity issues that affect your application by creating health events in Internet Monitor. Internet Monitor then gives you access to the resulting performance and availability map, by overlaying the traffic profile that it creates from your active viewers, based on your application resources.

Using this information, Internet Monitor shows you just relevant events (that is, the events from places where you have active viewers), and just the impact those events have on your overall viewer volume. So, how much impact an event has, percentage-wise, is based on your total traffic worldwide.

Internet Monitor stores internet measurements for pairs of your client locations and ASNs, or *city-networks*. Internet Monitor also creates aggregated CloudWatch metrics for traffic to your application, and to each AWS Region and edge location.

In addition, Internet Monitor publishes internet measurements to CloudWatch Logs internet every five minutes for the top 500 city-networks that send traffic to each monitor, to support using CloudWatch tools and other methods with your data. Optionally, you can choose to publish internet measurements for all monitored city-networks (up to the 500,000 city-networks service limit) to an Amazon S3 bucket. For more information, see Publish internet measurements to Amazon S3 in Internet Monitor.

The benefits of Internet Monitor include the following:

- Using Internet Monitor doesn't place additional load or cost on your application that's hosted on AWS.
- You don't need to include performance measurement code in your client-side resources, or in your application.
- You can get visibility into performance and availability across the internet that your application is connected to, including "last mile" information.

Note that because Internet Monitor creates measurements based on your AWS resources, Internet Monitor only creates events that are specific to your application traffic. Global internet issues in general are not reported. In addition, when the service location is an AWS Region, the measurements and events emitted are designed to represent connectivity at a Regional level and don’t accurately represent connectivity between an end user location and an Availability Zone.

How AWS measures connectivity issues and calculates measurements

Internet Monitor uses internet connectivity data between different AWS Regions and Amazon CloudFront points of presence (POPs) to different client locations through Autonomous System Numbers (ASNs), typically internet service providers (ISPs). This is the connectivity data that is used internally by AWS operators, on a daily basis, to proactively detect connectivity issues across the global internet.

For every AWS Region, we know which portions of the internet communicate with the Region and do the following:

- We actively monitor those portions of the internet, with a rolling 30-day window.
- We use both network and higher-level protocol probes, including both inbound and outbound probing.

AWS has active and passive probes that measure the latency (performance) at the 90th percentile and reachability (availability) from every AWS Region and from the CloudFront service to the entire internet. Abnormal patterns in connectivity between a service and a customer location are monitored, and then reported as alerts to the customer.

See the following sections for details:

- Calculating availability and RTT
- Calculating performance and availability scores
- Calculating TTFB and RTT (latency)
- Regional and Availability Zone measurements and aggregation

Calculating availability and RTT

Round-trip time (RTT) is how long it takes for a request from the user to return a response to the user. When round-trip time is aggregated across end user locations, the value is weighted by the amount of your traffic that is driven by each end user location.

As an example, with two end user locations, one serving 90% of traffic with a 5 ms RTT, and the other serving 10% of traffic with a 10 ms RTT, the result is an aggregated RTT of 5.5 ms (which comes from 5 ms * 0.9 + 10 ms * 0.1).

Note that there are differences for resources about measuring last-mile latency. For Internet Monitor latency measurements, VPCs, Network Load Balancers, and WorkSpaces directories do not include last-mile latency.

Calculating performance and availability scores

AWS has substantial historical data about internet performance and availability between AWS services and different city-networks (locations and ASNs). By applying statistical analysis to the data, Internet Monitor can detect when the performance and availability for your application has dropped, compared to an estimated baseline that it has calculated. To make it easier to see those drops, that information is reported to you in the form of health scores: a performance score and an availability score.

Health scores are calculated at different granularities. At the finest granularity, we compute the health score for a geographic region, such as a city or a metro area, and an ASN (a *city-network*). We also roll up the individual health scores to overall health score numbers for an application in a monitor. If you view performance or availability scores without filtering for any specific geography or service provider, Internet Monitor provides overall health scores.

Overall health scores span your whole application for the specified time period. When the performance or availability score for your application's city-network pairs across your application reaches or drops below the corresponding health event threshold for performance or availability Internet Monitor triggers a health event. By default, the threshold is 95% for both overall performance and availability. Internet Monitor also creates health events based on local thresholds—if the option is enabled, as it is by default—based on values that you configure. To learn more about configuring health event thresholds, see Change health event thresholds.

When you explore information in the monitor and log files to investigate issues and learn more, you can filter by specific cities (locations), networks (ASNs or internet service providers), or both. So, you can use filters to see health scores for different cities, ASNs, or city-network pairs, depending on the filters that you choose.

- An *availability score* represents the estimated percentage of traffic that is **not** seeing an availability drop. Internet Monitor estimates the percentage of traffic experiencing a drop from the total traffic seen and availability metrics measurements. For example, an availability score of 99% for an end user and service location pair is equivalent to 1% of the traffic experiencing an availability drop for that pair.
- A *performance score* represents the percentage of traffic that is **not** seeing a performance drop. For example, a performance score of 99% for an end user and service location pair is equivalent to 1% of the traffic experiencing a performance drop for that pair.

Calculating TTFB and RTT (latency)

Time to first byte (TTFB) refers to the time between when a client makes a request and when it receives the first byte of information from the server. AWS calculations for TTFB measure the time elapsed from Amazon EC2 or Amazon CloudFront to the Internet Monitor measurement node (including the last mile of the node). That is, Internet Monitor measures time from the user to the Amazon EC2 Region for TTFB for EC2, and from the user to CloudFront for TTFB for CloudFront.

For round-trip time (RTT), Internet Monitor includes the time from the city-network (that is, the client location and ASN, typically an internet service provider), as mapped by the public IP address, to the AWS Region. This means that Internet Monitor does not have last mile visibility for users who access the internet from behind a gateway or VPN.

Note that there are differences for resources about measuring last-mile latency. For Internet Monitor latency measurements, VPCs, Network Load Balancers, and WorkSpaces directories do not include last-mile latency.

Internet Monitor includes average TTFB information in the **Traffic optimization suggestions** section of the **Traffic insights** tab on the CloudWatch dashboard, to help you evaluate options for different setups for your application that can improve performance.

Regional and Availability Zone measurements and aggregation

Although Internet Monitor aggregates measurements and shares impact at a Regional level, it calculates impact at an Availability Zone (AZ) level. This means that, if, for an event, only one AZ is impacted and most of your traffic flows through that AZ, you do see impact for your traffic. However, for the same event, if your application traffic does not flow through an impacted AZ, you do not see impact.

Note that this applies only to resources that aren't WorkSpaces directories. WorkSpaces directories are measured only on a Regional level.

Geolocation accuracy in Internet Monitor

For location information, Internet Monitor uses IP-geolocation data supplied by MaxMind. The accuracy of the location information in Internet Monitor measurements depends on the accuracy of MaxMind's data.

Be aware that `Metro` level measurements might not be accurate for locations outside of the United States.

When Internet Monitor creates and resolves health events

Internet Monitor creates and closes health events for the application traffic that you monitor based on the current thresholds that are set. Internet Monitor has a default threshold configuration, and you can also set your own configuration for thresholds. Internet Monitor determines the overall impact that connectivity issues are having on your application, and the impact on local areas where your application has clients, and creates health events when the thresholds are crossed.

Internet Monitor calculates the impact of connectivity issues on a client location based on the historical data about internet performance and availability for network traffic that's available to the service through AWS. It applies the information relevant to your application, based on the geographic locations for ASNs and services where clients use your application: the city-network pairs that are affected. The locations are determined from the resources that you add to your monitor. Then Internet Monitor uses statistical analysis to detect when performance and availability has dropped, affecting the client experience for your application.

The performance and availability scores that Internet Monitor calculates are represented as the percentage of traffic that is **not** seeing a drop. Impact is the opposite of this: it's a representation of how much an issue is problematic for a customer's end users. So if there is a global availability drop of 93%, for example, the corresponding impact would be 7%.

When the performance or availability score for your application's city-network pairs globally reaches or drops below the corresponding health event threshold for performance or availability, this triggers Internet Monitor to generate a health event. By default, the threshold is 95% for both performance and availability. The values to meet, or drop below, the threshold are cumulative, so it could mean several smaller events combine to meet the threshold percentage, or that a single event meets or falls below the threshold level.

As long as performance or availability scores that triggered the event are at or below the corresponding health event threshold percentage for overall impact, the health event stays active. When the score or combined scores that triggered the event rise above the threshold, Internet Monitor resolves the health event.

Internet Monitor also creates health events based on local thresholds and the percentage of overall traffic that an issue has an impact on. You can configure options for local thresholds, or turn off local thresholds altogether.

The default health event threshold, for both performance scores and availability scores, is 95%. If you like, you can specify your own custom thresholds for when Internet Monitor creates

health events. For more information about configuring thresholds, see Change health event thresholds.

Health event report timing

Internet Monitor uses an aggregator to gather all signals about internet issues, to create health events in monitors within minutes.

When possible, Internet Monitor analyzes the origin of a health event, to determine whether it was caused by AWS or an ASN. Health event analysis continues after an event is resolved. Internet Monitor can update events with new information for up to an hour.

How Internet Monitor works with IPv4 and IPv6 traffic

Internet Monitor measures health toward a network over only IPv4, and shows you health events, and availability and performance metrics, if you serve traffic to that network over any IP family (IPv4 or IPv6). If you serve traffic from a dual-stack resource, such as a dual-stack CloudFront distribution, Internet Monitor raises a health event and shows a drop in a performance score or availability score only if IPv4 traffic has the same issues for the resource as IPv6 traffic does.

Note that the Internet Monitor metrics for overall bytes in and bytes out accurately reflect all internet traffic (IPv4 and IPv6).

How Internet Monitor selects the subset of city-networks to include

When you set a maximum limit for the number of city-networks monitored by your monitor or choose a percentage of traffic to monitor, Internet Monitor chooses the city-networks to include (monitor) based on highest recent traffic volume.

For example, if you set a maximum city-networks limit of 100, Internet Monitor monitors (up to) 100 city-networks based on your application traffic during a recent one hour period. Specifically, Internet Monitor monitors the top 100 city-networks that have had the most traffic in the most recent one hour window *before* the latest one hour window.

To illustrate this, say that the current time is 2:30 PM. In this scenario, the traffic that you see in your monitor was captured between 1:00 PM and 2:00 PM, and the traffic volume measurement that Internet Monitor uses to determine the top 100 city-networks was captured between 12:00 PM and 1:00 PM.

How the global internet weather map is created (Frequently Asked Questions)

The Internet Monitor internet weather map is available on the Internet Monitor console to all authenticated AWS customers. This section includes details about how the internet weather map is created and how to use it.

What is the Internet Monitor internet weather map?

The internet weather map provides a visual representation of internet issues across the world. It highlights impacted client locations, that is, cities plus ASN (typically internet service providers). The map shows a combination of availability and performance issues that have recently impacted clients' internet experience for top client locations and AWS services globally.

Where does data for the map come from?

The data is based on a combination of active and passive probing of the internet. To learn more about how Internet Monitor measures data you can read the section How AWS measures connectivity issues.

How often is the map updated?

The internet weather map is updated every 15 minutes.

Which networks are tracked for outages?

AWS tracks networks all around the world that represent important IP prefixes used by customers for making internet connections to AWS. We scope outages to client locations that are top talkers for volume of traffic sent to and received from the AWS network.

What determines whether an internet event is included on the map?

Here are some high level criteria that we use to determine whether an internet event is included on the internet weather map:

- AWS detects that there is an availability or performance event.
- If the event is short lived, for example, it lasts less than 5 minutes, we ignore it.
- Then, if the event is in a client location that is classified as a top talker, it's considered an outage.

What thresholds are used for the internet weather map?

Thresholds for determining outages are not static for the internet weather map. Internet Monitor determines what constitutes an event based on detecting a deviation from expected values. You can learn more about how this works by reviewing how Internet Monitor

determines when to create health events for monitors that you create with the service. When you create a monitor, Internet Monitor generates internet traffic health measurements that are specific to your own application traffic. Internet Monitor also alerts you to health events for issues that affect your application's internet traffic.

What can I do with this data?

The internet weather map provides a quick summary of key internet events that happened around the world in the last 24 hours. It helps you to get a sense of the internet monitoring experience, without needing to onboard your own internet traffic to Internet Monitor. To leverage the full potential of the internet monitoring capabilities of AWS and to personalize it for your applications and services hosted on AWS, you can create a monitor in Internet Monitor.

When you create a monitor, you enable Internet Monitor to identify the specific internet paths that affect your application clients, and you get access to features and capabilities that can help you improve your client experience. You'll also be proactively notified of new internet issues that specifically impact your application traffic and clients.

How can I get more details about events?

Click an outage on the map to see details that include when an event started and ended, the impacted city and ASN, and what type of issue it was (that is, a performance issue or an availability issue).

To get more detailed information about events, and to get custom measurements for your application traffic, create a monitor in Internet Monitor.

Internet Monitor example use cases

This section describes several specific examples of use cases for Internet Monitor, with links to blog posts with more details. These examples illustrate how you can use the capabilities of Internet Monitor to monitor your application health and improve latency to enhance your users' experience.

Set up alerts and decide on actions to take

You can use Internet Monitor to get insights about average internet performance metrics over time, and about health events by city-network (client location and ASN, typically an internet service provider). Using Internet Monitor, you can identify the events that are impacting end user experience for applications hosted on Amazon Virtual Private Clouds (VPCs), Network Load Balancers, Amazon WorkSpaces, or Amazon CloudFront.

After you create a monitor, you have several options for how to be alerted about Internet Monitor health events. These include notifications based on CloudWatch Alarms using event metrics or Amazon EventBridge rules to filter for health events. You can choose different options for notifications or actions based on alarms, including, for example, AWS SMS notifications or updates to a CloudWatch log group.

To see an example with detailed guidance, see the following blog post: Introducing Internet Monitor.

Identify latency issues and improve TTFB to improve multiplayer gameplay experience

Use Internet Monitor to help you to quickly identify where game players in global cloud gaming apps are experiencing latency issues globally, and provide insights into improving performance. By identifying where the most players currently have the slowest time to first byte (TTFB), you know how to improve latency to make your biggest player base happier.

Now, when you're ready to deploy the next EC2 server for your game, choose the AWS Region that Internet Monitor suggests will lower TTFB in the area with the high latency and large group of players.

For details about setting up and using Internet Monitor for this use case, see the following blog post: Using Internet Monitor for a Better Gaming Experience.

Identify potential performance and internet connection issues for users on Amazon WorkSpaces

Internet Monitor provides you with the IP prefixes and ASN (typically, the internet service provider or ISP) for your users, which can be helpful to diagnose performance and internet connection issues for users to their WorkSpaces. You can also use this data to view your fleet as a whole and monitor your WorkSpaces user connections.

For more information about how to use Internet Monitor for this use case, see the following blog post: Using Internet Monitor with Amazon WorkSpaces Personal.

Global internet weather map in Internet Monitor

Internet Monitor displays a global internet weather map that is available to all AWS customers. To view the map, in the Amazon CloudWatch console, navigate to **Network Monitoring**, and then choose **Internet monitors**.

The internet weather map highlights internet events ("outages") all over the world that affect AWS customers, with the specific cities and networks (ASNs, typically internet service providers) where there are issues with performance or availability. The map includes internet events from the past 24 hours.

You don't need to create a monitor in Internet Monitor to view the internet weather map. Unlike health events in Internet Monitor, internet events are not specific to individual customers or their application traffic.

On the internet weather map, you can choose an internet event to learn details about it. For an internet event, you can see the start time, end time (if the event is over), the current status (Active or Resolved), and the outage issue type (Availability or Performance). To learn more about how the internet weather map is created and what is included, see the global internet weather map FAQ.

To view and work with detailed information that is specific to your application traffic and client locations, you can create a monitor in Internet Monitor for your application. Then, you'll see performance and availability patterns and events, current and historical, as well as get health event alerts, tailored to just your application footprint and customers. The internet weather map gives you an overall view, while a specific monitor filters the information to just the measurements and details that are relevant to your application. With a monitor, you can also explore historical metrics and get recommendations for improving client experience for your application. To learn more, see Getting started with Internet Monitor using the console.

Internet Monitor cross-account observability

With Internet Monitor cross-account observability, you can monitor your applications that span multiple AWS accounts within a single AWS Region.

You can use Amazon CloudWatch Observability Access Manager to set up one or more of your AWS accounts as a monitoring account. You'll provide the monitoring account with the ability to view data in your source account by creating a *sink* in your monitoring account. A sink is a resource that represents an attachment point in a monitoring account. For Internet Monitor, the resource attachment point is a monitor. You use the sink to create a link from your source account to your monitoring account. For more information, see CloudWatch cross-account observability.

Required resources

For proper functionality of CloudWatch Application Insights cross-account observability, ensure that the following telemetry types are shared through the CloudWatch Observability Access Manager.

- Monitors in Internet Monitor
- Metrics in Amazon CloudWatch
- Log groups in Amazon CloudWatch Logs

Pricing for Internet Monitor

With Internet Monitor, there are no upfront costs or long-term commitments. Pricing for Internet Monitor has two components: a per monitored resource fee and a per city-network fee. A *city-network* is the location where clients access your application resources from and the network (ASN, such as an internet service provider or ISP) that clients access the resources through. Note that you are also charged standard CloudWatch prices for logs and any additional metrics, dashboards, alarms, or insights that you create.

You choose a percentage of traffic to monitor when you create a monitor. To help control your bill, you can also set a limit for the maximum number of city-networks to monitor. You can update the percentage of traffic to monitor or the maximum city-networks limit at any time by editing your monitor. The first 100 city-networks (across all monitors per account) are included. After that, you only pay for the actual additional number of city-networks that you monitor, up to the maximum number.

You pay only the actual additional number of city-networks that you monitor, up to the maximum number, with no charge for the first 100 city-networks (across all monitors per account). A flat amount equivalent to the cost of 100 city-networks is deducted from your monthly bill.

For example, a large global company could choose to monitor 100% of its internet-facing traffic, and set a city-networks maximum of 50,000, for one monitor with one resource. Assuming the traffic reached 50,000 city-networks, that portion of its bill would be around 2,700 USD/month. For another company, in fewer geographic areas, with one monitor with one resource and 200 city-networks, this portion of the bill would be around 13 USD/month. For more information, see Choose a city-networks maximum limit.

You can try out different options with the pricing calculator. To explore pricing options, on the Pricing calculator for CloudWatch page, scroll down to Internet Monitor.

For more information about Internet Monitor and CloudWatch pricing, see the Amazon CloudWatch pricing page.

Getting started with Internet Monitor using the console

To help you get started with Internet Monitor, this chapter provides the steps for creating and configuring a *monitor*. You create a monitor in Internet Monitor for your application by naming it, and then adding AWS resources that your application uses.

You create a monitor in Internet Monitor for your application by adding AWS resources that it uses, and then setting several configuration options. The resources that you add, Amazon Virtual Private Cloud VPCs, Network Load Balancers (NLBs), CloudFront distributions, or WorkSpaces directories, provide the information for Internet Monitor to map internet traffic information for your application. After you create your monitor, wait 15-30 minutes to generate the traffic profile specific to where your application is used.

Then, use the Internet Monitor dashboard, or other tools, to visualize and explore performance and availability about your client usage. These tools provide insights for you using your application traffic's measurements gathered for you by the monitor.

The steps here walk you through setting up your monitor by using the console. To see examples of using the AWS Command Line Interface with the Internet Monitor API actions, to create a monitor, view events, and so on, see Examples of using the CLI with Internet Monitor.

Tasks

- Step 1: Create a monitor
- Step 2: Configure the monitor
- Step 3: View metrics and explore history
- Step 4: Get suggestions to improve latency
- Step 5 (Optional): Delete the monitor

Step 1: Create a monitor

To create a monitor using the console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Internet monitors**.
3. Choose **Create monitor**.
4. For **Monitor name**, enter the name you want to use for this monitor in Internet Monitor.

5. Choose **Add resources**, and then select the resources to set the monitoring boundaries for Internet Monitor to use for this monitor.

> **Note**
>
> Be aware of the following:
>
> - To generate meaningful output with Internet Monitor, VPCs that you add must be connected to the internet by having an Internet Gateway configured.
> - You can add only one type of resource to a single monitor. For example, VPCs or CloudFront distributions or WorkSpaces directories, but not a combination of different types.

6. Leave the default percentage of traffic as 100%, or choose another percentage of your internet traffic to monitor.
7. Choose **Create monitor**.

Step 2: Configure the monitor

After you create a monitor, you can edit the monitor at any time, for example, to change the application traffic percentage, update the maximum city-networks limit or add or remove resources. To make updates in the Internet Monitor console, follow the procedure in this section. Note that you can't change the name of a monitor.

For more information about configuring a monitor, see Edit a monitor in Internet Monitor.

To configure a monitor using the console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Internet monitors**.
3. Choose your monitor, and then choose the **Action** menu.
4. Choose **Update monitor**.
5. Make the desired updates. For example, to change the percentage of traffic to monitor, under **Application traffic to monitor**, select or enter a percentage.
6. Choose **Update**.

Step 3: View metrics and explore history

Visualize data about your internet traffic, from an overview perspective or by drilling down into details.

To visualize data and get insights for application traffic using the console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Internet monitors**.
3. Choose a monitor to work with.
4. Choose from the following tabs:

   - **Overview** — Review a general summary of your monitor and your application traffic performance.
   - **Health events** — View current and historical health events that currently impact, or previously impacted, locations where clients access your application.
   - **Analyze** — See information about top monitored traffic in client locations (by traffic volume), summarized in several customizable ways. Visualize metrics and historical trends for health scores and metrics.

In the next section, learn about how Internet Monitor provides suggestions for improving latency for your application traffic.

Step 4: Get suggestions to improve latency

Get suggestions for how to optimize latency, so that your clients experience the best internet performance for your application.

Internet Monitor evaluates your monitored application traffic, and then makes suggestion about whether you can reduce latency, for example, by changing the AWS Regions that you've configured for your application.

For more information, see Get suggestions to optimize application performance in Internet Monitor (Optimize page).

To get suggestions for improving application latency using the console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

2. In the left navigation pane, under **Network Monitoring**, choose **Internet monitors**.
3. Choose a monitor to work with.
4. Choose **Optimize**, and then view the top suggestions.

Step 5 (Optional): Delete the monitor

If you created a monitor as a test or if you're no longer using a monitor, you can delete it. Before you can delete a monitor, you must disable it.

To delete a monitor

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Internet monitors**.
3. Choose your monitor, and then choose the **Action** menu.
4. Choose **Disable**.
5. Choose the **Action** menu again, and then choose **Delete**.
6. Follow the guidance in the modal dialog to confirm deleting the monitor.

Configure a monitor using the console

This chapter includes procedures and recommendations for creating and configuring monitors in Internet Monitor.

The steps provided in these sections primarily use the AWS Management Console. You can also use Internet Monitor API operations with the AWS Command Line Interface (AWS CLI) or AWS SDKs to create and configure a monitor. For detailed information about working with Internet Monitor API operations, see the following resources:

- If you plan to work with Internet Monitor with the CLI, see Examples of using the CLI with Internet Monitor.
- For detailed information about working with Internet Monitor API operations, see the Internet Monitor API Reference.

Contents

- Create a monitor in Internet Monitor using the console

- Add resources to your monitor
- Choose a percentage of traffic to monitor for your application
- Use a monitor in Internet Monitor
- Edit a monitor in Internet Monitor
- Delete a monitor in Internet Monitor
- Advanced configuration options for a monitor

Create a monitor in Internet Monitor using the console

You create a monitor in Internet Monitor to visualize and explore performance and availability data about your application's client traffic. You create a monitor by adding AWS resources that your application uses, and then setting several configuration options. The resources that you add to the monitor provide the information — for example, through resource flow logs — for Internet Monitor to learn which internet traffic is specific to your AWS application.

After you create your monitor, wait 15 to 30 minutes before reviewing the monitor dashboard. Internet Monitor needs a few minutes to generate a traffic profile for where your application is used by your end users, and then to begin publishing data for your traffic.

Typically, it's simplest to create one monitor in Internet Monitor for one application. Within the same monitor, you can search through and sort measurements and metrics by different locations and ASNs, or other information. You don't need to create separate monitors for applications in different areas.

The steps provided here walk you through setting up your monitor by using the console. To work with Internet Monitor API actions using the AWS Command Line Interface, see Examples of using the CLI with Internet Monitor.

To create a monitor using the console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Internet monitors**.
3. Choose **Create monitor**.
4. For **Monitor name**, enter the name that you want to use for this monitor.
5. Choose **Add resources**, and then select the resources that will determine the internet traffic profile for this monitor.

> **Note**
>
> Be aware of the following:
>
> - To generate meaningful output with Internet Monitor, VPCs that you add must be connected to the internet by having an Internet Gateway configured.
> - You can specify only one type of resource for each monitor.

6. Choose a percentage of your application's internet traffic to monitor.
7. Optionally, under **Advanced settings**, specify one or more of the following additional options.

   - **City-networks maximum** — The default city-networks maximum value is `500000`. If you like, you can lower this limit, to restrict the number of city-networks (locations and ASNs) that Internet Monitor will monitor traffic for. You can change the city-networks maximum at any time by editing your monitor. For more information, see Choose a city-networks maximum limit.
   - **Amazon S3 bucket storage** — You can specify an Amazon S3 bucket name and custom prefix to publish internet measurements for your application's internet traffic to Amazon S3, for all monitored city-networks.

     Internet Monitor stores internet measurements for pairs of your client locations and ASNs, or *city-networks*. Internet Monitor also creates aggregated CloudWatch metrics for traffic to your application, and to each AWS Region and edge location. In addition, Internet Monitor publishes internet measurements for your application traffic to CloudWatch Logs every five minutes, to support using CloudWatch tools and other methods with your data. If you choose to publish measurements to S3, measurements are still published to CloudWatch Logs. For more information, see Publish internet measurements to Amazon S3 in Internet Monitor.
   - **Tags** — Add one or more tags for your monitor.
8. Choose **Create monitor**.

After you create a monitor, wait about 15-30 minutes for Internet Monitor to create a traffic profile and begin publishing your data. Then, you can view information about your application's internet traffic performance by navigating to the monitor dashboard in the console.

To view the Internet Monitor dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Network Monitoring**, then **Internet monitors**.
3. To see more information about a specific monitor, on the **Monitors** tab, choose a monitor.

Add resources to your monitor

When you create a monitor, you must associate your application's resources with it: Amazon Virtual Private Clouds (VPCs), Network Load Balancers, Amazon CloudFront distributions, Network Load Balancers (NLBs), or Amazon WorkSpaces directories. Then, Internet Monitor knows where your application's internet-facing traffic and clients are located, and it can create and maintain a traffic profile that determines the relevant measurements to publish for your monitor.

You can add the following types of resources to a monitor in Internet Monitor as *monitored resources*.

- **VPCs:** Each VPC that you add in a Region is a monitored resource. When you add a VPC, Internet Monitor monitors the traffic for any internet-facing application in the VPC, for example, an application hosted on an Amazon EC2 instance, behind a Network Load Balancer, or in an AWS Fargate container.
- **Network Load Balancers:** Each NLB that you add is a monitored resource.
- **CloudFront distributions:** Each CloudFront distribution that you add is a monitored resource.
- **WorkSpaces directories:** Each WorkSpaces directory that you add in a Region is a monitored resource.

When you monitor traffic for VPCs, traffic for applications that are hosted on load balancers behind the VPC is monitored. You can choose to monitor traffic for individual Network Load Balancer load balancers instead of monitoring a VPC with multiple load balancers. This can be helpful, for example, if you need to understand and configure features for better performance or efficiencies at the load balancer level. Or, you might need compliance information at the Network Load Balancer level.

When you add resources to a monitor in Internet Monitor, be aware of the following:

- Internet Monitor doesn't support adding different types of resources together in one monitor.

- To generate meaningful output with Internet Monitor, VPCs that you add must be connected to the internet by having an Internet Gateway configured.
- Internet Monitor doesn't support adding different types of resources together in one monitor.
- There are Regional differences for opt-in Regions to keep in mind when you add VPCs or NLBs as resources. For more information, see Supported AWS Regions for Internet Monitor.
- In addition, there are differences for resources about measuring last-mile latency. For Internet Monitor latency measurements, VPCs, NLBs, and WorkSpaces directories do not include last-mile latency.

Choose a percentage of traffic to monitor for your application

The coverage that you choose for the percentage of application traffic to monitor determines how many city-networks (client locations and ASNs, typically internet service providers) for your application are monitored, up to an optional city-networks maximum limit that you can also set.

You can choose the percentage of traffic to monitor when you create a monitor, or, with an existing monitor, by choosing **Edit monitor** on any Internet Monitor dashboard page in the console.

If you choose to monitor less than 100% of your application traffic, you might have an observability gap in with your monitor. That's because if there are health events that Internet Monitor creates where you aren't monitoring traffic, you won't be aware of those issues. With a traffic percentage set to less than 100%, you might also have less coverage for the performance and availability score information about client access to your application.

The following sections describe options to explore traffic percentage settings and coverage, and to get an idea about the impact of increasing or decreasing coverage.

- Explore changing your application traffic percentage
- View the number of city-networks monitored at different traffic percentage settings

Explore changing your application traffic percentage

You can explore values that you might want to change your application traffic percentage to, by viewing the number of city-networks monitored when you change the percentage. The procedure in this section provides step-by-step information.

In the Internet Monitor console, you can try increasing or decreasing the application traffic percentage for your monitor, and view the estimated number of your city-networks that would

be covered as a result. With this option, you can quickly see how changing your traffic percentage affects the number of city-monitors are monitored. This can help you to get a feel for what a good application traffic percentage to choose might be, for your application.

To explore monitoring coverage and update percentage of traffic monitored

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Internet monitors**.
3. In your list of monitors, choose a monitor.
4. On the **Configure** tab, in the **View and evaluate traffic coverage** section, you can evaluate the impact on the total number of city-networks that are monitored, depending on a traffic percentage that you choose. You can also update the percentage of traffic that you monitor or change the city-networks limit for your monitor.

   - **Explore traffic percentage options:** Under **Compare options for traffic coverage**, in the drop-down menu, choose one or more traffic percentages to graph and compare. For each traffic percentage that you choose, you can see the number of city-networks that will be monitored when you set that traffic percentage coverage.

     To learn more, see View number of city-networks monitored at different percentages.
   - **Change monitoring coverage:** Under **Explore other traffic coverage options**, choose **Update monitoring coverage**.

     In the **Explore and set traffic monitoring coverage** dialog, click the arrows to increase or decrease the percentage of traffic to monitor. By choosing 100% traffic, you can see how many city-networks are monitored with full coverage for monitoring your application.

     Note: To learn more about how the number of city-networks monitored (estimated here) might affect your costs, choose the link to the CloudWatch Pricing calculator, and then scroll down to Internet Monitor.

     To set a new percentage of traffic to monitor, choose **Update monitor coverage**. Or, to keep the current coverage level, choose **Cancel**.

View the number of city-networks monitored at different traffic percentage settings

You can view the number of city-networks that would be monitored for your application at different application traffic percentages. The procedure in this section provides step-by-step information.

In the Internet Monitor console, you can view graphs that show how coverage for your city-networks would change at different of application traffic percentages, over a time interval that you specify. This is a quick way to visualize and compare the monitoring coverage for your application at specific traffic percentages, all on one graph.

To view graphs of application traffic percentage and corresponding city-networks coverage

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Internet monitors**.
3. In your list of monitors, choose a monitor.
4. Choose the **Configure** page, and scroll down to **Traffic coverage**.
5. Under **Compare options for traffic coverage**, in the drop-down list, select one or more percentages. You can choose one or more application traffic percentages, and the graph of **Total monitored city-networks** is updated to display the monitoring coverage Internet Monitor provides for that traffic percentage. By choosing **City-networks at 100% traffic**, you can see how many city-networks are monitored with full coverage for monitoring your application.

Keep in mind the following:

- Traffic coverage is computed based on the number of city-networks in the previous hour of your application traffic. This means that, after you choose a specific percentage of traffic to monitor, fewer city-networks might be monitored for your application than is shown here in a traffic coverage comparison graph.
- To make sure that all your application traffic is monitored, set `TrafficPercentageToMonitor` to 100 and don't set `MaxCityNetworksToMonitor`. Alternatively, you can set `MaxCityNetworksToMonitor` to 500,000, the upper limit in Internet Monitor.
- If you set a city-networks maximum limit, the total number of monitored city-networks never exceeds that limit, regardless of the application traffic percentage option that you select.
- You can learn more about how the number of city-networks monitored might affect your costs. On the Pricing calculator for CloudWatch page, scroll down to Internet Monitor.

To set a new percentage of traffic to monitor, under **Explore other traffic coverage options**, choose **Update monitoring coverage**. In the dialog, choose a percentage of traffic, and then choose **Update monitor coverage**.

Use a monitor in Internet Monitor

There are several ways to use an Internet Monitor monitor after you create it: for example, you can view information in the CloudWatch dashboard, get information by using the AWS Command Line Interface, and set health alerts.

Your monitor provides information about your application and configuration preferences so that Internet Monitor can customize measurements and metrics to publish in events for you. Internet Monitor collects measurements from the global infrastructure footprint for AWS. These measurements are a tremendous amount of network performance and availability information, from all over the world. By using information from the resources that you add for your application, Internet Monitor publishes performance and availability measurements for you that is scoped to the city-networks (that is, client locations and ASNs, typically internet service providers or ISPs) where your application is active. So, the measurements and metrics in the Internet Monitor dashboard and in CloudWatch Logs —about availability, performance, monitored bytes transferred, and round-trip time—are specific to your client locations and ASNs.

Internet Monitor also determines when there are anomalies in performance and availability. By default, Internet Monitor overlays your traffic with the availability and performance measurements that AWS has collected for each source-destination pair in your client locations, to determine when there are notable drops in performance or availability. When there's significant degradation for your application's locations and scope, Internet Monitor generates a *health event*, and publishes information about the issue to your monitor.

After you create a monitor, you can use it to access or be alerted to the information that Internet Monitor provides, in the following ways:

- **Use the CloudWatch dashboard** to view and explore performance, availability, and health events; explore your application's historical data; and get insights into new ways to configure your application for better performance. To learn more, see the following:
  - Track real-time performance and availability in Internet Monitor (Overview page)
  - Analyze historical data in Internet Monitor (Analyze page)
  - Get suggestions to optimize application performance in Internet Monitor (Optimize page)

- **Configure health event thresholds** to change what triggers Internet Monitor to create a health event for your application. You can configure overall thresholds and local (city-network) thresholds. To learn more, see Change health event thresholds.
- **Use AWS CLI commands** with Internet Monitor API actions to view traffic profile information, view measurements, list health events, and so on. To learn more, see Examples of using the CLI with Internet Monitor.
- **Use standard CloudWatch tools,** such as CloudWatch Contributor Insights, CloudWatch Metrics explorer, and CloudWatch Logs Insights to visualize the data in CloudWatch. To learn more, see Exploring your data with CloudWatch tools and the Internet Monitor query interface.
- **Use Athena with S3 logs** to access and analyze Internet Monitor internet measurements for your application, if you turned on publishing measurements to S3.
- **Create Amazon EventBridge notifications** to alert you when Internet Monitor determines there is a health event. To learn more, see Using Internet Monitor with Amazon EventBridge.
- **Receive an AWS Health Dashboard notification** automatically, when Internet Monitor determines that an issue is caused by the AWS network. The notification includes the steps that AWS is taking to mitigate the problem.

Edit a monitor in Internet Monitor

Using the **Action** menu, you can edit a monitor in Amazon CloudWatch Internet Monitor after you create it. For example, you can edit a monitor to do the following:

- Change the percentage of application traffic to monitor
- Set or update the city-networks maximum limit
- Change health event thresholds for availability or performance scores
- Add or remove resources
- Enable or update publishing events to Amazon S3

Note that you can't change the name of a monitor after you create it.

To make changes to a monitor, use the following procedure.

To edit a monitor

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

2. In the left navigation pane, under **Network Monitoring**, choose **Internet monitors**.
3. Choose your monitor, and then choose the **Action** menu.
4. Choose **Update monitor**.
5. Make the desired updates. For example, to change the percentage of traffic to monitor, under **Application traffic to monitor**, select or enter a percentage.
6. Choose **Update**.

For more information about the options that you can update, see the following:

- To learn more about resources that you add in Internet Monitor, see Add resources to your monitor.
- To learn more about the application traffic percentage, see Choose a percentage of traffic to monitor for your application.
- To learn more about changing the threshold for health events, see Change health event thresholds.
- To learn more about the city-networks maximum limit, see Choose a city-networks maximum limit.
- To learn more about opting to publish events to S3, see Publish internet measurements to Amazon S3 in Internet Monitor.

Delete a monitor in Internet Monitor

Using the **Action** menu, you can delete a monitor in Amazon CloudWatch Internet Monitor. You first disable the monitor, and then delete it.

To delete a monitor

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, under **Network monitoring**, choose **Internet Monitor**.
3. Choose your monitor, and then choose the **Action** menu.
4. Choose **Disable**.
5. Choose the **Action** menu again, and then choose **Delete**.

Advanced configuration options for a monitor

This section provides the steps for configuring advanced options for a monitor in Internet Monitor. These configuration options are optional but can be useful in some scenarios.

For example, you might choose to set a city-network maximum limit if traffic for the application that you monitor with Internet Monitor occasionally spikes, and you want to help make sure that your bill for Internet Monitor is predictable.

Or, you might want to set custom or local thresholds for health events, because you want to pay close attention to issues in specific geographies where you have a concentration of clients.

The topics in this section provide detailed descriptions of each feature, and list the steps to configure options for your needs.

Contents

- Choose a city-networks maximum limit
- Change health event thresholds for a monitor
- Publish internet measurements to Amazon S3 in Internet Monitor

Choose a city-networks maximum limit

In addition to setting a traffic percentage for your monitor in Internet Monitor, you can also set a maximum limit for the number of city-networks monitored. This section describes how the city-networks limit can help you manage billing costs, and provides information and an example to help you determine a limit to set, if you choose to set one.

Internet Monitor can monitor traffic for some or all of the locations where clients access your AWS application resources. You can set a monitoring limit for the number of *city-networks*, that is, the client locations and the ASNs (typically internet service providers) that clients access your application through.

You choose a percentage of application traffic to monitor when you create your monitor. The default percentage is 100%. You can update the percentage at any time, by editing the monitor.

The maximum limit that you set for the number of city-networks helps to make sure that your bill is predictable. For more information, see Amazon CloudWatch Pricing. You can also learn how different values for the number of city-networks actually monitored can affect your bill by using

the CloudWatch price calculator. To explore options, on the Pricing calculator for CloudWatch page, scroll down to Internet Monitor.

To update your monitor and change the maximum city-networks limit, see Edit a monitor in Internet Monitor.

How billing works with city-networks maximum limits

Setting a maximum limit for the number of city-networks monitored can help prevent unexpected costs in your bill. This is useful, for example, if your traffic patterns vary widely. Billing costs increase for each city-network that is monitored after the first 100 city-networks, which are included (across all monitors per account). If you set a city-networks maximum limit, it caps the number of city-networks that Internet Monitor monitors for your application, regardless of the percentage of traffic that you choose to monitor.

You only pay for the number of city-networks that are actually monitored. The city-network maximum limit that you choose lets you set a cap on the total that can be included when Internet Monitor monitors traffic with your monitor. You can change the maximum limit at any time by editing your monitor.

To explore options, on the Pricing calculator for CloudWatch page, scroll down to Internet Monitor. For more information on Internet Monitor pricing, see the Internet Monitor section on the Amazon CloudWatch Pricing page.

How to choose a city-networks maximum limit

Optionally, you can set a city-networks maximum limit. To help you decide on a maximum limit that you might want to select, consider how much traffic you want to monitor for your application. Be aware that if you choose 100% for the *traffic percentage to monitor* for your monitor, and then specify a city-networks maximum limit, depending on the limit that you choose, you might not monitor 100% of your application traffic. The city-networks maximum that you set takes precedence over the traffic percentage to monitor that you set.

To view how the percentage of traffic to monitor that you choose affects the number of city-monitors that are included for your application monitoring, which can help you decide whether to set a city-networks maximum limit, follow the steps in View the number of city-networks monitored at different traffic percentage settings.

To explore your options in more detail, you can use Internet Monitor metrics, as described in the following examples. These examples show how to select a maximum city-networks limit that is best for you, depending on the breadth of application internet traffic coverage you want. Using the

queries for Internet Monitor metrics in CloudWatch Metrics can help you understand more about your application internet traffic coverage.

Example of determining a city-networks maximum limit

As an example, say that you've set a monitoring maximum limit of 100 city-networks and that your application is accessed by clients across 2637 city-networks. In CloudWatch Metrics, you'd see the following Internet Monitor metrics returned:

```
CityNetworksMonitored 100
TrafficMonitoredPercent  12.5
CityNetworksFor90PercentTraffic  2143
CityNetworksFor100PercentTraffic  2637
```

From this example, you can see that you're currently monitoring 12.5% of your internet traffic, with the maximum limit set to 100 city-networks. If you want to monitor 90% of your traffic, the next metric provides information about that: `CityNetworksFor90PercentTraffic` indicates that you would need to monitor 2,143 city-networks for 90% coverage. To do that, you would update your monitor and set the maximum city-networks limit to 2,143.

Similarly, say you'd like to have 100% internet traffic monitoring for your application. The next metric, `CityNetworksFor100PercentTraffic`, indicates that to do this, you should update your monitor to set the maximum city-networks limit to 2,637.

If you now set the maximum to 5,000 city-networks, since that's greater than 2,637, you see the following metrics returned:

```
CityNetworksMonitored 2637
TrafficMonitoredPercent  100
CityNetworksFor90PercentTraffic  2143
CityNetworksFor100PercentTraffic  2637
```

From these metrics, you can see that with the higher limit, you monitor all 2,637 city-networks, which is 100% of your internet traffic.

Change health event thresholds for a monitor

Internet Monitor uses a default threshold to determine when to create a health event for your monitor. Optionally, you can change that default global threshold, to set another value. You can also set local threshold. This section describes how global and local thresholds work together, and provides steps for setting custom thresholds.

You can change the overall threshold that triggers Internet Monitor to create a health event. The default health event threshold, for both performance scores and availability scores, is 95%. That is, when the overall performance or availability score for your application falls to 95% or below, Internet Monitor creates a health event. For the overall threshold, the health event can be triggered by a single large issue, or by the combination of multiple smaller issues.

You can also change the local—that is, city-network—threshold, combined with a percentage of the overall level of impact, that—in combination—will trigger a health event. By setting a threshold that creates a health event when a score drops below the threshold for one or more city-networks (locations and ASNs, typically ISPs), you can get insights into when there are issues in locations with lower traffic, for example.

An additional local threshold option works together with the local threshold for availability or performance scores. The second factor is the percentage of your overall traffic that must be impacted before Internet Monitor creates a health event based on the local threshold.

By configuring the threshold options for overall traffic and local traffic, you can fine-tune how frequently health events are created, to align with your application usage and your needs. Be aware that when you set the local threshold to be lower, typically more health events are created, depending on your application and the other threshold configuration values that you set.

In summary, you can configure health event thresholds—for performance scores, availability scores, or both—in the following ways:

- Choose different global thresholds for triggering a health event.
- Choose different local thresholds for triggering a health event. With this option, you can also change the percentage of impact on your overall application that must be exceeded before Internet Monitor creates an event.
- Choose to turn off triggering a health event based on local thresholds, or enable local threshold options.

To update health event thresholds for performance scores, availability scores, or both, follow these steps.

To change threshold configuration options

1. In the AWS Management Console, navigate to CloudWatch, and then, in the left navigation pane, choose Internet Monitor.

2. On the **Configure** page, in the **Health event thresholds** section, choose **Update thresholds**.
3. On the **Set health event threshold**page, choose the new values and options that you want for thresholds and other options that trigger Internet Monitor to create a health event. You can do any of the following:

   - Choose a new value for **Availability score threshold**, **Performance score threshold**, or both.

     The graphs in the sections for each setting display the current threshold setting and the actual recent health event scores, for availability or performance, for your application. By viewing the typical values, you can get an idea of values that you might want to change a threshold to.

     Tip: To view a larger graph and change the timeframe, choose the expander in the upper right corner of the graph.

   - Choose to turn on or off a local threshold for availability or performance, or both. When an option is enabled, you can set the threshold and impact level for when you want Internet Monitor to create a health event.
4. After you configure threshold options, save your updates by choosing **Update health event thresholds**.

To learn more about how health events work, see When Internet Monitor creates and resolves health events.

Publish internet measurements to Amazon S3 in Internet Monitor

You can choose to have Internet Monitor publish internet measurements to Amazon S3 for your internet-facing traffic to the monitored city-networks (client locations and ASNs, typically internet service providers) in your monitor, up to the 500,000 city-networks service limit. Internet Monitor automatically publishes internet measurements to CloudWatch Logs every five minutes for the top 500 (by traffic volume) city-networks for each monitor. Measurements that it publishes to S3 include the top 500 that are published to CloudWatch Logs.

You can choose the option to publish to S3, and specify the bucket to publish the measurements, to when you create or update your monitor. The bucket must already be created in S3 before you can specify it in Internet Monitor. There's a service limit of 500,000 city-networks for internet measurements published to S3. Internet Monitor publishes internet measurements to S3 as events, a series of compressed log file objects that are stored in the bucket.

When you create the S3 bucket for Internet Monitor to publish measurements to, make sure that you follow the permissions guidance provided by CloudWatch Logs. Doing so ensures that Internet Monitor can publish logs directly to S3, and that AWS can, if needed, create and change the resource policies associated with the log group receiving the logs. For more information, see Logs sent to CloudWatch Logs in the Amazon CloudWatch Logs User Guide.

The published log files are compressed. If you open the log files using the Amazon S3 console, they are decompressed and the internet measurement events are displayed. If you download the files, you must decompress them to view the events.

You can also query the internet measurements in the log files using Amazon Athena. Amazon Athena is an interactive query service that makes it easier to analyze data in Amazon S3, by using standard SQL. For more information, see Use Amazon Athena to query internet measurements in Amazon S3 log files.

Examples of using the CLI with Internet Monitor

This section includes examples for using the AWS Command Line Interface with Internet Monitor operations.

Before you begin, make sure that you log in to use the AWS CLI with the same AWS account that has the Amazon VPC VPCs, Network Load Balancers, Amazon CloudFront distributions, or Amazon WorkSpaces directories that you want to monitor. Internet Monitor doesn't support accessing resources across accounts. For more information about using the AWS CLI, see the AWS CLI Command Reference. For more information about using API actions with Internet Monitor, see the Internet Monitor API Reference Guide.

Topics

- List health events
- View specific health event
- View monitor list
- Edit monitor
- Delete monitor

Create a monitor

When you create a monitor in Internet Monitor, you provide a name and associate resources with the monitor to show where your application's internet traffic is. You specify a traffic percentage that defines how much of your application traffic is monitored. That also determines the number of city-networks, that is, client locations and ASNs, typically internet service providers or ISPs, that are monitored. You can also opt to set a limit for the maximum number of city-networks to monitor for your application resources, to help control your bill. For more information, see Choose a city-networks maximum limit.

Finally, you can choose if you want to publish all internet measurements for your application to Amazon S3. Internet measurements for the top 500 city-networks (by traffic volume) are automatically published to CloudWatch Logs by Internet Monitor, but you can choose to publish all measurements to S3 as well.

To create a monitor with the AWS CLI, you use the `create-monitor` command. The following command creates a monitor that monitors 100% of traffic but sets a maximum city-networks limit of 10,000, adds a VPC resource, and opts to publish internet measurements to Amazon S3.

> **Note**
>
> Internet Monitor publishes to CloudWatch Logs internet measurements every five minutes for the top 500 city-networks (client locations and ASNs, typically internet service providers or ISPs) that send traffic to each monitor. Optionally, you can choose to publish internet measurements for all monitored city-networks (up to the 500,000 city-networks service limit) to an Amazon S3 bucket. For more information, see Publish internet measurements to Amazon S3 in Internet Monitor.

```
aws internetmonitor create-monitor --monitor-name "TestMonitor" \
    --traffic-percentage-to-monitor 100 \
    --max-city-networks-to-monitor 10000 \
    --resources "arn:aws:ec2:us-east-1:111122223333:vpc/vpc-11223344556677889" \
    --internet-measurements-log-delivery S3Config="{BucketName=amzn-s3-demo-
bucket,LogDeliveryStatus=ENABLED}"
```

```
{
    "Arn": "arn:aws:internetmonitor:us-east-1:111122223333:monitor/TestMonitor",
    "Status": "ACTIVE"
```

```
}
```

> **Note**
>
> You can't change the name of a monitor.

View monitor details

To view information about a monitor with the AWS CLI, you use the `get-monitor` command.

```
aws internetmonitor get-monitor --monitor-name "TestMonitor"
```

```
{
    "ClientLocationType": "city",
    "CreatedAt": "2022-09-22T19:27:47Z",
    "ModifiedAt": "2022-09-22T19:28:30Z",
    "MonitorArn": "arn:aws:internetmonitor:us-east-1:111122223333:monitor/TestMonitor",
    "MonitorName": "TestMonitor",
    "ProcessingStatus": "OK",
    "ProcessingStatusInfo": "The monitor is actively processing data",
    "Resources": [
        "arn:aws:ec2:us-east-1:111122223333:vpc/vpc-11223344556677889"
    ],
    "MaxCityNetworksToMonitor": 10000,
    "Status": "ACTIVE"
}
```

List health events

When performance degrades for your application's internet traffic, Internet Monitor creates health events in your monitor. To see a list of current health events with the AWS CLI, use the `list-health-events` command.

```
aws internetmonitor list-health-events --monitor-name "TestMonitor"
```

```
{
    "HealthEvents": [
        {
            "EventId": "2022-06-20T01-05-05Z/latency",
```

```
            "Status": "RESOLVED",
            "EndedAt": "2022-06-20T01:15:14Z",
            "ServiceLocations": [
                {
                    "Name": "us-east-1"
                }
            ],

}
```

View monitor list

To see a list of all monitors in your account with the CLI, run the `list-monitors` command.

```
aws internetmonitor list-monitors
```

```
{
    "Monitors": [
        {
            "MonitorName": "TestMonitor",
            "ProcessingStatus": "OK",
            "Status": "ACTIVE"
        }
    ],
    "NextToken": " zase12"
}
```

Edit monitor

To update information about your monitor by using the CLI, use the `update-monitor` command and specify the name of the monitor to update. For example, you can update the percentage of traffic to monitor, the limit of the maximum number of city-networks to monitor, add or remove the resources that Internet Monitor uses to monitor traffic, and change the monitor status from `ACTIVE` to `INACTIVE`, or vice versa. Note that you can't change the name of the monitor.

The response for an `update-monitor` call returns just the `MonitorArn` and the `Status`.

The following example shows how to use the `update-monitor` command to change the maximum number of city-networks to monitor to `50000`:

```
aws internetmonitor update-monitor --monitor-name "TestMonitor" --max-city-networks-to-
monitor 50000
```

```
{
    "MonitorArn": "arn:aws:internetmonitor:us-east-1:111122223333:monitor/TestMonitor",
    "Status": " ACTIVE "
}
```

The following example shows how to add and remove resources:

```
aws internetmonitor update-monitor --monitor-name "TestMonitor" \
    --resources-to-add "arn:aws:ec2:us-east-1:111122223333:vpc/vpc-11223344556677889" \
    --resources-to-remove "arn:aws:ec2:us-east-1:111122223333:vpc/vpc-2222444455556666"
```

```
{
    "MonitorArn": "arn:aws:internetmonitor:us-east-1:111122223333:monitor/TestMonitor",
    "Status": "ACTIVE"
}
```

The following example shows how to use the `update-monitor` command to change the monitor status to `INACTIVE`:

```
aws internetmonitor update-monitor --monitor-name "TestMonitor" --status "INACTIVE"
```

```
{
    "MonitorArn": "arn:aws:internetmonitor:us-east-1:111122223333:monitor/TestMonitor",
    "Status": "INACTIVE"
}
```

Delete monitor

You can delete a monitor with the CLI by using the `delete-monitor` command. First, you must set the monitor to be inactive. To do that, use the `update-monitor` command to change the status to `INACTIVE`. Confirm that the monitor is inactive by using the `get-monitor` command and checking the status.

When the monitor status is `INACTIVE`, then you can use the CLI to run the `delete-monitor` command to delete the monitor. The response for a successful `delete-monitor` call is empty.

```
aws internetmonitor delete-monitor --monitor-name "TestMonitor"
```

```
{}
```

Monitor and optimize with the Internet Monitor dashboard

Using the Internet Monitor dashboard in the AWS Management Console, you can visualize data and get insights and suggestions about your AWS application's internet traffic, and configure options for your monitor.

After you create a monitor to monitor your application's internet performance and availability, Internet Monitor stores internet measurements for pairs of your client locations and ASNs, or *city-networks*. Internet Monitor also creates aggregated CloudWatch metrics for traffic to your application, and to each AWS Region and edge location. You can filter, explore, and get action-oriented suggestions from your monitor's information in several different ways. The Internet Monitor dashboard guides you through viewing and getting insights about the data for your monitored traffic.

To get started, on the CloudWatch console, under **Network Monitoring**, choose **Internet monitors**. Then, select a monitor to work with.

> **Note**
>
> This section primarily describes how to filter and view Internet Monitor metrics using the AWS Management Console. Alternatively, you can use Internet Monitor API operations with the AWS CLI or an SDK to work directly with Internet Monitor events stored in CloudWatch Logs files. For more information, see Using your monitor and measurements information. For more information about using API operations, see Examples of using the CLI with Internet Monitor and the Internet Monitor API Reference.

There are five pages (tabs) in the Internet Monitor dashboard:

- On the **Overview** page, you can get an overall view of your monitored traffic, including current performance and availability information, a summary of recent and current health events, and the top suggestion for potentially improving performance for your clients.
- On the **Health events** page, you can see current and historical health events that currently impact, or previously impacted, locations where clients access your application.

- On the **Analyze** page, you can view information about top monitored traffic in client locations (by traffic volume), summarized in several customizable ways. You can also see historical trends for health scores and metrics. You can filter by location, ASN, date, and so on, and visualize metrics for your internet traffic over time.
- On the **Optimize** page, Internet Monitor predicts your application's performance improvement for top AWS Regions (or Amazon CloudFront), based on your traffic patterns and past performance. For each top configuration, associated tables provide a breakdown of reduced latency by client location. On a second page, you can select multiple Regions (and, if you like, include CloudFront configurations) to compare latency reductions. For each configuration (Region) that you selected, the page displays an associated table of latency details, listed by city location.
- On the **Configure** page, you can see monitor details and configure options, such as the percentage of traffic to monitor.

In addition to these dashboard options, you can use tools for deeper dives into details of the metrics that Internet Monitor collects with your monitor. Internet Monitor generates and publishes log files with the measurements about your traffic, so you can use other CloudWatch tools in the console to further visualize the data published by Internet Monitor, including CloudWatch Contributor Insights, CloudWatch Metrics, and CloudWatch Logs Insights. For more information, see Exploring your data with CloudWatch tools and the Internet Monitor query interface.

Learn about using Internet Monitor to explore your performance and availability measurements in the following sections.

Topics

- Track real-time performance and availability in Internet Monitor (Overview page)
- View health events and metrics in Internet Monitor (Health events page)
- Analyze historical data in Internet Monitor (Analyze page)
- Get suggestions to optimize application performance in Internet Monitor (Optimize page)
- Monitoring details in Internet Monitor (Configure page)

Track real-time performance and availability in Internet Monitor (Overview page)

The **Overview** page in the Internet Monitor console shows you a high-level view of performance and availability for the traffic that your monitor tracks, and a timeline of when health events have

impacted your monitored traffic. The page also provides the top suggestion for a configuration change that could reduce latency for clients who use your application in your top client location (by traffic volume).

Traffic overview and Status

The **Traffic overview** section provides an overall look at your application's availability and performance. Note that this section shows *aggregated* overall performance and availability scores that consider all of the traffic for applications towards all end users and service locations. You can see health scores for specific client locations and service locations by searching and filtering measurements information on the **Analyze** tab.

Under **Status**, you can see if your monitor is actively creating data for your monitor or is waiting for data to be available. You can also see the percentage of your application's traffic that you're monitoring. If you want to change the percentage, see the **Configure** page.

Internet Monitor uses a statistical process to create availability and performance scores for your monitored traffic. AWS has substantial historical data about internet performance and availability for network traffic between geographic locations for different ASNs and AWS services. Internet Monitor uses the connectivity data that AWS has captured from its global networking footprint to calculate a baseline of availability and performance for internet traffic. This is the same data that we use at AWS to monitor our own internet uptime and availability.

With those measurements as a baseline, Internet Monitor can detect when the performance and availability for your application has dropped, compared to the baseline. To make it easier to see those drops, we report that information to you as a performance score and an availability score.

For more information, see How AWS calculates performance and availability scores.

Health events timeline

The **Health events timeline** graph displays health events that have occurred during the past 24 hours. A summary below the graph shows your application's current and recent impact. For details, you can choose **See more health events**.

To change the thresholds for health events, go to the **Configure** page.

Reduce latency for your top Region

Internet Monitor automatically evaluates the AWS Region that your current application configuration uses most (that is, the Region with the highest client volume), and determines if another Region could provide a better aggregate time to first byte (TTFB) for your clients.

Note that because this is the aggregate TTFB, if you move traffic from one Region to another, TTFB for most locations is expected to improve but clients in some Regions could see no change or reduced performance..

To explore more latency improvement suggestions, including details at more granular levels (such as by client location), see the **Optimize** page.

View health events and metrics in Internet Monitor (Health events page)

The **Health events** page in the Internet Monitor console provides a map of health events that impact the client locations and ASNs for your application. You can click circles on the map for more details about an event. The **Health events** tables lists locations that have been impacted by an event, and specifics about the impact.

Internet traffic overview

The **Internet traffic overview** map shows you the internet traffic and health events that are specific to the locations and ASNs that your clients access your application from. The countries that are gray on the map are those that include traffic for your application.

Each circle on the map indicates a health event in an area, for a time period that you select. Internet Monitor creates health events when it detects a problem, at a specific (but customizable) threshold, with connectivity between one of your resources hosted in AWS and a city-network where a client is accessing your application.

Choose a circle on the map to display more details about the health event for that location. In addition, for clusters that have health events, you can see detailed information in the **Health events** table below the map.

Note that Internet Monitor creates health events in a monitor when it determines that an event has significant impact on your application. The map is blank if there aren't any health events that exceed the threshold for impact on traffic for your client locations in the time period that you've selected. For more information, see When Internet Monitor creates and resolves health events.

Health events

The **Health events** table lists client locations that have been affected by health events, along with information about the events. The following columns are included in the table.

Column	Description
Event type	Specifies whether current events are *overall* health events or *local* health events, or if the health event is in the *past*.
Client location	The location of the end users who were impacted by the event, who experienced increased latency or reduced availability. To learn more about client location accuracy in Internet Monitor, see Geolocation information and accuracy in Internet Monitor.
ISP name (ASN)	The network that the traffic traveled over. Typically, this is the internet service provider (ISP) or Autonomous System Number (ASN) for the network traffic.
Service location	The AWS location for the network traffic, which can be an AWS Region or an internet edge location.
Traffic impact	How much impact was caused by the event, in increased latency or reduced availability. For latency, this is the percentage of how much latency increased during the event compared to typical performance for traffic, from this client location to this AWS location using this client network.
Impact type	The type of impact for the health event. Health events are typically caused by latency increases (performance issues) or reachability (availability issues).

Column	Description
	You might also be able to click on the impact type to see the cause of the impairment. When possible, Internet Monitor analyzes the origin of a health event, to determine whether it was caused by AWS or an ASN (internet service provider). Note that this analysis continues after the event is resolved. Internet Monitor can update events with new information for up to an hour.

If you choose one of the client locations in the **Health events** table, you can see more details about the health event at that location. For example, you can see when the event started, when it ended, and the local traffic impact.

Network path visualization

If Internet Monitor has finished impairment analysis for an event, you can view **Network path visualization** to see the full network path for traffic to a client location. The full path shows you each node along the network path for your application for the health event, between the AWS location and the client, for a client-location pair.

When Internet Monitor has determined the cause of an impairment, Internet Monitor adds a dashed red circle around the node. Impairments can be caused by ASNs, typically internet service providers (ISPs), or the cause can be AWS. If there were multiple causes for an impairment, multiple nodes are circled.

Analyze historical data in Internet Monitor (Analyze page)

On the **Analyze** page in the Internet Monitor console, you can view your application's the top client locations for the traffic that you monitor, by traffic volume. You can also view graphs showing performance and availability scores for your traffic over time, as well as graphs of other internet traffic metrics for your application's monitored traffic.

To start exploring Internet Monitor data for your application traffic, select a time period. Then, choose a specific geographical location, such a city, and (optionally) other filters. Internet Monitor

applies the filters to your data, and then you can see graphs of the data that show measurements for your application. The graphs included on the **Analyze** page include your application's performance score, availability score, monitored bytes transferred (for VPCs, Network Load Balancers, and CloudFront distributions) or client connection counts (for WorkSpaces directories), and round-trip time (RTT) for your application over time.

The options at the top of the **Analyze** page determine the timeframe and types of traffic shown in the graphs on the page. You can filter by client locations or ASN, or choose to show traffic graphs at a specific granularity (the default is city level).

Top client locations

The **Top client locations** graph displays your top monitored traffic locations, by default. You can choose another field to sort the graph by, or you can sort the graph in other ways, for example, by lowest traffic locations.

The filters that you choose for the page determine the Regions, timeframe, and so on for the locations.

Traffic health scores

This section shows you graphs of traffic health scores and metrics for your monitored traffic. These graphs reflect data for the filters that you choose at the top of the page.

The **Traffic health scores** graph shows you performance and availability information for your local and overall traffic by calling out health events that have impacted your monitored client traffic. AWS has substantial historical data about internet performance and availability for network traffic between geographic locations for different ASNs and AWS services. Internet Monitor uses the connectivity data that AWS has captured from its global networking footprint to calculate a baseline of performance and availability for internet traffic. This is the same data that we use at AWS to monitor our own internet uptime and availability.

With those measurements as a baseline, Internet Monitor can detect when the performance and availability for your application has dropped, compared to the baseline. To make it easier to see those drops, we report that information to you as a performance score and an availability score. For more information, see How AWS calculates performance and availability scores.

Additional graphs show the monitored bytes transferred (for VPCs, Network Load Balancers, and CloudFront distributions) or client connection counts (for WorkSpaces directories), and round-trip time (RTT) for your application traffic.

Note that when round-trip time (RTT) is aggregated across end-user locations, the value is weighted by the amount of your traffic that is driven by each client location. For example, with two client locations, one serving 90% of traffic with a 5 ms RTT, and the other serving 10% of traffic with a 10 ms RTT, the result is an aggregated RTT of 5.5 ms (which comes from 5 ms * 0.9 + 10 ms * 0.1).

You can also explore the internet measurements that Internet Monitor stores for your monitored traffic by using CloudWatch tools or other methods. For more information, see Exploring your data with CloudWatch tools and the Internet Monitor query interface. In addition, you can create CloudWatch alarms based on Internet Monitor data, for example, to notify you of health events. For more information, see Create alarms with Internet Monitor.

Get suggestions to optimize application performance in Internet Monitor (Optimize page)

Use the **Optimize** page in the Internet Monitor console to get suggestions for how to optimize application performance for your clients. Internet Monitor evaluates your monitored application traffic, and determines if you can reduce latency by changing the AWS Regions that you've configured for your application. Optionally, you can also view latency changes if you choose to include Amazon CloudFront in the suggestions.

You can review suggestions for your application's top Regions by traffic volume, or for top client locations, also by traffic volume.

Suggestions to reduce latency for top Regions

To help you quickly understand your best options for reducing latency for your clients, Internet Monitor automatically provides suggestions for improving latency in your application for your top Regions (by traffic volume).

You can also explore configuration changes for all the Regions where your application serves clients. This includes getting details about each suggested change at deeper levels of granularity, for example, by specific client location. To explore all Regional configurations and expected latency changes for your application, choose **Optimization suggestions for all Regions**.

Suggestions to reduce latency for all Regions

To explore suggestions for reducing latency for all Regions where clients access your application, choose **Optimization suggestions for all Regions** to open a new dashboard

page. On this page, you can select different Regions to configure, with the option of including CloudFront as a configuration comparison, and then compare the times to first byte (TTFBs) for each selected configuration.

Then, for each comparison, you can also see a table with at a more granular level (by client location), with the average expected TTFB for each one.

Suggestions to reduce latency for top locations

Internet Monitor also provides suggestions for reducing application latency for your clients by specific location. When the table lists multiple suggestions for the same location, expand the city location for that row to see details.

Be aware that if you change a configuration to use a different Region or to use CloudFront, latency improvements can vary by client location. For example, latency might improve for some locations, but stay the same or worsen for others.

Suggestions to reduce latency by updating routing configurations

Note: These suggestions are only relevant for application traffic to Regional load balancers. The table is not shown for monitors that you create for CloudFront distributions or WorkSpaces resources.

With Internet Monitor, you can view information about latency toward AWS locations for IPv4 IP prefixes that access your application using different DNS resolvers (typically ISPs). Using this information, you can take steps to reduce latency for specific groups of users by routing a set of IP address prefixes, specified by a CIDR collection, to your endpoints in a Region that results in lower latency for your users. If you don't already have a CIDR collection for the prefixes, you can go to Amazon Route 53 to create one. Then, you can update your routing in Route 53 to route IP addresses in the collection to a specific Region.

If you want to create a CIDR collection for a set of IP address prefixes, you can easily do so by selecting a row or rows that includes the IP prefixes that you want, and then choosing **Add to CIDR collection**. Then, in the Route 53 console, you can configure a routing policy that routes IP addresses in the collection to the Region with lower latency for your application.

To learn more about IP-based routing in Route 53, see IP-based routing.

By viewing the suggestions on this page, you can start planning configurations and deployments that can improve performance for your clients. Note that you might see a dash (-) instead of a value in a column, when data is not available to display.

For more information about TTFB calculations, see AWS calculations for TTFB and latency. To review a specific example of how to improve performance, see Using Internet Monitor for a Better Gaming Experience.

Monitoring details in Internet Monitor (Configure page)

On the **Configure** page, you can see details about your monitor, including a list of resources that you monitor traffic for and the thresholds for when health events are triggered. You can also explore and compare values for the traffic percentage for your monitor, and its impact on how many city-networks are included for (monitored by) your monitor. Finally, you can view information about measurements that are published to an Amazon S3 bucket.

You can configure a monitor to change most options, such as the percentage of traffic to monitor. For more information, see Configure your monitor.

Monitor details

The **Monitor details** section includes basic information about your monitor, including the name, the percentage of traffic currently being monitored for your application, a city-networks maximum limit (if you've set one), and status information about the monitor.

The following explains the values that you might see for **Status** and **Status info** (data processing status).

Status	Description
Active	Monitor is created and active.
Pending	Monitor is currently being created and is not yet active.
Inactive	Monitor is created but has been set to inactive.
Error	Monitor is in an error state.

Status details (Data processing status)	Description

Status details (Data processing status)	Description
OK	Monitor is actively processing data.
Inactive	Monitor is inactive and is not processing data.
Collecting data	Monitor is actively collecting data.
Insufficient data	Monitor is actively processing data, but there aren't enough datapoints to produce insights.
Fault access CloudWatch	Monitor has encountered a problem delivering CloudWatch metrics data and log events.

Health event thresholds

In this section, you can see the current thresholds for health events that are configured for this monitor. If you haven't configured any custom thresholds, the values shown here are the default values.

By default, health events are not triggered based on local thresholds. If local health event thresholds would be useful for your Internet Monitor scenario, you can enable the option and specify the thresholds to use.

You can learn more about how health event thresholds work, and review the potential impact of adding local thresholds or changing existing thresholds. For more information, see Change health event thresholds.

Traffic coverage

In this section, you can explore options for the traffic coverage for your monitor. When you change the traffic percentage for a monitor, Internet Monitor monitors different amounts of application traffic. If you set a traffic percentage to less than 100% (100% is the default value), some portion of the city-networks that your clients use to access your application might not be monitored. By exploring the impact of different traffic percentage values, you can see how different values that you might set would impact your city-networks coverage.

The **Total monitored city-networks** graph shows you how many city-networks are currently monitored, and how many would be monitored if you set the traffic percentage to 100%. To view different traffic percentage values on the graph, select percentages in the drop-down menu.

After you explore the options, you can change the traffic percentage to monitor by choosing **Update monitoring coverage**.

If you want to set a maximum city-networks limit, at the top of the page, choose **Edit monitor**. Then, under **Advanced options**, set a maximum city-networks value.

Configure your monitor

As on every page in the Internet Monitor dashboard, you can choose **Edit monitor** to change options for your monitor, including adding or removing resources. For details about how to update the following configuration options, see the provided links.

View health event thresholds

In this section, you can see the current thresholds for health events that are configured for this monitor.

To update health thresholds, see Change health event thresholds.

View and evaluate traffic coverage

In this section, you can compare the effect of changing the percentage of traffic that you monitor for your application on the number of city-networks that are included (for monitoring) when you choose different percentage values.

You can also change the percentage of traffic that you monitor, or change the limit for the number of city-networks your monitor includes. To change the percentage of traffic, choose **Update monitoring coverage**.

For detailed steps and information, see Explore changing your application traffic percentage.

Configuration details for publishing internet measurements to Amazon S3

If you have configured Internet Monitor to publish internet measurements for your monitor to an Amazon S3 bucket, the information about your configuration is shown here.

To configure this option, see Publishing internet measurements to S3.

Exploring your data with CloudWatch tools and the Internet Monitor query interface

In addition to visualizing your performance and availability for your application with the Internet Monitor dashboard, there are several methods that you can use to dive deeper into the data that Internet Monitor generates for you. These methods include using CloudWatch tools with Internet Monitor data stored in CloudWatch Log files and using the Internet Monitor query interface. The tools that you can use include CloudWatch Logs Insights, CloudWatch Metrics, CloudWatch Contributor Insights, and Amazon Athena. You can use some or all these tools, as well as the dashboard, to explore Internet Monitor data, depending on your needs.

Internet Monitor aggregates CloudWatch metrics about traffic to your application and to each AWS Region, and includes data such as total traffic impact, availability, and round-trip time. This data is published to CloudWatch Logs and is also available to use with the Internet Monitor query interface. Details about geo-granularity and other aspects of the information available to explore for each one varies.

Internet Monitor publishes data for your monitor at 5 minute intervals, and then makes the data available in several ways. The following table lists scenarios for accessing Internet Monitor data, and describes features of the data that is collected for each one.

Feature	CloudWatch Logs	Export to S3	Query interface	CloudWatch dashboard
Enabled by default	Yes	No	Yes	Yes
Number of city-networks that data is collected for	Top 500 (see note below)	All	All	All
Data retention	User controlled	User controlled	30 days	30 days
Geo-granularities that data is collected for	All (city-network, metro+network, subdivision+networ	City-network	All (city-network, metro+network, subdivision+networ	All (city-network, metro+network, subdivision+networ

Feature	CloudWatch Logs	Export to S3	Query interface	CloudWatch dashboard
	k, country+network)		k, country+network)	k, country+network)
How to query and filter data	Use CloudWatch Logs Insights to explore Internet Monitor measurements	Use Amazon Athena to query internet measurements in Amazon S3 log files	Use the Internet Monitor query interface	Monitor and optimize with the Internet Monitor dashboard

Note: Top 500 measurements are captured for city-networks; top 250 for metro+networks, top 100 for subdivision+networks, top 50 for country+networks.

This chapter describes how to query and explore your data by using CloudWatch tools or the Internet Monitor query interface, together with examples for each method.

Contents

- Use CloudWatch Logs Insights to explore Internet Monitor measurements
- Use Contributor Insights to identify top locations and ISPs
- View Internet Monitor metrics or set alarms in CloudWatch Metrics
- Use Amazon Athena to query internet measurements in Amazon S3 log files
- Use the Internet Monitor query interface

Use CloudWatch Logs Insights to explore Internet Monitor measurements

You can use CloudWatch Logs Insights queries to filter a subset of logs for a specific city or geography (client location), client ASN (ISP), and AWS source location. Internet Monitor publishes granular measurements of availability and round-trip time to CloudWatch Logs that you can explore using CloudWatch Logs Insights.

To learn more about client location accuracy in Internet Monitor, see Geolocation information and accuracy in Internet Monitor.

The examples in this section can help you create CloudWatch Logs Insights queries to learn more about your own application traffic measurements and metrics. If you use these examples in CloudWatch Logs Insights, replace *monitorName* with your own monitor name.

View traffic optimization suggestions

On the **Traffic insights** tab in Internet Monitor, you can view traffic optimization suggestions, filtered by a location. To see the same information that is displayed in the **Traffic optimization suggestions** section on that tab, but without the location granularity filter, you can use the following CloudWatch Logs Insights query.

1. In the AWS Management Console, navigate to CloudWatch Logs Insights.
2. For **Log Group**, select `/aws/internet-monitor/`*monitorName*`/byCity` and `/aws/internet-monitor/`*monitorName*`/byCountry`, and then specify a time range.
3. Add the following query, and then run the query.

```
fields @timestamp,
clientLocation.city as @city, clientLocation.subdivision as @subdivision,
 clientLocation.country as @country,
`trafficInsights.timeToFirstByte.currentExperience.serviceName` as @serviceNameField,
concat(@serviceNameField, ` (`, `serviceLocation`, `)`) as @currentExperienceField,
concat(`trafficInsights.timeToFirstByte.ec2.serviceName`, ` (`,
 `trafficInsights.timeToFirstByte.ec2.serviceLocation`, `)`) as @ec2Field,
`trafficInsights.timeToFirstByte.cloudfront.serviceName` as @cloudfrontField,
concat(`clientLocation.networkName`, ` (AS`, `clientLocation.asn`, `)`) as @networkName
| filter ispresent(`trafficInsights.timeToFirstByte.currentExperience.value`)
| stats avg(`trafficInsights.timeToFirstByte.currentExperience.value`) as @averageTTFB,
avg(`trafficInsights.timeToFirstByte.ec2.value`) as @ec2TTFB,
avg(`trafficInsights.timeToFirstByte.cloudfront.value`) as @cloudfrontTTFB,
sum(`bytesIn` + `bytesOut`) as @totalBytes,
latest(@ec2Field) as @ec2,
latest(@currentExperienceField) as @currentExperience,
latest(@cloudfrontField) as @cloudfront,
count(*) by @networkName, @city, @subdivision, @country
| display @city, @subdivision, @country, @networkName, @totalBytes, @currentExperience,
 @averageTTFB, @ec2, @ec2TTFB, @cloudfront, @cloudfrontTTFB
| sort @totalBytes desc
```

View internet availability and RTT (p50, p90, and p95)

To view the internet availability and round-trip time (p50, p90, and p95) for traffic, you can use the following CloudWatch Logs Insights query.

End user geography: Chicago, IL, United States

End user network (ASN): AS7018

AWS service location: US East (N. Virginia) Region

To view the logs, do the following:

1. In the AWS Management Console, navigate to CloudWatch Logs Insights.
2. For **Log Group**, select `/aws/internet-monitor/`*`monitorName`*`/byCity` and `/aws/internet-monitor/`*`monitorName`*`/byCountry`, and then specify a time range.
3. Add the following query, and then run the query.

The query returns all the performance data for users connecting from AS7018 in Chicago, IL towards US East (N. Virginia) Region over the selected time period.

```
fields @timestamp,
internetHealth.availability.experienceScore as availabilityExperienceScore,
internetHealth.availability.percentageOfTotalTrafficImpacted as
 percentageOfTotalTrafficImpacted,
internetHealth.performance.experienceScore as performanceExperienceScore,
internetHealth.performance.roundTripTime.p50 as roundTripTimep50,
internetHealth.performance.roundTripTime.p90 as roundTripTimep90,
internetHealth.performance.roundTripTime.p95 as roundTripTimep95
 | filter clientLocation.country == `United States`
 and clientLocation.city == `Chicago`
 and serviceLocation == `us-east-1`
 and clientLocation.asn == 7018
```

For more information, see Analyzing log data with CloudWatch Logs Insights.

Use Contributor Insights to identify top locations and ISPs

CloudWatch Contributor Insights can help you identify top client locations and ASNs (typically, internet service providers or ISPs) for your AWS application. Use the following sample Contributor Insights rules to get started with rules that are useful with Internet Monitor. For more information, see Create a Contributor Insights rule in CloudWatch.

To learn more about client location accuracy in Internet Monitor, see Geolocation information and accuracy in Internet Monitor.

> **Note**
>
> Internet Monitor stores internet measurements data every five minutes, so after you set up a Contributor Insights rule, you must adjust the period to five minutes to see a graph.

View top locations and ASNs impacted by an availability impact

To view top client locations and ASNs impacted by a drop in availability, you can use the following Contributor Insights rule in the Syntax editor. Replace *monitor-name* with your own monitor name.

```
{
    "Schema": {
        "Name": "CloudWatchLogRule",
        "Version": 1
    },
    "AggregateOn": "Sum",
    "Contribution": {
        "Filters": [
            {
                "Match": "$.clientLocation.city",
                "IsPresent": true
            }
        ],
        "Keys": [
            "$.clientLocation.city",
            "$.clientLocation.networkName"
        ],
        "ValueOf": "$.awsInternetHealth.availability.percentageOfTotalTrafficImpacted"
    },
    "LogFormat": "JSON",
    "LogGroupNames": [
        "/aws/internet-monitor/monitor-name/byCity"
    ]
}
```

View top client locations and ASNs impacted by a latency impact

To view top client locations and ASNs impacted by an increase in round-trip time (latency), you can use the following Contributor Insights rule in the Syntax editor. Replace *monitor-name* with your own monitor name.

```
{
    "Schema": {
        "Name": "CloudWatchLogRule",
        "Version": 1
    },
    "AggregateOn": "Sum",
    "Contribution": {
        "Filters": [            {
                "Match": "$.clientLocation.city",
                "IsPresent": true
            }
        ],
        "Keys": [
            "$.clientLocation.city",
            "$.clientLocation.networkName"
        ],
        "ValueOf": "$.awsInternetHealth.performance.percentageOfTotalTrafficImpacted"
    },
    "LogFormat": "JSON",
    "LogGroupNames": [
        "/aws/internet-monitor/monitor-name/byCity"
    ]
}
```

View top client locations and ASNs impacted by total percentage of traffic

To view top client locations and ASNs impacted by total percentage of traffic, you can use the following Contributor Insights rule in the Syntax editor. Replace *monitor-name* with your own monitor name.

```
{
    "Schema": {
        "Name": "CloudWatchLogRule",
        "Version": 1
    },
    "AggregateOn": "Sum",
    "Contribution": {
        "Filters": [
```

```
            {
                "Match": "$.clientLocation.city",
                "IsPresent": true
            }
        ],
        "Keys": [
            "$.clientLocation.city",
            "$.clientLocation.networkName"
        ],
        "ValueOf": "$.percentageOfTotalTraffic"
    },
    "LogFormat": "JSON",
    "LogGroupNames": [
        "/aws/internet-monitor/monitor-name/byCity"
    ]
}
```

View Internet Monitor metrics or set alarms in CloudWatch Metrics

You can view or set alarms on Internet Monitor metrics by using CloudWatch alarms and CloudWatch Metrics in the CloudWatch console. Internet Monitor publishes metrics to your account, including metrics for performance, availability, round-trip time, and throughput (bytes per second). To find all metrics for your monitor, in the CloudWatch Metrics dashboard, see the custom namespace `AWS/InternetMonitor`.

To see examples for using several of these metrics to help determine values to choose for a city-networks maximum limit for your monitor, see Choosing a city-network maximum value. To learn more about setting alarms for Internet Monitor, see Create alarms with Internet Monitor.

Metrics are aggregated across all internet traffic to your VPCs, Network Load Balancers, CloudFront distributions, or WorkSpaces directories in the monitor, and to all traffic to each AWS Region and internet edge location that is monitored. Regions are defined by the service location, which can either be all locations or a specific Region, such as `us-east-1`.

Note: *city-networks* are pairs of client locations and the ASNs the clients use (typically internet service providers or ISPs).

Internet Monitor provides the following metrics.

Metric	Description
PerformanceScore	A performance score represents the estimated percentage of traffic that is not seeing a performance drop.
AvailabilityScore	An availability score represents the estimated percentage of traffic that is not seeing an availability drop.
BytesIn	Bytes transferred in for your application internet traffic at all application city-networks.
BytesOut	Bytes transferred out for your application internet traffic at all application city-networks.
BytesInMonitored	Bytes transferred in for your application internet traffic at monitored city-networks.
BytesOutMonitored	Bytes transferred out for your application internet traffic at monitored city-networks.
Round-trip time (RTT)	Round-trip time between the AWS Regions, ASNs (typically internet service providers or ISPs), and locations (such as cities) specific to your VPCs, Network Load Balancers, CloudFront distributions, or WorkSpaces directories.
CityNetworksMonitored	The number of city-networks Internet Monitor monitored for your application internet traffic. This is never more than the upper limit that you set as the maximum city-networks for the monitor.
TrafficMonitoredPercent	The percentage of total application internet traffic for this monitor that is represented (included) by the city-networks that Internet Monitor is monitoring. This is less than 100

Metric	Description
	(that is, less than 100%) if clients access your application in more city-networks than the maximum city-networks limit that you have set for the monitor.
CityNetworksFor100PercentTraffic	The number that you should set your city-networks maximum limit to if you want to monitor 100% of your application internet traffic in Internet Monitor.
CityNetworksFor99PercentTraffic	The number that you should set your city-networks maximum limit to if you want to monitor 99% of your application internet traffic in Internet Monitor.
CityNetworksFor95PercentTraffic	The number that you should set your city-networks maximum limit to if you want to monitor 95% of your application internet traffic in Internet Monitor.
CityNetworksFor90PercentTraffic	The number that you should set your city-networks maximum limit to if you want to monitor 90% of your application internet traffic in Internet Monitor.
CityNetworksFor75PercentTraffic	The number that you should set your city-networks maximum limit to if you want to monitor 75% of your application internet traffic in Internet Monitor.
CityNetworksFor50PercentTraffic	The number that you should set your city-networks maximum limit to if you want to monitor 50% of your application internet traffic in Internet Monitor.

Metric	Description
CityNetworksFor25PercentTraffic	The number that you should set your city-networks maximum limit to if you want to monitor 25% of your application internet traffic in Internet Monitor.

For more information, see Metrics in Amazon CloudWatch.

Use Amazon Athena to query internet measurements in Amazon S3 log files

You can use Amazon Athena to query and view the internet measurements that Internet Monitor publishes to an Amazon S3 bucket. There's an option in Internet Monitor to publish internet measurements for your application to an S3 bucket for internet-facing traffic for your monitored city-networks (client locations and ASNs, typically internet service providers or ISPs). Regardless of whether you choose to publish measurements to S3, Internet Monitor automatically publishes internet measurements to CloudWatch Logs every five minutes for the top 500 (by traffic volume) city-networks for each monitor.

This chapter includes steps for how to create a table in Athena for internet measurements located in an S3 log file, and then provides example queries to see different views of the measurements. For example, you can query for your top 10 impacted city-networks by latency impact.

Using Amazon Athena to create a table for internet measurements in Internet Monitor

To start using Athena with your Internet Monitor S3 log files, you first create a table for the internet measurements.

Follow the steps in this procedure to create a table in Athena based on the S3 log files. Then, you can run Athena queries on the table, such as these example internet measurements queries, to get information about your measurements.

To create an Athena table

1. Open the Athena console at https://console.aws.amazon.com/athena/.
2. In the Athena query editor, enter a query statement to generate a table with Internet Monitor internet measurements. Replace the value for the LOCATION parameter with the location of S3 bucket where your Internet Monitor internet measurements are stored.

```
CREATE EXTERNAL TABLE internet_measurements (
    version INT,
    timestamp INT,
    clientlocation STRING,
    servicelocation STRING,
    percentageoftotaltraffic DOUBLE,
    bytesin INT,
    bytesout INT,
    clientconnectioncount INT,
    internethealth STRING,
    trafficinsights STRING
)
PARTITIONED BY (year STRING, month STRING, day STRING)
ROW FORMAT SERDE 'org.openx.data.jsonserde.JsonSerDe'
LOCATION
's3://amzn-s3-demo-bucket/bucket_prefix/AWSLogs/account_id/
internetmonitor/AWS_Region/'
TBLPROPERTIES ('skip.header.line.count' = '1');
```

3. Enter a statement to create a partition to read the data. For example, the following query creates a single partition for a specified date and location:

```
ALTER TABLE internet_measurements
ADD PARTITION (year = 'YYYY', month = 'MM', day = 'dd')
LOCATION
's3://amzn-s3-demo-bucket/bucket_prefix/AWSLogs/account_id/
internetmonitor/AWS_Region/YYYY/MM/DD';
```

4. Choose **Run**.

Example Athena statements for internet measurements

The following is an example of a statement to generate a table:

```
CREATE EXTERNAL TABLE internet_measurements (
    version INT,
    timestamp INT,
    clientlocation STRING,
    servicelocation STRING,
    percentageoftotaltraffic DOUBLE,
    bytesin INT,
    bytesout INT,
```

```
    clientconnectioncount INT,
    internethealth STRING,
    trafficinsights STRING
)
PARTITIONED BY (year STRING, month STRING, day STRING)
ROW FORMAT SERDE 'org.openx.data.jsonserde.JsonSerDe'
LOCATION 's3://internet-measurements/TestMonitor/AWSLogs/1111222233332/internetmonitor/
us-east-2/'
TBLPROPERTIES ('skip.header.line.count' = '1');
```

The following is an example of a statement to create a partition to read the data:

```
ALTER TABLE internet_measurements
ADD PARTITION (year = '2023', month = '04', day = '07')
LOCATION 's3://internet-measurements/TestMonitor/AWSLogs/1111222233332/internetmonitor/
us-east-2/2023/04/07/'
```

Sample Amazon Athena queries to use with internet measurements in Internet Monitor

This section includes example queries that you can use with Amazon Athena to get information about your application's internet measurements published to Amazon S3.

Query your top 10 impacted (by total percentage of traffic) client locations and ASNs

Run this Athena query to return your top 10 impacted (by total percentage of traffic) city-networks—that is, client locations and ASNs, typically internet service providers.

```
SELECT json_extract_scalar(clientLocation, '$.city') as city,
    json_extract_scalar(clientLocation, '$.networkname') as networkName,
    sum(percentageoftotaltraffic) as percentageoftotaltraffic
FROM internet_measurements
GROUP BY json_extract_scalar(clientLocation, '$.city'),
    json_extract_scalar(clientLocation, '$.networkname')
ORDER BY percentageoftotaltraffic desc
limit 10
```

Query your top 10 impacted (by availability) client locations and ASNs

Run this Athena query to return your top 10 impacted (by total percentage of traffic) city-networks—that is, client locations and ASNs, typically internet service providers.

```
SELECT json_extract_scalar(clientLocation, '$.city') as city,
```

```
    json_extract_scalar(clientLocation, '$.networkname') as networkName,
    sum(
        cast(
            json_extract_scalar(
                internetHealth,
                '$.availability.percentageoftotaltrafficimpacted'
            )
        as double )
    ) as percentageOfTotalTrafficImpacted
FROM internet_measurements
GROUP BY json_extract_scalar(clientLocation, '$.city'),
    json_extract_scalar(clientLocation, '$.networkname')
ORDER BY percentageOfTotalTrafficImpacted desc
limit 10
```

Query your top 10 impacted (by latency) client locations and ASNs

Run this Athena query to return your top 10 impacted (by latency impact) city-networks—that is, client locations and ASNs, typically internet service providers.

```
SELECT json_extract_scalar(clientLocation, '$.city') as city,
    json_extract_scalar(clientLocation, '$.networkname') as networkName,
    sum(
        cast(
            json_extract_scalar(
                internetHealth,
                '$.performance.percentageoftotaltrafficimpacted'
            )
        as double )
    ) as percentageOfTotalTrafficImpacted
FROM internet_measurements
GROUP BY json_extract_scalar(clientLocation, '$.city'),
    json_extract_scalar(clientLocation, '$.networkname')
ORDER BY percentageOfTotalTrafficImpacted desc
limit 10
```

Query traffic highlights for your client locations and ASNs

Run this Athena query to return traffic highlights, including availability score, performance score, and time to first byte for your city-networks—that is, client locations and ASNs, typically internet service providers. .

```
SELECT json_extract_scalar(clientLocation, '$.city') as city,
    json_extract_scalar(clientLocation, '$.subdivision') as subdivision,
    json_extract_scalar(clientLocation, '$.country') as country,
    avg(cast(json_extract_scalar(internetHealth, '$.availability.experiencescore') as
 double)) as availabilityScore,
    avg(cast(json_extract_scalar(internetHealth, '$.performance.experiencescore') as
 double)) performanceScore,
    avg(cast(json_extract_scalar(trafficinsights,
 '$.timetofirstbyte.currentexperience.value') as double)) as averageTTFB,
    sum(bytesIn) as bytesIn,
    sum(bytesOut) as bytesOut,
    sum(bytesIn + bytesOut) as totalBytes
FROM internet_measurements
where json_extract_scalar(clientLocation, '$.city') != 'N/A'
GROUP BY
json_extract_scalar(clientLocation, '$.city'),
    json_extract_scalar(clientLocation, '$.subdivision'),
    json_extract_scalar(clientLocation, '$.country')
ORDER BY totalBytes desc
limit 100
```

For more information about using Athena, see the Amazon Athena User Guide.

Use the Internet Monitor query interface

An option for understanding more about internet traffic for your AWS application is to use the Internet Monitor *query interface*. To use the query interface, you create a query with data filters that you choose, and then run the query to return a subset of your Internet Monitor data. Exploring the data that the query returns can give you insights into how your application is performing on the internet.

You can query and explore all the metrics that Internet Monitor captures with your monitor, including availability and performance scores, bytes transferred, round-trip times, and time to first byte (TTFB).

Internet Monitor uses the query interface to provide the data that you can explore in the Internet Monitor console dashboard. By using search options in the dashboard—on the **Analyze** page or the **Optimize** page—you can query and filter internet data for your application.

If you'd like more flexibility to explore and filter your data than the dashboard provides, you can use the query interface yourself, by using Internet Monitor API operations with the AWS Command Line Interface or with an AWS SDK. This section introduces the types of queries that you can use

with the query interface, and the filters that you can specify to create a subset of data, to get insights about internet traffic for your application.

Topics

- How to use the query interface
- Query examples
- Get query results
- Troubleshooting

How to use the query interface

You create a query with the query interface by choosing a *query type*, and then specifying filter values, to return a specific desired subset of your log file data. Then, you can work with the data subset, to further filter and sort, create reports, and so on.

The query process works like this:

1. When you run a query, Internet Monitor returns a `query ID` that is unique to the query. This section describes the query types that are available, and options for filtering data in queries. To understand how this works, you can also review the section on query examples.
2. You specify the query ID with your monitor name with the GetQueryResults API operation to return data results for the query. Each query type returns a different set of data fields. To learn more, see Get query results.

The query interface provides the following query types. Each query type returns a different set of information about your traffic from the log files, as shown.

- **Measurements:** Provides availability score, performance score, total traffic, and round-trip times, at 5 minute intervals.
- **Top locations:** Provides availability score, performance score, total traffic, and time to first byte (TTFB) information, for the top location and ASN combinations that you're monitoring, by traffic volume.
- **Top locations details:** Provides TTFB for Amazon CloudFront, your current configuration, and the best performing Amazon EC2 configuration, at 1 hour intervals.
- **Overall traffic suggestions:** Provides TTFB, using a 30-day weighted average, for all traffic in each AWS location that is monitored.

- **Overall traffic suggestions details:** Provides TTFB, using a 30-day weighted average, for each top location, for a proposed AWS location.
- **Routing suggestions:** Provides the predicted average round-trip time (RTT) from an IP prefix toward an AWS location for a DNS resolver. The RTT is calculated at one hour intervals, over a one hour period.

You can filter the data more by using specific criteria. With most query types, except routing suggestions, you can filter by specifying one or more of the following criteria:

- **AWS location:** For AWS location, you can specify CloudFront or an AWS Region, such as `us-east-2`.
- **ASN:** Specify the autonomous system number (ASN) of a DNS resolver (typically, an ISP), for example, 4225.
- **Client location:** For location, specify a city, metro, subdivision, or country.
- **Proposed AWS location:** Specify an AWS Region, such as `us-east-2`, or an AWS Local Zone. You can use this filter with the overall traffic suggestions details query type.
- **Geo:** Specify `geo` for some queries. This is required for queries that use the `Top locations` query type, but not allowed for other query types. To understand when to specify `geo` for filter parameters, see the query examples section.

For the routing suggestions query type, you can filter the data more by specifying one or more of the following criteria:

- **Current AWS location:** Specify an AWS Region, such as `us-east-2`.
- **Proposed AWS location:** Specify an AWS Region, such as `us-east-2`, or an AWS Local Zone.
- **IPv4 prefix:** Specify an IPv4 prefix in the standard format, similar to `192.0.2.0/24`.
- **Monitor ARN:** Specify the ARN for a specific monitor.
- **DNS resolver IP:** Specify the IP address of a DNS resolver.
- **DNS resolver ISP:** Specify the name of a DNS resolver (typically an ISP), for example, `Cloudflare`.
- **DNS resolver ASN:** Specify the autonomous system number (ASN) of a DNS resolver, for example, 4225.

The operators that you can use for filtering your data are EQUALS and NOT_EQUALS. For details about filtering parameters, see the FilterParameter API operation.

To see details about the query interface operations, see the following API operations in the Internet Monitor API Reference Guide:

- To create and run a query, see the StartQuery API operation.
- To stop a query, see the StopQuery API operation.
- To return data for a query that you've created, see the GetQueryResults API operation.
- To retrieve the status of a query, see the GetQueryStatus API operation.

Query examples

To create a query that you can use to retrieve a filtered set of data from your monitor's log file, you use the StartQuery API operation. You specify a query type and filter parameters for the query. Then, when you use the Internet Monitor query interface API operation to get query results using the query, it will retrieve the subset of your data that you want to work with.

To illustrate how query types and filter parameters work, let's look at some examples.

Example 1

Let's say that you want to retrieve all of your monitor's log file data for a specific country, except for one city. The following example shows filter parameters for a query that you could create with the StartQuery operation for this scenario.

```
{
   MonitorName: "TestMonitor"
   StartTime: "2023-07-12T20:00:00Z"
   EndTime: "2023-07-12T21:00:00Z"
   QueryType: "MEASUREMENTS"
   FilterParameters: [
      {
       Field: "country",
       Operator: "EQUALS",
       Values: ["Germany"]
      },
      {
       Field: "city",
       Operator: "NOT_EQUALS",
       Values: ["Berlin"]
```

```
      },
    ]
}
```

Example 2

As another example, let's say that you want to see your top locations by metropolitan area. You could use the following example query for this scenario.

```
{
   MonitorName: "TestMonitor"
   StartTime: "2023-07-12T20:00:00Z"
   EndTime: "2023-07-12T21:00:00Z"
   QueryType: "TOP_LOCATIONS"
   FilterParameters: [
      {
       Field: "geo",
       Operator: "EQUALS",
       Values: ["metro"]
      },
    ]
}
```

Example 3

Now, let's say that you want to see the top city-network combinations in the Los Angeles metro area. To do this, specify `geo=city`, and then set `metro` to Los Angeles. Now, the query returns the top city-networks in the Los Angeles metro area instead of the top metro+networks overall.

Here's the example query that you could use:

```
{
   MonitorName: "TestMonitor"
   StartTime: "2023-07-12T20:00:00Z"
   EndTime: "2023-07-12T21:00:00Z"
   QueryType: "TOP_LOCATIONS"
   FilterParameters: [
      {
       Field: "geo",
       Operator: "EQUALS",
       Values: ["city"]
      },
      {
```

```
        Field: "metro",
        Operator: "EQUALS",
        Values: ["Los Angeles"]
       }
    ]
}
```

Example 4

Next, let's say that you want to retrieve TTFB data for a specific subdivision (for example, a U.S. state).

The following is an example query for this scenario:

```
{
   MonitorName: "TestMonitor"
   StartTime: "2023-07-12T20:00:00Z"
   EndTime: "2023-07-12T21:00:00Z"
   QueryType: "TOP_LOCATION_DETAILS"
   FilterParameters: [
      {
       Field: "subdivision",
       Operator: "EQUALS",
       Values: ["California"]
      },
    ]
}
```

Example 5

Now, let's say that you want to retrieve TTFB data for every location where your application has client traffic.

The following is an example query for this scenario:

```
{
   MonitorName: "TestMonitor"
   StartTime: "2023-07-12T20:00:00Z"
   EndTime: "2023-07-12T21:00:00Z"
   QueryType: "OVERALL_TRAFFIC_SUGGESTIONS"
   FilterParameters: []
}
```

```
Results:
[us-east-1, 40, us-west-2, 30],
[us-east-1, 40, us-west-1, 35],
[us-east-1, 40, us-east-1, 44],
[us-east-1, 40, CloudFront, 22],
...
[us-east-2, 44, us-west-2, 30],
[us-east-2, 44, us-west-1, 35],
...
```

Example 6

Let's say that you want to retrieve TTFB data for a specific new AWS Region.

The following is an example query for this scenario:

```
{
   MonitorName: "TestMonitor"
   StartTime: "2023-07-12T20:00:00Z"
   EndTime: "2023-07-12T21:00:00Z"
   QueryType: "OVERALL_TRAFFIC_SUGGESTIONS_DETAILS"
   FilterParameters: [
      {
       Field: "proposed_aws_location",
       Operator: "EQUALS",
       Values: ["us-west-2"]
      },
   ]
}

Results:
[San Jose, San Jose-Santa Clara, California, United States, 7922, us-east-1, 40, 350,
 350, us-west-2, 45]
[San Jose, San Jose-Santa Clara, California, United States, 7922, us-west-1, 35, 450,
 450, us-west-2, 45]
```

Example 7

A final example is to retrieve data for specific DNS resolvers.

The following is an example query for this scenario:

```
{
   MonitorName: "TestMonitor"
```

```
   StartTime: "2023-07-12T20:00:00Z"
   EndTime: "2023-07-12T21:00:00Z"
   QueryType: "ROUTING_SUGGESTIONS"
   FilterParameters: [
      {
       Field: "proposed_aws_location",
       Operator: "EQUALS",
       Values: ["us-east-1"]
      },
   ]
}

Results:
[162.158.180.245, 13335, Cloudflare, [5.4.0.0/14], us-east-2, 200.0, us-east-1, 160.0]
[162.158.180.243, 13313, Cloudflare, [5.4.0.0/10], us-east-2, 150.0, us-east-1, 125.0]
```

Get query results

After you define a query, you can return a set of results with the query by running another Internet Monitor API operation, GetQueryResults. When you run `GetQueryResults`, you specify the query ID for the query that you've defined, along with the name of your monitor. `GetQueryResults` retrieves data for the specified query into a result set.

When you run a query, make sure that the query has finished running before you use `GetQueryResults` to look at the results. You can determine if the query has completed by using the GetQueryStatus API operation. When the `Status` for the query is SUCCEEDED, you can go ahead with reviewing the results.

When your query completes, you can use the following information to help you review the results. Each query type that you use to create a query includes a unique set of data fields from the log files, as described in the following list:

Measurements

The `measurements` query type returns the following data:

`timestamp, availability, performance, bytes_in, bytes_out, rtt_p50, rtt_p90, rtt_p95`

Top locations

The `top locations` query type groups data by location, and provides the data averaged over the time period. The data that it returns includes the following:

`aws_location, city, metro, subdivision, country, asn, availability, performance, bytes_in, bytes_out, current_fbl, best_ec2, best_ec2_region, best_cf_fbl`

Note that `city`, `metro`, and `subdivision` are only returned if you choose that location type for the `geo` field. The following location fields are returned, depending on the location type that you specify for `geo`:

```
city = city, metro, subdivision, country
metro = metro, subdivision, country
subdivision = subdivision, country
country = country
```

Top locations details

The `top locations details` query type returns data grouped hour by hour. The query returns the following data:

`timestamp, current_service, current_fbl, best_ec2_fbl, best_ec2_region, best_cf_fbl`

Overall traffic suggestions

The `overall traffic suggestions` query type returns data grouped hour by hour. The query returns the following data:

`current_aws_location, proposed_aws_location, average_fbl, traffic, optimized_traffic_excluding_cf, optimized_traffic_including_cf`

Overall traffic suggestions details

The `overall traffic suggestions details` query type returns data grouped hour by hour. The query returns the following data:

`aws_location, city, metro, subdivision, country, asn, traffic, current_aws_location, fbl_data`

Routing suggestions

The `routing suggestions` query type returns data grouped hour by hour. The query returns the following data:

```
dns_resolver_ip, dns_resolver_asn, dns_resolver_isp, ipv4_prefixes,
current_aws_location, current_latency, proposed_aws_location,
proposed_latency
```

When you run the `GetQueryResults` API operation, Internet Monitor returns the following in the response:

- A *data string array* that contains the results that the query returns. The information is returned in arrays that are aligned with the `Fields` field, also returned by the API call. Using the `Fields` field, you can parse the information from the `Data` repository and then further filter or sort it for your purposes.
- An *array of fields* that lists the fields that the query returned data for (in the `Data` field response). Each item in the array is a name-datatype pair, such as `availability_score-float`.

Troubleshooting

If errors are returned when you use query interface API operations, verify that you have the required permissions to use Internet Monitor. Specifically, make sure that you have the following permissions:

```
internetmonitor:StartQuery
internetmonitor:GetQueryStatus
internetmonitor:GetQueryResults
internetmonitor:StopQuery
```

These permissions are included in the recommended AWS Identity and Access Management policy to use the Internet Monitor dashboard in the console. For more information, see AWS managed policies for Internet Monitor.

Add a monitor using other AWS services

A simple way to add monitoring with Internet Monitor is to choose to create a monitor when you add a supported resource when you create a resource—or use monitoring for the resource—in console.

Resources with an integrated option for adding Internet Monitor include the following:

- VPCs
- Network Load Balancers
- Amazon CloudFront distributions

The following sections provide more information about Internet Monitor integrations in the service consoles for supported resources.

Contents

- Add a monitor with a Network Load Balancer
- Add an Internet Monitor monitor with Amazon VPC
- Add an Internet Monitor monitor with CloudFront

Add a monitor with a Network Load Balancer

When you create a Network Load Balancer in the AWS Management Console, you can optionally choose to also set up monitoring for traffic to and from the Network Load Balancer using a monitor in Internet Monitor. You can add the Network Load Balancer to an existing monitor, or you can opt to create a new monitor for your Network Load Balancer traffic.

By using Internet Monitor with your Network Load Balancer, you can view and evaluate measurements and metrics about availability, performance, monitored bytes transferred, and round-trip times that are specific to your application's client locations and ASNs (typically, internet service providers). Internet Monitor also determines when there are anomalies in performance and availability, and then creates health events in your monitor, which you can choose to be notified about. To learn more about how you can use a monitor to manage and improve your clients' experience with your application, see Use a monitor in Internet Monitor.

Important

To create a monitor, or add a Network Load Balancer to an existing monitor, you must have the correct permissions in place. For more information, see Identity and Access Management for Internet Monitor.

Add a Network Load Balancer to an existing monitor

When you create the Network Load Balancer in the AWS Management Console, you can choose to have Internet Monitor add the new Network Load Balancer to an existing monitor. Under **Integrations**, choose Internet Monitor, and then choose **Add monitor**. Choose **Select an existing monitor**, and then enter a monitor name. Or choose **View monitors** to go to the Internet Monitor console, and then scroll down to see a list of available monitors.

After you add the Network Load Balancer to a monitor, wait a few minutes, and then metrics for traffic to and from the load balancer will start being shown on the Internet Monitor console. To learn more about the **Status** and **Data processing status** values, see Monitoring details in Internet Monitor (Configure page).

You can edit the monitor at any time, to remove the load balancer or add another Network Load Balancer, or other resources. You can also change the percentage of traffic that you're monitoring, or make other changes. If you choose to remove the Network Load Balancer from the monitor, traffic from clients to that load balancer is no longer monitored by Internet Monitor.

To learn more about updating a monitor, see Edit a monitor in Internet Monitor.

Create a monitor for a Network Load Balancer

Under **Integrations**, choose Internet Monitor, and then choose **Monitor resource traffic**. Choose **Create a new monitor**, and then enter a monitor name. Leave the default traffic percentage to monitor, 100%, or specify a custom percentage, and then choose **Create monitor**.

After you create the monitor, wait a few minutes, and then metrics for traffic to and from the Network Load Balancer will start being shown on the Internet Monitor console. If you like, you can also choose a percentage of client traffic that you want to monitor for your application (the default is 100%).

You can learn more by reviewing the information in Step 1: Create a monitor.

Pricing

With Internet Monitor, you pay only for what you use. Pricing for Internet Monitor has two components: a per monitored resource fee and a per city-network fee. A city-network is the location that clients access your application resources from and the network (an ASN, such as an internet service provider or ISP) that clients access the resources through.

For more information, including pricing examples, see Pricing for Internet Monitor.

Stop monitoring a Network Load Balancer

If you'd like to stop monitoring your Network Load Balancer resource with Internet Monitor, do the following in the Internet Monitor console:

To remove a resource from a monitor

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Internet monitors**.
3. Choose your monitor, and then choose the **Action** menu.
4. Choose **Update monitor**.
5. Under **Added resources**, choose **Remove resources**.
6. Choose the Network Load Balancer to remove, and then choose **Remove**.
7. Choose **Update**.

Add an Internet Monitor monitor with Amazon VPC

When you create a Amazon Virtual Private Cloud VPC in the AWS Management Console, you can optionally choose to also set up monitoring for it in Internet Monitor. You can add the VPC to an existing monitor, or you can opt to create a new monitor for the VPC in the Amazon VPC console.

By using Internet Monitor with your VPC, you can view and evaluate measurements and metrics about availability, performance, monitored bytes transferred, and round-trip times that are specific to your application's client locations and ASNs (typically internet service providers). Internet Monitor also determines when there are anomalies in performance and availability and creates health events in your monitor, which you can choose to be notified about. To learn more about how you can use a monitor to manage and improve your clients' experience with your application, see Use a monitor in Internet Monitor.

> **Important**
>
> To create a monitor, or add a VPC to an existing monitor, you must have the correct permissions in place. For more information, see Identity and Access Management for Internet Monitor.

Add a VPC to an existing monitor

You can choose to have Internet Monitor add a new VPC to an existing monitor for you when you create the VPC in the AWS Management Console. After you add the VPC, wait a few minutes, and then metrics for the VPC will start being shown on the Internet Monitor console.

You can edit the monitor at any time, to remove the VPC or add another VPC or other resources. You can also change the percentage of traffic that you're monitoring, or make other changes. If you choose to remove the VPC from the monitor, traffic from clients to that VPC is no longer monitored by Internet Monitor.

To learn more about updating a monitor, see Edit a monitor in Internet Monitor.

Create a monitor for a VPC

If you opt to create a monitor for a VPC, the **Create monitor** wizard walks you through the steps. You add the VPC as a monitored resource when you create the monitor. If you like, you can also choose a percentage of client traffic that you want to monitor for your application (the default is 100%).

You can learn more by reviewing the information in Step 1: Create a monitor.

Pricing

With Internet Monitor, you pay only for what you use. Pricing for Internet Monitor has two components: a per monitored resource fee and a per city-network fee. A city-network is the location that clients access your application resources from and the network (an ASN, such as an internet service provider or ISP) that clients access the resources through.

For more information, including pricing examples, see Pricing for Internet Monitor

Stop monitoring a VPC

If you'd like to stop monitoring your VPC resource with Internet Monitor, do the following in the Internet Monitor console:

To remove a resource from a monitor

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Internet monitors**.
3. Choose your monitor, and then choose the **Action** menu.

4. Choose **Update monitor**.
5. Under **Added resources**, choose **Remove resources**.
6. Choose the VPC to remove, and then choose **Remove**.
7. Choose **Update**.

Add an Internet Monitor monitor with CloudFront

On the metrics dashboard for a distribution in Amazon CloudFront console, you can set up additional monitoring for a distribution in Internet Monitor. You can add the distribution to an existing monitor, or you can create a new monitor for the distribution.

By using Internet Monitor with your CloudFront distribution, you can view and evaluate measurements and metrics about availability, performance, monitored bytes transferred, and round-trip times that are specific to your application's client locations and ASNs (typically internet service providers). Internet Monitor also determines when there are anomalies in performance and availability and creates health events in your monitor, which you can choose to be notified about. To learn more about how you can use a monitor to manage and improve your clients' experience with your application, see Use a monitor in Internet Monitor.

> **Important**
>
> To create a monitor, or add a distribution to an existing monitor, you must have the correct permissions in place. For more information, see Identity and Access Management for Internet Monitor.

Add a distribution to an existing monitor

You can choose to have Internet Monitor add a distribution to an existing monitor directly from the CloudFront metrics dashboard in the AWS Management Console. After you add the distribution, wait a few minutes, and then metrics for the distribution will start being shown on the Internet Monitor console.

You can edit the monitor at any time, to remove the distribution or add another distribution or other resources. You can also change the percentage of traffic that you're monitoring, or make other changes. If you choose to remove the distribution from the monitor, traffic from clients to that distribution is no longer monitored by Internet Monitor.

To learn more about updating a monitor, see Edit a monitor in Internet Monitor.

Create a monitor for a distribution

If you opt to create a monitor for a distribution, the **Create monitor** wizard walks you through the steps. You add the distribution as a monitored resource when you create the monitor. If you like, you can also choose a percentage of client traffic that you want to monitor for your application (the default is 100%).

You can learn more by reviewing the information in Step 1: Create a monitor.

Pricing

With Internet Monitor, you pay only for what you use. Pricing for Internet Monitor has two components: a per monitored resource fee and a per city-network fee. A city-network is the location that clients access your application resources from and the network (an ASN, such as an internet service provider or ISP) that clients access the resources through.

For more information, including pricing examples, see Pricing for Internet Monitor.

Stop monitoring a distribution

If you'd like to stop monitoring your distribution resource with Internet Monitor, do the following in the Internet Monitor console:

To remove a resource from a monitor

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Internet monitors**.
3. Choose your monitor, and then choose the **Action** menu.
4. Choose **Update monitor**.
5. Under **Added resources**, choose **Remove resources**.
6. Choose the distribution to remove, and then choose **Remove**.
7. Choose **Update**.

Create alarms with Internet Monitor

You can create Amazon CloudWatch alarms based on Internet Monitor metrics, just as you can for other Amazon CloudWatch metrics.

For example, you can create an alarm based on the Internet Monitor metric `PerformanceScore`, and configure it to send a notification when the metric is lower than a value that you choose. You configure alarms for Internet Monitor metrics following the same guidelines as for other CloudWatch metrics.

Following are the example Internet Monitor metrics that you might choose to create an alarm for:

- **PerformanceScore**
- **AvailabilityScore**
- **RoundtripTime**

To see all the metrics available for Internet Monitor, see View Internet Monitor metrics or set alarms in CloudWatch Metrics.

The following procedure provides an example of setting an alarm on **PerformanceScore** by navigating to the metric in the CloudWatch dashboard. Then, you follow the standard CloudWatch steps to create an alarm based on a threshold that you choose, and set up a notification or choose other options.

To create an alarm for PerformanceScore in CloudWatch Metrics

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Choose **Metrics**, and then choose **Classic metrics**.
3. Filter for Internet Monitor by choosing `AWS/InternetMonitor`.
4. Choose **MeasurementSource, MonitorName**.
5. In the list, select **PerformanceScore**.
6. On the **GraphedMetrics** tab, under **Actions**, choose the bell icon to create an alarm based on a static threshold.

Now, follow the standard CloudWatch steps to choose options for the alarm. For example, you can choose to be notified by an Amazon SNS message if **PerformanceScore** is below a specific threshold number. Alternatively, or in addition, you can add the alarm to a dashboard.

Keep in mind the following:

- Internet Monitor metrics are typically calculated and published within 20 minutes.

- When you create an alarm based on Internet Monitor metrics, make sure that you take into account the short delay before publication when you set an alarm's lookback period. We recommend that you configure **Evaluation Periods** with lookback period that is a minimum of 25 minutes.

To learn more about using CloudWatch alarms with Internet Monitor, see the following blog post: Using Internet Monitor for enhanced internet observability.

For more information about options when you create a CloudWatch alarm, see Create a CloudWatch alarm based on a static threshold.

Using Internet Monitor with Amazon EventBridge

Health events that Internet Monitor creates for networking issues are published with Amazon EventBridge, so that you can send notifications about a degradation in end users' experience for your application. Both overall (global) health events and local health events are published to EventBridge. Global health events have an impact type of `AVAILABILITY` or `PERFORMANCE`, and local health events have an impact type of `LOCAL_AVAILABILITY` or `LOCAL_PERFORMANCE`.

To use EventBridge to work with Internet Monitor health events, follow the guidance here.

To set up a rule for Internet Monitor in EventBridge

1. In the AWS Management Console, in EventBridge, choose **Rules**, then enter a name and a description. Create the rule on the **Default** event bus.
2. In Step 2, select **Other** for the event source, and then, under **Event pattern**, match the following source.

```
{
  "source": ["aws.internetmonitor"]
}
```

3. In Step 3, for the target, select **AWS Service** and **CloudWatch Logs Group**, then select an existing log group or create a new one.
4. Add any desired tags, and then create the rule. This should populate your selected CloudWatch Logs Group with events from EventBridge.

Filtering health events by impact type

You can use event patterns to filter health events by impact type. This is useful if you want to receive only global health events, only local health events, or both.

Receive only global health events:

```
{
  "source": ["aws.internetmonitor"],
  "detail": {
    "impactType": ["AVAILABILITY", "PERFORMANCE"]
  }
}
```

Receive only local health events:

```
{
  "source": ["aws.internetmonitor"],
  "detail": {
    "impactType": ["LOCAL_AVAILABILITY", "LOCAL_PERFORMANCE"]
  }
}
```

Receive all health events (default):

```
{
  "source": ["aws.internetmonitor"]
}
```

For more information about how EventBridge rules work with event patterns, see Amazon EventBridge event patterns in the Amazon EventBridge User Guide.

Troubleshoot CloudWatch logs and metrics access errors

To support some features, Internet Monitor must interact with certain Amazon CloudWatch resources, including logs and metrics. If Internet Monitor can't access the CloudWatch resources that it requires access to, Internet Monitor sets a status code of `FAULT_ACCESS_CLOUDWATCH` for the monitor.

There are several reasons that your monitor might have the state `FAULT_ACCESS_CLOUDWATCH`. The following sections list possible causes for these errors, and suggested troubleshooting steps.

Internet Monitor couldn't access CloudWatch logs in your account

Internet Monitor publishes diagnostic logs about your monitored application traffic. It publishes these logs to log groups in CloudWatch Logs in the following location: `/aws/internet-monitor/monitor_name/[byCity|byMetro|bySubdivision|byCountry]`. Internet Monitor was unable to access these log groups.

Error states and potential solutions:

- **PutLogEvents throttling error:** The Internet Monitor service might have been throttled when it tried to publish your monitor's logs to CloudWatch. Review the throttling limits for your account, and, if necessary, request an increase in the limit.
- **Log group not found:** Disable, and then re-enable your monitor. Enabling a monitor restarts log group creation, which might correct the problem.
- **PutLogEvents access denied error:** Contact AWS support for assistance.
- **PutLogEvents unknown or general error:** Contact AWS support for assistance.

Internet Monitor couldn't access CloudWatch metrics in your account

Internet Monitor delivers specific CloudWatch metrics about the application traffic that is tracked by a monitor. An error occurred when Internet Monitor tried to deliver these metrics to CloudWatch.

Error states and potential solutions:

- **PutMetricData throttling error:** The Internet Monitor service might have been throttled when it tried to publish your monitor's metrics to CloudWatch. Review the throttling limits for your account, and, if necessary, request an increase in the limit.
- **PutMetricData access denied error:** Contact AWS support for assistance.
- **PutMetricData unknown or general error:** Contact AWS support for assistance.

Data protection and data privacy with Internet Monitor

The AWS shared responsibility model applies to data protection and data privacy in Internet Monitor. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS cloud. You are responsible for maintaining control over your content that

is hosted on this infrastructure. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see The AWS Shared Responsibility Model and GDPR blog post on the AWS Security Blog. For more resources about complying with GDPR requirements, see the General Data Protection Regulation (GDPR) Center.

We strongly recommend that you never put sensitive identifying information, such as your end users' account numbers, email addresses, or other personal information, into free-form fields. Any data that you enter into Internet Monitor or other services might be included in diagnostic logs.

Identity and Access Management for Internet Monitor

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Internet Monitor resources. IAM is an AWS service that you can use with no additional charge.

Important

Internet Monitor resource changes on July 8, 2024
If you created IAM policies that included Internet Monitor resources before July 8, 2024, be aware of the following change to Internet Monitor resources and resource types:

- Resource-level permissions for the **GetHealthEvent** action are now supported only on the **Monitor** resource type. The permissions are not supported on the **HealthEvent** resource.

To see more information about the actions, resources, and condition keys that you can specify in policies to manage access to AWS resources in Internet Monitor, see Actions, resources, and condition keys for Internet Monitor.

- AWS managed policies for Internet Monitor
- Service-linked role for Internet Monitor

Upgrade IAM policies to IPv6

Internet Monitor customers use IAM policies to set an allowed range of IP addresses, to prevent any IP addresses outside the configured range from being able to access Internet Monitor APIs.

The *internetmonitor.region.api.aws* endpoint, where you access Internet Monitor APIs, is being upgraded to support dual-stack (IPv4 and IPv6).

IP address filtering policies that are not updated to handle IPv6 addresses might result in clients losing access to Internet Monitor APIs.

Customers impacted by the upgrade to include IPv6

Customers who are using dual-stack with policies that contain the *aws:sourceIp* filter are impacted by this upgrade. Dual-stack means that the network supports both IPv4 and IPv6.

If you use dual-stack, you must update your IAM policies that are currently configured with IPv4 format addresses to include IPv6 format addresses.

The following summarizes recommended actions, depending on your scenario. To confirm the endpoint that your SDK uses, see Identify the Internet Monitor endpoint used by your code.

Endpoint	Using IAM policy with `aws:sourceIp` condition?	Recommended action
`internetmonitor.region.amazonaws.com` (not dual-stack)	Yes	To restrict access to IPv4 only, take no further action. Or, if you anticipate that you will need IPv6 support in the future, you can take action to ensure compatibility with both IPv4 and IPv6. To ensure future compatibility, on or after November 1, 2024, update your SDK, and then update your application to use the dual-stack endpoint by setting `useDualstackEndpoi`

Endpoint	Using IAM policy with `aws:sourceIp` condition?	Recommended action
		`nt=true` . For more information, see Dual-stack and FIPS endpoints. If you choose to use both IPv4 and IPv6, you must also update the IP address filtering condition (`aws:sourceIp`) in your IAM policies to include IPv6 addresses.
`internetmonitor.region.amazonaws.com` (not dual-stack)	No	To restrict access to IPv4 only, take no further action. Or, if you anticipate that you will need IPv6 support in the future, you can take action to ensure compatibility with both IPv4 and IPv6. To ensure future compatibility, on or after November 1, 2024, update your SDK, and then update your application to use the dual-stack endpoint by setting `useDualstackEndpoint=true` . For more information, see Dual-stack and FIPS endpoints.

Endpoint	Using IAM policy with `aws:sourceIp` condition?	Recommended action
`internetmonitor.region.api.aws`	Yes	To ensure future compatibility with both IPv4 and IPv6, update your SDK, and then update your application to use the dual-stack endpoint by setting `useDualstackEndpoint=true`. For more information, see Dual-stack and FIPS endpoints. When you make the change to use both IPv4 and IPv6, you must also update the IP address filtering condition (`aws:sourceIp`) in your IAM policies to include IPv6 addresses. If you instead want to restrict access to IPv4 only, set `useDualstackEndpoint=false`. For more information, see Dual-stack and FIPS endpoints.

Endpoint	Using IAM policy with `aws:sourceIp` condition?	Recommended action
`internetmonitor.region.api.aws`	No	To ensure future compatibility with both IPv4 and IPv6, update your SDK, and then update your application to use the dual-stack endpoint by setting `useDualstackEndpoint=true`. For more information, see Dual-stack and FIPS endpoints. If you instead want to restrict access to IPv4 only, set `useDualstackEndpoint=false`. For more information, see Dual-stack and FIPS endpoints.

For help with access issues, contact Support.

What is IPv6?

IPv6 is the next generation IP standard intended to eventually replace IPv4. IPv4 uses a 32-bit addressing scheme, to support 4.3 billion devices. IPv6 instead uses 128-bit addressing, to support approximately 340 trillion trillion trillion (or 2 to the 128th power) devices.

The following are examples of IPv6 addresses:

```
2001:cdba:0000:0000:0000:0000:3257:9652
2001:cdba:0:0:0:0:3257:9652
2001:cdba::3257:965
```

IPv6 offers a larger address space, improved routing efficiency, and better support for new internet services. By updating to dual-stack and supporting IPv6, Internet Monitor enables improved

performance and scalability. Follow the steps in this section to update your configurations and take advantage of dual-stack support.

Identify the Internet Monitor endpoint used by your code

If you use an Internet Monitor SDK, start by verifying which endpoint your code is using: the IPv4 endpoint or the dual-stack (IPv4 and IPv6) endpoint. If you don't use an SDK with Internet Monitor, you can skip this section.

You can run the following code example to determine the Internet Monitor endpoint that you're using. For this example, we're using the Internet Monitor SDK for Go in the US East (N. Virginia) Region.

```
package main

import (
    "fmt"
    "log"

    "github.com/aws/aws-sdk-go/aws"
    "github.com/aws/aws-sdk-go/aws/session"
    "github.com/aws/aws-sdk-go/service/internetmonitor"
)

func main() {
    // Create a new session with the default configuration
    sess := session.Must(session.NewSession(&aws.Config{
        Region: aws.String("us-east-1"),
    }))

    // Create a new Internet Monitor client
    internetMonitorClient := internetmonitor.New(sess)

    // Get the endpoint URL
    endpoint := internetMonitorClient.Endpoint

    fmt.Printf("Internet Monitor endpoint URL: %s\n", endpoint)
}
```

When you run this code, it returns the Internet Monitor endpoint. If you see the following response, you're using the Internet Monitor domain that supports only IPv4. You can tell because the format of the endpoint URL includes `amazonaws.com`.

```
Internet Monitor endpoint URL: https://internetmonitor.us-east-1.amazonaws.com
```

If you see the following response instead, then you're using the domain which is being upgraded to support dual-stack (IPv4 and IPv6). Here, you can tell because the endpoint URL includes `api.aws`. However, note that until the upgrade is complete, this endpoint supports only IPv4.

```
Internet Monitor endpoint URL: https://internetmonitor.us-east-1.api.aws
```

Update an IAM policy for IPv6

IAM policies use the `aws:SourceIp` filter to set an allowed range of IP addresses.

Dual-stack supports both IPv4 and IPV6 traffic. If your network uses dual-stack, you must ensure that any IAM polices that are used for IP address filtering are updated to include IPv6 address ranges.

For example, this policy allows IPv4 address ranges `192.0.2.0.*` and `203.0.113.0.*`, identified in the `Condition` element.

```
# https://docs.aws.amazon.com/IAM/latest/UserGuide/
reference_policies_examples_aws_deny-ip.html
{
    "Version": "2012-10-17",
    "Statement": {
        "Effect": "Deny",
        "Action": "*",
        "Resource": "*",
        "Condition": {
            "NotIpAddress": {
                "*aws:SourceIp*": [
                    "*192.0.2.0/24*",
                    "*203.0.113.0/24*"
                ]
            },
            "Bool": {
                "aws:ViaAWSService": "false"
            }
        }
    }
}
```

To update this policy, we'll change the policy's `Condition` element to add IPv6 address ranges, as shown in the following example:

```
"Condition": {
            "NotIpAddress": {
                "*aws:SourceIp*": [
                    "*192.0.2.0/24*", <<Existing IPv4 address - DO NOT REMOVE>>
                    "*203.0.113.0/24*", <<Existing IPv4 address  - DO NOT REMOVE>>
                    "*2001:DB8:1234:5678::/64*", <<New IPv6 IP address>>
                    "*2001:cdba:3257:8593::/64*" <<New IPv6 IP address>>
                ]
            },
            "Bool": {
                "aws:ViaAWSService": "false"
            }
        }
```

Important

Do not remove the existing IPv4 addresses in the policy. They are required for backward compatibility.

For more information about managing access permissions with IAM, see Managed policies and inline policies in the *AWS Identity and Access Management User Guide*.

Test the network after updating policies

After you update your IAM policies to include support for IPv6 addresses, we recommend that you test that your network can access an IPv6 endpoint. This section provides several examples, depending on the operating system that you use.

Test network with Linux/Unix or Mac OS X

If you use Linux/Unix or Mac OS X, you can test that your network can access the IPv6 endpoint by using the following curl command.

```
curl -v -s -o /dev/null http://ipv6.ec2-reachability.amazonaws.com/
```

If you are connected over IPv6, the connected IP address displays information similar to the following:

```
* About to connect() to aws.amazon.com port 443 (#0)
*   Trying IPv6 address... connected
* Connected to aws.amazon.com (IPv6 address) port 443 (#0)
> GET / HTTP/1.1
> User-Agent: curl/7.18.1 (x86_64-unknown-linux-gnu) libcurl/7.18.1 OpenSSL/1.0.1t
 zlib/1.2.3
> Host: aws.amazon.com
```

Test network with Windows

If you use Windows, you can test that your network can access a dual-stack endpoint over IPv6 or IPv4 by using a `ping` command, such as the following:

```
ping aws.amazon.com
```

If `ping` accesses the endpoint over IPv6, the command returns IPv6 addresses.

Verify that clients can support IPv6

We recommend that before you switch to using the *internetmonitor.{region}.api.aws* endpoint, that you first verify that your clients can access other AWS service endpoints that are already IPv6-enabled. The following steps describe how to verify this by using an existing IPv6 endpoint.

This example uses Linux and curl version 8.6.0, and uses the Amazon Athena service, which has IPv6-enabled endpoints located at the *api.aws* domain.

> **Note**
>
> Switch your AWS Region to the same Region where the client is located. In this example, we use the US East (N. Virginia) – `us-east-1` endpoint.

Use the following example to verify that your clients can access an IPv6-enabled AWS endpoint.

1. Verify that the Athena endpoint resolves with an IPv6 address by using the following command.

   ```
   dig +short AAAA athena.us-east-1.api.aws
   2600:1f18:e2f:4e05:1a8a:948e:7c08:d2d6
   2600:1f18:e2f:4e03:4a1e:83b0:8823:4ce5
   ```

```
2600:1f18:e2f:4e04:34c3:6e9a:2b0d:dc79
```

2. Now, determine if your client network can make a connection using IPv6 by using the following command:

```
curl --ipv6 -o /dev/null --silent -w "\nremote ip: %{remote_ip}\nresponse code:
 %{response_code}\n" https://athena.us-east-1.api.aws

remote ip: 2600:1f18:e2f:4e05:1a8a:948e:7c08:d2d6
response code: 404
```

If the remote IP address was identified **and** the response code is not `0`, a network connection was successfully made to the endpoint using IPv6.

If the remote IP address is blank or the response code is `0`, the client network or the network path to the endpoint is IPv4-only. You can verify this with the following curl command:

```
curl -o /dev/null --silent -w "\nremote ip: %{remote_ip}\nresponse code:
 %{response_code}\n" https://athena.us-east-1.api.aws

remote ip: 3.210.103.49
response code: 404
```

If you run this command, and a remote IP address was identified **and** the response code is not `0`, a network connection was successfully made to the endpoint using IPv4.

How Internet Monitor works with IAM

Before you use IAM to manage access to Internet Monitor, learn what IAM features are available to use with Internet Monitor.

To see tables showing a similar high-level view of how AWS services work with most IAM features, see AWS services that work with IAM in the *IAM User Guide*.

IAM features you can use with Internet Monitor

IAM feature	Internet Monitor support
Identity-based policies	Yes

IAM feature	Internet Monitor support
Resource-based policies	No
Policy actions	Yes
Policy resources	Yes
Policy condition keys (service-specific)	Yes
ACLs	No
ABAC (tags in policies)	Partial
Temporary credentials	Yes
Principal permissions	Yes
Service roles	No
Service-linked roles	Yes

Identity-based policies for Internet Monitor

Supports identity-based policies: Yes

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Define custom IAM permissions with customer managed policies in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. To learn about all of the elements that you can use in a JSON policy, see IAM JSON policy elements reference in the *IAM User Guide*.

Resource-based policies within Internet Monitor

Supports resource-based policies: No

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM role trust policies and Amazon S3 bucket policies. In services that

support resource-based policies, service administrators can use them to control access to a specific resource.

Policy actions for Internet Monitor

Supports policy actions: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Action` element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Include actions in a policy to grant permissions to perform the associated operation.

To see a list of Internet Monitor actions, see Actions defined by Internet Monitor in the *Service Authorization Reference*.

Policy actions in Internet Monitor use the following prefix before the action:

```
internetmonitor
```

To specify multiple actions in a single statement, separate them with commas.

```
"Action": [
      "internetmonitor:action1",
      "internetmonitor:action2"
         ]
```

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word `Describe`, include the following action:

```
"Action": "internetmonitor:Describe*"
```

Policy resources for Internet Monitor

Supports policy resources: Yes

In the *Service Authorization Reference*, you can see the following information related to Internet Monitor:

- To see a list of Internet Monitor resource types and their ARNs, see Resources defined by Internet Monitor.
- To learn the actions that you can specify with the ARN of each resource, see Actions defined by Internet Monitor.

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Resource` JSON policy element specifies the object or objects to which the action applies. As a best practice, specify a resource using its Amazon Resource Name (ARN). For actions that don't support resource-level permissions, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

Policy condition keys for Internet Monitor

Supports service-specific policy condition keys: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Condition` element specifies when statements execute based on defined criteria. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request. To see all AWS global condition keys, see AWS global condition context keys in the *IAM User Guide*.

To see a list of Internet Monitor condition keys, see Condition keys for Internet Monitor in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see Actions defined by Internet Monitor.

ACLs in Internet Monitor

Supports ACLs: No

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

ABAC with Internet Monitor

Supports ABAC (tags in policies): Partial

Internet Monitor has *partial* support for tags in policies. It supports tagging for one resource, monitors.

To use tags with Internet Monitor, use the AWS Command Line Interface or an AWS SDK. Tagging for Internet Monitor is not supported with the AWS Management Console.

To learn more about using tags in policies in general, review the following information.

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes called tags. You can attach tags to IAM entities and AWS resources, then design ABAC policies to allow operations when the principal's tag matches the tag on the resource.

To control access based on tags, you provide tag information in the condition element of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see Define permissions with ABAC authorization in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see Use attribute-based access control (ABAC) in the *IAM User Guide*.

Using temporary credentials with Internet Monitor

Supports temporary credentials: Yes

Temporary credentials provide short-term access to AWS resources and are automatically created when you use federation or switch roles. AWS recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see Temporary security credentials in IAM and AWS services that work with IAM in the *IAM User Guide*.

Cross-service principal permissions for Internet Monitor

Supports forward access sessions (FAS): Yes

Forward access sessions (FAS) use the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. For policy details when making FAS requests, see Forward access sessions.

Service roles for Internet Monitor

Supports service roles: No

A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Create a role to delegate permissions to an AWS service in the *IAM User Guide*.

Service-linked role for Internet Monitor

Supports service-linked roles: Yes

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

For more information about the service-linked role for Internet Monitor, see Service-linked role for Internet Monitor.

For details about creating or managing service-linked roles in general in AWS, see AWS services that work with IAM. Find a service in the table that includes a `Yes` in the **Service-linked role** column. Choose the **Yes** link to view the service-linked role documentation for that service.

Cross-service confused deputy prevention

A confused deputy is an entity (a service or an account) that is coerced by a different entity to perform an action. This type of impersonation can happen cross-account and cross-service.

To prevent confused deputies, AWS provides tools that help you protect your data for all services using service principals that have been given access to resources in your AWS account. This section focuses on cross-service confused deputy prevention specific to Internet Monitor; however, you can learn more about this topic in the confused deputy problem section of the *IAM User Guide*.

To limit the permissions that IAM gives to Internet Monitor to access your resources, we recommend using the global condition context keys `aws:SourceArn` and `aws:SourceAccount` in your resource policies.

If you use both of these global condition context keys, and the `aws:SourceArn` value contains the AWS account ID, the `aws:SourceAccount` value and the AWS account in `aws:SourceArn` must use the same AWS account ID when used in the same policy statement.

For Internet Monitor, you specify your account ID for `aws:SourceAccount` and your monitor ARN for `aws:SourceArn`. For cross-service access, you also use your monitor ARN for `aws:SourceArn`.

> **Note**
>
> The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the **full ARN** of the resource. If you don't know the full ARN, or if you're specifying multiple resources, use the `aws:SourceArn` global context condition key with wildcards (*) for the unknown portions of the ARN. For example, `arn:aws:internetmonitor:us-east-1:111122223333:*`.

The following is an example of an assume role policy that shows how you can prevent a confused deputy issue.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": {
    "Sid": "ConfusedDeputyPreventionExamplePolicy",
    "Effect": "Allow",
    "Principal": {
      "Service": "internetmonitor.amazonaws.com"
    },
    "Action": "sts:AssumeRole",
    "Condition": {
      "ArnLike": {
        "aws:SourceArn": "arn:aws:internetmonitor:us-east-1:111122223333:monitor/
confused-deputy-monitor"
      },
      "StringEquals": {
        "aws:SourceAccount": "111122223333"
      }
    }
  }
```

```
}
```

AWS managed policies for Internet Monitor

An AWS managed policy is a standalone policy that is created and administered by AWS. AWS managed policies are designed to provide permissions for many common use cases so that you can start assigning permissions to users, groups, and roles.

Keep in mind that AWS managed policies might not grant least-privilege permissions for your specific use cases because they're available for all AWS customers to use. We recommend that you reduce permissions further by defining customer managed policies that are specific to your use cases.

You cannot change the permissions defined in AWS managed policies. If AWS updates the permissions defined in an AWS managed policy, the update affects all principal identities (users, groups, and roles) that the policy is attached to. AWS is most likely to update an AWS managed policy when a new AWS service is launched or new API operations become available for existing services.

For more information, see AWS managed policies in the *IAM User Guide*.

AWS managed policy: CloudWatchInternetMonitorServiceRolePolicy

This policy is attached to the service-linked role named **AWSServiceRoleForInternetMonitor** to allow Internet Monitor to access resources in your account, such as Amazon Virtual Private Cloud resources or Network Load Balancers, so that you can select them when you create a monitor. For more information, see Service-linked role for Internet Monitor.

AWS managed policy: CloudWatchInternetMonitorReadOnlyAccess

You can attach `CloudWatchInternetMonitorReadOnlyAccess` to your IAM entities. This policy grants access to read-only actions to work with monitors and data in with Internet Monitor. Attach it to IAM users and other principals who need access to only read-only actions.

Specifically, the scope of this policy includes `internetmonitor:` so that users can use read-only Internet Monitor actions and resources. It includes some `cloudwatch:` policies to retrieve information on CloudWatch metrics. It includes some `logs:` policies to manage log queries.

To view the permissions for this policy, see CloudWatchInternetMonitorReadOnlyAccess in the *AWS Managed Policy Reference*.

AWS managed policy: CloudWatchInternetMonitorFullAccess

You can attach `CloudWatchInternetMonitorFullAccess` to your IAM entities. This policy grants full access to Actions for Internet Monitor for working with Internet Monitor. Attach it to IAM users and other principals who need full access to Internet Monitor actions.

Specifically, scope of this policy includes `internetmonitor:` so that users can use Internet Monitor actions and resources. It includes some `cloudwatch:` policies to retrieve information on CloudWatch alarms and metrics. It includes some `logs:` policies to manage log queries. It includes some `ec2:`, `cloudfront:`, `elasticloadbalancing:`, and `workspaces:` policies to work with resources that you add to monitors so that Internet Monitor can create a traffic profile for your application. It contains some `iam:` policies to manage IAM roles.

To view the permissions for this policy, see CloudWatchInternetMonitorFullAccess in the *AWS Managed Policy Reference*.

Internet Monitor updates to AWS managed policies

To view details about updates to AWS managed policies for Internet Monitor since this service began tracking these changes, see CloudWatch updates to AWS managed policies. For automatic alerts about managed policy changes in CloudWatch, subscribe to the RSS feed on the CloudWatch Document history page.

Service-linked role for Internet Monitor

Internet Monitor uses an AWS Identity and Access Management (IAM) service-linked role. A service-linked role is a unique type of IAM role that is linked directly to Internet Monitor. The service-linked role is predefined by Internet Monitor and includes all the permissions that the service requires to call other AWS services on your behalf.

Internet Monitor defines the permissions of the service-linked role, and unless defined otherwise, only Internet Monitor can assume the role. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete the role only after first deleting its related resources. This restriction protects your Internet Monitor resources because you can't inadvertently remove permissions to access the resources.

For information about other services that support service-linked roles, see AWS services that work with IAM and look for the services that have **Yes** in the **Service-linked role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Internet Monitor

Internet Monitor uses the service-linked role named **AWSServiceRoleForInternetMonitor**. This role allows Internet Monitor to access resources in your account, such as Amazon Virtual Private Cloud resources, Amazon CloudFront distributions, Amazon WorkSpaces directories, and Network Load Balancers, so that you can select them when you create a monitor.

This service-linked role uses the managed policy `CloudWatchInternetMonitorServiceRolePolicy`.

The **AWSServiceRoleForInternetMonitor** service-linked role trusts the following service to assume the role:

- `internetmonitor.amazonaws.com`

To view the permissions for this policy, see CloudWatchInternetMonitorServiceRolePolicy in the *AWS Managed Policy Reference*.

Creating a service-linked role for Internet Monitor

You do not need to manually create the service-linked role for Internet Monitor. The first time that you create a monitor, Internet Monitor creates **AWSServiceRoleForInternetMonitor** for you.

For more information, see Creating a service-linked role in the *IAM User Guide*.

Editing a service-linked role for Internet Monitor

After Internet Monitor creates a service-linked role in your account, you cannot change the name of the role because various entities might reference the role. You can edit the description of the role using IAM. For more information, see Editing a service-linked role in the *IAM User Guide*.

Deleting a service-linked role for Internet Monitor

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete the role. That way you don’t have an unused entity that is not actively monitored or maintained. However, you must clean up the resources for the service-linked role before you can manually delete it.

After you've removed your resources from your monitors in Internet Monitor and then deleted the monitors, you can delete the service-linked role **AWSServiceRoleForInternetMonitor**.

> **Note**
>
> If the Internet Monitor service is using the role when you try to delete it, then the deletion might fail. If that happens, wait for a few minutes and then try again.

To manually delete the service-linked role using IAM

Use the IAM console, the AWS CLI, or the AWS API to delete the **AWSServiceRoleForInternetMonitor** service-linked role. For more information, see Deleting a service-linked role in the *IAM User Guide*.

Updates to the Internet Monitor service-linked role

For updates to **AWSServiceRoleForInternetMonitor**, the AWS managed policy for the Internet Monitor service-linked role, see CloudWatch updates to AWS managed policies. For automatic alerts about managed policy changes in CloudWatch, subscribe to the RSS feed on the CloudWatch Document history page.

Using Network Synthetic Monitor

Network Synthetic Monitor provides visibility into the performance of the network connecting your AWS hosted applications to your on-premises destinations, and allows you to identify the source of any network performance degradation within minutes. Network Synthetic Monitor is fully managed by AWS, and doesn't require separate agents on monitored resources. Use Network Synthetic Monitor to visualize packet loss and latency of your hybrid network connections, and set alerts and thresholds. Then, based on this information, you can take action to improve your end users' experience.

Network Synthetic Monitor is intended for network operators and application developers who want real-time insights into network performance.

Network Synthetic Monitor key features

- Use Network Synthetic Monitor to benchmark your changing hybrid network environment with continuous real-time packet loss and latency metrics.
- When you connect by using AWS Direct Connect, Network Synthetic Monitor can help you to rapidly diagnose network degradation within the AWS network with the network health indicator

(NHI), which Network Synthetic Monitor writes to your Amazon CloudWatch account. The NHI metric is a binary value, based on a probabilistic score about whether network degradation is within AWS.

- Network Synthetic Monitor provides a fully-managed agent approach to monitoring, so you don't need to install agents either on VPCs or on-premises. To get started, you just need to specify a VPC subnet and an on-premises IP address. You can establish a private connection between your VPC and Network Synthetic Monitor resources by using AWS PrivateLink. For more information, see Using CloudWatch, CloudWatch Synthetics, and CloudWatch Network Monitoring with interface VPC endpoints.
- Network Synthetic Monitor publishes metrics to CloudWatch Metrics. You can create dashboards to view your metrics, and also create actionable thresholds and alarms on the metrics that are specific to your application.

For more information, see How Network Synthetic Monitor works.

Network Synthetic Monitor terminology and components

- **Probes** — A probe is the traffic that's sent from an AWS-hosted resource to an on-premises destination IP address. Network Synthetic Monitor metrics measured by the probe are written into your CloudWatch account for every probe that's configured in a monitor.
- **Monitor** — A monitor displays network performance and other health information for traffic that you have created Network Synthetic Monitor *probes* for. You add probes as part of creating a monitor, and then you can view network performance metrics information using the monitor. When you create a monitor for an application, you add an AWS hosted resource as the network source. Network Synthetic Monitor then creates a list of all possible probes between the AWS hosted resource and your destination IP addresses. You select the destinations that you want to monitor traffic for.
- **AWS network source** — An AWS network source is a monitor probe's originating AWS source, which is a subnet in one of your VPCs.
- **Destination** — A destination is the target in your on-premises network for the AWS network source. A destination is a combination of your on-premises IP addresses, network protocols, ports, and network packet size. IPv4 and IPv6 addresses are both supported.

Network Synthetic Monitor requirements and limitations

The following summarizes requirements and limitations for Network Synthetic Monitor. For specific quotas (or limits), see Network Synthetic Monitor.

- Monitor subnets must be owned by the same account as the monitor.
- Network Synthetic Monitor doesn't provide automatic network failover in the event of an AWS network issue.
- There's a charge for each probe that you create. For pricing details, see Pricing for Network Synthetic Monitor.
- Don't use reserved or AWS-internal IP addresses as probe destinations. Network Synthetic Monitor can't correctly measure round-trip time and packet loss for these addresses because the probe traffic doesn't leave the AWS data center, which results in round-trip time values below 1 millisecond. Specifically, avoid the following destination addresses:
  - Any address in the link-local range `169.254.0.0/16`. This range includes the Instance Metadata Service address `169.254.169.254` and the addresses `169.254.254.1` and `169.254.254.2`, which are used by Network Synthetic Monitor probe infrastructure.
  - The address `10.0.0.2`.

How Network Synthetic Monitor works

Network Synthetic Monitor is fully managed by AWS, and doesn't require separate agents on monitored resources. Instead, you specify *probes* by providing a VPC subnet and on-premises IP addresses.

When you create a monitor in Network Synthetic Monitor for AWS-hosted resources, AWS creates and manages the infrastructure in the background that is required to perform round-trip time and packet loss measurements. Because AWS manages the required configurations, you can scale your monitoring rapidly, without needing to install or uninstall agents within your AWS infrastructure.

When probes are created, customized elastic network interfaces (ENIs) are created and attached to probe instances and customer subnets. If Network Synthetic Monitor replaces a probe instance, for example, if it becomes unhealthy, Network Synthetic Monitor detaches the ENIs and reattaches them to the probe replacement. This means that ENI IP addresses are not changed after they are created, unless you delete a probe and create a new one for the same source and destination.

Network Synthetic Monitor focuses monitoring on the routes taken by flows from your AWS-hosted resources instead of broadly monitoring all flows from your AWS Region. If your workloads spread across multiple Availability Zones, Network Synthetic Monitor can monitor routes from each of your private subnets.

Network Synthetic Monitor publishes round-trip time and packet loss metrics to your Amazon CloudWatch account, based on the aggregation interval that you set when you create a monitor. You can also use CloudWatch to set individual latency and packet loss thresholds for each monitor. For example, you might create an alarm for a packet loss sensitive workload to notify you if the packet loss average is higher than a static 0.1% threshold. You can also use CloudWatch anomaly detection to alarm on packet loss or latency metrics that are outside your desired ranges.

Availability and performance measurements

Network Synthetic Monitor sends periodic active probes from your AWS resource to your on-premises destinations. When you create a monitor, you specify the following:

- **Aggregation interval:** The time, in seconds, that CloudWatch receives the measured results. This will be either every 30 or 60 seconds. The aggregation period you choose for the monitor applies to all probes in that monitor.
- **Probe sources (AWS resources):** A source for a probe is a VPC and associated subnets, or just a VPC subnet, in the Regions where your network operates.
- **Probe destinations (customer resources):** A destination for a probe is the combination of on-premises IP addresses, network protocols, ports, and network packet size.
- **Probe protocol:** One of the supported protocols, ICMP or TCP. For more information, see Supported communication protocols.
- **Port (for TCP):** The port that your network uses to connect.
- **Packet size (for TCP):** The size, in bytes, of each packet transmitted between your AWS hosted resource and your destination on a single probe. You can specify a different packet size for each probe in a monitor.

A monitor publishes the following metrics:

- **Round-trip time:** This metric, measured in microseconds, is a measure of performance. It records the time it takes for the probe to be transmitted to the destination IP address and for the associated response to be received. The round-trip time is the average time observed during the aggregation interval.

- **Packet loss:** This metric measures the percentage of total packets sent and records the number of transmissions that didn't receive an associated response. No response implies that the packets were lost along the network path.

Supported communication protocols

Network Synthetic Monitor supports two protocols for probes: ICMP and TCP.

ICMP-based probes carry ICMP echo requests from your AWS hosted resources to the destination address, and expect an ICMP echo reply in response. Network Synthetic Monitor uses the information on the ICMP echo request and reply messages to calculate round-trip time and packet loss metrics.

TCP-based probes carry TCP SYN packets from your AWS hosted resources to the destination address and port, and expect a TCP SYN+ACK packet in response. Network Synthetic Monitor uses the information on the TCP SYN and TCP SYN+ACK messages to calculate round-trip time and packet loss metrics. Network Synthetic Monitor periodically switches source TCP ports (using ports in the range 1024–65535) to increase network coverage, which increases the probability of detecting packet loss. Ensure that your firewall rules allow TCP traffic from this entire source port range to the configured destination port.

Network health indicator for AWS

Network Synthetic Monitor publishes a network health indicator (NHI) metric that provides information on issues with the AWS network for paths that include destinations connected through Direct Connect.

The NHI binary value is based on a statistical measure of the health of the AWS-controlled network path from the AWS hosted resource, where the monitor is deployed, to the Direct Connect location. Network Synthetic Monitor uses anomaly detection to calculate availability drops or lower performance along the network paths.

NHI is not accurate for Direct Connect attachments that use intermediary routing with Cloud WAN. When you have a hybrid network that includes Cloud WAN, do not use the NHI value as an indication of a performance issue.

> **Note**
>
> Each time that you create a new monitor, add a probe, or re-activate a probe, the NHI for the monitor is delayed by a few hours while AWS collects data to perform anomaly detection.

To provide the NHI value, Network Synthetic Monitor applies statistical correlation across AWS sample datasets, as well as to the packet loss and round-trip latency metrics for traffic simulating your network path. NHI can be one of two values: 1 or 0. A value of 1 indicates that Network Synthetic Monitor observed a network degradation within the AWS controlled network path. A value of 0 indicates that Network Synthetic Monitor did not observe any network degradation for the AWS network along the path. Using the NHI value enables you to more quickly gain awareness of the cause of network issues. For example, you can set alerts on the NHI metric so you're notified about ongoing issues with the AWS network along your network paths.

Support for IPv4 and IPv6 addresses

Network Synthetic Monitor provides availability and performance metrics over IPv4 or IPv6 networks, and can monitor either IPv4 or IPv6 addresses from dual-stack VPCs. Network Synthetic Monitor doesn't allow both IPv4 and IPv6 destinations to be configured in the same monitor; you can create separate monitors for IPv4-only and IPv6-only destinations.

Supported AWS Regions for Network Synthetic Monitor

The AWS Regions where Network Synthetic Monitor is supported are listed in this section. For more information about Regions that Network Synthetic Monitor is supported in, including opt-in Regions, see Network Synthetic Monitor endpoints and quotas in the *Amazon Web Services General Reference*.

Region name	Region
Africa (Cape Town)	af-south-1
Asia Pacific (Hong Kong)	ap-east-1
Asia Pacific (Hyderabad)	ap-south-2
Asia Pacific (Jakarta)	ap-southeast-3

Region name	Region
Asia Pacific (Malaysia)	ap-southeast-5
Asia Pacific (Melbourne)	ap-southeast-4
Asia Pacific (Mumbai)	ap-south-1
Asia Pacific (Osaka)	ap-northeast-3
Asia Pacific (Seoul)	ap-northeast-2
Asia Pacific (Singapore)	ap-southeast-1
Asia Pacific (Sydney)	ap-southeast-2
Asia Pacific (Thailand)	ap-southeast-7
Asia Pacific (Tokyo)	ap-northeast-1
Canada (Central)	ca-central-1
Canada West (Calgary)	ca-west-1
Europe (Frankfurt)	eu-central-1
Europe (Ireland)	eu-west-1
Europe (London)	eu-west-2
Europe (Milan)	eu-south-1
Europe (Paris)	eu-west-3
Europe (Spain)	eu-south-2
Europe (Stockholm)	eu-north-1
Europe (Zurich)	eu-central-2
Israel (Tel Aviv)	il-central-1

Region name	Region
Mexico (Central)	mx-central-1
Middle East (Bahrain)	me-south-1
Middle East (UAE)	me-central-1
South America (São Paulo)	sa-east-1
US East (N. Virginia)	us-east-1
US East (Ohio)	us-east-2
US West (N. California)	us-west-1
US West (Oregon)	us-west-2

Pricing for Network Synthetic Monitor

With Network Synthetic Monitor, there are no upfront costs or long-term commitments. Pricing for Network Synthetic Monitor has the following two components:

- An hourly fee per monitored AWS resource
- CloudWatch metrics fees

When you create a monitor in Network Synthetic Monitor, you associate AWS resources (sources) with it to be monitored. For Network Synthetic Monitor, these resources are subnets in Amazon Virtual Private Cloud (VPC). For each resource, you can create up to four probes, each of which is for traffic from a subnet in the VPC to four of your destination IP addresses. To help control your bill, you can adjust your subnet coverage and on-premises IP address destination coverage by reducing the number of resources that you monitor.

For more information about pricing, see the Amazon CloudWatch pricing page.

Network Synthetic Monitor API operations

The following table lists Network Synthetic Monitor API operations that you can use with Amazon CloudWatch. Refer to this table for links to relevant documentation.

Action	API reference	More information
Create a monitor between a source subnet and destination IP address.	See CreateMonitor	See Create a monitor
Create a probe within a monitor.	See CreateProbe	See Activate or deactivate a probe
Remove a monitor.	See DeleteMonitor	See Delete a monitor
Delete a specific probe.	See DeleteProbe	See Delete a probe
Get information about a monitor.	See GetMonitor	See Working with monitors and probes in Network Synthetic Monitor
Get information about a specific probe.	See GetProbe	See Working with monitors and probes in Network Synthetic Monitor
Get a list of all your monitors.	See ListMonitors	See Working with monitors and probes in Network Synthetic Monitor
List tags assigned to a resource.	See ListTagsForResource	See Tag or untag resources
Add key-value pairs, or tags, to a monitor or probe.	See TagResource	See Tag or untag resources
Remove a key-value pair, or tag, from a monitor or probe.	See UntagResource	See Tag or untag resources
Update an aggregation period for a monitor.	See UpdateMonitor	See Edit a monitor
Update a probe in a monitor.	See UpdateProbe	See Edit a probe

Working with monitors and probes in Network Synthetic Monitor

To get started, create a monitor with probes in Network Synthetic Monitor to measure network performance over a specified aggregation period. Then, you can update a monitor to make desired changes, for example, to change the aggregation period, deactivate or activate probes, or add or remove tags.

The following sections provide step-by-step instructions for completing these tasks for your monitors and probes by using the Amazon CloudWatch console. You can also make changes to your monitor by using the AWS Command Line Interface.

Topics

- Create a monitor
- Edit a monitor
- Delete a monitor
- Activate or deactivate a probe
- Add a probe to a monitor
- Edit a probe
- Delete a probe
- Tag or untag resources

Create a monitor

The following sections describe how to create a monitor in Network Synthetic Monitor, including the required probes. When you create a monitor, you specify probes by choosing source subnets, and then adding up to four destinations for each one. Each source-destination pair is a probe.

You can make changes to a monitor after you create it, for example, to add, remove, or deactivate probes. For more information, see Working with monitors and probes in Network Synthetic Monitor.

You can work with monitors and probes by using either the Amazon CloudWatch console or the AWS Command Line Interface. To work with Network Synthetic Monitor programmatically, see the Network Synthetic Monitor API Reference and networkmonitor in the AWS Command Line Interface Command Reference.

The following procedures provide step-by-step instructions for how to create a monitor by using the Amazon CloudWatch console.

- Define monitor details
- Choose sources and destinations
- Confirm probes
- Review and create monitor

> **Important**
>
> These steps are designed to be completed all at once. You can't save in-process work to continue later.

Define monitor details

The first step to create a monitor is to define the basic details, by giving the monitor a name and defining the aggregation period. Optionally, you can also add tags.

To define monitor details

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/, and then, under **Network Monitoring**, choose **Synthetic monitors**.
2. Choose **Create monitor**.
3. For **Monitor name**, enter a name for the monitor.
4. For **Aggregation period**, choose how often you want to send metrics to CloudWatch: **30 seconds** or **60 seconds**.

   > **Note**
   >
   > A shorter aggregation period provides faster detection of network issues. However, the aggregation period that you choose can affect your billing costs. For more information about pricing, see the Amazon CloudWatch pricing page.

5. (Optional) For **Tags**, add **Key** and **Value** pairs to help identify this resource, so that you can search or filter on specific information.

1. Choose **Add new tag**.
2. Enter a **Key** name and associated **Value**.
3. Choose **Add new tag** to add the new tag.

   You can add multiple tags by choosing **Add new tag**, or you can remove a tag by choosing **Remove**.
4. If you want to associate your tags with the probes for the monitor, keep **Add tags to probes created by monitor** selected. This adds the tags to the monitor probes, which can be helpful for tag-based authentication or metering.

6. Choose **Next**. On the next page, you'll specify sources and destinations, to create probes for the monitor.

Choose sources and destinations

For each monitor in Network Synthetic Monitor, you specify one or more probes, which are a combination of an AWS source and a destination.

- A source for a probe is a VPC and associated subnets (or just a VPC subnet) in the Regions where your network operates.
- A destination is the combination of on-premises IP addresses, network protocols, ports, and network packet size.

> **Important**
>
> These steps are designed to be completed all at once. You can't save in-process work to continue later.

To choose sources and destinations

1. Prerequisite: Define monitor details.
2. Under **AWS network source**, choose one or more subnets to include in the monitor. To choose all subnets within a VPC, choose the VPC. Or, choose specific subnets within a VPC. The subnets that you choose are the monitor sources.

3. For **Destination 1**, enter a destination IP address of the on-premises network. IPv4 and IPv6 addresses are both supported.

   > **Note**
   >
   > Don't enter a reserved or AWS-internal IP address as a destination, such as an address in the link-local range `169.254.0.0/16` or the address `10.0.0.2`. Network Synthetic Monitor can't correctly measure round-trip time and packet loss for these addresses, and reports round-trip time values below 1 millisecond. For more information, see Network Synthetic Monitor requirements and limitations.

4. Choose **Advanced settings**.
5. For **Protocol**, choose the network protocol for the on-premises destination. The protocol can be either **ICMP** or **TCP**.
6. If you choose **TCP**, enter the following information:

   1. Enter the **Port** that your network uses to connect. The port must be a number from **1** to **65535**.
   2. Enter the **Packet size**. This is the size, in bytes, of each packet that's sent on the probe, between the source and destination. Packet size must be a number from **56** to **8500**.

7. Choose **Add destination** to add another on-premises destination to the monitor. Repeat these steps for each destination that you want to add.
8. When you're finished adding sources and destinations, choose **Next** to confirm the probes for the monitor.

Confirm probes

On the **Confirm probes** page, review all the probes that will be created for the monitor, to make sure that they're the correct set of sources and destinations.

The **Confirm probes** page shows all the possible combinations of the sources and destinations for the probe specifications that you provided in the previous step. For example, if you have six source subnets and four destination IP addresses, there are 24 possible probe combinations, so 24 probes will be created.

Important

- These steps are intended to be completed in one session. You can't save in-process work to continue later.
- The **Confirm probes** page does not indicate whether a probe is valid. We recommend that you review this page carefully, and then delete any probes that aren't valid. You might be charged for probes that aren't valid if you don't remove them.

To confirm monitor probes

1. Prerequisite: Choose sources and destinations.
2. On the **Confirm probes** page, review the list of source and destination probe combinations.
3. Choose any probes that you want to remove from the monitor, and then choose **Remove**.

   Note

   You are not prompted to confirm deleting a probe. If you delete a probe and want to restore it, you must set it up again. You can add a probe to an existing monitor by following the steps in Add a probe to a monitor.
4. Choose **Next**, and then review the monitor details.

Review and create monitor

The final step is to review the details of the monitor and the probes for the monitor, and then create the monitor. You can change any information about the monitor at this point.

When you have finished reviewing and updating any information that isn't correct, create the monitor.

As soon as you create the monitor, Network Synthetic Monitor begins tracking metrics and you'll start being charged for probes in the monitor.

Important

- This step is intended to be completed in one session. You can't save in-process work to continue later.

- If you choose to edit a section, you must step through the process to create a monitor from the point that you make the edits. Earlier monitor creation pages maintain the information that you already entered.

To review and create a monitor

1. On the **Review and create probes** page, choose **Edit** for any section where you want to make changes.
2. Make changes in that section, and then choose **Next**.
3. When you're finished making edits, choose **Create monitor**.

   The Network Synthetic Monitor page displays the current state of monitor creation in the **Monitors** section. When Network Synthetic Monitor is still creating the monitor, the **State** is **Pending**. When the **State** changes to **Active**, you can view CloudWatch metrics in the monitor dashboard.

   For information on working with the monitor dashboard, see Network Synthetic Monitor dashboards.

Note

It can take several minutes for a newly-added monitor to begin collecting network metrics.

Edit a monitor

You can edit information for a Network Synthetic Monitor, including change the name, setting a new aggregation period, or adding or removing tags. Changing a monitor's information does not change any of its associated probes.

You can work with monitors and probes by using either the Amazon CloudWatch console or the AWS Command Line Interface. To work with Network Synthetic Monitor programmatically, see the Network Synthetic Monitor API Reference and networkmonitor in the AWS Command Line Interface Command Reference.

To edit a monitor using the console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/, and then, under **Network Monitoring**, choose **Synthetic monitors**.
2. In the **Monitors** section, choose the monitor that you want to edit.
3. On the monitor dashboard page, choose **Edit**.
4. For the **Monitor name**, enter the new name for the monitor.
5. For the **Aggregation period**, choose how often you want to send metrics to CloudWatch. Valid periods are:

   - **30 seconds**
   - **60 seconds**

   > **Note**
   >
   > A shorter aggregation period provides faster detection of network issues. However, the aggregation period that you choose can affect your billing costs. For more information about pricing, see the Amazon CloudWatch pricing page.

6. (Optional) In the **Tags** section, add **Key** and **Value** pairs to further help identify this resource, allowing you to search or filter on specific information. You can also just change the **Value** of any current **Key**.

   1. Choose **Add new tag**.
   2. Enter a **Key** name and associated **Value**.
   3. Choose **Add new tag** to add the new tag.

      You can add multiple tags by choosing **Add new tag**, or you can remove a tag by choosing **Remove**.

   4. If you want to associate your tags with the monitor, keep **Add tags to probes created by monitor** checked. This adds the tags to the monitor probes, which can be helpful if you're using tag-based authentication or metering.

7. Choose **Save changes**.

Delete a monitor

Before you can delete a monitor in Network Synthetic Monitor, you must deactivate or delete all probes associated with the monitor, regardless of the monitor **State**. After a monitor is deleted, you are no longer be charged for probes in the monitor. Be aware that you can't restore a deleted monitor.

You can work with monitors and probes by using either the Amazon CloudWatch console or the AWS Command Line Interface. To work with Network Synthetic Monitor programmatically, see the Network Synthetic Monitor API Reference and networkmonitor in the AWS Command Line Interface Command Reference.

To delete a monitor using the console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/, and then, under **Network Monitoring**, choose **Synthetic monitors**.
2. In the **Monitors** section, choose the monitor that you want to delete.
3. Choose **Actions**, and then choose **Delete**.
4. If you have any active probes for the monitor, you're prompted to deactivate them. Choose **Deactivate probes**.

   > **Note**
   >
   > You can't cancel or undo this action after you choose **Deactivate probes**. Deactivated probes, however, aren't removed from the monitor. If you like, you can reactivate them later. For more information, see Activate or deactivate a probe.

5. Enter **`confirm`** in the confirmation field, and then choose **Delete**.

Alternatively, you can delete a monitor programmatically, for example, by using the AWS Command Line Interface.

To delete a monitor by using the CLI

1. To delete a monitor, you need the monitor name. If you don't know the name, get a list of your monitors by running the list-monitors command. Note the name of the monitor that you want to delete.

2. Verify whether the monitor contains any active probes. Use get-monitor with the monitor name from the previous step. This returns a list of any probes associated with that monitor.
3. If the monitor contains active probes, you must first either set the probes to inactive or delete them.
   - To set a probe to inactive, use update-probe, and set the state to `INACTIVE`.
   - To delete a probe, use delete-probe.
4. After the probes are set to `INACTIVE` or deleted, you can delete the monitor by running the delete-monitor command. Inactive probes are not deleted when you delete the monitor.

Activate or deactivate a probe

You can activate or deactivate a probe in a monitor in Network Synthetic Monitor. You might want to deactivate a probe, for example, if you aren't currently using it but might want to use it again in the future. By deactivating a probe instead of deleting it, you won't need to spend time setting it up again. You are not billed for deactivated probes.

You can work with monitors and probes by using either the Amazon CloudWatch console or the AWS Command Line Interface. To work with Network Synthetic Monitor programmatically, see the Network Synthetic Monitor API Reference and networkmonitor in the AWS Command Line Interface Command Reference.

To set a probe to active or inactive by using the console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/, and then, under **Network Monitoring**, choose **Synthetic monitors**.
2. Choose the **Monitor details** tab.
3. In the **Probes** section, choose the probe that you want to activate or deactivate.
4. Choose **Actions**, and then choose **Activate** or **Deactivate**.

> **Note**
>
> When you reactivate a probe, you begin incurring billing charges on the probe again.

Add a probe to a monitor

You can add a probe to an existing monitor in Network Synthetic Monitor. Note that when you add probes to a monitor, your billing structure is updated to include the new probe.

You can work with monitors and probes by using either the Amazon CloudWatch console or the AWS Command Line Interface. To work with Network Synthetic Monitor programmatically, see the Network Synthetic Monitor API Reference and networkmonitor in the AWS Command Line Interface Command Reference.

To add a probe to a monitor using the console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/, and then, under **Network Monitoring**, choose **Synthetic monitors**.
2. In the **Monitors** section, do one of the following:
   - Choose the **Name** link of the monitor that you want to add a probe to. Choose the **Monitor details** tab, and then in the **Probes** section, choose **Add probe**.
   - Choose the monitor check box, choose **Actions**, and then choose **Add probe**.
3. On the **Add probe** page, do the following:
   1. Under **AWS network source**, choose a subnet to add to the monitor.

      > **Note**
      >
      > You can only add one probe at a time and up to four probes per monitor.

   2. Enter the destination **IP address** of the on-premises network. Both IPv4 and IPv6 addresses are supported.
   3. Choose **Advanced settings**.
   4. Choose the network **Protocol** for the destination. It can be either **ICMP** or **TCP**.
   5. If the **Protocol** is **TCP**, enter the following information. Otherwise, skip to the next step:
      - Enter the **Port** that your network uses to connect. The port must be a number from **1** to **65535**.
      - Enter the **Packet size**. This is the size, in bytes, of each packet sent along the probe between the source and destination. Packet size must be a number from **56** to **8500**.

4. (Optional) In the **Tags** section, add **Key** and **Value** pairs to further help identify this resource, allowing you to search or filter on specific information.

   1. Choose **Add new tag**.
   2. Enter a **Key** name and associated **Value**.
   3. Choose **Add new tag** to add the new tag.

      You can add multiple tags by choosing **Add new tag**, or you can remove any tag by choosing **Remove**.

5. Choose **Add probe**.

   While the probe is being activated, the **State** shows **Pending**. It might take several minutes for the probe to become **Active**.

Edit a probe

You can change any information for an existing probe, regardless of whether that probe is active or inactive.

You can work with monitors and probes by using either the Amazon CloudWatch console or the AWS Command Line Interface. To work with Network Synthetic Monitor programmatically, see the Network Synthetic Monitor API Reference and networkmonitor in the AWS Command Line Interface Command Reference.

To edit a probe by using the console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/, and then, under **Network Monitoring**, choose **Synthetic monitors**.

   Under **Name**, choose a monitor link to open the monitor dashboard.

2. Choose the **Monitor details** tab.
3. In the **Probes** section, choose the link for the probe that you want to edit.
4. On the probe details page, choose **Edit**.
5. On the **Edit *probe*** page, enter the new destination **IP address** for the probe. IPv4 and IPv6 addresses are both supported.
6. Choose **Advanced settings**.
7. Choose a network **Protocol**, **ICMP** or **TCP**.

8. If the **Protocol** is **TCP**, enter the following information:
   - Enter the **Port** that your network uses to connect. The port must be a number from **1** to **65535**.
   - Enter the **Packet size**. This is the size, in bytes, of each packet sent along the probe between the source and destination. Packet size must be a number from **56** to **8500**.
9. (Optional) Add, change, or remove Tags for the probe.
10. Choose **Save changes**.

Delete a probe

You can delete a probe rather than deactivating it if you know that you won't need it again later. You can't recover a deleted probe; instead, you must recreate it. Billing charges end for a probe when the probe is deleted.

You can work with monitors and probes by using either the Amazon CloudWatch console or the AWS Command Line Interface. To work with Network Synthetic Monitor programmatically, see the Network Synthetic Monitor API Reference and networkmonitor in the AWS Command Line Interface Command Reference.

To delete a probe using the console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/, and then, under **Network Monitoring**, choose **Synthetic monitors**.
2. In the **Monitors** section, under **Name**, choose a monitor link to open the monitor dashboard.
3. Choose the **Monitor details** tab.
4. Choose the monitor check box, choose **Actions**, and then choose **Delete**.
5. In the **Delete probe** dialog box, do the following:
6. Choose **Delete** to confirm that you want to delete the probe.

   The **State** of the probe in the **Probes** section shows **Deleting**. After it's deleted, the probe is removed from the **Probes** section.

Tag or untag resources

You can work with resource tags in Network Synthetic Monitor, to add or remove tags.

You can update tags by updating monitors or probes in the console. Or, you can work with tags programmatically, for example, by using the AWS Command Line Interface.

To update monitor tags by using the CLI

- To list resource tags, use list-tags-for-resources.
- To tag a resource, use tag-resource.
- To untag a resource, use untag-resource.

Network Synthetic Monitor dashboards

You can use dashboards in Network Synthetic Monitor to determine if a network issue is caused by AWS, by using the network health indicator (NHI), and view probe round-trip time and packet loss. You can view this information and metrics for monitors, as well as for individual probes.

Network Synthetic Monitor creates several metrics that you can view in CloudWatch Metrics. You can specify alarms for the metrics that Network Synthetic Monitor returns. For more information, see Probe alarms.

Topics

- Monitor dashboards
- Probe dashboards
- Specify metrics time frame

Monitor dashboards

You can use the monitor dashboard in Network Synthetic Monitor to view the network health indicator (NHI), as well as probe round-trip time and packet loss at a monitor level. That is, a monitor dashboard shows this information for all the probes created for the monitor.

Network Synthetic Monitor also has dashboards for probes, to view the information at a probe level. For more information, see Probe dashboards.

To access a monitor dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/, and then under **Network Monitoring**, choose **Synthetic monitors**.
2. In the **Monitors** section, choose the **Name** link to open the monitor dashboard.

Overview page

The **Overview** page displays the following information for a monitor:

- **Network health** — Network health displays the network health indicator (NHI) value, which pertains to health of only the AWS network. The NHI status is displayed as **Healthy** or **Degraded**. A **Healthy** status indicates that Network Synthetic Monitor did not observe issues with the AWS network. A **Degraded** status indicates that Network Synthetic Monitor observed an issue with the AWS network. The status bar in this section shows the status of the network health indicator over a default time of one hour. Hover over any point in the status bar to view additional details.
- **Probe traffic summary** — Displays the current state of the traffic between the source AWS subnets specified for the probes in the monitor and the probes' destination IP addresses. This summary displays the following:
  - **Probes in alarm** — This number indicates how many of your probes in this monitor are in a degraded state. An alarm is triggered when a metric that you've set up as an alarm is triggered. For information on creating alarms for metrics in Network Synthetic Monitor, see Probe alarms.
  - **Packet loss** — The number of packets that were lost from the source subnet to the destination IP address. This is represented as a percentage of the total packets sent.
  - **Round-trip time** — The time it takes, displayed in milliseconds, for a packet from the source subnet to reach the destination IP address, and then come back again. Round-trip time is the average RTT observed during the aggregation period.

The data is represented on an interactive graph, so you can explore to learn details.

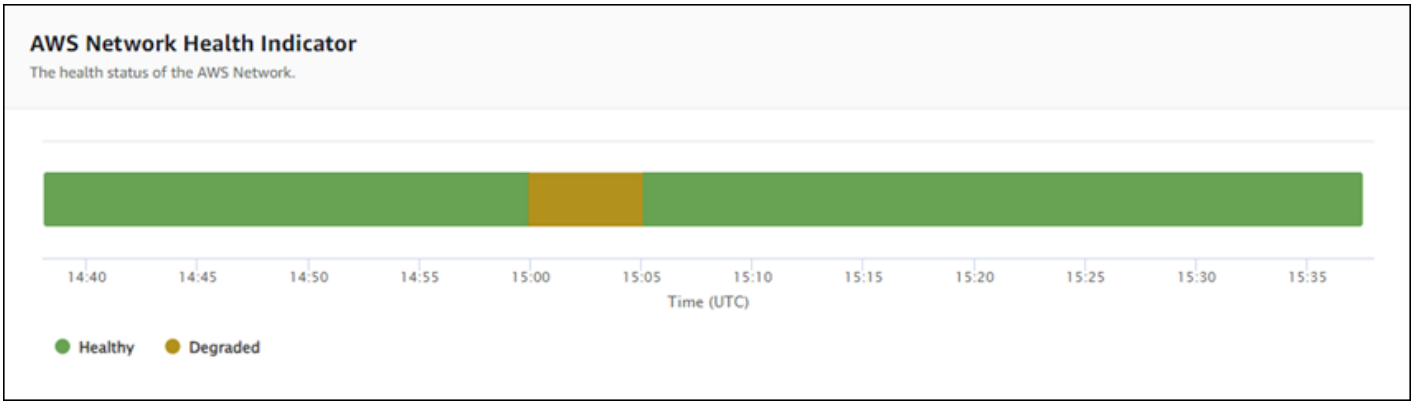
By default, data is displayed for a two-hour time frame, calculated from the current date and time. However, you can change the range to fit your needs. For more information, see Specify metrics time frame.

Tracking metrics

The **Overview** dashboard in Network Synthetic Monitor displays a graphical representation of a monitor and probes. The following graphs are shown:

- **Network health indicator** — This represents the the NHI values over a specified period. NHI indicates whether a network issue is due to problems with the AWS network. NHI is displayed as **Healthy** (no issue with the AWS network) or **Degraded** (there is an issue with the AWS network).

In the following example, you can see that from 15:00 UTC until 15:05 UTC, there was a network issue that was due to an AWS network issue (**Degraded**). After 15:05, the network issue with the AWS network ended, so the value returned to **Healthy**. You can hover over any section of the graph to see additional details.



> **Note**
>
> The NHI indicates that an issue is due to the AWS network. It does not describe the overall health of the AWS network nor the health of Network Synthetic Monitor probes.

- **Packet loss** — This graph displays a line that shows the percentage of packet loss for each probe in a monitor. The legend at the bottom of the page displays each of the probes in the monitor, color-coded for uniqueness. You can hover over a probe in the chart to see the source subnet, the destination IP address, and the percentage of packet loss.

  In the following example, a packet loss alarm was created for a probe from a subnet to IP address 127.0.0.1. The alarm was triggered when the packet loss threshold was exceeded for the probe. If you hover over the graph, you can see the probe source and destination, and that there was a 30.97% packet loss for this probe on November 21 at 02:41:30.

- **Round-trip time** — This graph displays a line that shows the round-trip time for each probe. The legend at the bottom of the page displays each of the probes in the monitor, color-coded for uniqueness. You can hover over a probe in the chart to see the source subnet, the destination IP address, and the round-trip time.

  The following example shows that on Tuesday, Nov 21, at 21:45:30, the round-trip time for a probe from a subnet to IP address 127.0.0.1 was 0.075 seconds.

Monitor details

The **Monitor details** page displays details about your monitor, including a list of the probes for the monitor. You can update or add tags, or add a probe. The page includes the following sections:

- **Monitor details** — This page provides details about your monitor. You can't edit information in this section. However, you can view details of the Network Synthetic Monitor service-linked role: choose the **Role name** link to see details.
- **Probes** — This section displays a list of all probes associated with the monitor. Choose a **VPC** or **Subnet ID** link to open the VPC or subnet details in the Amazon VPC Console. You can modify a probe, to activate or deactivate it. For more information, see Working with monitors and probes in Network Synthetic Monitor.

  The **Probes** section displays information about each probe set up for that monitor, including the probe **ID**, the **VPC ID**, the **Subnet ID**, **IP address**, **Protocol**, and whether the probe is **Active** or **Inactive**.

  If you've created an alarm for a probe, the current **Status** of the alarm is shown. A status of **OK** indicates that there are no metrics events have triggered any alarms. A status of **In alarm** indicates that a metric that you created in CloudWatch triggered an alarm. If no status is displayed for a probe, then there isn't a CloudWatch alarm for it. For information on the types of Network Synthetic Monitor probe alarms that you can create, see Probe alarms.
- **Tags** — View the current tags for a monitor. You can add or remove tags by choosing **Manage tags**. This opens the **Edit probe** page. For more information on editing tags, see Edit a monitor.

Probe dashboards

You can use a **Probe** dashboard in Network Synthetic Monitor to view the network health indicator (NHI) for a probe, as well as information about round-trip time and packet loss for specific probes. There are two dashboards for probes: an **Overview** page and **Probe details** page.

You can create CloudWatch alarms to set packet loss and round-trip time metric thresholds. When a threshold is reached for a metric, a CloudWatch alarm notifies you. For information on creating probe alarms, see Probe alarms.

To access a probe dashboard

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/, and then, under **Network Monitoring**, choose **Synthetic monitors**.

2. In the **Monitors** section, choose the **Name** link to open the dashboard for a specific monitor.
3. To view the dashboard for a specific probe, choose the **ID** link for the probe.

Overview page

The **Overview** page displays the following information for a probe:

- **Network health** — Network health displays the network health indicator (NHI) value, which pertains only to health of the AWS network. The NHI status is provided as **Healthy** or **Degraded**. A **Healthy** status indicates that Network Synthetic Monitor did not observe issues with the AWS network for a probe. A **Degraded** status indicates that Network Synthetic Monitor observed an issue with the AWS network. The status bar in this section shows the status of the network health indicator over a default time of one hour. Hover over any point in the status bar to view additional details.
- **Packet loss** — The number of packets that were lost from the source subnet to the destination IP address for this probe.
- **Round-trip time** — The time it takes, in milliseconds, for a packet from the source subnet to reach the destination IP address, and then come back again. Round-trip time (RTT) is the average RTT observed during the aggregation period.

Probe details

The **Probe details** page displays information about a probe, including the source and destination. You can also edit the probe, for example, to activate or deactivate it. For more information, see Working with monitors and probes in Network Synthetic Monitor.

- **Probe details** — This section provides general information about the probe, which can't be edited.
- **Probe source and destination** — This section displays details about the probe. Choose a **VPC** or **Subnet ID** link to open the VPC or subnet details in the Amazon VPC Console. You can modify a probe, for example, to activate or deactivate it.
- **Tags** — View the current tags for a monitor. You can add or remove tags by choosing **Manage tags**. This opens the **Edit probe** page. For more information on editing tags, see Edit a probe.

Specify metrics time frame

Metrics and events on the dashboards in Network Synthetic Monitor use a default time of two hours, calculated from the current time, but you can set a custom metrics default time frame to use. You can change the default to one of the following presets for the metrics time frame:

- **1h** — one hour
- **2h** — two hours
- **1d** — one day
- **1w** — one week

You can also set a custom time frame. Choose **Custom**, choose an **Absolute** or **Relative** time, and then set the time frame to a time of your own choosing. Relative time supports only 15 days back from today's date, following CloudWatch guidelines.

Additionally, you can choose the time displayed in the charts to be based on either the UTC time zone or a local time zone.

For more information, see Changing the time range or time zone format of a CloudWatch dashboard.

Probe alarms

You can create Amazon CloudWatch alarms based on Network Synthetic Monitor metrics, just as you can for other Amazon CloudWatch metrics. Any alarm that you create will appear in the probe's **Status** column of the **Monitor details** section of the Network Synthetic Monitor dashboard when the alarm is triggered. The status will either be **OK** or **In Alarm**. If no status displays for a probe, then no alarm was created for that probe.

For example, you can create an alarm based on the Network Synthetic Monitor metric `PacketLoss`, and configure it to send a notification when the metric is higher than a value that you choose. You configure alarms for Network Synthetic Monitor metrics following the same guidelines as for other CloudWatch metrics.

The following metrics are available under `AWS/NetworkMonitor` when creating a CloudWatch alarm for Network Synthetic Monitor.

- **HealthIndicator**

- **PacketLoss**
- **RTT (Round-trip time)**

For the steps to create a Network Synthetic Monitor alarm in CloudWatch, see Create a CloudWatch alarm based on a static threshold.

Data security and data protection in Network Synthetic Monitor

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from data centers and network architectures that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security *of* the cloud and security *in* the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS Compliance Programs. To learn about the compliance programs that apply to Network Synthetic Monitor, see AWS Services in Scope by Compliance Program.
- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your company's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Network Synthetic Monitor. The following topics show you how to configure Network Synthetic Monitor to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your Network Synthetic Monitor resources.

Topics

- Data protection in Network Synthetic Monitor
- Infrastructure Security in Network Synthetic Monitor

Data protection in Network Synthetic Monitor

The AWS shared responsibility model applies to data protection in Network Synthetic Monitor. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of

the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see Data Privacy FAQ. For information about data protection in Europe, see the General Data Protection Regulation (GDPR) Center.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual users with AWS IAM Identity Center or AWS Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with AWS CloudTrail. For information about using CloudTrail trails to capture AWS activities, see Working with CloudTrail trails in the *AWS CloudTrail User Guide*.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-3 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-3.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a **Name** field. This includes when you work with Network Synthetic Monitor or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Infrastructure Security in Network Synthetic Monitor

As a managed service, Network Synthetic Monitor is protected by the AWS global network security procedures that are described in the Amazon Web Services: Overview of Security Processes whitepaper.

You use AWS published API calls to access Network Synthetic Monitor through the network. Clients must support Transport Layer Security (TLS) 1.0 or later. We recommend TLS 1.2 or later. Clients must also support cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

Identity and access management for Network Synthetic Monitor

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be authenticated (signed in) and authorized (have permissions) to use Network Synthetic Monitor resources. IAM is an AWS service that you can use with no additional charge. You can use features of IAM to allow other users, services, and applications to use your AWS resources fully or in a limited way, without sharing your security credentials.

By default, IAM users don't have permission to create, view, or modify AWS resources. To allow an IAM user to access resources, such as a global network, and perform tasks, you must:

- Create an IAM policy that grants the user permission to use the specific resources and API actions they need
- Attach the policy to the IAM user or to the group to which the user belongs

When you attach a policy to a user or group of users, it allows or denies the user permissions to perform the specified tasks on the specified resources.

Condition keys

The `Condition` element (or Condition block) lets you specify conditions in which a statement is in effect. The Condition element is optional. You can build conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request. For more information, see IAM JSON policy elements: Condition operators in the *AWS Identity and Access Management User Guide*.

If you specify multiple `Condition` elements in a statement, or multiple keys in a single `Condition` element, AWS evaluates them using a logical `AND` operation. If you specify multiple

values for a single condition key, AWS evaluates the condition using a logical OR operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name.

You can attach tags to Network Synthetic Monitor resources or pass tags in a request to Cloud WAN. To control access based on tags, you provide tag information in the condition element of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys. See IAM JSON policy elements: Condition in the *AWS Identity and Access Management User Guide* for more information.

To see all AWS global condition keys, see AWS global condition context keys in the *AWS Identity and Access Management User Guide*.

Tag core network resources

A tag is a metadata label that either you or AWS assigns to an AWS resource. Each tag consists of a key and a value. For tags that you assign, you define the key and the value. For example, you might define the key as `purpose` and the value as `test` for one resource. Tags help you do the following:

- Identify and organize your AWS resources. Many AWS services support tagging, so you can assign the same tag to resources from different services to indicate that the resources are related.
- Control access to your AWS resources. For more information, see Controlling access to AWS resources using tags in the *AWS Identify and Access Management User Guide*.

How Network Synthetic Monitor works with IAM

Before you use IAM to manage access to Network Synthetic Monitor, learn what IAM features are available to use with Network Synthetic Monitor.

IAM features you can use with Network Synthetic Monitor

IAM feature	Network Synthetic Monitor support
Identity-based policies	Yes
Resource-based policies	No
Policy actions	Yes

IAM feature	Network Synthetic Monitor support
Policy resources	Yes
Policy condition keys	Yes
ACLs	No
ABAC (tags in policies)	Partial
Temporary credentials	Yes
Principal permissions	Yes
Service roles	No
Service-linked roles	Yes

To get a high-level view of how Network Synthetic Monitor and other AWS services work with most IAM features, see AWS services that work with IAM in the *IAM User Guide*.

Identity-based policies for Network Synthetic Monitor

Supports identity-based policies: Yes

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Define custom IAM permissions with customer managed policies in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. To learn about all of the elements that you can use in a JSON policy, see IAM JSON policy elements reference in the *IAM User Guide*.

Identity-based policy examples for Network Synthetic Monitor

To view examples of Network Synthetic Monitor identity-based policies, see Identity-based policy examples for Amazon CloudWatch.

Resource-based policies within Network Synthetic Monitor

Supports resource-based policies: No

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. For more information, see Cross account resource access in IAM in the *IAM User Guide*.

Policy actions for Network Synthetic Monitor

Supports policy actions: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Action` element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Include actions in a policy to grant permissions to perform the associated operation.

To see a list of Network Synthetic Monitor actions, see Actions defined by Network Synthetic Monitor in the *Service Authorization Reference*.

Policy actions in Network Synthetic Monitor use the following prefix before the action:

```
networkmonitor
```

To specify multiple actions in a single statement, separate them with commas.

```
"Action": [
      "networkmonitor:action1",
      "networkmonitor:action2"
         ]
```

To view examples of Network Synthetic Monitor identity-based policies, see Identity-based policy examples for Amazon CloudWatch.

Policy resources for Network Synthetic Monitor

Supports policy resources: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Resource` JSON policy element specifies the object or objects to which the action applies. As a best practice, specify a resource using its Amazon Resource Name (ARN). For actions that don't support resource-level permissions, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

To see a list of Network Synthetic Monitor resource types and their ARNs, see Resources defined by Network Synthetic Monitor in the *Service Authorization Reference*. To learn with which actions you can specify the ARN of each resource, see Actions defined by Network Synthetic Monitor.

Policy condition keys for Network Synthetic Monitor

Supports service-specific policy condition keys: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Condition` element specifies when statements execute based on defined criteria. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request. To see all AWS global condition keys, see AWS global condition context keys in the *IAM User Guide*.

To see a list of Network Synthetic Monitor condition keys, see Condition keys for Network Synthetic Monitor in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see Actions defined by Network Synthetic Monitor.

ACLs in Network Synthetic Monitor

Supports ACLs: No

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

ABAC with Network Synthetic Monitor

Supports ABAC (tags in policies): Partial

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes called tags. You can attach tags to IAM entities and AWS resources, then design ABAC policies to allow operations when the principal's tag matches the tag on the resource.

To control access based on tags, you provide tag information in the condition element of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see Define permissions with ABAC authorization in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see Use attribute-based access control (ABAC) in the *IAM User Guide*.

Using temporary credentials with Network Synthetic Monitor

Supports temporary credentials: Yes

Temporary credentials provide short-term access to AWS resources and are automatically created when you use federation or switch roles. AWS recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see Temporary security credentials in IAM and AWS services that work with IAM in the *IAM User Guide*.

Cross-service principal permissions for Network Synthetic Monitor

Supports forward access sessions (FAS): Yes

Forward access sessions (FAS) use the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. For policy details when making FAS requests, see Forward access sessions.

Service roles for Network Synthetic Monitor

Supports service roles: No

A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Create a role to delegate permissions to an AWS service in the *IAM User Guide*.

> **Warning**
>
> Changing the permissions for a service role might break Network Synthetic Monitor functionality. Edit service roles only when Network Synthetic Monitor provides guidance to do so.

Using a service-linked role for Network Synthetic Monitor

Supports service-linked roles: Yes

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

For details about creating or managing service-linked roles, see AWS services that work with IAM. Find a service in the table that includes a `Yes` in the **Service-linked role** column. Choose the **Yes** link to view the service-linked role documentation for that service.

Identity-based policy examples for Network Synthetic Monitor

By default, users and roles don't have permission to create or modify Network Synthetic Monitor resources. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies.

To learn how to create an IAM identity-based policy by using these example JSON policy documents, see Create IAM policies (console) in the *IAM User Guide*.

For details about actions and resource types defined by Network Synthetic Monitor, including the format of the ARNs for each of the resource types, see Actions, resources, and condition keys for Network Synthetic Monitor in the *Service Authorization Reference*.

Topics

- Policy best practices

- Using the Network Synthetic Monitor console
- Allow users to view their own permissions
- Troubleshooting Network Synthetic Monitor identity and access

Policy best practices

Identity-based policies determine whether someone can create, access, or delete Network Synthetic Monitor resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with AWS managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *AWS managed policies* that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see AWS managed policies or AWS managed policies for job functions in the *IAM User Guide*.
- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see Policies and permissions in IAM in the *IAM User Guide*.
- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as CloudFormation. For more information, see IAM JSON policy elements: Condition in the *IAM User Guide*.
- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see Validate policies with IAM Access Analyzer in the *IAM User Guide*.
- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your AWS account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see Secure API access with MFA in the *IAM User Guide*.

For more information about best practices in IAM, see Security best practices in IAM in the *IAM User Guide*.

Using the Network Synthetic Monitor console

To access the Network Synthetic Monitor console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the Network Synthetic Monitor resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for entities (users or roles) with that policy.

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that they're trying to perform.

To ensure that users and roles can still use the Network Synthetic Monitor console, also attach the Network Synthetic Monitor *ConsoleAccess* or *ReadOnly* AWS managed policy to the entities. For more information, see Adding permissions to a user in the *IAM User Guide*.

Allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ViewOwnUserInfo",
            "Effect": "Allow",
            "Action": [
                "iam:GetUserPolicy",
                "iam:ListGroupsForUser",
                "iam:ListAttachedUserPolicies",
                "iam:ListUserPolicies",
                "iam:GetUser"
            ],
            "Resource": ["arn:aws:iam::*:user/${aws:username}"]
        },
        {
```

```
            "Sid": "NavigateInConsole",
            "Effect": "Allow",
            "Action": [
                "iam:GetGroupPolicy",
                "iam:GetPolicyVersion",
                "iam:GetPolicy",
                "iam:ListAttachedGroupPolicies",
                "iam:ListGroupPolicies",
                "iam:ListPolicyVersions",
                "iam:ListPolicies",
                "iam:ListUsers"
            ],
            "Resource": "*"
        }
    ]
}
```

Troubleshooting Network Synthetic Monitor identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with Network Synthetic Monitor and IAM.

Topics

- I am not authorized to perform an action in Network Synthetic Monitor
- I am not authorized to perform iam:PassRole
- I want to allow people outside of my AWS account to access my Network Synthetic Monitor resources

I am not authorized to perform an action in Network Synthetic Monitor

If you receive an error that you're not authorized to perform an action, your policies must be updated to allow you to perform the action.

The following example error occurs when the `mateojackson` IAM user tries to use the console to view details about a fictional *`my-example-widget`* resource but doesn't have the fictional `networkmonitor:`*`GetWidget`* permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:
 networkmonitor:GetWidget on resource: my-example-widget
```

In this case, the policy for the `mateojackson` user must be updated to allow access to the *`my-example-widget`* resource by using the `networkmonitor:GetWidget` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I am not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, your policies must be updated to allow you to pass a role to Network Synthetic Monitor.

Some AWS services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named `marymajor` tries to use the console to perform an action in Network Synthetic Monitor. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform:
 iam:PassRole
```

In this case, Mary's policies must be updated to allow her to perform the `iam:PassRole` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I want to allow people outside of my AWS account to access my Network Synthetic Monitor resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Network Synthetic Monitor supports these features, see How Amazon CloudWatch works with IAM.

- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the *IAM User Guide*.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see Cross account resource access in IAM in the *IAM User Guide*.

AWS managed policies for Network Synthetic Monitor

To add permissions to users, groups, and roles, it is easier to use AWS managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see AWS managed policies in the *IAM User Guide*.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services do not remove permissions from an AWS managed policy, so policy updates won't break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the `ReadOnlyAccess` AWS managed policy provides read-only access to all AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see AWS managed policies for job functions in the *IAM User Guide*.

AWS managed policy: CloudWatchNetworkMonitorServiceRolePolicy

The `CloudWatchNetworkMonitorServiceRolePolicy` is attached to a service-linked role that allows the service to perform actions on your behalf and access resources associated with CloudWatch Network Synthetic Monitor. You cannot attach this policy to your IAM identities. For more information, see Using a service-linked role for Network Synthetic Monitor.

Network Synthetic Monitor updates to AWS managed policies

To view details about updates to AWS managed policies for Network Synthetic Monitor since this service began tracking these changes, see CloudWatch updates to AWS managed policies. For automatic alerts about managed policy changes in CloudWatch, subscribe to the RSS feed on the CloudWatch Document history page.

IAM permissions for Network Synthetic Monitor

To use Network Synthetic Monitor users must have the correct permissions.

For more information about security in Amazon CloudWatch, see Identity and access management for Amazon CloudWatch.

Permissions required to view a monitor

To view a monitor for Network Synthetic Monitor in the AWS Management Console, you must be signed in as a user or role that has the following permissions:

JSON

```
{
"Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "cloudwatch:GetMetricData",
                "networkmonitor:Get*",
                "networkmonitor:List*"
                ],
            "Resource": "*"
        }
    ]
}
```

Permissions required to create a monitor

To create a monitor in Network Synthetic Monitor, users must have permission to create a service-linked role that is associated with Network Synthetic Monitor. To learn more about the service-linked role, see Using a service-linked role for Network Synthetic Monitor.

To create a monitor for Network Synthetic Monitor in the AWS Management Console, you must be signed in as a user or role that has the permissions included in the following policy.

> **Note**
>
> If you create an identity-based permissions policy that is more restrictive, users with that policy won't be able to create a monitor.

JSON

```
{
"Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "networkmonitor:*"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": "iam:CreateServiceLinkedRole",
            "Resource": "arn:aws:iam::*:role/aws-service-role/
networkmonitor.amazonaws.com/AWSServiceRoleForNetworkMonitor",
            "Condition": {
                "StringLike": {
                    "iam:AWSServiceName": "networkmonitor.amazonaws.com"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": [
                "iam:AttachRolePolicy",
                "iam:GetRole",
                "iam:PutRolePolicy"
            ],
            "Resource": "arn:aws:iam::*:role/aws-service-role/
networkmonitor.amazonaws.com/AWSServiceRoleForNetworkMonitor"
        },
```

```
        {
            "Action": [
                "ec2:CreateSecurityGroup",
                "ec2:CreateNetworkInterface",
                "ec2:CreateTags"
            ],
            "Effect": "Allow",
            "Resource": "*"
        }
    ]
}
```

Using a service-linked role for Network Synthetic Monitor

Network Synthetic Monitor uses the following service-linked role for the permissions that it requires to call other AWS services on your behalf:

- AWSServiceRoleForNetworkMonitor

AWSServiceRoleForNetworkMonitor

Network Synthetic Monitor uses the service-linked role named AWSServiceRoleForNetworkMonitor to update and manage monitors.

The AWSServiceRoleForNetworkMonitor service-linked role trusts the following service to assume the role:

- networkmonitor.amazonaws.com

The CloudWatchNetworkMonitorServiceRolePolicy is attached to the service linked role and grants access for the service to access VPC and EC2 resources in your account, as well as manage the monitors that you create.

Permissions groupings

The policy is grouped into the following sets of permissions:

- **cloudwatch** - This allows the service principal to publish network monitoring metrics to CloudWatch resources.

- **ec2** - This allows the service principal to describe VPCs and subnets in your account to create or update monitors and probes. This also allows the service principal to create, modify, and delete security groups, network interfaces, and their associated permissions to configure the monitor or probe to send monitoring traffic to your endpoints.

To view the permissions for this policy, see CloudWatchNetworkMonitorServiceRolePolicy in the *AWS Managed Policy Reference*.

Create the service-linked role

`AWSServiceRoleForNetworkMonitor`

You don't need to manually create the `AWSServiceRoleForNetworkMonitor` role.

- Network Synthetic Monitor creates the `AWSServiceRoleForNetworkMonitor` role when you create your first monitor with the feature. This role then applies to all additional monitors that you create.

To create a service-linked role on your behalf, you must have the required permissions. For more information, see Service-Linked Role Permissions in the *IAM User Guide*.

Edit the service-linked role

You can edit the `AWSServiceRoleForNetworkMonitor` descriptions using IAM. For more information, see Editing a Service-Linked Role in the *IAM User Guide*.

Delete the service-linked role

If you no longer need to use Network Synthetic Monitor, we recommend that you delete the `AWSServiceRoleForNetworkMonitor` role.

You can delete these service-linked roles only after you delete your monitors. For more information, see Delete a monitor.

You can use the IAM console, the IAM CLI, or the IAM API to delete service-linked roles. For more information, see Deleting a Service-Linked Role in the *IAM User Guide*.

After you delete `AWSServiceRoleForNetworkMonitor` Network Synthetic Monitor will create the role again when you create a new monitor.

Supported Regions for the Network Synthetic Monitor service-linked role

Network Synthetic Monitor supports the service-linked role in all of AWS Regions where the service is available. For more information, see AWS endpoints in the *AWS General Reference*.

Delete the service-linked role

If you no longer need to use Network Synthetic Monitor, we recommend that you delete the `AWSServiceRoleForNetworkMonitor` role.

You can delete these service-linked roles only after you delete your monitors. For more information, see Delete a monitor.

You can use the IAM console, the IAM CLI, or the IAM API to delete service-linked roles. For more information, see Deleting a Service-Linked Role in the *IAM User Guide*.

After you delete `AWSServiceRoleForNetworkMonitor` Network Synthetic Monitor will create the role again when you create a new monitor.

CloudWatch observability solutions

CloudWatch observability solutions offer a catalog of readily available configurations to help you quickly implement monitoring for various AWS services and common workloads, such as Java Virtual Machines (JVM), Apache Kafka, Apache Tomcat, and NGINX. These solutions provide focused guidance on key monitoring tasks, including the installation and configuration of the CloudWatch agent, deployment of pre-defined custom dashboards, and setup of metric alarms. They are designed to assist developers and operations teams in leveraging AWS monitoring and observability tools more effectively.

The solutions include guidance on when to use specific observability features like Detailed Monitoring metrics for infrastructure, Container Insights for container monitoring, and Application Signals for application monitoring. By providing working examples and practical configurations, these solutions aim to simplify the initial setup process, allowing you to establish functional monitoring more quickly and customize as needed for their specific requirements.

To get started with observability solutions, visit the observability solutions page in the CloudWatch console.

For open-source solutions that work with Amazon Managed Grafana, see Amazon Managed Grafana solutions

The available solutions are detailed below. Some solutions use the CloudWatch agent, and others use a Amazon CloudWatch managed Prometheus collector to scrape Prometheus-compatible metrics and deliver them to CloudWatch.

Topics

- CloudWatch solution: JVM workload on Amazon EC2
- CloudWatch solution: NGINX workload on Amazon EC2
- CloudWatch solution: NVIDIA GPU workload on Amazon EC2
- CloudWatch solution: Kafka workload on Amazon EC2
- CloudWatch solution: Tomcat workload on Amazon EC2
- CloudWatch solution: Amazon EC2 health
- Amazon CloudWatch solution: Prometheus metric collection on Amazon Amazon EC2
- Amazon CloudWatch solution: Prometheus metric collection on Amazon ECS
- Amazon CloudWatch solution: Amazon MSK insights

How do solution dashboards work?

The dashboards for CloudWatch solutions use search-powered variables (dropdowns) that allow you to explore and visualize different aspects of your workloads dynamically.

By combining the flexibility of search-powered variables with the pre-configured metric widgets, the dashboard provides deep insights into your workloads, enabling proactive monitoring, troubleshooting, and optimization. This dynamic approach ensures that you can quickly adapt the dashboard to your specific monitoring needs, without the need for extensive customization or configuration.

Do solutions support cross-Region observability?

CloudWatch solution dashboards display metrics of the Region where the solution dashboard is created. However, the solution dashboard doesn't display metrics across multiple Regions. If you have a use case to view data from multiple Regions in a single dashboard, you'll need to customize the dashboard JSON to add the Regions that you want to view. To do this, use the `region` attribute of the metric format to query the metrics from different Regions. For more information about modifying dashboard JSON, see Metric Widget: Format for Each Metric in the Array.

Do solution dashboards support Cross-account cross-Region CloudWatch console?

When using CloudWatch cross-account observability, solution dashboards in the central monitoring account display metrics from source accounts in the same Region. To differentiate metrics for similar workloads across accounts, provide unique grouping dimension values in agent configurations. For instance, assign distinct `ClusterName` values for Kafka brokers in different accounts for Kafka workload, enabling precise cluster selection and metric viewing in the dashboard.

Do solution dashboards support CloudWatch cross-account observability?

If you have enabled cross-account using Cross-account cross-Region CloudWatch console, you won't be able to use the solution dashboard created in the monitoring account to view metrics from source accounts. Instead, you'll need to create dashboards in the respective source accounts. However, you can create the dashboard in the source account and view it from the monitoring account by switching the account ID setting in the console.

What are the limitations for a solution dashboard?

Solution dashboards leverage Search expressions to filter and analyze metrics for the workloads. This enables dynamic views based on dropdown option selections. These search

expressions might return more than 500 time series, but each dashboard widget can't display more than 500 time series. If a metric search in the solution dashboard results in more than 500 time series across all Amazon EC2; instances, the graph displaying the top contributors might show inaccurate results. For more information about search expressions, see CloudWatch search expression syntax.

CloudWatch displays the metric information on the dashboards if you click the `i` icon on the dashboard widget. However, this currently doesn't work for dashboard widgets that use search expressions. The solution dashboards use search expressions, so you won't be able to see the metric description in the dashboard.

Can I customize the agent configuration or the dashboard provided by a solution?

You can customize the agent configuration and the dashboard. Be aware that if you customize the agent configuration, you must update the dashboard accordingly or it will display empty metric widgets. Also be aware that if CloudWatch releases a new version of a solution, you might have to repeat your customizations if you apply the newer version of the solution.

How are solutions versioned?

Each solution provides the most up-to-date instructions and resources. We always recommend using the latest version available. While the solutions themselves are not versioned, the associated artifacts (such as CloudFormation templates for dashboards and agent installations) are versioned.

You can identify the version of a previously deployed artifact by checking the CloudFormation template's description field or the filename of the template you downloaded. To determine if you're using the latest version, compare your deployed version with the one currently referenced in the solution documentation.

CloudWatch solution: JVM workload on Amazon EC2

This solution helps you configure out-of-the-box metric collection using CloudWatch agents for JVM application running on EC2 instances. Additionally, it helps you set up a pre-configured CloudWatch dashboard. For general information about all CloudWatch observability solutions, see CloudWatch observability solutions.

Topics

- Requirements

- Benefits
- Costs
- CloudWatch agent configuration for this solution
- Deploy the agent for your solution
- Create the JVM solution dashboard

Requirements

This solution is relevant for the following conditions:

- Supported versions: Java LTS versions 8, 11, 17, and 21
- Compute: Amazon EC2
- Supports up to 500 EC2 instances across all JVM workloads in a given AWS Region
- Latest version of CloudWatch agent
- SSM agent installed on EC2 instance

> **Note**
>
> AWS Systems Manager (SSM agent) is pre-installed on some Amazon Machine Images (AMIs) provided by AWS and trusted third-parties. If the agent isn't installed, you can install it manually using the procedure for your operating system type.
>
> - Manually installing and uninstalling SSM Agent on EC2 instances for Linux
> - Manually installing and uninstalling SSM Agent on EC2 instances for macOS
> - Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server

Benefits

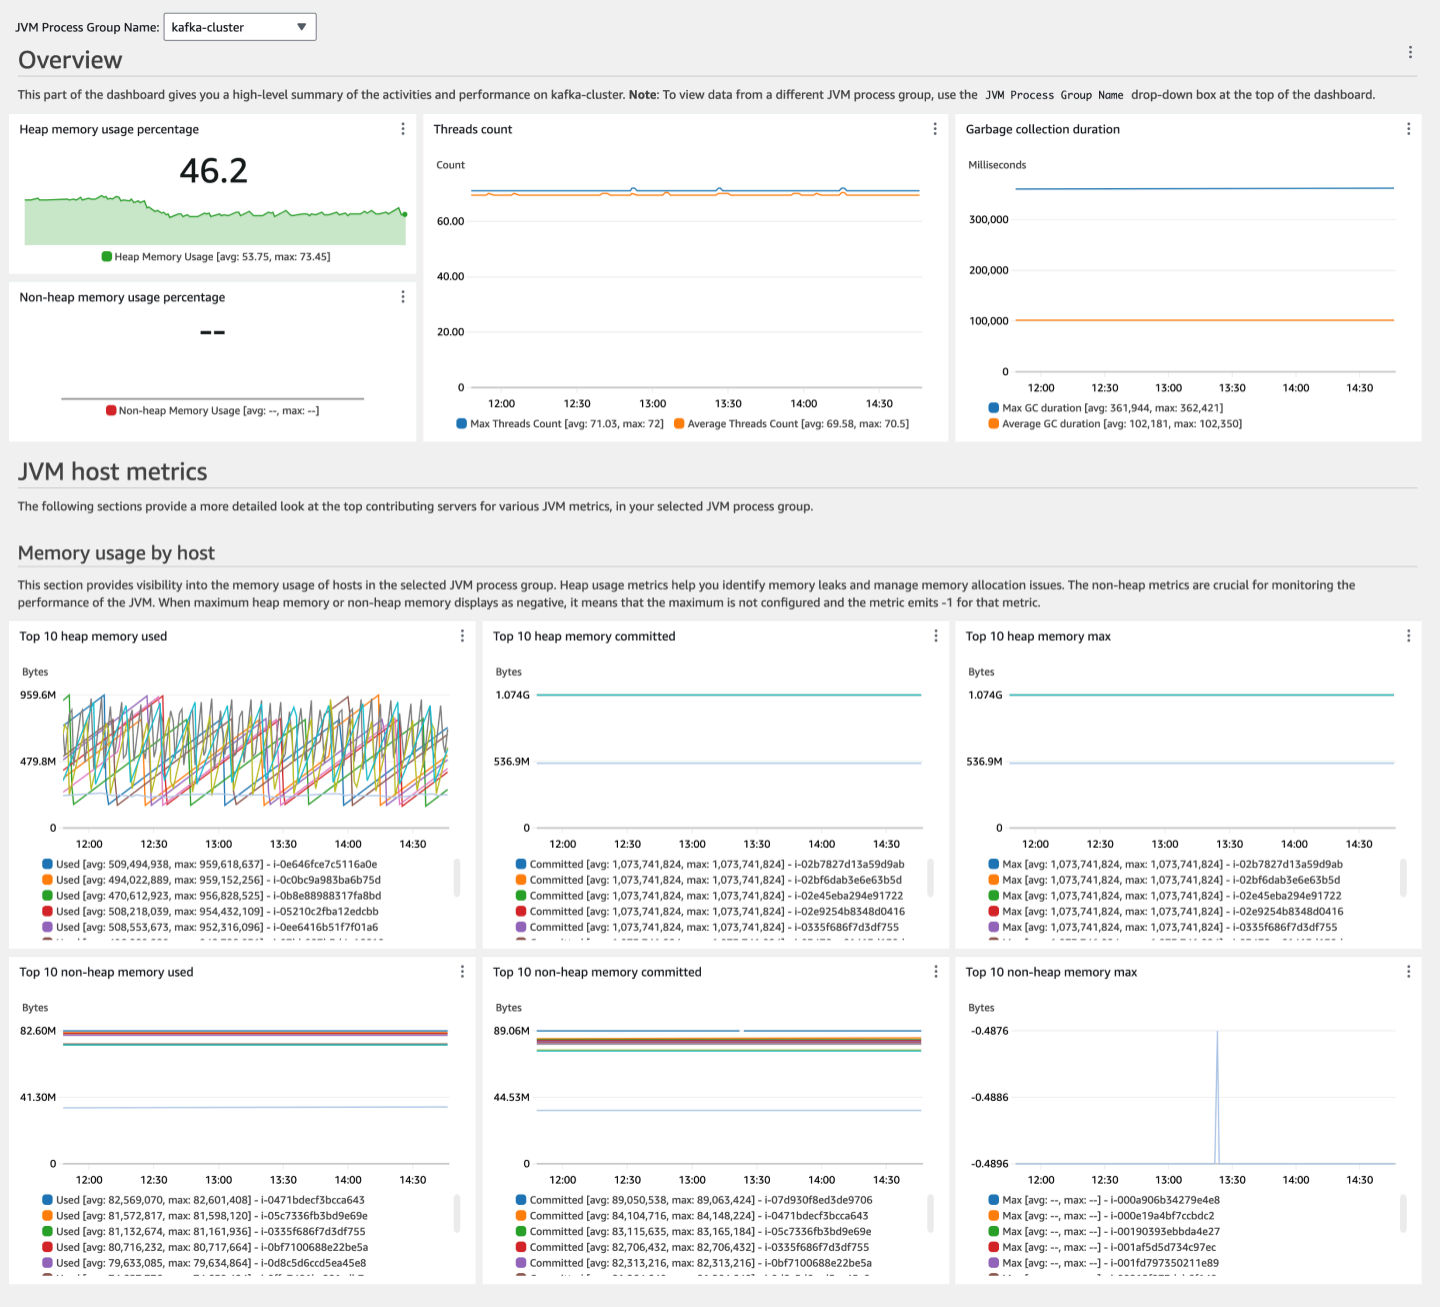
The solution delivers JVM monitoring, providing valuable insights for the following use cases:

- Monitor JVM heap and non-heap memory usage.
- Analyze thread and class loading for concurrency issues.
- Track garbage collection to identify memory leaks.
- Switch between different JVM applications configured via the solution under the same account.

Below are the key advantages of the solution:

- Automates metric collection for JVM using CloudWatch agent configuration, eliminating manual instrumentation.
- Provides a pre-configured, consolidated CloudWatch dashboard for JVM metrics. The dashboard will automatically handle metrics from new JVM EC2 instances configured using the solution, even if those metrics don't exist when you first create the dashboard. It also allows you to group the metrics into logical applications for easier focus and management.

The following image is an example of the dashboard for this solution.



Costs

This solution creates and uses resources in your account. You are charged for standard usage, including the following:

- All metrics collected by the CloudWatch agent are charged as custom metrics. The number of metrics used by this solution depends on the number of EC2 hosts.

- Each JVM host configured for the solution publishes a total of 18 metrics plus one metric (`disk_used_percent`) for which the metric count depends on the number of paths for the host.
- One custom dashboard.
- API operations requested by the CloudWatch agent to publish the metrics. With the default configuration for this solution, the CloudWatch agent calls the **PutMetricData** once every minute for each EC2 host. This means the **PutMetricData** API will be called `30*24*60=43,200` in a 30-day month for each EC2 host.

For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

The pricing calculator can help you estimate approximate monthly costs for using this solution.

To use the pricing calculator to estimate your monthly solution costs

1. Open the Amazon CloudWatch pricing calculator.
2. For **Choose a Region**, select the Region where you would like to deploy the solution.
3. In the **Metrics** section, for **Number of metrics**, enter **`(18 + average number of disk paths per EC2 host) * number of EC2 instances configured for this solution`**.
4. In the **APIs** section, for **Number of API requests**, enter **`43200 * number of EC2 instances configured for this solution`**.

   By default, the CloudWatch agent performs one **PutMetricData** operation each minute for each EC2 host.
5. In the **Dashboards and Alarms** section, for **Number of Dashboards**, enter **1**.
6. You can see your monthly estimated costs at the bottom of the pricing calculator.

CloudWatch agent configuration for this solution

The CloudWatch agent is software that runs continuously and autonomously on your servers and in containerized environments. It collects metrics, logs, and traces from your infrastructure and applications and sends them to CloudWatch and X-Ray.

For more information about the CloudWatch agent, see Collect metrics, logs, and traces using the CloudWatch agent.

The agent configuration in this solution collects the foundational metrics for the solution. The CloudWatch agent can be configured to collect more JVM metrics than the dashboard displays by default. For a list of all JVM metrics that you can collect, see Collect JVM metrics. For general information about CloudWatch agent configuration, see Metrics collected by the CloudWatch agent.

Expose JMX ports for the JVM application

The CloudWatch agent relies on JMX to collect the metrics related to the JVM process. To make this possible, you must expose the JMX port from your JVM application. Instructions for exposing the JMX port depend on the workload type you are using for your JVM application. See the documentation for your application to find these instructions.

In general, to enable a JMX port for monitoring and management, you would set the following system properties for your JVM application. Be sure to specify an unused port number. The following example sets up unauthenticated JMX. If your security policies/requirements require you to enable JMX with password authentication or SSL for remote access, refer to the JMX documentation to set the required property.

```
-Dcom.sun.management.jmxremote
-Dcom.sun.management.jmxremote.port=port-number
-Dcom.sun.management.jmxremote.authenticate=false
-Dcom.sun.management.jmxremote.ssl=false
```

Review the starting scripts and configuration files of your application to find the best place to add these arguments. When you run a `.jar` file from the command line, this command could look like the following, where *`pet-search.jar`* is the name of the application jar.

```
$ java -jar -Dcom.sun.management.jmxremote -Dcom.sun.management.jmxremote.port=9999 -
Dcom.sun.management.jmxremote.authenticate=false -
Dcom.sun.management.jmxremote.ssl=false pet-search.jar
```

Agent configuration for this solution

The metrics collected by the agent are defined in the agent configuration. The solution provides agent configurations to collect the recommended metrics with suitable dimensions for the solution's dashboard.

The steps for deploying the solution are described later in Deploy the agent for your solution. The following information is intended to help you understand how to customize the agent configuration for your environment.

You must customize some parts of the following agent configuration for your environment:

- The JMX port number is the port number that you configured in the previous section of this documentation. It is in the `endpoint` line in the configuration.
- `ProcessGroupName`– Provide meaningful names for the `ProcessGroupName` dimension. These names should represent the cluster, application, or services grouping for EC2 instances running the same application or process. This helps you to group metrics from instances belonging to the same JVM process group, providing a unified view of cluster, application, and service performance in the solution dashboard.

For example, if you have two Java applications running in the same account, one for the `order-processing` application and another for the `inventory-management` application, you should set the `ProcessGroupName` dimensions accordingly in the agent configuration of each instance.

- For the `order-processing` application instances, set `ProcessGroupName=order-processing`.
- For the `inventory-management` application instances, set `ProcessGroupName=inventory-management`.

When you follow these guidelines, the solution dashboard will automatically group the metrics based on the `ProcessGroupName` dimension. The dashboard will include dropdown options to select and view metrics for a specific process group, allowing you to monitor the performance of individual process groups separately.

Agent configuration for JVM hosts

Use the following CloudWatch agent configuration on EC2 instances where your Java applications is deployed. Configuration will be stored as a parameter in SSM's Parameter Store, as detailed later in Step 2: Store the recommended CloudWatch agent configuration file in Systems Manager Parameter Store.

Replace *`ProcessGroupName`* with the name of your process group. Replace *`port-number`* with the JMX port of your Java application. If JMX was enabled with password authentication or SSL

for remote access, see Collect Java Management Extensions (JMX) metrics for information about setting up TLS or authorization in agent configuration as required.

The EC2 metrics shown in this configuration (configuration shown outside the JMX block) only work for Linux and macOS instances. If you are using Windows instances, you can choose to omit these metrics in the configuration. For information about metrics collected on Windows instances, see Metrics collected by the CloudWatch agent on Windows Server instances.

        ]
      }
    }
  }
}
```

Deploy the agent for your solution

There are several approaches for installing the CloudWatch agent, depending on the use case. We recommend using Systems Manager for this solution. It provides a console experience and makes it simpler to manage a fleet of managed servers within a single AWS account. The instructions in this section use Systems Manager and are intended for when you don't have the CloudWatch agent running with existing configurations. You can check whether the CloudWatch agent is running by following the steps in Verify that the CloudWatch agent is running.

If you are already running the CloudWatch agent on the EC2 hosts where the workload is deployed and managing the agent configurations, you can skip the instructions in this section and follow your existing deployment mechanism to update the configuration. Be sure to merge the agent configuration of JVM with your existing agent configuration, and then deploy the merged configuration. If you are using Systems Manager to store and manage the configuration for the CloudWatch agent, you can merge the configuration to the existing parameter value. For more information, see Managing CloudWatch agent configuration files.

> **Note**
>
> Using Systems Manager to deploy the following CloudWatch agent configurations will replace or overwrite any existing CloudWatch agent configuration on your EC2 instances.

You can modify this configuration to suit your unique environment or use case. The metrics defined in this solution are the minimum required for the recommended dashboard.

The deployment process includes the following steps:

- Step 1: Ensure that the target EC2 instances have the required IAM permissions.
- Step 2: Store the recommended agent configuration file in the Systems Manager Parameter Store.
- Step 3: Install the CloudWatch agent on one or more EC2 instances using an CloudFormation stack.
- Step 4: Verify the agent setup is configured properly.

Step 1: Ensure the target EC2 instances have the required IAM permissions

You must grant permission for Systems Manager to install and configure the CloudWatch agent. You must also grant permission for the CloudWatch agent to publish telemetry from your EC2 instance to CloudWatch. Make sure that the IAM role attached to the instance has the **CloudWatchAgentServerPolicy** and **AmazonSSMManagedInstanceCore** IAM policies attached.

- After the role is created, attach the role to your EC2 instances. Follow the steps in Launch an instance with an IAM role to attach a role while launching a new EC2 instance. To attach a role to an existing EC2 instance, follow the steps in Attach an IAM role to an instance.

Step 2: Store the recommended CloudWatch agent configuration file in Systems Manager Parameter Store

Parameter Store simplifies the installation of the CloudWatch agent on an EC2 instance by securely storing and managing configuration parameters, eliminating the need for hard-coded values. This ensures a more secure and flexible deployment process, enabling centralized management and easier updates to configurations across multiple instances.

Use the following steps to store the recommended CloudWatch agent configuration file as a parameter in Parameter Store.

To create the CloudWatch agent configuration file as a parameter

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. From the navigation pane, choose **Application Management**, **Parameter Store**.
3. Follow these steps to create a new parameter for the configuration.
   a. Choose **Create parameter**.
   b. In the **Name** box, enter a name that you'll use to reference the CloudWatch agent configuration file in later steps. For example, **`AmazonCloudWatch-JVM-Configuration`**.
   c. (Optional) In the **Description** box, type a description for the parameter.
   d. For **Parameter tier**, choose **Standard**.
   e. For **Type**, choose **String**.
   f. For **Data type**, choose **text**.
   g. In the **Value** box, paste the corresponding JSON block that was listed in Agent configuration for JVM hosts. Be sure to customize the grouping dimension value and port number as described.
   h. Choose **Create parameter**.

Step 3: Install the CloudWatch agent and apply the configuration using an CloudFormation template

You can use AWS CloudFormation to install the agent and configure it to use the CloudWatch agent configuration that you created in the previous steps.

To install and configure the CloudWatch agent for this solution

1. Open the CloudFormation **Quick create stack** wizard using this link: https://console.aws.amazon.com/cloudformation/home?#/stacks/quickcreate?templateURL=https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/CloudWatchAgent/CFN/v1.0.0/cw-agent-installation-template-1.0.0.json .
2. Verify that the selected Region on the console is the Region where the JVM workload is running.
3. For **Stack name**, enter a name to identity this stack, such as **`CWAgentInstallationStack`**.

4. In the **Parameters** section, specify the following:

   a. For **CloudWatchAgentConfigSSM**, enter the name of the Systems Manager parameter for the agent configuration that you created earlier, such as **`AmazonCloudWatch-JVM-Configuration`**.

   b. To select the target instances, you have two options.

      i. For **InstanceIds**, specify a comma-delimited list of instance IDs list of instance IDs where you want to install the CloudWatch agent with this configuration. You can list a single instance or several instances.

      ii. If you are deploying at scale, you can specify the **TagKey** and the corresponding **TagValue** to target all EC2 instances with this tag and value. If you specify a **TagKey**, you must specify a corresponding **TagValue**. (For an Auto Scaling group, specify **`aws:autoscaling:groupName`** for the **TagKey** and specify the Auto Scaling group name for the **TagValue** to deploy to all instances within the Auto Scaling group.)

      If you specify both the **InstanceIds** and the **TagKeys** parameters, the **InstanceIds** will take precedence and the tags will be ignored.

5. Review the settings, then choose **Create stack**.

If you want to edit the template file first to customize it, choose the **Upload a template file** option under **Create Stack Wizard** to upload the edited template. For more information, see Creating a stack on CloudFormation console. You can use the following link to download the template: https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/CloudWatchAgent/CFN/v1.0.0/cw-agent-installation-template-1.0.0.json .

> **Note**
>
> After this step is completed, this Systems Manager parameter will be associated with the CloudWatch agents running in the targeted instances. This means that:
>
> 1. If the Systems Manager parameter is deleted, the agent will stop.
> 2. If the Systems Manager parameter is edited, the configuration changes will automatically apply to the agent at the scheduled frequency which is 30 days by default.

3. If you want to immediately apply changes to this Systems Manager parameter, you must run this step again. For more information about associations, see Working with associations in Systems Manager.

Step 4: Verify the agent setup is configured properly

You can verify whether the CloudWatch agent is installed by following the steps in Verify that the CloudWatch agent is running. If the CloudWatch agent is not installed and running, make sure you have set up everything correctly.

- Be sure you have attached a role with correct permissions for the EC2 instance as described in Step 1: Ensure the target EC2 instances have the required IAM permissions.
- Be sure you have correctly configured the JSON for the Systems Manager parameter. Follow the steps in Troubleshooting installation of the CloudWatch agent with CloudFormation.

If everything is set up correctly, then you should see the JVM metrics being published to CloudWatch. You can check the CloudWatch console to verify they are being published.

To verify that JVM metrics are being published to CloudWatch

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Choose **Metrics**, **Classic metrics**.
3. Make sure you've selected the Region where you deployed the solution, and choose **Custom namespaces**, **CWAgent**.
4. Search for the metrics mentioned in Agent configuration for JVM hosts, such as `jvm.memory.heap.used`. If you see results for these metrics, then the metrics are being published to CloudWatch.

Create the JVM solution dashboard

The dashboard provided by this solution presents metrics for the underlying Java Virtual Machine (JVM) for the server. It offers an overview of the JVM by aggregating and presenting metrics across all instances, providing a high-level summary of the overall health and operational state. Additionally, the dashboard shows a breakdown of the top contributors (top 10 per metric widget)

for each metric. This helps you to quickly identify outliers or instances that significantly contribute to the observed metrics.

The solution dashboard doesn't display EC2 metrics. To view EC2 metrics, you'll need to use the EC2 automatic dashboard to see EC2 vended metrics and use the EC2 console dashboard to see EC2 metrics that are collected by the CloudWatch agent. For more information about automatic dashboards for AWS services, see Viewing a CloudWatch dashboard for a single AWS service.

To create the dashboard, you can use the following options:

- Use CloudWatch console to create the dashboard.
- Use AWS CloudFormation console to deploy the dashboard.
- Download the AWS CloudFormation infrastructure as code and integrate it as part of your continuous integration (CI) automation.

By using the CloudWatch console to create a dashboard, you can preview the dashboard before actually creating and being charged.

> **Note**
>
> The dashboard created with CloudFormation in this solution displays metrics from the Region where the solution is deployed. Be sure to create the CloudFormation stack in the Region where your JVM metrics are published.
> If CloudWatch agent metrics are getting published to a different namespace than `CWAgent` (for example, if you've provided a customized namespace), you'll have to change the CloudFormation configuration to replace `CWAgent` with the customized namespace you are using.

To create the dashboard via CloudWatch Console

> **Note**
>
> Solution dashboards currently display garbage collection-related metrics only for the G1 Garbage Collector, which is the default collector for the latest Java versions. If you are using a different garbage collection algorithm, the widgets pertaining to garbage collection are empty. However, you can customize these widgets by changing the dashboard CloudFormation template and applying the appropriate garbage

collection type to the name dimension of the garbage collection-related metrics. For example, if you are using parallel garbage collection, change the **`name=\"G1 Young Generation\"`** to **`name=\"Parallel GC\"`** of the garbage collection count metric `jvm.gc.collections.count`.

1. Open the CloudWatch Console **Create Dashboard** using this link: https://console.aws.amazon.com/cloudwatch/home?#dashboards?dashboardTemplate=JvmOnEc2&referrer=os-catalog .
2. Verify that the selected Region on the console is the Region where the JVM workload is running.
3. Enter the name of the dashboard, then choose **Create Dashboard**.

   To easily differentiate this dashboard from similar dashboards in other Regions, we recommend including the Region name in the dashboard name, such as **`JVMDashboard-us-east-1`**.
4. Preview the dashboard and choose **Save** to create the dashboard.

To create the dashboard via CloudFormation

1. Open the CloudFormation **Quick create stack** wizard using this link: https://console.aws.amazon.com/cloudformation/home?#/stacks/quickcreate?templateURL=https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/JVM_EC2/CloudWatch/CFN/v1.0.0/dashboard-template-1.0.0.json .
2. Verify that the selected Region on the console is the Region where the JVM workload is running.
3. For **Stack name**, enter a name to identity this stack, such as **`JVMDashboardStack`**.
4. In the **Parameters** section, specify the name of the dashboard under the **DashboardName** parameter.

   To easily differentiate this dashboard from similar dashboards in other Regions, we recommend including the Region name in the dashboard name, such as **`JVMDashboard-us-east-1`**.
5. Acknowledge access capabilities for transforms under **Capabilities and transforms**. Note that CloudFormation doesn't add any IAM resources.
6. Review the settings, then choose **Create stack**.

7. After the stack status is **CREATE_COMPLETE**, choose the **Resources** tab under the created stack and then choose the link under **Physical ID** to go to the dashboard. You can also access the dashboard in the CloudWatch console by choosing **Dashboards** in the left navigation pane of the console, and finding the dashboard name under **Custom Dashboards**.

If you want to edit the template file to customize it for any purpose, you can use **Upload a template file** option under **Create Stack Wizard** to upload the edited template. For more information, see Creating a stack on CloudFormation console. You can use this link to download the template: https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/JVM_EC2/CloudWatch/CFN/v1.0.0/dashboard-template-1.0.0.json.

> **Note**
>
> Solution dashboards currently display garbage collection-related metrics only for the G1 Garbage Collector, which is the default collector for the latest Java versions. If you are using a different garbage collection algorithm, the widgets pertaining to garbage collection are empty. However, you can customize these widgets by changing the dashboard CloudFormation template and applying the appropriate garbage collection type to the name dimension of the garbage collection-related metrics. For example, if you are using parallel garbage collection, change the **`name=\"G1 Young Generation\"`** to **`name=\"Parallel GC\"`** of the garbage collection count metric `jvm.gc.collections.count`.

Get started with the JVM dashboard

Here are a few tasks that you can try out with the new JVM dashboard. These tasks allow you to validate that the dashboard is working correctly and provide you some hands-on experience using it to monitor a JVM process group. As you try these out, you'll get familiar with navigating the dashboard and interpreting the visualized metrics.

Select a process group

Use the **JVM Process Group Name** dropdown list to select the process group that you want to monitor. The dashboard automatically updates to display metrics for the selected process group. If you have multiple Java applications or environments, each might be represented as a separate process group. Selecting the appropriate process group ensures that you're viewing metrics specific to the application or environment that you want to analyze.

Review memory usage

From the dashboard overview section, find the **Heap Memory Usage Percentage** and **Non-Heap Memory Usage Percentage** widgets. These show the percentage of heap and non-heap memory being used across all JVMs in the selected process group. A high percentage indicates potential memory pressure that could lead to performance issues or `OutOfMemoryError` exceptions. You can also drill down to heap usage by host under **Memory usage by host** to check the hosts with high usage.

Analyze threads and classes loaded

In the **Threads and Classes Loaded by Host** section, find the **Top 10 Threads Count** and **Top 10 Classes Loaded** widgets. Look for any JVMs with an abnormally high number of threads or classes compared to others. Too many threads can indicate thread leaks or excessive concurrency, while a large number of loaded classes could point to potential class loader leaks or inefficient dynamic class generation.

Identify garbage collection issues

In the **Garbage Collection** section, find the **Top 10 Garbage Collections Invocations Per Minute** and **Top 10 Garbage Collection Duration** widgets for the different garbage collector types: **Young**, **Concurrent**, and **Mixed**. Look for any JVMs that have an unusually high number of collections or long collection durations compared to others. This could indicate configuration issues or memory leaks.

CloudWatch solution: NGINX workload on Amazon EC2

This solution helps you configure out-of-the-box metric collection using CloudWatch agents for NGINX application running on EC2 instances. For general information about all CloudWatch observability solutions, see CloudWatch observability solutions.

Topics

- Requirements
- Benefits
- Costs
- CloudWatch agent configuration for this solution
- Deploy the agent for your solution
- Create the NGINX solution dashboard

Requirements

This solution is relevant for the following conditions:

- Supported versions: NGINX version 1.24
- Compute: Amazon EC2
- Supports up to 500 EC2 instances across all NGINX workloads in a given AWS Region
- Latest version of CloudWatch agent
- Prometheus Exporter: nginxinc/nginx-prometheus-exporter (Apache 2.0 license)
- SSM agent installed on EC2 instance

> **Note**
>
> AWS Systems Manager (SSM agent) is pre-installed on some Amazon Machine Images (AMIs) provided by AWS and trusted third-parties. If the agent isn't installed, you can install it manually using the procedure for your operating system type.
>
> - Manually installing and uninstalling SSM Agent on EC2 instances for Linux
> - Manually installing and uninstalling SSM Agent on EC2 instances for macOS
> - Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server

Benefits

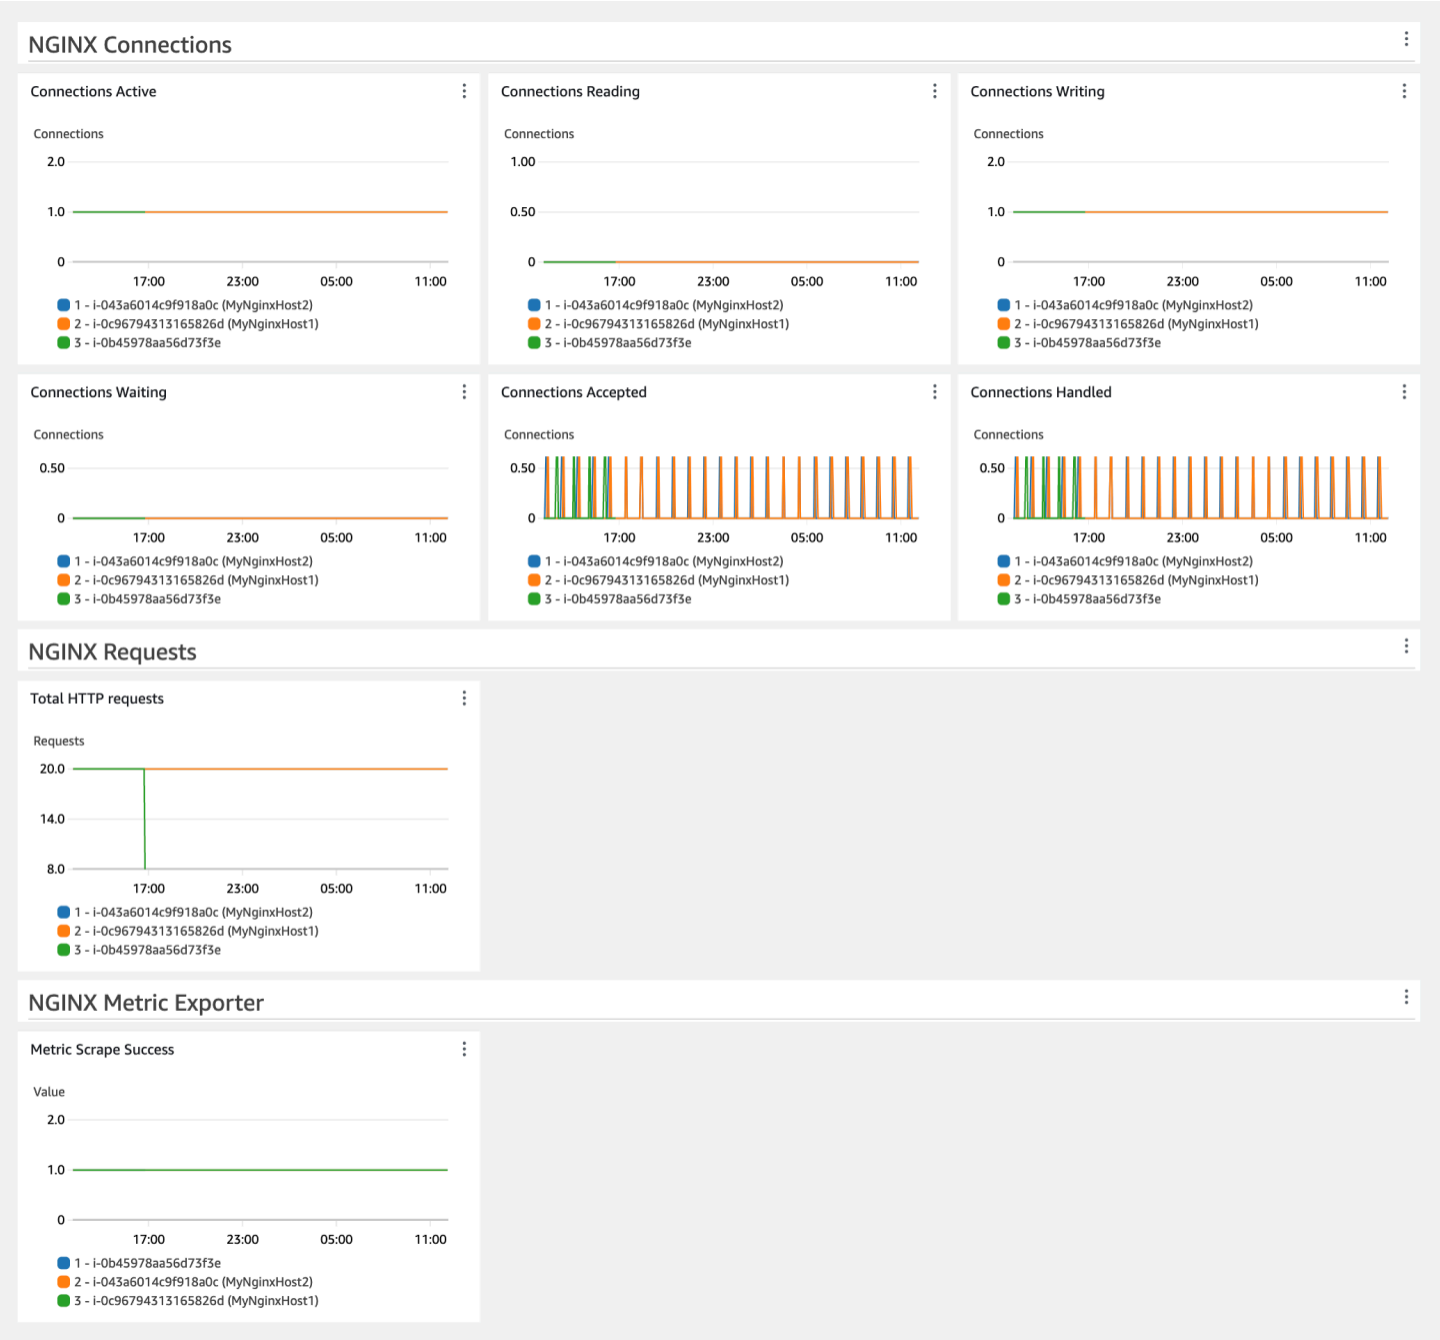
The solution delivers NGINX monitoring, providing valuable insights for the following use cases:

- Review connection metrics to identify potential bottlenecks, connection issues, or unexpected usage.
- Analyze HTTP request volume to understand overall traffic load on the NGINX.

Below are the key advantages of the solution:

- Automates metric collection for NGINX using CloudWatch agent configuration, eliminating manual instrumentation.
- Provides a pre-configured, consolidated CloudWatch dashboard for NGINX metrics. The dashboard will automatically handle metrics from new NGINX EC2 instances configured using the solution, even if those metrics don't exist when you first create the dashboard.

The following image is an example of the dashboard for this solution.



Costs

This solution creates and uses resources in your account. You are charged for standard usage, including the following:

- All metrics collected by the CloudWatch agent for this solution are published to CloudWatch Logs using the Embedded Metric Format (EMF). These CloudWatch logs are charged based on

their volume and retention period. Therefore, you will not be billed for any **PutMetricData** API calls for this solution. The metrics extracted and ingested from your logs are charged as custom metrics. The number of metrics used by this solution depends on the number of EC2 hosts.

  - Each NGINX EC2 host configured for the solution publishes a total of eight metrics.
- One custom dashboard.

For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

The pricing calculator can help you estimate approximate monthly costs for using this solution.

To use the pricing calculator to estimate your monthly solution costs

1. Open the Amazon CloudWatch pricing calculator.
2. For **Choose a Region**, select the AWS Region where you would like to deploy the solution.
3. In the **Metrics** section, for **Number of metrics**, enter **`8 * number of EC2 instances configured for this solution`**.
4. In the **Logs** section, for **Standard Logs: Data Ingested**, enter the estimated daily log volume generated by the CloudWatch Agent across all EC2 hosts. For example, five EC2 instances produce less than 1000 bytes per day. Once set up, you can check your byte usage using the `IncomingBytes` metric, vended by CloudWatch Logs. Be sure to select the appropriate log group.
5. In the **Logs** section, for **Log Storage/Archival (Standard and Vended Logs)**, select **`Yes to Store Logs: Assuming 1 month retention`**. Modify this value if you decide to make custom changes to the retention period.
6. In the **Dashboards and Alarms** section, for **Number of Dashboards**, enter **1**.
7. You can see your monthly estimated costs at the bottom of the pricing calculator.

CloudWatch agent configuration for this solution

The CloudWatch agent is software that runs continuously and autonomously on your servers and in containerized environments. It collects metrics, logs, and traces from your infrastructure and applications and sends them to CloudWatch and X-Ray.

For more information about the CloudWatch agent, see Collect metrics, logs, and traces using the CloudWatch agent.

The agent configuration in this solution collects a set of metrics to help you get started monitoring and observing your NGINX workload. The CloudWatch agent can be configured to collect more NGINX metrics than the dashboard displays by default. For a list of all NGINX metrics that you can collect, see Metrics for NGINX OSS.

Before configuring the CloudWatch agent, you must first configure NGINX to expose its metrics. Secondly, you must install and configure the third party Prometheus metric exporter.

Expose NGINX metrics

> **Note**
>
> The following commands are for Linux. Check NGINX for Windows page for equivalent commands in Windows Server.

You must first enable the `stub_status` module. Add a new location block in your NGINX configuration file. Add the following lines in the `server` block of your `nginx.conf` to enable NGINX's `stub_status` module:

```
location /nginx_status {
          stub_status on;
          allow 127.0.0.1; # Allow only localhost to access
          deny all; # Deny all other IPs
        }
```

Before reloading NGINX, validate your NGINX configuration:

```
sudo nginx -t
```

This validation command helps to prevent any unforeseen errors, which can cause your website to gown down. The following example demonstrates a successful response:

```
nginx: the configuration file /etc/nginx/nginx.conf syntax is ok
nginx: configuration file /etc/nginx/nginx.conf test is successful
```

Once you've successfully validated the updated configuration, reload NGINX (no output is expected):

```
sudo systemctl reload nginx
```

This command instructs the NGINX process to reload the configuration. Reloads are more graceful compared to a full restart. A reload starts the new worker process with a new configuration, gracefully shutting down old worker processes.

Test the NGINX status endpoint:

```
curl http://127.0.0.1/nginx_status
```

The following example demonstrates a successful response:

```
Active connections: 1
server accepts handled requests
6 6 6
Reading: 0 Writing: 1 Waiting: 0
```

The following example demonstrates a failure response (review the previous steps before proceeding):

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.1//EN" "http://www.w3.org/TR/xhtml11/DTD/
xhtml11.dtd">
  <html xmlns="http://www.w3.org/1999/xhtml" xml:lang="en">
      <head>
          <title>The page is not found</title>
          ...
```

Configure Prometheus metric exporter

Download the latest NGINX Prometheus exporter release from the official GitHub repository. You must download the relevant binary for your platform.

The following example demonstrates commands for AMD64:

```
cd /tmp
wget https://github.com/nginxinc/nginx-prometheus-exporter/releases/download/v1.3.0/
nginx-prometheus-exporter_1.3.0_linux_amd64.tar.gz
tar -xzvf nginx-prometheus-exporter_1.3.0_linux_amd64.tar.gz
sudo cp nginx-prometheus-exporter /usr/local/bin/
rm /tmp/nginx-prometheus-exporter*
```

Run the Prometheus exporter and point it to the NGINX stub status page:

```
nohup /usr/local/bin/nginx-prometheus-exporter -nginx.scrape-uri http://127.0.0.1/
nginx_status &>/dev/null &
```

The following example demonstrates a response (background job ID and PID):

```
[1] 74699
```

Test the NGINX Prometheus endpoint

Validate that the NGINX Prometheus exporter has started to expose the relevant metrics:

```
curl http://localhost:port-number/metrics
```

The following example demonstrates a successful response:

```
# HELP go_gc_duration_seconds A summary of the pause duration of garbage collection
 cycles.
# TYPE go_gc_duration_seconds summary
go_gc_duration_seconds{quantile="0"} 0
go_gc_duration_seconds{quantile="0.25"} 0
...
# HELP nginx_connections_accepted Accepted client connections
# TYPE nginx_connections_accepted counter
nginx_connections_accepted 14
# HELP nginx_connections_active Active client connections
# TYPE nginx_connections_active gauge
nginx_connections_active 1
...
# TYPE promhttp_metric_handler_requests_total counter
promhttp_metric_handler_requests_total{code="200"} 1
promhttp_metric_handler_requests_total{code="500"} 0
promhttp_metric_handler_requests_total{code="503"} 0
```

Agent configuration for this solution

The metrics collected by the agent are defined in the agent configuration. The solution provides agent configurations to collect the recommended metrics with suitable dimensions for the solution's dashboard.

The steps for deploying the solution are described later in Deploy the agent for your solution. The following information is intended to help you understand how to customize the agent configuration for your environment.

You must customize some parts of the agent and Prometheus configurations for your environment such as the port number used by the Prometheus exporter.

The port used by the Prometheus exporter can be verified using the following command:

```
sudo netstat -antp | grep nginx-prom
```

The following example demonstrates a response (see port value 9113):

```
tcp6 0 0 :::9113 :::* LISTEN 76398/nginx-prometh
```

Agent configuration for NGINX hosts

The CloudWatch agent with Prometheus monitoring needs two configurations to scrape the Prometheus metrics. Each configuration will be stored as a separate parameter in SSM's Parameter Store, as detailed later in Step 2: Store the recommended CloudWatch agent configuration file in Systems Manager Parameter Store.

The first configuration is for the Prometheus exporter, as documented in Prometheus' scrape_config documentation. The second configuration is for the CloudWatch agent.

Prometheus configuration

Replace *port-number* with the port of your server.

```
global:
  scrape_interval: 30s
  scrape_timeout: 10s

scrape_configs:
- job_name: 'nginx'
  metrics_path: /metrics
  static_configs:
    - targets: ['localhost:port-number']
  ec2_sd_configs:
    - port: port-number
  relabel_configs:
    - source_labels: ['__meta_ec2_instance_id']
```

```
      target_label: InstanceId
  metric_relabel_configs:
    - source_labels: ['__name__']
      regex: 'nginx_up|nginx_http_requests_total|nginx_connections_.*'
      action: keep
```

CloudWatch agent configuration

As per the previous CloudWatch agent configuration, these metrics are published via CloudWatch Logs using the embedded metric format (EMF). These logs are configured to use the log group `nginx`. You can customize the *`log_group_name`* with a different name that represents the CloudWatch logs.

If you are using Windows Server, set *`prometheus_config_path`* in the following configuration to `C:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\\prometheus.yaml`.

```
{
"agent": {
  "metrics_collection_interval": 60
},
"logs": {
  "metrics_collected": {
      "prometheus": {
          "log_group_name": "nginx",
          "prometheus_config_path": "/opt/aws/amazon-cloudwatch-agent/etc/
prometheus.yaml",
          "emf_processor": {
              "metric_declaration_dedup": true,
              "metric_namespace": "CWAgent",
              "metric_declaration":[
                  {
                      "source_labels":["InstanceId"],
                      "metric_selectors":["nginx_up", "nginx_http_requests_total",
 "nginx_connections*"],
                      "dimensions": [["InstanceId"]]
                  }
              ]
          }
      }
  }
}
}
```

Deploy the agent for your solution

There are several approaches for installing the CloudWatch agent, depending on the use case. We recommend using Systems Manager for this solution. It provides a console experience and makes it simpler to manage a fleet of managed servers within a single AWS account. The instructions in this section use Systems Manager and are intended for when you don't have the CloudWatch agent running with existing configurations. You can check whether the CloudWatch agent is running by following the steps in Verify that the CloudWatch agent is running.

If you are already running the CloudWatch agent on the EC2 hosts where the workload is deployed and managing agent configurations, you can skip the instructions in this section and follow your existing deployment mechanism to update the configuration. Be sure to merge new CloudWatch agent and Prometheus configurations with your existing configurations, and then deploy the merged configurations. If you are using Systems Manager to store and manage the configuration for the CloudWatch agent, you can merge the configuration to the existing parameter value. For more information, see Managing CloudWatch agent configuration files.

> **Note**
>
> Using Systems Manager to deploy the following CloudWatch agent configurations will replace or overwrite any existing CloudWatch agent configuration on your EC2 instances. You can modify this configuration to suit your unique environment or use case. The metrics defined in configuration are the minimum required for the dashboard provided the solution.

The deployment process includes the following steps:

- Step 1: Ensure that the target EC2 instances have the required IAM permissions.
- Step 2: Store the recommended agent configuration file in the Systems Manager Parameter Store.
- Step 3: Install the CloudWatch agent on one or more EC2 instances using an CloudFormation stack.
- Step 4: Verify the agent setup is configured properly.

Step 1: Ensure the target EC2 instances have the required IAM permissions

You must grant permission for Systems Manager to install and configure the CloudWatch agent. You must grant permission for the CloudWatch agent to publish telemetry from your EC2 instance to CloudWatch. You must also grant the CloudWatch agent EC2 read access. EC2 read access is required for the EC2 InstanceId to be added as a metric dimension. This additional requirement is driven by `prometheus.yaml` as detailed above because it uses `__meta_ec2_instance_id` via EC2 Service Discovery.

Make sure that the IAM role attached to the instance has the **CloudWatchAgentServerPolicy**, **AmazonSSMManagedInstanceCore**, and **AmazonEC2ReadOnlyAccess** IAM policies attached.

- After the role is created, attach the role to your EC2 instances. To attach a role to an EC2 instance, follow the steps in Attach an IAM role to an instance.

Step 2: Store the recommended CloudWatch agent configuration file in Systems Manager Parameter Store

Parameter Store simplifies the installation of the CloudWatch agent on an EC2 instance by securely storing and managing configuration parameters, eliminating the need for hard-coded values. This ensures a more secure and flexible deployment process, enabling centralized management and easier updates to configurations across multiple instances.

Use the following steps to store the recommended CloudWatch agent configuration file as a parameter in Parameter Store.

To create the CloudWatch agent configuration file as a parameter

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. Verify that the selected Region on the console is the Region where NGINX is running.
3. From the navigation pane, choose **Application Management**, **Parameter Store**
4. Follow these steps to create a new parameter for the configuration.

    a. Choose **Create parameter**.

    b. In the **Name** box, enter a name that you'll use to reference the CloudWatch agent configuration file in later steps. For example, **`AmazonCloudWatch-NGINX-CloudWatchAgent-Configuration`**.

c. (Optional) In the **Description** box, type a description for the parameter.

d. For **Parameter tier**, choose **Standard**.

e. For **Type**, choose **String**.

f. For **Data type**, choose **text**.

g. In the **Value** box, paste the corresponding JSON block that was listed in Agent configuration for NGINX hosts. Be sure to customize as required. For example, the relevant `log_group_name`.

h. Choose **Create parameter**.

To create the Prometheus configuration file as a parameter

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. From the navigation pane, choose **Application Management**, **Parameter Store**
3. Follow these steps to create a new parameter for the configuration.

   a. Choose **Create parameter**.

   b. In the **Name** box, enter a name that you'll use to reference the configuration file in later steps. For example, **`AmazonCloudWatch-NGINX-Prometheus-Configuration`**.

   c. (Optional) In the **Description** box, type a description for the parameter.

   d. For **Parameter tier**, choose **Standard**.

   e. For **Type**, choose **String**.

   f. For **Data type**, choose **text**.

   g. In the **Value** box, paste the corresponding YAML block that was listed in the Agent configuration for NGINX hosts. Be sure to customize as required. For example, the relevant port number as per `targets`.

   h. Choose **Create parameter**.

Step 3: Install the CloudWatch agent and apply the configuration using an CloudFormation template

You can use AWS CloudFormation to install the agent and configure it to use the CloudWatch agent configuration that you created in the previous steps.

To install and configure the CloudWatch agent for this solution

1. Open the CloudFormation **Quick create stack** wizard using this link: https://console.aws.amazon.com/cloudformation/home?#/stacks/quickcreate?templateURL=https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/CloudWatchAgent/CFN/v1.0.0/cw-agent-installation-template-with-prometheus-config-1.0.0.json .
2. Verify that the selected Region on the console is the Region where the NGINX workload is running.
3. For **Stack name**, enter a name to identity this stack, such as **`CWAgentInstallationStack`**.
4. In the **Parameters** section, specify the following:
   a. For **CloudWatchAgentConfigSSM**, enter the name of the AWS Systems Manager parameter for the agent configuration that you created earlier, such as **`AmazonCloudWatch-NGINX-CloudWatchAgent-Configuration`**.
   b. For **PrometheusConfigSSM**, enter the name of the AWS Systems Manager parameter for the agent configuration that you created earlier, such as **`AmazonCloudWatch-NGINX-Prometheus-Configuration`**.
   c. To select the target instances, you have two options.
      i. For **InstanceIds**, specify a comma-delimited list of instance IDs list of instance IDs where you want to install the CloudWatch agent with this configuration. You can list a single instance or several instances.
      ii. If you are deploying at scale, you can specify the **TagKey** and the corresponding **TagValue** to target all EC2 instances with this tag and value. If you specify a **TagKey**, you must specify a corresponding **TagValue**. (For an Auto Scaling group, specify **`aws:autoscaling:groupName`** for the **TagKey** and specify the Auto Scaling group name for the **TagValue** to deploy to all instances within the Auto Scaling group.)
5. Review the settings, then choose **Create stack**.

If you want to edit the template file first to customize it, choose the **Upload a template file** option under **Create Stack Wizard** to upload the edited template. For more information, see Creating a stack on CloudFormation console. You can use the following link to download the template: https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/CloudWatchAgent/CFN/v1.0.0/cw-agent-installation-template-with-prometheus-config-1.0.0.json.

Note

After this step is completed, this Systems Manager parameter will be associated with the CloudWatch agents running in the targeted instances. This means that:

1. If the Systems Manager parameter is deleted, the agent will stop.
2. If the Systems Manager parameter is edited, the configuration changes will automatically apply to the agent at the scheduled frequency which is 30 days by default.
3. If you want to immediately apply changes to this Systems Manager parameter, you must run this step again. For more information about associations, see Working with associations in Systems Manager.

Step 4: Verify the agent setup is configured properly

You can verify whether the CloudWatch agent is installed by following the steps in Verify that the CloudWatch agent is running. If the CloudWatch agent is not installed and running, make sure you have set up everything correctly.

- Be sure you have attached a role with correct permissions for the EC2 instance as described in Step 1: Ensure the target EC2 instances have the required IAM permissions.
- Be sure you have correctly configured the JSON for the Systems Manager parameter. Follow the steps in Troubleshooting installation of the CloudWatch agent with CloudFormation.

If everything is set up correctly, then you should see the NGINX metrics being published to CloudWatch. You can check the CloudWatch console to verify they are being published.

To verify that NGINX metrics are being published to CloudWatch

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Choose **Metrics**, **Classic metrics**.
3. Make sure you've selected the Region where you deployed the solution, and choose **Custom namespaces**, **CWAgent**.
4. Search for metrics such as `nginx_http_requests_total`. If you see results for these metrics, then the metrics are being published to CloudWatch.

Create the NGINX solution dashboard

The dashboard provided by this solution presents NGINX workload metrics by aggregating and presenting metrics across all instances. The dashboard shows a breakdown of the top contributors (top 10 per metric widget) for each metric. This helps you to quickly identify outliers or instances that significantly contribute to the observed metrics.

To create the dashboard, you can use the following options:

- Use CloudWatch console to create the dashboard.
- Use AWS CloudFormation console to deploy the dashboard.
- Download the AWS CloudFormation infrastructure as code and integrate it as part of your continuous integration (CI) automation.

By using the CloudWatch console to create a dashboard, you can preview the dashboard before actually creating and being charged.

> **Note**
>
> The dashboard created with CloudFormation in this solution displays metrics from the Region where the solution is deployed. Be sure to create the CloudFormation stack in the Region where your NGINX metrics are published.
> If you've specified a custom namespace other than `CWAgent` in the CloudWatch agent configuration, you'll have to change the CloudFormation template for the dashboard to replace `CWAgent` with the customized namespace you are using.

To create the dashboard via CloudWatch Console

1. Open the CloudWatch Console **Create Dashboard** using this link: https://console.aws.amazon.com/cloudwatch/home?#dashboards?dashboardTemplate=NginxOnEc2&referrer=os-catalog .
2. Verify that the selected Region on the console is the Region where the NGINX workload is running.
3. Enter the name of the dashboard, then choose **Create Dashboard**.

To easily differentiate this dashboard from similar dashboards in other Regions, we recommend including the Region name in the dashboard name, such as **`NGINXDashboard-us-east-1`**.

4. Preview the dashboard and choose **Save** to create the dashboard.

To create the dashboard via CloudFormation

1. Open the CloudFormation **Quick create stack** wizard using this link: https://console.aws.amazon.com/cloudformation/home?#/stacks/quickcreate?templateURL=https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/NGINX_EC2/CloudWatch/CFN/v1.0.0/dashboard-template-1.0.0.json .
2. Verify that the selected Region on the console is the Region where the NGINX workload is running.
3. For **Stack name**, enter a name to identity this stack, such as **`NGINXDashboardStack`**.
4. In the **Parameters** section, specify the name of the dashboard under the **DashboardName** parameter.
5. To easily differentiate this dashboard from similar dashboards in other Regions, we recommend including the Region name in the dashboard name, such as **`NGINXDashboard-us-east-1`**.
6. Acknowledge access capabilities for transforms under **Capabilities and transforms**. Note that CloudFormation doesn't add any IAM resources.
7. Review the settings, then choose **Create stack**.
8. After the stack status is **CREATE_COMPLETE**, choose the **Resources** tab under the created stack and then choose the link under **Physical ID** to go to the dashboard. You can also access the dashboard in the CloudWatch console by choosing **Dashboards** in the left navigation pane of the console, and finding the dashboard name under **Custom Dashboards**.

If you want to edit the template file first to customize it, choose the **Upload a template file** option under **Create Stack Wizard** to upload the edited template. For more information, see Creating a stack on CloudFormation console. You can use the following link to download the template: https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/NGINX_EC2/CloudWatch/CFN/v1.0.0/dashboard-template-1.0.0.json.

Get started with the NGINX dashboard

Here are a few tasks that you can try out with the new NGINX dashboard. These tasks allow you to validate that the dashboard is working correctly and provide you some hands-on experience using it to monitor a NGINX workload. As you try these out, you'll get familiar with navigating the dashboard and interpreting the visualized metrics.

Review connection metrics

In the **Connections** section, you can find several key metrics that provide insights into the client connection handling of your NGINX server. Monitoring these connection metrics can help you identify potential bottlenecks, connection issues, or unexpected connection patterns.

- Accepted client connections
- Active client connections
- Handled client connections
- Connections reading requests
- Idle client connections
- Connections writing responses

Analyze HTTP request volume

The `request` metric in the **HTTP Requests** section shows the total number of HTTP requests handled by the NGINX server. Tracking this metric over time can help you understand the overall traffic load on your NGINX infrastructure and plan for resource allocation and scaling accordingly.

CloudWatch solution: NVIDIA GPU workload on Amazon EC2

This solution helps you configure out-of-the-box metric collection using CloudWatch agents for NVIDIA GPU workloads running on EC2 instances. Additionally, it helps you set up a pre-configured CloudWatch dashboard. For general information about all CloudWatch observability solutions, see CloudWatch observability solutions.

Topics

- Requirements
- Benefits
- CloudWatch agent configuration for this solution

- Deploy the agent for your solution
- Create the NVIDIA GPU solution dashboard

Requirements

This solution is relevant for the following conditions:

- Compute: Amazon EC2
- Supports up to 500 GPUs across all EC2 instances in a given AWS Region
- Latest version of CloudWatch agent
- SSM agent installed on EC2 instance
- The EC2 instance must have an NVIDIA driver installed. NVIDIA drivers are pre-installed on some Amazon Machine Images (AMIs). Otherwise, you can manually install the driver. For more information, see Install NVIDIA drivers on Linux instances.

> **Note**
>
> AWS Systems Manager (SSM agent) is pre-installed on some Amazon Machine Images (AMIs) provided by AWS and trusted third-parties. If the agent isn't installed, you can install it manually using the procedure for your operating system type.
>
> - Manually installing and uninstalling SSM Agent on EC2 instances for Linux
> - Manually installing and uninstalling SSM Agent on EC2 instances for macOS
> - Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server

Benefits

The solution delivers NVIDIA monitoring, providing valuable insights for the following use cases:

- Analyze GPU and memory usage for performance bottlenecks or the need for additional resources.
- Monitor temperature and power draw to ensure GPUs operate within safe limits.
- Evaluate encoder performance for GPU video workloads.
- Verify PCIe connectivity for expected generation and width.

- Monitor GPU clock speeds to detect scaling and throttling issues.

Below are the key advantages of the solution:

- Automates metric collection for NVIDIA using CloudWatch agent configuration, eliminating manual instrumentation.
- Provides a pre-configured, consolidated CloudWatch dashboard for NVIDIA metrics. The dashboard will automatically handle metrics from new NVIDIA EC2 instances configured using the solution, even if those metrics don't exist when you first create the dashboard.

The following image is an example of the dashboard for this solution.

Costs

This solution creates and uses resources in your account. You are charged for standard usage, including the following:

- All metrics collected by the CloudWatch agent are charged as custom metrics. The number of metrics used by this solution depends on the number of EC2 hosts.
  - Each EC2 host configured for the solution publishes a total of 17 metrics per GPU.
- One custom dashboard.
- API operations requested by the CloudWatch agent to publish the metrics. With the default configuration for this solution, the CloudWatch agent calls the **PutMetricData** once every minute for each EC2 host. This means the **PutMetricData** API will be called `30*24*60=43,200` in a 30-day month for each EC2 host.

For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

The pricing calculator can help you estimate approximate monthly costs for using this solution.

To use the pricing calculator to estimate your monthly solution costs

1. Open the Amazon CloudWatch pricing calculator.
2. For **Choose a Region**, select the Region where you would like to deploy the solution.
3. In the **Metrics** section, for **Number of metrics**, enter **`17 * average number of GPUs per EC2 host * number of EC2 instances configured for this solution`**.
4. In the **APIs** section, for **Number of API requests**, enter **`43200 * number of EC2 instances configured for this solution`**.
5. By default, the CloudWatch agent performs one **PutMetricData** operation each minute for each EC2 host.
6. In the **Dashboards and Alarms** section, for **Number of Dashboards**, enter **1**.
7. You can see your monthly estimated costs at the bottom of the pricing calculator.

CloudWatch agent configuration for this solution

The CloudWatch agent is software that runs continuously and autonomously on your servers and in containerized environments. It collects metrics, logs, and traces from your infrastructure and applications and sends them to CloudWatch and X-Ray.

For more information about the CloudWatch agent, see Collect metrics, logs, and traces using the CloudWatch agent.

The agent configuration in this solution collects a set of metrics to help you get started monitoring and observing your NVIDIA GPU. The CloudWatch agent can be configured to collect more NVIDIA GPU metrics than the dashboard displays by default. For a list of all NVIDIA GPU metrics that you can collect, see Collect NVIDIA GPU metrics.

Agent configuration for this solution

The metrics collected by the agent are defined in the agent configuration. The solution provides agent configurations to collect the recommended metrics with suitable dimensions for the solution's dashboard.

Use the following CloudWatch agent configuration on EC2 instances with NVIDIA GPUs. Configuration will be stored as a parameter in SSM's Parameter Store, as detailed later in Step 2: Store the recommended CloudWatch agent configuration file in Systems Manager Parameter Store.

```
{
    "metrics": {
        "namespace": "CWAgent",
        "append_dimensions": {
            "InstanceId": "${aws:InstanceId}"
        },
        "metrics_collected": {
            "nvidia_gpu": {
                "measurement": [
                    "utilization_gpu",
                    "temperature_gpu",
                    "power_draw",
                    "utilization_memory",
                    "fan_speed",
                    "memory_total",
                    "memory_used",
                    "memory_free",
                    "pcie_link_gen_current",
                    "pcie_link_width_current",
                    "encoder_stats_session_count",
                    "encoder_stats_average_fps",
                    "encoder_stats_average_latency",
                    "clocks_current_graphics",
                    "clocks_current_sm",
```

```
                    "clocks_current_memory",
                    "clocks_current_video"
                ],
                "metrics_collection_interval": 60
            }
        }
    },
    "force_flush_interval": 60
}
```

Deploy the agent for your solution

There are several approaches for installing the CloudWatch agent, depending on the use case. We recommend using Systems Manager for this solution. It provides a console experience and makes it simpler to manage a fleet of managed servers within a single AWS account. The instructions in this section use Systems Manager and are intended for when you don't have the CloudWatch agent running with existing configurations. You can check whether the CloudWatch agent is running by following the steps in Verify that the CloudWatch agent is running.

If you are already running the CloudWatch agent on the EC2 hosts where the workload is deployed and managing agent configurations, you can skip the instructions in this section and follow your existing deployment mechanism to update the configuration. Be sure to merge the agent configuration of NVIDIA GPU with your existing agent configuration, and then deploy the merged configuration. If you are using Systems Manager to store and manage the configuration for the CloudWatch agent, you can merge the configuration to the existing parameter value. For more information, see Managing CloudWatch agent configuration files.

> **Note**
>
> Using Systems Manager to deploy the following CloudWatch agent configurations will replace or overwrite any existing CloudWatch agent configuration on your EC2 instances. You can modify this configuration to suit your unique environment or use case. The metrics defined in configuration are the minimum required for the dashboard provided the solution.

The deployment process includes the following steps:

- Step 1: Ensure that the target EC2 instances have the required IAM permissions.

- Step 2: Store the recommended agent configuration file in the Systems Manager Parameter Store.
- Step 3: Install the CloudWatch agent on one or more EC2 instances using an CloudFormation stack.
- Step 4: Verify the agent setup is configured properly.

Step 1: Ensure the target EC2 instances have the required IAM permissions

You must grant permission for Systems Manager to install and configure the CloudWatch agent. You must also grant permission for the CloudWatch agent to publish telemetry from your EC2 instance to CloudWatch. Make sure that the IAM role attached to the instance has the **CloudWatchAgentServerPolicy** and **AmazonSSMManagedInstanceCore** IAM policies attached.

- After the role is created, attach the role to your EC2 instances. To attach a role to an EC2 instance, follow the steps in Attach an IAM role to an instance.

Step 2: Store the recommended CloudWatch agent configuration file in Systems Manager Parameter Store

Parameter Store simplifies the installation of the CloudWatch agent on an EC2 instance by securely storing and managing configuration parameters, eliminating the need for hard-coded values. This ensures a more secure and flexible deployment process, enabling centralized management and easier updates to configurations across multiple instances.

Use the following steps to store the recommended CloudWatch agent configuration file as a parameter in Parameter Store.

To create the CloudWatch agent configuration file as a parameter

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. Verify that the selected Region on the console is the Region where the NVIDIA GPU workload is running.
3. From the navigation pane, choose **Application Management**, **Parameter Store**.
4. Follow these steps to create a new parameter for the configuration.

    a. Choose **Create parameter**.

b. In the **Name** box, enter a name that you'll use to reference the CloudWatch agent configuration file in later steps. For example, **`AmazonCloudWatch-NVIDIA-GPU-Configuration`**.

c. (Optional) In the **Description** box, type a description for the parameter.

d. For **Parameter tier**, choose **Standard**.

e. For **Type**, choose **String**.

f. For **Data type**, choose **text**.

g. In the **Value** box, paste the corresponding JSON block that was listed in Agent configuration for this solution.

h. Choose **Create parameter**.

Step 3: Install the CloudWatch agent and apply the configuration using an CloudFormation template

You can use AWS CloudFormation to install the agent and configure it to use the CloudWatch agent configuration that you created in the previous steps.

To install and configure the CloudWatch agent for this solution

1. Open the CloudFormation **Quick create stack** wizard using this link: https://console.aws.amazon.com/cloudformation/home?#/stacks/quickcreate?templateURL=https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/CloudWatchAgent/CFN/v1.0.0/cw-agent-installation-template-1.0.0.json.
2. Verify that the selected Region on the console is the Region where the NVIDIA GPU workload is running.
3. For **Stack name**, enter a name to identity this stack, such as **`CWAgentInstallationStack`**.
4. In the **Parameters** section, specify the following:

   a. For **CloudWatchAgentConfigSSM**, enter the name of the Systems Manager parameter for the agent configuration that you created earlier, such as **`AmazonCloudWatch-NVIDIA-GPU-Configuration`**.

   b. To select the target instances, you have two options.

i. For **InstanceIds**, specify a comma-delimited list of instance IDs list of instance IDs where you want to install the CloudWatch agent with this configuration. You can list a single instance or several instances.

ii. If you are deploying at scale, you can specify the **TagKey** and the corresponding **TagValue** to target all EC2 instances with this tag and value. If you specify a **TagKey**, you must specify a corresponding **TagValue**. (For an Auto Scaling group, specify **`aws:autoscaling:groupName`** for the **TagKey** and specify the Auto Scaling group name for the **TagValue** to deploy to all instances within the Auto Scaling group.)

5. Review the settings, then choose **Create stack**.

If you want to edit the template file first to customize it, choose the **Upload a template file** option under **Create Stack Wizard** to upload the edited template. For more information, see Creating a stack on CloudFormation console.

> **Note**
>
> After this step is completed, this Systems Manager parameter will be associated with the CloudWatch agents running in the targeted instances. This means that:
>
> 1. If the Systems Manager parameter is deleted, the agent will stop.
> 2. If the Systems Manager parameter is edited, the configuration changes will automatically apply to the agent at the scheduled frequency which is 30 days by default.
> 3. If you want to immediately apply changes to this Systems Manager parameter, you must run this step again. For more information about associations, see Working with associations in Systems Manager.

Step 4: Verify the agent setup is configured properly

You can verify whether the CloudWatch agent is installed by following the steps in Verify that the CloudWatch agent is running. If the CloudWatch agent is not installed and running, make sure you have set up everything correctly.

- Be sure you have attached a role with correct permissions for the EC2 instance as described in Step 1: Ensure the target EC2 instances have the required IAM permissions.

- Be sure you have correctly configured the JSON for the Systems Manager parameter. Follow the steps in Troubleshooting installation of the CloudWatch agent with CloudFormation.

If everything is set up correctly, then you should see the NVIDIA GPU metrics being published to CloudWatch. You can check the CloudWatch console to verify they are being published.

To verify that NVIDIA GPU metrics are being published to CloudWatch

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Choose **Metrics**, **Classic metrics**.
3. Make sure you've selected the Region where you deployed the solution, and choose **Custom namespaces**, **CWAgent**.
4. Search for the metrics mentioned in Agent configuration for this solution, such as `nvidia_smi_utilization_gpu`. If you see results for these metrics, then the metrics are being published to CloudWatch.

Create the NVIDIA GPU solution dashboard

The dashboard provided by this solution presents NVIDIA GPUs metrics by aggregating and presenting metrics across all instances. The dashboard shows a breakdown of the top contributors (top 10 per metric widget) for each metric. This helps you to quickly identify outliers or instances that significantly contribute to the observed metrics.

To create the dashboard, you can use the following options:

- Use CloudWatch console to create the dashboard.
- Use AWS CloudFormation console to deploy the dashboard.
- Download the AWS CloudFormation infrastructure as code and integrate it as part of your continuous integration (CI) automation.

By using the CloudWatch console to create a dashboard, you can preview the dashboard before actually creating and being charged.

> **Note**
>
> The dashboard created with CloudFormation in this solution displays metrics from the Region where the solution is deployed. Be sure to create the CloudFormation stack in the Region where your NVIDIA GPU metrics are published.
> If you've specified a custom namespace other than CWAgent in the CloudWatch agent configuration, you'll have to change the CloudFormation template for the dashboard to replace CWAgent with the customized namespace you are using.

To create the dashboard via CloudWatch Console

1. Open the CloudWatch Console **Create Dashboard** using this link: https://console.aws.amazon.com/cloudwatch/home?#dashboards?dashboardTemplate=NvidiaGpuOnEc2&referrer=os-catalog .
2. Verify that the selected Region on the console is the Region where the NVIDIA GPU workload is running.
3. Enter the name of the dashboard, then choose **Create Dashboard**.

   To easily differentiate this dashboard from similar dashboards in other Regions, we recommend including the Region name in the dashboard name, such as **`NVIDIA-GPU-Dashboard-us-east-1`**.
4. Preview the dashboard and choose **Save** to create the dashboard.

To create the dashboard via CloudFormation

1. Open the CloudFormation **Quick create stack** wizard using this link: https://console.aws.amazon.com/cloudformation/home?#/stacks/quickcreate?templateURL=https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/NVIDIA_GPU_EC2/CloudWatch/CFN/v1.0.0/dashboard-template-1.0.0.json.
2. Verify that the selected Region on the console is the Region where the NVIDIA GPU workload is running.
3. For **Stack name**, enter a name to identity this stack, such as **`NVIDIA-GPU-DashboardStack`**.
4. In the **Parameters** section, specify the name of the dashboard under the **DashboardName** parameter.

5. To easily differentiate this dashboard from similar dashboards in other Regions, we recommend including the Region name in the dashboard name, such as **`NVIDIA-GPU-Dashboard-us-east-1`**.
6. Acknowledge access capabilities for transforms under **Capabilities and transforms**. Note that CloudFormation doesn't add any IAM resources.
7. Review the settings, then choose **Create stack**.
8. After the stack status is **CREATE_COMPLETE**, choose the **Resources** tab under the created stack and then choose the link under **Physical ID** to go to the dashboard. You can also access the dashboard in the CloudWatch console by choosing **Dashboards** in the left navigation pane of the console, and finding the dashboard name under **Custom Dashboards**.

If you want to edit the template file to customize it for any purpose, you can use **Upload a template file** option under **Create Stack Wizard** to upload the edited template. For more information, see Creating a stack on CloudFormation console. You can use this link to download the template: https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/NVIDIA_GPU_EC2/CloudWatch/CFN/v1.0.0/dashboard-template-1.0.0.json .

Get started with the NVIDIA GPU dashboard

Here are a few tasks that you can try out with the new NVIDIA GPU dashboard. These tasks allow you to validate that the dashboard is working correctly and provide you some hands-on experience using it to monitor your NVIDIA GPUs. As you try these out, you'll get familiar with navigating the dashboard and interpreting the visualized metrics.

Review GPU utilization

From the **Utilization** section, find the **GPU Utilization** and **Memory Utilization** widgets. These show the percentage of time the GPU is being actively used for computations and the percentage of global memory being read or written, respectively. High utilization could indicate potential performance bottlenecks or the need for additional GPU resources.

Analyze GPU memory usage

In the **Memory** section, find the **Total Memory**, **Used Memory**, and **Free Memory** widgets. These provide insights into the overall memory capacity of the GPUs and how much memory is currently being consumed or available. Memory pressure could lead to performance issues or out-of-memory errors, so it's important to monitor these metrics and ensure sufficient memory is available for your workloads.

Monitor temperature and power draw

In the **Temperature / Power** section, find the **GPU Temperature** and **Power Draw** widgets. These metrics are essential for ensuring that your GPUs are operating within safe thermal and power limits.

Identify encoder performance

In the **Encoder** section, find the **Encoder Session Count**, **Average FPS**, and **Average Latency** widgets. These metrics are relevant if you're running video encoding workloads on your GPUs. Monitor these metrics to ensure that your encoders are performing optimally and identify any potential bottlenecks or performance issues.

Check PCIe link status

In the **PCIe** section, find the **PCIe Link Generation** and **PCIe Link Width** widgets. These metrics provide information about the PCIe link connecting the GPU to the host system. Ensure that the link is operating at the expected generation and width to avoid potential performance limitations due to PCIe bottlenecks.

Review GPU clocks

In the **Clock** section, find the **Graphics Clock**, **SM Clock**, **Memory Clock**, and **Video Clock** widgets. These metrics show the current operating frequencies of various GPU components. Monitoring these clocks can help identify potential issues with GPU clock scaling or frequency throttling, which could impact performance.

CloudWatch solution: Kafka workload on Amazon EC2

This solution helps you configure out-of-the-box metric collection using CloudWatch agents for Kafka workloads (brokers, producers, and consumers) running on EC2 instances. Additionally, it helps you set up a pre-configured CloudWatch dashboard. For general information about all CloudWatch observability solutions, see CloudWatch observability solutions.

Topics

- Requirements
- Benefits
- Costs
- CloudWatch agent configuration for this solution

- Deploy the agent for your solution
- Create the Kafka solution dashboard
- Configure the agent for multiple Kafka roles on the same instance

Requirements

This solution is relevant for the following conditions:

- Workload: Kafka v0.8.2.x and later
- Compute: Amazon EC2
- Supports up to 500 EC2 instances across all Kafka workloads in a given AWS Region
- Latest version of CloudWatch agent
- SSM agent installed on EC2 instance

> **Note**
>
> AWS Systems Manager (SSM agent) is pre-installed on some Amazon Machine Images (AMIs) provided by AWS and trusted third-parties. If the agent isn't installed, you can install it manually using the procedure for your operating system type.
>
> - Manually installing and uninstalling SSM Agent on EC2 instances for Linux
> - Manually installing and uninstalling SSM Agent on EC2 instances for macOS
> - Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server

Benefits

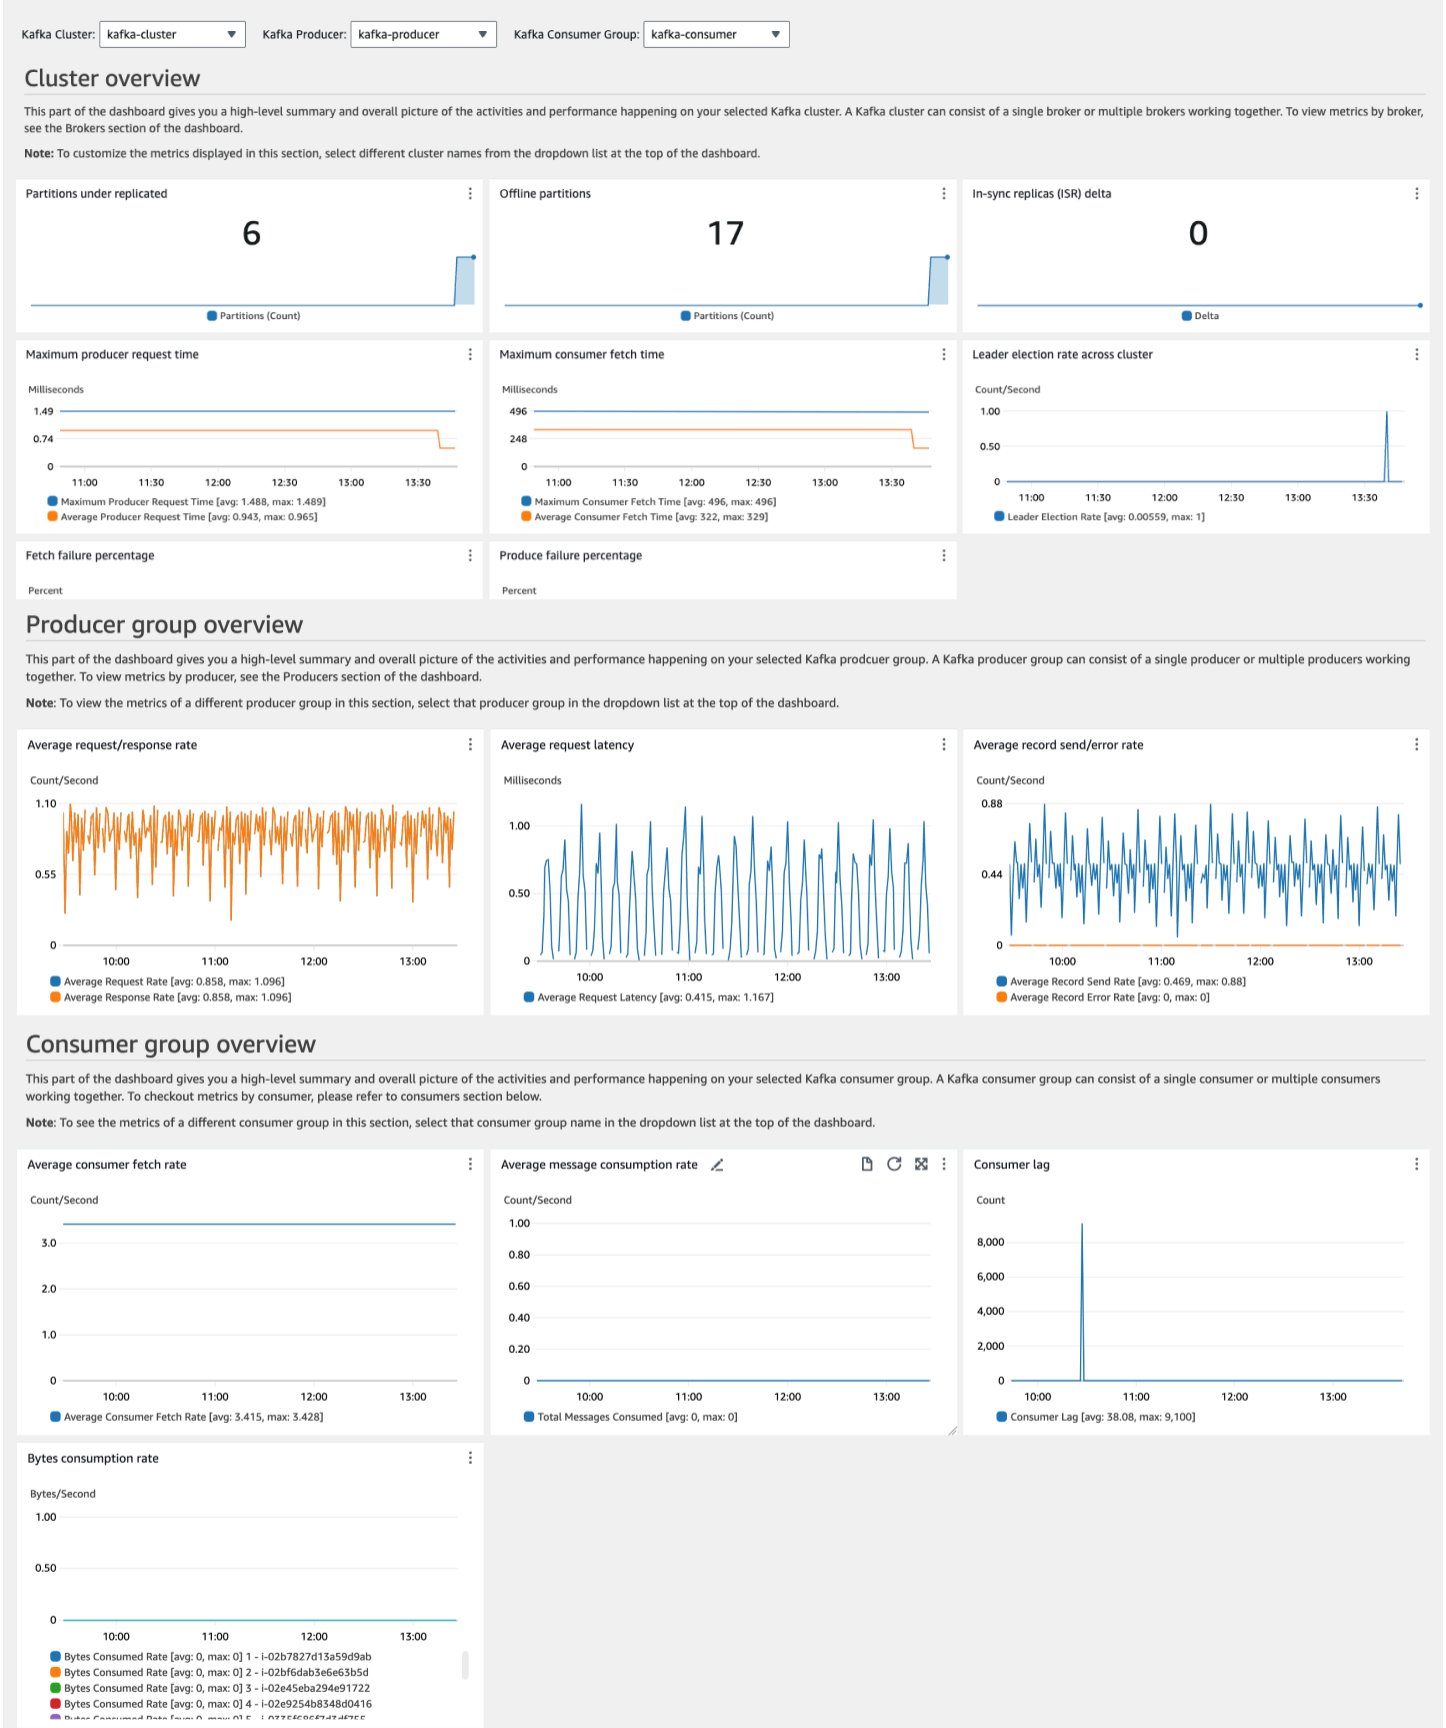
The solution delivers Kafka server monitoring, providing valuable insights for the following use cases:

- Monitor Kafka cluster health via replication and sync metrics.
- Track broker performance through request failures and latencies along with network traffic.
- Monitor producer/consumer errors, latencies, and consumer lag.
- Analyze underlying JVM performance for Kafka clusters.
- Switch between multiple Kafka clusters, producers, and consumers configured via the solution under the same account.

Below are the key advantages of the solution:

- Automates metric collection for Kafka and the underlying JVM using CloudWatch agent configuration, eliminating manual instrumentation.
- Provides a pre-configured, consolidated CloudWatch dashboard for Kafka and JVM metrics. The dashboard will automatically handle metrics from new Kafka EC2 instances configured using the solution, even if those metrics don't exist when you first create the dashboard. It also allows you to group the metrics into logical applications for easier focus and management.

The following image is an example of the dashboard for this solution.



End of preview

Create dashboard to view in full

Costs

This solution creates and uses resources in your account. You are charged for standard usage, including the following:

- All metrics collected by the CloudWatch agent are charged as custom metrics. The number of metrics used by this solution depends on the number of EC2 hosts.
  - Each broker host configured for the solution publishes 33 metrics plus one metric (`disk_used_percent`) for which the metric count for each EC2 host depends on the number of disk paths for that host.
  - Each producer host configured for the solution publishes three metrics with the `topic` dimension and three metrics without the `topic` dimension. For the metrics with the `topic` dimension, each topic counts as a separate metric.
  - Each consumer host configured for the solution publishes two metrics with `topic` dimensions and three metrics without `topic` dimensions. For the metrics with topic dimensions, each topic counts as a separate metric.
- One custom dashboard.
- API operations requested by the CloudWatch agent to publish the metrics. With the default configuration for this solution, the CloudWatch agent calls the **PutMetricData** once every minute for each EC2 host. This means the **PutMetricData** API will be called `30*24*60=43,200` in a 30-day month for each EC2 host.

For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

The pricing calculator can help you estimate approximate monthly costs for using this solution.

To use the pricing calculator to estimate your monthly solution costs

1. Open the Amazon CloudWatch pricing calculator.
2. In the **Metrics** section, for **Number of metrics**, enter **`broker_metrics_count + producer_metrics_count + consumer_metrics_count`**. Calculate these as follows:
   - `broker_metrics_count` = (33 + average number of disk paths per EC2 host) * number_of_ec2_broker_hosts
   - `producer_metrics_count` = (3 * average_number_of_topics_per_producer_host + 3) * number_of_ec2_producer_hosts

- `consumer_metrics_count` = (2 * average_number_of_topics_per_consumer_host + 3) * number_of_ec2_consumer_hosts

3. In the **APIs** section, for **Number of API requests**, enter **`43200 * number of EC2 instances configured for this solution`**.

   By default, the CloudWatch agent performs one **PutMetricData** operation each minute for each EC2 host.

4. In the **Dashboards and Alarms** section, for **Number of Dashboards**, enter **1**.
5. You can see your monthly estimated costs at the bottom of the pricing calculator.

CloudWatch agent configuration for this solution

The CloudWatch agent is software that runs continuously and autonomously on your servers and in containerized environments. It collects metrics, logs, and traces from your infrastructure and applications and sends them to CloudWatch and X-Ray.

For more information about the CloudWatch agent, see Collect metrics, logs, and traces using the CloudWatch agent.

The agent configuration in this solution collects the foundational metrics for Kafka, JVM, and EC2. The CloudWatch agent can be configured to collect more Kafka and JVM metrics than the dashboard displays by default. For a list of all Kafka metrics that you can collect, see Collect Kafka metrics. For a list of all JVM metrics that you can collect, see Collect JVM metrics. For a list of EC2 metrics, see Metrics collected by the CloudWatch agent on Linux and macOS instances.

Expose JMX ports for the Kafka broker, producer, and consumer roles

The CloudWatch agent relies on JMX to collect the metrics related to the Kafka brokers, producers, and consumers. To make this possible, you must expose the JMX port on your servers and applications.

For Kafka brokers, you must use the `JMX_PORT` environment variable to set the port. You'll have to restart the brokers after you set this environment variable. Review the starting scripts and configuration files of your application to find the best place to add these arguments.

For example, for Linux and macOS systems, you can use the following command to set the JMX port. Be sure to specify an unused port number.

```
export JMX_PORT=port-number
```

For Kafka producers and consumers, instructions for exposing the JMX port depend on the workload type you are using for your producer or consumer JVM application. See the documentation for your application to find these instructions.

In general, to enable a JMX port for monitoring and management, you would set the following system properties for your JVM application. The following example sets up unauthenticated JMX. If your security policies/requirements require you to enable JMX with password authentication or SSL for remote access, refer to the JMX documentation to set the required property.

```
-Dcom.sun.management.jmxremote
-Dcom.sun.management.jmxremote.port=port-number
-Dcom.sun.management.jmxremote.authenticate=false
-Dcom.sun.management.jmxremote.ssl=false
```

To verify the JMX port, run `ps aux | grep jmxremote.port`. The results should show that the JMX port was set on the JVM processes.

Agent configuration for this solution

The metrics collected by the agent are defined in the agent configuration. The solution provides agent configurations to collect the recommended metrics with suitable dimensions for the solution's dashboard. Each Kafka role, such as broker, producer, or consumer, has its own agent configuration that enables the collection of Kafka metrics and underlying JVM and EC2 metrics.

The steps for deploying the solution are described later in Deploy the agent for your solution. The following information is intended to help you understand how to customize the agent configuration for your environment.

You must customize some parts of the following agent configuration for your environment:

- The JMX port number is the port number that you configured in the previous section of this documentation. The port number is in the `endpoint` line in the configuration.
- `ClusterName`– This is used as a dimension for broker metrics collected. Provide a meaningful name that represents the cluster grouping for the instances that run the Kafka broker.
- `ProcessGroupName`– This is used as a dimension for JVM metrics collected for brokers. Provide the same value as you provide for `ClusterName`. This enables viewing the JVM metrics of the same Kafka broker group as the broker metrics in the solution dashboard.

- `ProducerGroupName`– This is used as a dimension for producer metrics collected. Provide a meaningful name that represents the group of producer instances. For this value, you can specify your producer application or service that you want to use for a combined view of producer metrics in the solution dashboard.
- `ConsumerGroupName`– This is used as a dimension for consumer metrics collected. Provide a meaningful name that represents the group of consumer instances This is not the same as the consumer group concept in Kafka. This is just a grouping dimension where you can specify your consumer application or service that you want to use for a combined view of consumer metrics in the solution dashboard

For example, if you have two Kafka clusters running in the same account, one for the `order-processing` application and another for the `inventory-management` application, you should set the `ClusterName` and `ProcessGroupName` dimensions accordingly in the agent configuration of the broker instance.

- For the `order-processing` cluster broker instances, set `ClusterName=order-processing` and `ProcessGroupName=order-processing`.
- For the `inventory-management` cluster broker instances, set `ClusterName=inventory-management` and `ProcessGroupName=inventory-management`.
- Similarly, set the `ProducerGroupName` for producer instances and `ConsumerGroupName` for consumer instances based on their respective applications.

When you correctly set the above dimensions, the solution dashboard will automatically group the metrics based on the `ClusterName`, `ProducerGroupName`, and `ConsumerGroupName` dimensions. The dashboard will include dropdown options to select and view metrics for specific clusters and groups, allowing you to monitor the performance of individual clusters and groups separately.

Be sure to deploy the relevant agent configuration to the correct EC2 instances. Each configuration will be stored as a separate Parameter in SSM's Parameter Store, as detailed later in Step 2: Store the recommended CloudWatch agent configuration file in Systems Manager Parameter Store.

The following instructions describe the situation where the producer, consumer, and broker roles are deployed to separate EC2 instances, without any overlap. If you are running multiple Kafka roles on the same EC2 instances, see Configure the agent for multiple Kafka roles on the same instance for more information.

Agent configuration for Kafka broker agents

Use the following CloudWatch agent configuration on EC2 instances where Kafka broker agents are deployed. Replace *ClusterName* with the name of the cluster to use to group these metrics for a unified view. The value you specify for *ClusterName* is used as both the ClusterName dimension and the ProcessGroupName dimension. Replace *port-number* with the JMX port of your Kafka server. If JMX was enabled with password authentication or SSL for remote access, see Collect Java Management Extensions (JMX) metrics for information about setting up TLS or authorization as required.

The EC2 metrics shown in this configuration (configuration shown outside the JMX block) only work for Linux and macOS instances. If you are using Windows instances, you can choose to omit these metrics in the configuration. For information about metrics collected on Windows instances, see Metrics collected by the CloudWatch agent on Windows Server instances.

```
{
  "metrics": {
    "namespace": "CWAgent",
    "append_dimensions": {
      "InstanceId": "${aws:InstanceId}"
    },
    "metrics_collected": {
      "jmx": [
        {
          "endpoint": "localhost:port-number",
          "kafka": {
            "measurement": [
              "kafka.request.time.avg",
              "kafka.request.failed",
              "kafka.request.count",
              "kafka.purgatory.size",
              "kafka.partition.under_replicated",
              "kafka.partition.offline",
              "kafka.network.io",
              "kafka.leader.election.rate",
              "kafka.isr.operation.count"
            ]
          },
          "append_dimensions": {
            "ClusterName": "ClusterName"
          }
        },
```

```
        {
          "endpoint": "localhost:port-number",
          "jvm": {
            "measurement": [
              "jvm.classes.loaded",
              "jvm.gc.collections.count",
              "jvm.gc.collections.elapsed",
              "jvm.memory.heap.committed",
              "jvm.memory.heap.max",
              "jvm.memory.heap.used",
              "jvm.memory.nonheap.committed",
              "jvm.memory.nonheap.max",
              "jvm.memory.nonheap.used",
              "jvm.threads.count"
            ]
          },
          "append_dimensions": {
            "ProcessGroupName": "ClusterName"
          }
        }
      ],
      "disk": {
        "measurement": [
          "used_percent"
        ]
      },
      "mem": {
        "measurement": [
          "used_percent"
        ]
      },
      "swap": {
        "measurement": [
          "used_percent"
        ]
      },
      "netstat": {
        "measurement": [
          "tcp_established",
          "tcp_time_wait"
        ]
      }
    }
  }
```

```
}
```

Agent configuration for Kafka producers

Use the following CloudWatch agent configuration on Amazon EC2 instances where Kafka producers are deployed. Replace *ProducerGroupName* with the name of the application or group that you want to use to group your metrics for a unified view. Replace *port-number* with the JMX port of your Kafka producer application.

The solution doesn't enable JVM metrics for Kafka producers because the solution dashboard doesn't display JVM metrics related to JVM for producers. You can customize the agent configuration to emit JVM metrics as well, however, JVM metrics related to producers are not visible on the solution dashboard.

```
{
  "metrics": {
    "namespace": "CWAgent",
    "append_dimensions": {
      "InstanceId": "${aws:InstanceId}"
    },
    "metrics_collected": {
      "jmx": [
        {
          "endpoint": "localhost:port-number",
          "kafka-producer": {
            "measurement": [
              "kafka.producer.request-rate",
              "kafka.producer.byte-rate",
              "kafka.producer.request-latency-avg",
              "kafka.producer.response-rate",
              "kafka.producer.record-error-rate",
              "kafka.producer.record-send-rate"
            ]
          },
          "append_dimensions": {
            "ProducerGroupName": "ProducerGroupName"
          }
        }
      ]
    }
  }
}
```

Agent configuration for Kafka consumers

Use the following CloudWatch agent configuration on EC2 instances where Kafka consumers are running. Replace *ConsumerGroupName* with the name of the application or group to use to group these metrics for a unified view. Replace *port-number* with the JMX port of your Kafka consumer application.

The solution doesn't enable JVM metrics for Kafka consumers because the solution dashboard doesn't display JVM metrics related to JVM for consumers. You can customize the agent configuration to emit JVM metrics as well, however JVM metrics related to consumer are not visible on the solution dashboard.

```
{
  "metrics": {
    "append_dimensions": {
      "InstanceId": "${aws:InstanceId}"
    },
    "metrics_collected": {
      "jmx": [
        {
          "endpoint": "localhost:port-number",
          "kafka-consumer": {
            "measurement": [
              "kafka.consumer.fetch-rate",
              "kafka.consumer.total.bytes-consumed-rate",
              "kafka.consumer.records-consumed-rate",
              "kafka.consumer.bytes-consumed-rate",
              "kafka.consumer.records-lag-max"
            ]
          },
          "append_dimensions": {
            "ConsumerGroupName": "ConsumerGroupName"
          }
        }
      ]
    }
  }
}
```

Deploy the agent for your solution

There are several approaches for installing the CloudWatch agent, depending on the use case. We recommend using Systems Manager for this solution. It provides a console experience and makes it simpler to manage a fleet of managed servers within a single AWS account. The instructions in this section use Systems Manager and are intended for when you don't have the CloudWatch agent running with existing configurations. You can check whether the CloudWatch agent is running by following the steps in Verify that the CloudWatch agent is running.

If you are already running the CloudWatch agent on the EC2 hosts where the workload is deployed and managing the agent configurations, you can skip the instructions in this section and follow your existing deployment mechanism to update the configuration. Be sure to merge the agent configuration according to the role (broker, producer, or consumer) with your existing agent configuration, and then deploy the merged configuration. If you are using Systems Manager to store and manage the configuration for the CloudWatch agent, you can merge the configuration to the existing parameter value. For more information, see Managing CloudWatch agent configuration files.

> **Note**
>
> Using Systems Manager to deploy the following CloudWatch agent configurations will replace or overwrite any existing CloudWatch agent configuration on your EC2 instances. You can modify this configuration to suit your unique environment or use case. The metrics defined in this solution are the minimum required for the recommended dashboard.

The deployment process includes the following steps:

- Step 1: Ensure that the target EC2 instances have the required IAM permissions.
- Step 2: Store the recommended agent configuration file in the Systems Manager Parameter Store.
- Step 3: Install the CloudWatch agent on one or more EC2 instances using an CloudFormation stack.
- Step 4: Verify the agent setup is configured properly.

You must repeat these steps based on whether your broker, producer, and consumer are deployed on the same EC2 instance or different instances. For example, if the Kafka broker, producer, and

consumers are getting deployed on separate instances without overlap, you must repeat these steps three times with the appropriate agent configurations for broker, producer, and consumer EC2 instances.

Step 1: Ensure the target EC2 instances have the required IAM permissions

You must grant permission for Systems Manager to install and configure the CloudWatch agent. You must also grant permission for the CloudWatch agent to publish telemetry from your EC2 instance to CloudWatch. Make sure that the IAM role attached to the instance has the **CloudWatchAgentServerPolicy** and **AmazonSSMManagedInstanceCore** IAM policies attached.

- After the role is created, attach the role to your EC2 instances. Follow the steps in Launch an instance with an IAM role to attach a role while launching a new EC2 instance. To attach a role to an existing EC2 instance, follow the steps in Attach an IAM role to an instance.

Step 2: Store the recommended CloudWatch agent configuration file in Systems Manager Parameter Store

Parameter Store simplifies the installation of the CloudWatch agent on an EC2 instance by securely storing and managing configuration parameters, eliminating the need for hard-coded values. This ensures a more secure and flexible deployment process, enabling centralized management and easier updates to configurations across multiple instances.

Use the following steps to store the recommended CloudWatch agent configuration file as a parameter in Parameter Store.

To create the CloudWatch agent configuration file as a parameter

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. From the navigation pane, choose **Application Management**, **Parameter Store**.
3. Follow these steps to create a new parameter for the configuration.

    a. Choose **Create parameter**.

    b. Provide a name for the parameter that will store your CloudWatch agent configuration, such as **`AmazonCloudWatch-Kafka-Producer-Configuration`** for producers, **`AmazonCloudWatch-Kafka-Consumer-Configuration`** for consumers, or **`AmazonCloudWatch-Kafka-Broker-Configuration`** for brokers. If you have multiple

Kafka roles on a single EC2, name the roles accordingly for easier identification. This value will later be used to distribute this configuration to the agent running on your EC2 instance.

c. For **Parameter tier**, choose **Standard**.

d. For **Type**, choose **String**.

e. For **Data type**, choose **text**.

f. In the **Value** box, paste the full text of the CloudWatch agent configuration. Be sure to select the JSON block for the Kafka role that this instance is hosting. Refer to the configuration provided in Agent configuration for Kafka broker agents, Agent configuration for Kafka producers, and Agent configuration for Kafka consumers when storing the configuration for broker, producer, and consumer respectively. If you are running multiple Kafka roles on the same EC2 instance, be sure to merge the configuration if required as described in Configure the agent for multiple Kafka roles on the same instance on the same instance

g. Choose **Create parameter**.

Step 3: Install the CloudWatch agent and apply the configuration using an CloudFormation template

You can use AWS CloudFormation to install the agent and configure it to use the CloudWatch agent configuration that you created in the previous steps.

To install and configure the CloudWatch agent for this solution

1. Open the CloudFormation **Quick create stack** wizard using this link: https://console.aws.amazon.com/cloudformation/home?#/stacks/quickcreate?templateURL=https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/CloudWatchAgent/CFN/v1.0.0/cw-agent-installation-template-1.0.0.json.
2. Verify that the selected Region on the console is the Region where the Kafka workload is running.
3. For **Stack name**, enter a name to identity this stack, such as **`CWAgentInstallationStack`**.
4. In the **Parameters** section, specify the following:

   a. For **CloudWatchAgentConfigSSM**, enter the name of the Systems Manager parameter for the agent configuration that you created earlier, such as **`AmazonCloudWatch-Kafka-Broker-Configuration`** for brokers, **`AmazonCloudWatch-Kafka-Producer-`**

`Configuration` for producers, and **`AmazonCloudWatch-Kafka-Consumer-Configuration`** for consumers.

b. To select the target instances, you have two options.

i. For **InstanceIds**, specify a comma-delimited list of instance IDs list of instance IDs where you want to install the CloudWatch agent with this configuration. You can list a single instance or several instances.

ii. If you are deploying at scale, you can specify the **TagKey** and the corresponding **TagValue** to target all EC2 instances with this tag and value. If you specify a **TagKey**, you must specify a corresponding **TagValue**. (For an Auto Scaling group, specify **`aws:autoscaling:groupName`** for the **TagKey** and specify the Auto Scaling group name for the **TagValue** to deploy to all instances within the Auto Scaling group.)

If you specify both the **InstanceIds** and the **TagKeys** parameters, the **InstanceIds** will take precedence and the tags will be ignored.

5. Review the settings, then choose **Create stack**.

If you want to edit the template file first to customize it, choose the **Upload a template file** option under **Create Stack Wizard** to upload the edited template. For more information, see Creating a stack on CloudFormation console. You can use the following link to download the template: https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/CloudWatchAgent/CFN/v1.0.0/cw-agent-installation-template-1.0.0.json.

Note

After this step is completed, this Systems Manager parameter will be associated with the CloudWatch agents running in the targeted instances. This means that:

1. If the Systems Manager parameter is deleted, the agent will stop.
2. If the Systems Manager parameter is edited, the configuration changes will automatically apply to the agent at the scheduled frequency which is 30 days by default.
3. If you want to immediately apply changes to this Systems Manager parameter, you must run this step again. For more information about associations, see Working with associations in Systems Manager.

Step 4: Verify the agent setup is configured properly

You can verify whether the CloudWatch agent is installed by following the steps in Verify that the CloudWatch agent is running. If the CloudWatch agent is not installed and running, make sure you have set up everything correctly.

- Be sure you have attached a role with correct permissions for the EC2 instance as described in Step 1: Ensure the target EC2 instances have the required IAM permissions.
- Be sure you have correctly configured the JSON for the Systems Manager parameter. Follow the steps in Troubleshooting installation of the CloudWatch agent with CloudFormation.

If everything is set up correctly, then you should see the Kafka metrics being published to CloudWatch. You can check the CloudWatch console to verify they are being published.

To verify that Kafka metrics are being published to CloudWatch

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Choose **Metrics**, **Classic metrics**.
3. Make sure you've selected the Region where you deployed the solution, and choose **Custom namespaces**, **CWAgent**.
4. Search for the metrics mentioned in the agent configuration section of this document, such as `kafka.partition.offline` for brokers, `kafka.consumer.fetch.rate` for consumers, or `kafka.producer.request-rate` for producers. If you see results for these metrics, then the metrics are being published to CloudWatch.

Create the Kafka solution dashboard

This dashboard displays the newly emitted metrics for both Kafka and the underlying JVM. This dashboard provides a top contributor view for the health of your Kafka workload, across producers, brokers, and consumers. The top contributor view displays the top 10 per metric widget. This allows you to identify outliers at a glance.

The solution dashboard doesn't display EC2 metrics. To view EC2 metrics, you'll need to use the EC2 automatic dashboard to see EC2 vended metrics and use the EC2 console dashboard to see EC2 metrics that are collected by the CloudWatch agent. For more information about automatic dashboards for AWS services, see Viewing a CloudWatch dashboard for a single AWS service.

To create the dashboard, you can use the following options:

- Use CloudWatch console to create the dashboard.
- Use AWS CloudFormation console to deploy the dashboard.
- Download the AWS CloudFormation infrastructure as code and integrate it as part of your continuous integration (CI) automation.

By using the CloudWatch console to create a dashboard, you can preview the dashboard before actually creating and being charged.

> **Note**
>
> The dashboard created with CloudFormation in this solution displays metrics from the Region where the solution is deployed. Be sure to create the CloudFormation stack in the Region where your JVM and Kafka metrics are published.
> If you've specified a custom namespace other than `CWAgent` in the CloudWatch agent configuration, you'll have to change the CloudFormation template for the dashboard to replace `CWAgent` with the customized namespace you are using.

To create the dashboard via CloudWatch Console

> **Note**
>
> Solution dashboards currently display garbage collection-related metrics only for the G1 Garbage Collector, which is the default collector for the latest Java versions. If you are using a different garbage collection algorithm, the widgets pertaining to garbage collection are empty. However, you can customize these widgets by changing the dashboard CloudFormation template and applying the appropriate garbage collection type to the name dimension of the garbage collection-related metrics. For example, if you are using parallel garbage collection, change the **`name=\"G1 Young Generation\"`** to **`name=\"Parallel GC\"`** of the garbage collection count metric `jvm.gc.collections.count`.

1. Open the CloudWatch Console **Create Dashboard** using this link: https://console.aws.amazon.com/cloudwatch/home?#dashboards?dashboardTemplate=ApacheKafkaOnEc2&referrer=os-catalog .
2. Verify that the selected Region on the console is the Region where the Kafka workload is running.
3. Enter the name of the dashboard, then choose **Create Dashboard**.

   To easily differentiate this dashboard from similar dashboards in other Regions, we recommend including the Region name in the dashboard name, such as **`KafkaDashboard-us-east-1`**.
4. Preview the dashboard and choose **Save** to create the dashboard.

To create the dashboard via CloudFormation

1. Open the CloudFormation **Quick create stack** wizard using this link: https://console.aws.amazon.com/cloudformation/home?#/stacks/quickcreate?templateURL=https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/Kafka_EC2/CloudWatch/CFN/v1.0.0/dashboard-template-1.0.0.json.
2. Verify that the selected Region on the console is the Region where the Kafka workload is running.
3. For **Stack name**, enter a name to identity this stack, such as **`KafkaDashboardStack`**.
4. In the **Parameters** section, specify the name of the dashboard under the **DashboardName** parameter.

   To easily differentiate this dashboard from similar dashboards in other Regions, we recommend including the Region name in the dashboard name, such as **`KafkaDashboard-us-east-1`**.
5. Acknowledge access capabilities for transforms under **Capabilities and transforms**. Note that CloudFormation doesn't add any IAM resources.
6. Review the settings, then choose **Create stack**.
7. After the stack status is **CREATE_COMPLETE**, choose the **Resources** tab under the created stack and then choose the link under **Physical ID** to go to the dashboard. You can also access the dashboard in the CloudWatch console by choosing **Dashboards** in the left navigation pane of the console, and finding the dashboard name under **Custom Dashboards**.

If you want to edit the template file to customize it for any purpose, you can use **Upload a template file** option under **Create Stack Wizard** to upload the edited template. For more information, see Creating a stack on CloudFormation console. You can use this link to download the template: https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/Kafka_EC2/CloudWatch/CFN/v1.0.0/dashboard-template-1.0.0.json.

> **Note**
>
> Solution dashboards currently display garbage collection-related metrics only for the G1 Garbage Collector, which is the default collector for the latest Java versions. If you are using a different garbage collection algorithm, the widgets pertaining to garbage collection are empty. However, you can customize these widgets by changing the dashboard CloudFormation template and applying the appropriate garbage collection type to the name dimension of the garbage collection-related metrics. For example, if you are using parallel garbage collection, change the **`name=\"G1 Young Generation\"`** to **`name=\"Parallel GC\"`** of the garbage collection count metric `jvm.gc.collections.count`.

Get started with the Kafka dashboard

Here are a few tasks that you can try out with the new Kafka dashboard. These tasks allow you to validate that the dashboard is working correctly and provide you some hands-on experience using it to monitor a Kafka cluster. As you try these out, you'll get familiar with navigating the dashboard and interpreting the visualized metrics.

Using the dropdown lists

The dashboard provides dropdown lists at the top that you can use to filter and select the specific Kafka cluster, producer, and consumer groups that you want to monitor.

- To display metrics for a specific Kafka cluster, select that cluster name in the **Kafka Cluster** dropdown list.
- To display metrics for a specific Kafka producer group, select that producer group name in the **Kafka Producer** dropdown list.
- To display metrics for a specific Kafka consumer group, select that consumer group name in the **Kafka Consumer Group** dropdown list.

Verify cluster health

From the **Cluster Overview** section, find the **Partitions Under Replicated** and **In-Sync Replicas** widgets. These should ideally be zero or a small number. A large value for any of these metrics could indicate issues with the Kafka cluster that need investigation.

Investigate broker performance

In the **Brokers** section, find the **Failed Fetch Requests** and **Failed Producer Requests** widgets. These show the number of failed requests for fetch and produce operations, respectively. High failure rates could indicate issues with the brokers or network connectivity that require further investigation.

Monitor producer performance

In the **Producer Group Overview** section, find the **Average Request Rate**, **Average Request Latency**, and **Average Record Send/Error Rate** widgets. These will give you an overview of how the producers in the selected group are performing. You can also drill down to view metrics for specific producers and topics in the **Producers** section.

Monitor consumer lag

In the **Consumer Group Overview** section, find the **Consumer Lag** widget. This shows how far behind the consumers are in processing messages from the latest offsets in the partitions they are subscribed to. Ideally, the consumer lag should be low or zero. A high consumer lag could indicate that the consumers are unable to keep up with the rate of data production, leading to potential data loss or delays in processing. You can also drill down to view metrics for specific consumers and topics in the **Consumers** section.

Configure the agent for multiple Kafka roles on the same instance

The individual configurations for Kafka roles listed in CloudWatch agent configuration for this solution apply only when the producer, consumer, and broker roles are deployed on separate EC2 instances, without any overlap. If you are running multiple Kafka roles on the same Amazon EC2 instances, you have two options:

- Create a single agent configuration file which lists and configures all metrics for all the Kafka roles deployed on that instance. If you are going to use Systems Manager to manage agent configuration, this is the preferred option.

If you choose this option and the multiple Kafka roles are part of the same JVM process, you must specify the same endpoint for each Kafka role in the agent configuration. If the multiple Kafka roles are part of different JVM processes, the endpoint for each role can be different depending on the JMX port set for that process.

- Create separate agent configuration files for each Kafka role, and configure the agent to apply both configuration files. For instructions for applying multiple configuration files, see Creating multiple CloudWatch agent configuration files.

The following example shows a CloudWatch agent configuration where the producer and consumer roles are running on one instance as part of the same JVM process. In this case, the port number must be the same in both the producer and consumer parts of the configuration below. If instead the two roles were running as part of different JVM processes, you could specify different port numbers for each, according to the JMX port of each individual JVM process.

```
{
  "metrics": {
    "namespace": "CWAgent",
    "append_dimensions": {
      "InstanceId": "${aws:InstanceId}"
    },
    "metrics_collected": {
      "jmx": [
        {
          "endpoint": "localhost:port-number",
          "kafka-producer": {
            "measurement": [
              "kafka.producer.request-rate",
              "kafka.producer.byte-rate",
              "kafka.producer.request-latency-avg",
              "kafka.producer.response-rate",
              "kafka.producer.record-error-rate",
              "kafka.producer.record-send-rate"
            ]
          },
          "append_dimensions": {
            "ProducerGroupName": "ProducerGroupName"
          }
        },
        {
          "endpoint": "localhost:port-number",
```

```
          "kafka-consumer": {
            "measurement": [
              "kafka.consumer.fetch-rate",
              "kafka.consumer.total.bytes-consumed-rate",
              "kafka.consumer.records-consumed-rate",
              "kafka.consumer.bytes-consumed-rate",
              "kafka.consumer.records-lag-max"
            ]
          },
          "append_dimensions": {
            "ConsumerGroupName": "ConsumerGroupName"
          }
        }
      ]
    }
  }
}
```

CloudWatch solution: Tomcat workload on Amazon EC2

This solution helps you configure out-of-the-box metric collection using CloudWatch agents for Tomcat server running on EC2 instances. Additionally, it helps you set up a pre-configured CloudWatch dashboard. For general information about all CloudWatch observability solutions, see CloudWatch observability solutions.

Topics

- Requirements
- Benefits
- Costs
- CloudWatch agent configuration for this solution
- Deploy the agent for your solution
- Create the Tomcat solution dashboard

Requirements

This solution is relevant for the following conditions:

- Supported versions: Tomcat versions 9, 10.1, and 11 (beta)

- Compute: Amazon EC2
- Supports up to 500 EC2 instances across all Tomcat workloads in a given AWS Region
- Latest version of CloudWatch agent
- SSM agent installed on EC2 instance

> **Note**
>
> AWS Systems Manager (SSM agent) is pre-installed on some Amazon Machine Images (AMIs) provided by AWS and trusted third-parties. If the agent isn't installed, you can install it manually using the procedure for your operating system type.
>
> - Manually installing and uninstalling SSM Agent on EC2 instances for Linux
> - Manually installing and uninstalling SSM Agent on EC2 instances for macOS
> - Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server

Benefits

The solution delivers Tomcat server monitoring, providing valuable insights for the following use cases:

- Detect Tomcat server errors and performance issues.
- Monitor network traffic for data transfer problems.
- Track thread usage and active user sessions.
- Analyze underlying JVM performance for Tomcat server.

Below are the key advantages of the solution:

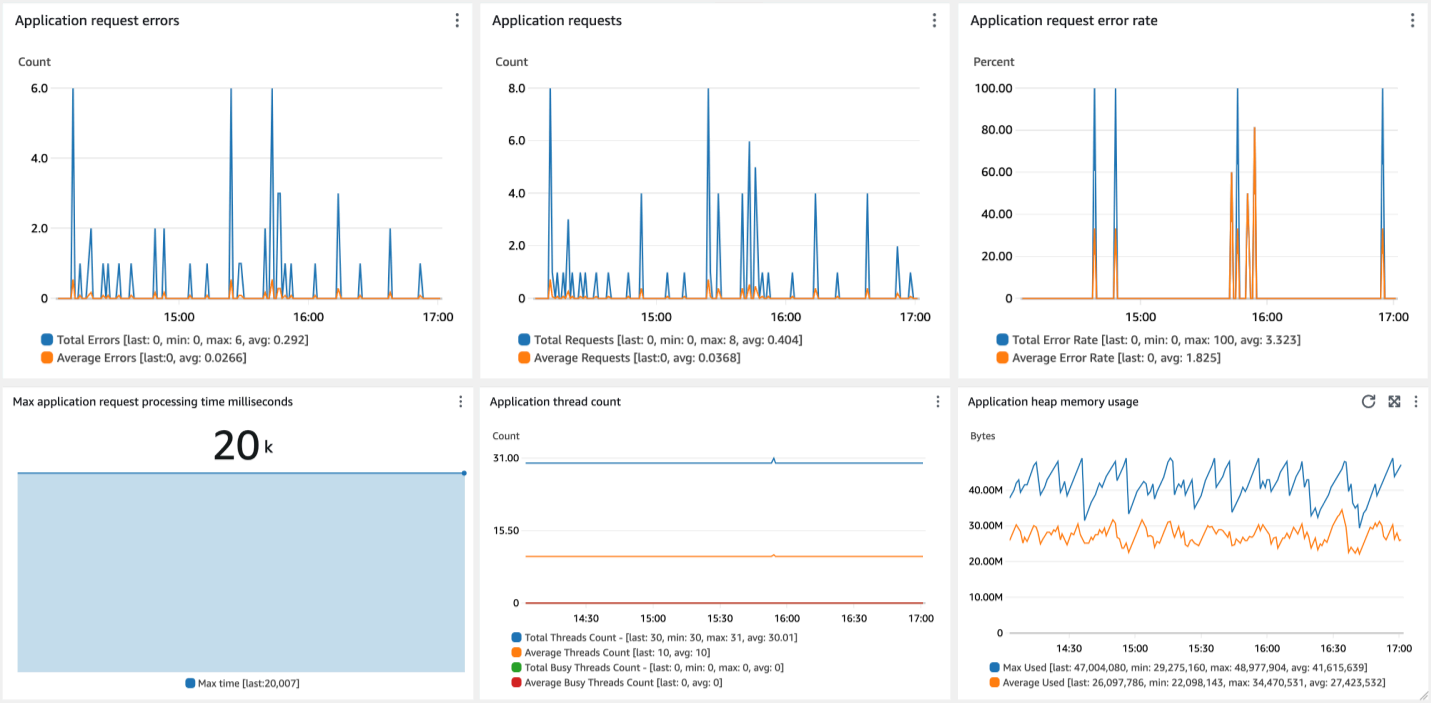
- Automates metric collection for Apache Tomcat and the underlying JVM using CloudWatch agent configuration, eliminating manual instrumentation.
- Provides a pre-configured, consolidated CloudWatch dashboard for Apache Tomcat and JVM metrics. The dashboard will automatically handle metrics from new Tomcat EC2 instances configured using the solution, even if those metrics don't exist when you first create the dashboard. It also allows you to group the metrics into logical applications for easier focus and management.

The following image is an example of the dashboard for this solution.

App overview

This part of the dashboard gives you a high-level summary and overall picture of your selected Tomcat App and selected duration using metrics aggregated from all instances in your cluster.

Note: View data from different Tomcat Apps using the `Tomcat App` dropdown at the top of the dashboard.



Breakdown by server

The following sections of the dashboard give you a more detailed look at the top contributing servers for different Tomcat App metrics.

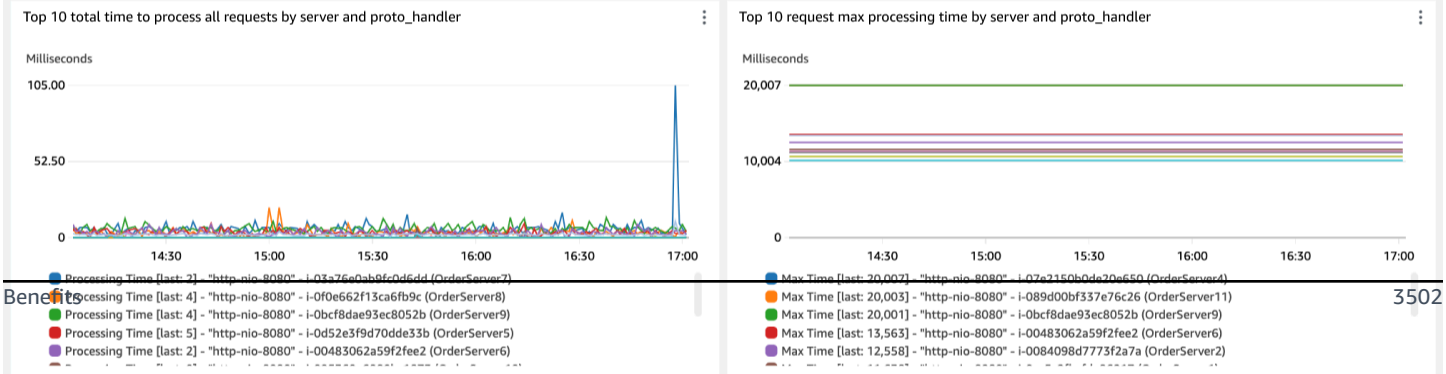
Note: View data from different Tomcat Apps using the `Tomcat App` dropdown at the top of the dashboard.

Requests

This section displays the number of errors encountered during request processing and total number of requests processed by Tomcat. Use the error count to identify and troubleshoot potential issues. Additionally, the count metric helps you understand the load on your server.

Request processing time

This section displays the total time spent processing all requests and the maximum time spent by Tomcat processing a single request. These metrics help identify performance bottlenecks and provide insights into the overall request load on your server.



Sessions and threads

This section provides insights into the thread and session management of your Tomcat server. It displays the number of busy threads and the total current thread count, allowing you to monitor thread utilization and

Costs

This solution creates and uses resources in your account. You are charged for standard usage, including the following:

- All metrics collected by the CloudWatch agent are charged as custom metrics. The number of metrics used by this solution depends on the number of EC2 hosts.
  - Each Tomcat host configured for the solution publishes a total of 27 metrics plus one metric (`disk_used_percent`) for which the metric count depends on number of disk paths for that host.
- One custom dashboard.
- API operations requested by the CloudWatch agent to publish the metrics. With the default configuration for this solution, the CloudWatch agent calls the **PutMetricData** once every minute. This means the **PutMetricData** API will be called `30*24*60=43,200` in a 30-day month for each EC2 host.

For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

The pricing calculator can help you estimate approximate monthly costs for using this solution.

To use the pricing calculator to estimate your monthly solution costs

1. Open the Amazon CloudWatch pricing calculator.
2. In the **Metrics** section, for **Number of metrics**, enter **`(27 + average number of disk paths per EC2 host) * number of EC2 instances configured for this solution`**.
3. In the **APIs** section, for **Number of API requests**, enter **`43200 * number of EC2 instances configured for this solution`**.

   By default, the solution performs one **PutMetricData** operation each minute for each EC2 host.
4. In the **Dashboards and Alarms** section, for **Number of Dashboards**, enter **1**.
5. You can see your monthly estimated costs at the bottom of the pricing calculator.

CloudWatch agent configuration for this solution

The CloudWatch agent is software that runs continuously and autonomously on your servers and in containerized environments. It collects metrics, logs, and traces from your infrastructure and applications and sends them to CloudWatch and X-Ray.

For more information about the CloudWatch agent, see Collect metrics, logs, and traces using the CloudWatch agent.

The agent configuration in this solution collects the foundational metrics for Tomcat, JVM, and EC2. The CloudWatch agent can be configured to collect more JVM metrics than the dashboard displays by default. For a list of all Tomcat metrics that you can collect, see Collect Tomcat metrics. For a list of all JVM metrics that you can collect, see Collect JVM metrics. For a list of Amazon EC2 metrics, see Metrics collected by the CloudWatch agent on Linux and macOS instances.

Expose JMX ports for the Tomcat server

The CloudWatch agent relies on JMX to collect the metrics related to the Tomcat server and JVM process. To make this possible, you must expose the JMX port from your servers. To enable a JMX port for monitoring and management, you would set system properties for your Tomcat servers. You can use the environment variable `CATALINA_OPTS` to set the required system properties for Tomcat. Review the startup scripts and configuration files of your Tomcat server on the best place to set the environment variable. Be sure that you specify an unused port number. You will need to restart the server after the change.

```
export CATALINA_OPTS="-Dcom.sun.management.jmxremote -
Dcom.sun.management.jmxremote.port=<<port-number>> -
Dcom.sun.management.jmxremote.ssl=false -
Dcom.sun.management.jmxremote.authenticate=false"
```

This example sets up unauthenticated JMX. If your security policies/requirements require you to enable JMX with password authentication or SSL for remote access, refer to the JMX documentation to set the required property.

To verify the JMX port, run `ps aux | grep jmxremote.port`. The results should show that the JMX port was set on the JVM processes.

Agent configuration for Tomcat solution

The metrics collected by the agent are defined in the agent configuration. The solution provides agent configurations to collect the recommended metrics with suitable dimensions for the solution's dashboard.

The steps for deploying the solution are described later in Deploy the agent for your solution. The following information is intended to help you understand how to customize the agent configuration for your environment.

You must customize some parts of the following agent configuration for your environment:

- The JMX port number is the port number that you configured in the previous section of this documentation. The port number is in the `endpoint` line in the configuration.
- `AppName` – This is used as a dimension for the Tomcat application metrics collected. Provide a meaningful name that represents the grouping for the instances that run the Tomcat application.
- `ProcessGroupName` – This is used as a dimension for JVM metrics collected for Tomcat hosts. Provide the value which is the same as `AppName` above. This is to enable viewing the JVM metrics of the same Tomcat app group as server metrics under the solution dashboard.

For example, if you have two Tomcat apps running in the same AWS account, one for the `billing-system` application and another for the `order-system` application, you can set the `AppName` and `ProcessGroupName` dimensions accordingly in the agent configuration of each instance.

- For the `billing-system` application instances, set `AppName=billing-system` and `ProcessGroupName=billing-system`.
- For the `order-system` application instances, set `AppName=order-system` and `ProcessGroupName=order-system`.

When you follow these guidelines, the solution will automatically group the metrics based on the `AppName` and `ProcessGroupName` dimensions. The dashboard will include dropdown options to select and view metrics for a specific Tomcat application, allowing you to monitor the performance of individual applications separately.

Agent configuration for Tomcat hosts

Use the following CloudWatch agent configuration on EC2 instances where your Tomcat applications are deployed. Configuration will be stored as a parameter in SSM's Parameter Store, as detailed later in Step 2: Store the recommended CloudWatch agent configuration file in Systems Manager Parameter Store.

Replace *AppName* with a meaningful name that represents the Tomcat application the instances are part of. Replace *port-number* with the JMX port of your Tomcat server. If JMX was enabled with password authentication or SSL for remote access, see Collect Java Management Extensions (JMX) metrics for information about setting up TLS or authorization in agent configuration as required.

The EC2 metrics shown in this configuration (configuration shown outside the JMX block) only work for Linux and macOS instances. If you are using Windows instances, you can choose to omit these metrics in the configuration. For information about metrics collected on Windows instances, see Metrics collected by the CloudWatch agent on Windows Server instances.

```
{
  "metrics": {
    "namespace": "CWAgent",
    "append_dimensions": {
      "InstanceId": "${aws:InstanceId}"
    },
    "metrics_collected": {
      "jmx": [
        {
          "endpoint": "localhost:port-number",
          "tomcat": {
            "measurement": [
              "tomcat.sessions",
              "tomcat.errors",
              "tomcat.processing_time",
              "tomcat.traffic",
              "tomcat.max_time",
              "tomcat.request_count",
              "tomcat.threads"
            ]
          },
          "append_dimensions": {
            "AppName": "AppName"
          }
        },
```

```
        {
          "endpoint": "localhost:port-number",
          "jvm": {
            "measurement": [
              "jvm.classes.loaded",
              "jvm.gc.collections.count",
              "jvm.gc.collections.elapsed",
              "jvm.memory.heap.committed",
              "jvm.memory.heap.max",
              "jvm.memory.heap.used",
              "jvm.memory.nonheap.committed",
              "jvm.memory.nonheap.max",
              "jvm.memory.nonheap.used",
              "jvm.threads.count"
            ]
          },
          "append_dimensions": {
            "ProcessGroupName": "AppName"
          }
        }
      ],
      "disk": {
        "measurement": [
          "used_percent"
        ]
      },
      "mem": {
        "measurement": [
          "used_percent"
        ]
      },
      "swap": {
        "measurement": [
          "used_percent"
        ]
      },
      "netstat": {
        "measurement": [
          "tcp_established",
          "tcp_time_wait"
        ]
      }
    }
  }
```

```
}
```

Deploy the agent for your solution

There are several approaches for installing the CloudWatch agent, depending on the use case. We recommend using Systems Manager for this solution. It provides a console experience and makes it simpler to manage a fleet of managed servers within a single AWS account. The instructions in this section use Systems Manager and are intended for when you don't have the CloudWatch agent running with existing configurations. You can check whether the CloudWatch agent is running by following the steps in Verify that the CloudWatch agent is running.

If you are already running the CloudWatch agent on the EC2 hosts where the JVM application is deployed and managing the agent configurations, you can skip the instructions in this section and follow your existing deployment mechanism to update the configuration. Be sure to merge the agent configuration of JVM with your existing agent configuration, and then deploy the merged configuration. If you are using Systems Manager to store and manage the configuration for the CloudWatch agent, you can merge the configuration to the existing parameter value. For more information, see Managing CloudWatch agent configuration files.

> **Note**
>
> Using Systems Manager to deploy the following CloudWatch agent configurations will replace or overwrite any existing CloudWatch agent configuration on your EC2 instances. You can modify this configuration to suit your unique environment or use case. The metrics defined in this solution are the minimum required for the recommended dashboard.

The deployment process includes the following steps:

- Step 1: Ensure that the target EC2 instances have the required IAM permissions.
- Step 2: Store the recommended agent configuration file in the Systems Manager Parameter Store.
- Step 3: Install the CloudWatch agent on one or more EC2 instances using an CloudFormation stack.
- Step 4: Verify the agent setup is configured properly.

Step 1: Ensure the target EC2 instances have the required IAM permissions

You must grant permission for Systems Manager to install and configure the CloudWatch agent. You must also grant permission for the CloudWatch agent to publish telemetry from your EC2 instance to CloudWatch. Make sure that the IAM role attached to the instance has the **CloudWatchAgentServerPolicy** and **AmazonSSMManagedInstanceCore** IAM policies attached.

- After the role is created, attach the role to your EC2 instances. Follow the steps in Launch an instance with an IAM role to attach a role while launching a new EC2 instance. To attach a role to an existing EC2 instance, follow the steps in Attach an IAM role to an instance.

Step 2: Store the recommended CloudWatch agent configuration file in Systems Manager Parameter Store

Parameter Store simplifies the installation of the CloudWatch agent on an EC2 instance by securely storing and managing configuration parameters, eliminating the need for hard-coded values. This ensures a more secure and flexible deployment process, enabling centralized management and easier updates to configurations across multiple instances.

Use the following steps to store the recommended CloudWatch agent configuration file as a parameter in Parameter Store.

To create the CloudWatch agent configuration file as a parameter

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. From the navigation pane, choose **Application Management**, **Parameter Store**.
3. Follow these steps to create a new parameter for the configuration.

    a. Choose **Create parameter**.

    b. In the **Name** box, enter a name that you'll use to reference the CloudWatch agent configuration file in later steps. For example, **`AmazonCloudWatch-Tomcat-Configuration`**.

    c. (Optional) In the **Description** box, type a description for the parameter.

    d. For **Parameter tier**, choose **Standard**.

    e. For **Type**, choose **String**.

    f. For **Data type**, choose **text**.

g. In the **Value** box, paste the corresponding JSON block that was listed in Agent configuration for Tomcat hosts. Be sure to customize the grouping dimension value and port number as described.

h. Choose **Create parameter**.

Step 3: Install the CloudWatch agent and apply the configuration using an CloudFormation template

You can use AWS CloudFormation to install the agent and configure it to use the CloudWatch agent configuration that you created in the previous steps.

To install and configure the CloudWatch agent for this solution

1. Open the CloudFormation **Quick create stack** wizard using this link: https://console.aws.amazon.com/cloudformation/home?#/stacks/quickcreate?templateURL=https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/CloudWatchAgent/CFN/v1.0.0/cw-agent-installation-template-1.0.0.json.
2. Verify that the selected Region on the console is the Region where the Tomcat workload is running.
3. For **Stack name**, enter a name to identity this stack, such as **`CWAgentInstallationStack`**.
4. In the **Parameters** section, specify the following:

   a. For **CloudWatchAgentConfigSSM**, enter the name of the Systems Manager parameter for the agent configuration that you created earlier, such as **`AmazonCloudWatch-Tomcat-Configuration`**.

   b. To select the target instances, you have two options.

      i. For **InstanceIds**, specify a comma-delimited list of instance IDs list of instance IDs where you want to install the CloudWatch agent with this configuration. You can list a single instance or several instances.

      ii. If you are deploying at scale, you can specify the **TagKey** and the corresponding **TagValue** to target all EC2 instances with this tag and value. If you specify a **TagKey**, you must specify a corresponding **TagValue**. (For an Auto Scaling group, specify **`aws:autoscaling:groupName`** for the **TagKey** and specify the Auto Scaling group name for the **TagValue** to deploy to all instances within the Auto Scaling group.)

If you specify both the **InstanceIds** and the **TagKeys** parameters, the **InstanceIds** will take precedence and the tags will be ignored.

5. Review the settings, then choose **Create stack**.

If you want to edit the template file first to customize it, choose the **Upload a template file** option under **Create Stack Wizard** to upload the edited template. For more information, see Creating a stack on CloudFormation console. You can use the following link to download the template: https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/CloudWatchAgent/CFN/v1.0.0/cw-agent-installation-template-1.0.0.json.

> **Note**
>
> After this step is completed, this Systems Manager parameter will be associated with the CloudWatch agents running in the targeted instances. This means that:
>
> 1. If the Systems Manager parameter is deleted, the agent will stop.
> 2. If the Systems Manager parameter is edited, the configuration changes will automatically apply to the agent at the scheduled frequency which is 30 days by default.
> 3. If you want to immediately apply changes to this Systems Manager parameter, you must run this step again. For more information about associations, see Working with associations in Systems Manager.

Step 4: Verify the agent setup is configured properly

You can verify whether the CloudWatch agent is installed by following the steps in Verify that the CloudWatch agent is running. If the CloudWatch agent is not installed and running, make sure you have set up everything correctly.

- Be sure you have attached a role with correct permissions for the EC2 instance as described in Step 1: Ensure the target EC2 instances have the required IAM permissions.
- Be sure you have correctly configured the JSON for the Systems Manager parameter. Follow the steps in Troubleshooting installation of the CloudWatch agent with CloudFormation.

If everything is set up correctly, then you should see the Tomcat metrics being published to CloudWatch. You can check the CloudWatch console to verify they are being published.

To verify that Tomcat metrics are being published to CloudWatch

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Choose **Metrics**, **Classic metrics**.
3. Make sure you've selected the Region where you deployed the solution, and choose **Custom namespaces**, **CWAgent**.
4. Search for the metrics mentioned in the agent configuration section of this document, such as `tomcat.errors`. If you see results for these metrics, then the metrics are being published to CloudWatch.

Create the Tomcat solution dashboard

This dashboard displays the newly emitted metrics, showing both the Tomcat application server and the underlying JVM. This dashboard provides a top contributor view for the health of your Tomcat workload. The top contributor view displays the top 10 per metric widget. This allows you to identify outliers at a glance. The dashboard also includes an overview of the cluster by aggregating and presenting metrics across all instances, providing a high-level summary of the overall health and operational state of the cluster.

The solution dashboard doesn't display EC2 metrics. To view EC2 metrics, you'll need to use the EC2 automatic dashboard to see EC2 vended metrics and use the EC2 console dashboard to see EC2 metrics that are collected by the CloudWatch agent. For more information about automatic dashboards for AWS services, see Viewing a CloudWatch dashboard for a single AWS service.

To create the dashboard, you can use the following options:

- Use CloudWatch console to create the dashboard.
- Use AWS CloudFormation console to deploy the dashboard.
- Download the AWS CloudFormation infrastructure as code and integrate it as part of your continuous integration (CI) automation.

By using the CloudWatch console to create a dashboard, you can preview the dashboard before actually creating and being charged.

> **Note**
>
> The dashboard created with CloudFormation in this solution displays metrics from the Region where the solution is deployed. Be sure to create the CloudFormation stack in the Region where your Tomcat metrics are published.
> If you've specified a custom namespace other than `CWAgent` in the CloudWatch agent configuration, you'll have to change the CloudFormation template for the dashboard to replace `CWAgent` with the customized namespace you are using.

To create the dashboard via CloudWatch Console

> **Note**
>
> Solution dashboards currently display garbage collection-related metrics only for the G1 Garbage Collector, which is the default collector for the latest Java versions. If you are using a different garbage collection algorithm, the widgets pertaining to garbage collection are empty. However, you can customize these widgets by changing the dashboard CloudFormation template and applying the appropriate garbage collection type to the name dimension of the garbage collection-related metrics. For example, if you are using parallel garbage collection, change the **`name=\"G1 Young Generation\"`** to **`name=\"Parallel GC\"`** of the garbage collection count metric `jvm.gc.collections.count`.

1. Open the CloudWatch Console **Create Dashboard** using this link: https://console.aws.amazon.com/cloudwatch/home?#dashboards?dashboardTemplate=ApacheTomcatOnEc2&referrer=os-catalog .
2. Verify that the selected Region on the console is the Region where the Tomcat workload is running.
3. Enter the name of the dashboard, then choose **Create Dashboard**.

   To easily differentiate this dashboard from similar dashboards in other Regions, we recommend including the Region name in the dashboard name, such as **`TomcatDashboard-us-east-1`**.
4. Preview the dashboard and choose **Save** to create the dashboard.

To create the dashboard via CloudFormation

1. Open the CloudFormation **Quick create stack** wizard using this link: https://console.aws.amazon.com/cloudformation/home?#/stacks/quickcreate?templateURL=https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/Tomcat_EC2/CloudWatch/CFN/v1.0.0/dashboard-template-1.0.0.json.
2. Verify that the selected Region on the console is the Region where the Tomcat workload is running.
3. For **Stack name**, enter a name to identity this stack, such as **`TomcatDashboard-us-east-1`**.
4. In the **Parameters** section, specify the name of the dashboard under the **DashboardName** parameter.
5. To easily differentiate this dashboard from similar dashboards in other Regions, we recommend including the Region name in the dashboard name, such as **`TomcatDashboard-us-east-1`**.
6. Acknowledge access capabilities for transforms under **Capabilities and transforms**. Note that CloudFormation doesn't add any IAM resources.
7. Review the settings, then choose **Create stack**.
8. After the stack status is **CREATE_COMPLETE**, choose the **Resources** tab under the created stack and then choose the link under **Physical ID** to go to the dashboard. You can also access the dashboard in the CloudWatch console by choosing **Dashboards** in the left navigation pane of the console, and finding the dashboard name under **Custom Dashboards**.

If you want to edit the template file to customize it for any purpose, you can use **Upload a template file** option under **Create Stack Wizard** to upload the edited template. For more information, see Creating a stack on CloudFormation console. You can use this link to download the template: https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/Tomcat_EC2/CloudWatch/CFN/v1.0.0/dashboard-template-1.0.0.json.

> **Note**
>
> Solution dashboards currently display garbage collection-related metrics only for the G1 Garbage Collector, which is the default collector for the latest Java versions. If you are using a different garbage collection algorithm, the widgets pertaining to garbage collection are empty. However, you can customize these widgets by changing the dashboard CloudFormation template and applying the appropriate garbage collection type to the name dimension of the garbage collection-related metrics. For

example, if you are using parallel garbage collection, change the **`name=\"G1 Young Generation\"`** to **`name=\"Parallel GC\"`** of the garbage collection count metric `jvm.gc.collections.count`.

Get started with the Tomcat monitoring dashboard

Here are a few tasks that you can try out with the new Tomcat dashboard. These tasks allow you to validate that the dashboard is working correctly and provide you some hands-on experience using it to monitor a Tomcat application. As you try these out, you'll get familiar with navigating the dashboard and interpreting the visualized metrics.

Using the dropdown list

The dashboard provides a dropdown list at the top that you can use to filter and select the specific Tomcat application that you want to monitor. To display metrics for a specific Tomcat application, select that application name in the **Tomcat App** dropdown list.

Verify application health

From the **App Overview** section, find the **Requests**, **Errors**, and **Error Rate** widgets. These provide a high-level summary of the application's request handling performance. Look for any abnormally high error counts or rates, which could indicate issues that need investigation.

Monitor request processing

In the **Request Processing Time** section, find the **Max Time** and **Total Time to Process All Requests** widgets. These metrics help you identify potential performance bottlenecks in request processing. Look for any servers with significantly higher max processing times compared to others.

Analyze network traffic

In the **Network Traffic** section, find the **Sent Traffic** and **Received Traffic** widgets. These show the amount of data being sent and received by the application over the network. Unexpectedly high traffic levels could indicate potential issues with network saturation or inefficient data transfer.

Investigate thread usage

In the **Sessions and Threads** section, find the **Busy Threads Count**, **Threads Count**, and **Sessions** widgets. These metrics provide insights into the application's thread management and active user

sessions. Look for any servers with an abnormally high number of busy threads or sessions, which could indicate potential resource constraints.

CloudWatch solution: Amazon EC2 health

This solution helps you configure out-of-the-box metric collection using CloudWatch agents for workloads running on EC2 instances. Additionally, it helps you set up a pre-configured CloudWatch dashboard.

Topics

- Requirements
- Benefits
- Costs
- CloudWatch agent configuration for this solution
- Deploy the agent for your solution
- Create the EC2 Health solution dashboard
- Get started with the EC2 Health solution dashboard

Requirements

This solution is relevant for the following conditions:

- Compute: Amazon EC2
- Platform: Linux and macOS
- Supports up to 500 EC2 instances in a given AWS Region
- Latest version of CloudWatch agent
- SSM agent installed on EC2 instance

> **Note**
>
> AWS Systems Manager (SSM agent) is pre-installed on some Amazon Machine Images (AMIs) provided by AWS and trusted third-parties. If the agent isn't installed, you can install it manually using the procedure for your operating system type.
>
> - Manually installing and uninstalling SSM Agent on EC2 instances for Linux

- Manually installing and uninstalling SSM Agent on EC2 instances for macOS
- Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server

Benefits

The solution delivers EC2 server monitoring using the CloudWatch Agent, providing additional system-level metrics on top of the standard EC2 namespace metrics for the following use cases:

- Detect CPU performance issues and resource constraints.
- Monitor disk utilization and storage capacity across different disks throughout your EC2 instances.
- Track memory usage patterns and potential memory leaks.
- Analyze I/O operations and their impact on overall performance.
- Observe network traffic patterns and potential anomalies.

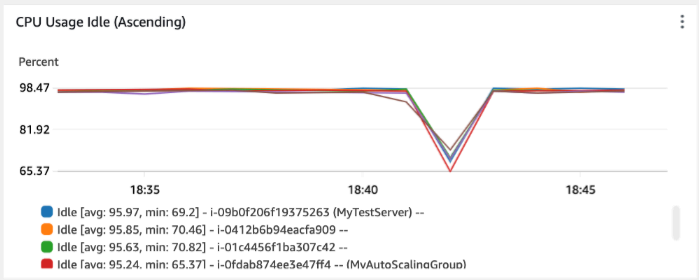
Below are the key advantages of the solution:

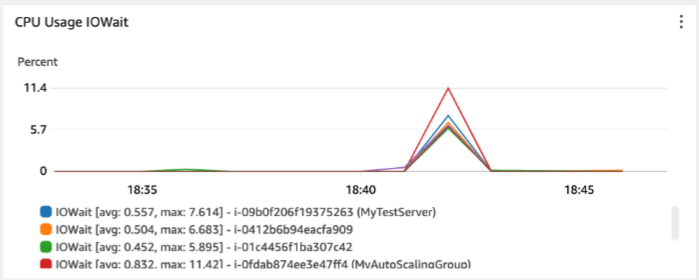
- Automates metric collection for EC2 instances eliminating manual instrumentation.
- Provides a pre-configured, consolidated CloudWatch dashboard for EC2 instance metrics. The dashboard will automatically handle metrics from new EC2 instances configured using the solution, even if those metrics don't exist when you first create the dashboard. It also allows you to observe EC2 instances managed via Auto Scaling groups.

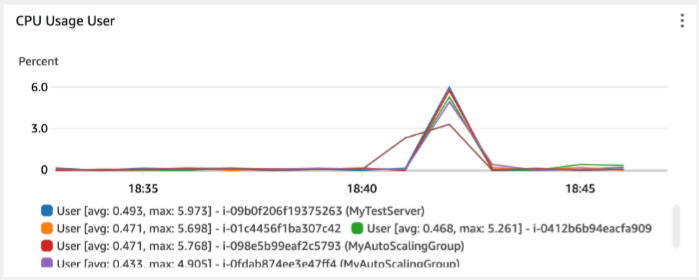
The following image is an example of the dashboard for this solution.

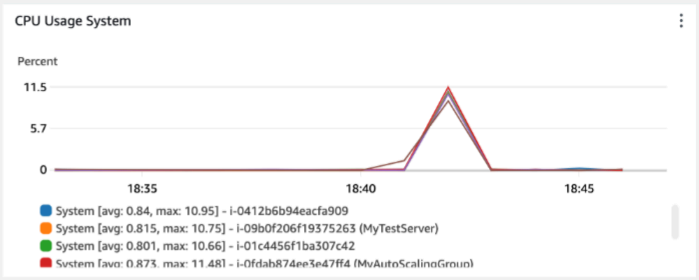
CloudWatch Agent Metrics

CPU



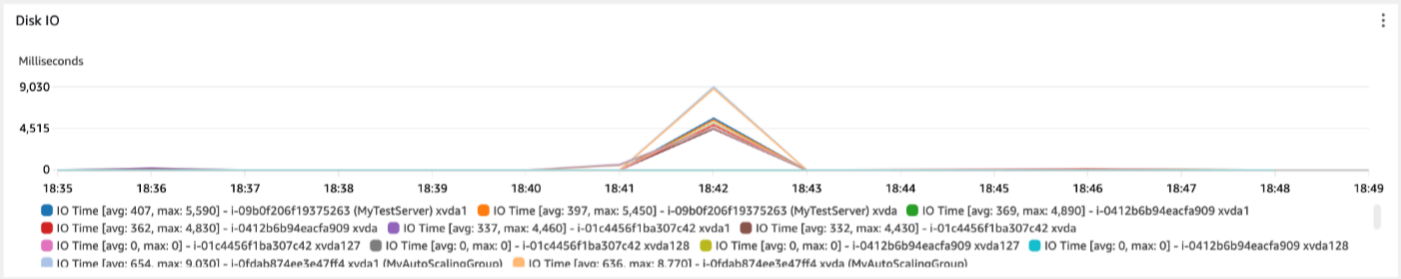




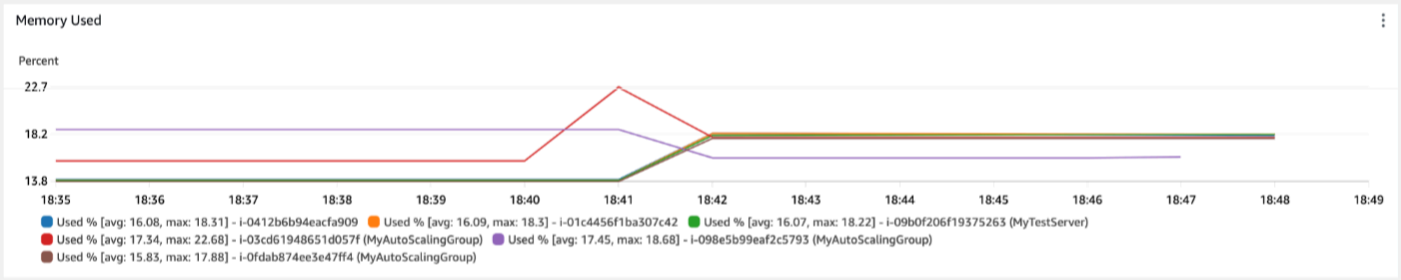


Disk

DiskIO



Memory



Swap

AWS/EC2 Vended Metrics

Costs

This solution creates and uses resources in your account. You are charged for standard usage, including the following:

- All metrics collected by the CloudWatch agent are charged as custom metrics. The number of metrics used by this solution depends on the number of EC2 hosts.

  The total number of CloudWatch agent metrics depends on the configuration of disks. Excluding disk and diskio metrics, the solution publishes six metrics. The number of disk metrics (`disk_used_percent`, `disk_inodes_free`) depend on the count of `device/fstype/path` dimensions. The diskio metric (`diskio_io_time`) depends on the count of `name` dimensions. For example, a single t2.micro with default settings as per EC2 console experience, produces a total of 22 CloudWatch agent metrics (4 CPU, 12 disk, 4 diskio, 1 memory, and 1 swap). Vended metrics like `AWS/EC2` are provided free of charge.
- One custom dashboard.
- API operations requested by the CloudWatch agent to publish the metrics. With the default configuration for this solution, the CloudWatch agent calls the **PutMetricData** once every minute. This means the **PutMetricData** API will be called `30*24*60=43,200` in a 30-day month for each EC2 host.

For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

The pricing calculator can help you estimate approximate monthly costs for using this solution.

To use the pricing calculator to estimate your monthly solution costs

1. Open the Amazon CloudWatch pricing calculator.
2. In the **Metrics** section, for **Number of metrics**, enter **`(6 + total count of disk and diskio metrics per EC2 host as described above) * number of EC2 instances configured for this solution`**.
3. In the **APIs** section, for **Number of API requests**, enter **`43200 * number of EC2 instances configured for this solution`**.
4. By default, the solution performs one **PutMetricData** operation each minute for each EC2 host.
5. In the **Dashboards and Alarms** section, for **Number of Dashboards**, enter **1**.
6. You can see your monthly estimated costs at the bottom of the pricing calculator.

CloudWatch agent configuration for this solution

The CloudWatch agent is software that runs continuously and autonomously on your servers and in containerized environments. It collects metrics, logs, and traces from your infrastructure and applications and sends them to CloudWatch and X-Ray.

For more information about the CloudWatch agent, see Collect metrics, logs, and traces with the CloudWatch agent.

The agent configuration in this solution collects a set of metrics to help you get started monitoring and observing your EC2 instances. The CloudWatch agent can be configured to collect more EC2 metrics than the dashboard displays by default. For a list of Amazon EC2 metrics, see Metrics collected by the CloudWatch agent on Linux and macOS instances. For information about metrics collected on Windows instances, see Metrics collected by the CloudWatch agent on Windows Server instances.

Agent configuration for EC2 Health solution

The metrics collected by the agent are defined in the agent configuration. The solution provides agent configurations to collect the recommended metrics with suitable dimensions for the solution's dashboard.

The steps for deploying the solution are described later in the section called “Deploy the agent for your solution”. The following information is intended to help you understand how to customize the agent configuration for your environment.

> **Note**
>
> If an EC2 instance is not part of an Auto Scaling group, the CloudWatch agent drops the `AutoScalingGroupName` dimension entirely. This behavior helps to prevent dimension names with null/empty values. Each metric widget included in the solution dashboard searches for metrics which include and exclude the `AutoScalingGroup` dimension. This helps to ensure that all EC2 instances where the solution is applied are supported by the same dashboard.

If you wish to make any modifications to the agent configuration, you must apply the same changes to the solution's accompanying dashboard. For example, if you decide to omit the ImageId

dimension, the same dimension must be removed from the metric search expression used in the dashboard widgets.

Agent configuration for EC2 Instances

Use the following CloudWatch agent configuration on Amazon EC2 instances where your workloads are deployed.

```
{
    "agent": {
      "metrics_collection_interval": 60,
      "run_as_user": "cwagent"
    },
    "metrics": {
      "append_dimensions": {
        "InstanceId": "${aws:InstanceId}",
        "InstanceType": "${aws:InstanceType}",
        "ImageId": "${aws:ImageId}",
        "AutoScalingGroupName": "${aws:AutoScalingGroupName}"
      },
      "metrics_collected": {
        "cpu": {
          "measurement": [
            "cpu_usage_idle",
             "cpu_usage_iowait",
             "cpu_usage_user",
             "cpu_usage_system"
          ],
          "totalcpu": true
        },
        "disk": {
          "measurement": [
            "used_percent",
            "inodes_free"
          ],
          "resources": [
            "*"
          ],
          "dimensions": [
            ["device", "fstype", "path"]
          ]
        },
        "diskio": {
```

```
            "measurement": [
              "io_time"
            ],
            "resources": [
              "*"
            ]
          },
        "mem": {
          "measurement": [
            "used_percent"
          ]
        },
        "swap": {
          "measurement": [
            "used_percent"
          ]
        }
      }
    }
}
```

Deploy the agent for your solution

There are several approaches for installing the CloudWatch agent, depending on the use case. We recommend using Systems Manager for this solution. It provides a console experience and makes it simpler to manage a fleet of managed servers within a single AWS account. The instructions in this section use Systems Manager and are intended for when you don't have the CloudWatch agent running with existing configurations. You can check whether the CloudWatch agent is running by following the steps in Verify that the CloudWatch agent is running.

If you are already running the CloudWatch agent on the EC2 hosts and managing the agent configurations, you can skip the instructions in this section and follow your existing deployment mechanism to update the configuration. Be sure to merge the EC2 Health agent configuration with your existing agent configuration, and then deploy the merged configuration. If you are using Systems Manager to store and manage the configuration for the CloudWatch agent, you can merge the configuration to the existing parameter value. For more information, see Managing CloudWatch agent configuration files.

> **Note**
>
> Using Systems Manager to deploy the following CloudWatch agent configurations will replace or overwrite any existing CloudWatch agent configuration on your EC2 instances. You can modify this configuration to suit your unique environment or use case. The metrics defined in configuration are the minimum required for the dashboard provided the solution.

The deployment process includes the following steps:

- Step 1: Ensure that the target EC2 instances have the required IAM permissions.
- Step 2: Store the recommended agent configuration file in the Systems Manager Parameter Store.
- Step 3: Install the CloudWatch agent on one or more EC2 instances using an CloudFormation stack.
- Step 4: Verify the agent setup is configured properly.

Step 1: Ensure the target EC2 instances have the required IAM permissions

You must grant permission for Systems Manager to install and configure the CloudWatch agent. You must also grant permission for the CloudWatch agent to publish telemetry from your EC2 instance to CloudWatch. Make sure that the IAM role attached to the instance has the **CloudWatchAgentServerPolicy** and **AmazonSSMManagedInstanceCore** IAM policies attached.

- After the role is created, attach the role to your EC2 instances. To attach a role to an EC2 instance, follow the steps in Attach an IAM role to an instance.

Step 2: Store the recommended CloudWatch agent configuration file in Systems Manager Parameter Store

Parameter Store simplifies the installation of the CloudWatch agent on an EC2 instance by securely storing and managing configuration parameters, eliminating the need for hard-coded values. This ensures a more secure and flexible deployment process, enabling centralized management and easier updates to configurations across multiple instances.

Use the following steps to store the recommended CloudWatch agent configuration file as a parameter in Parameter Store.

To create the CloudWatch agent configuration file as a parameter

1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. Verify that the selected Region on the console is the Region where the EC2 instances are running.
3. From the navigation pane, choose **Application Management**, **Parameter Store**.
4. Follow these steps to create a new parameter for the configuration.
   a. Choose **Create parameter**.
   b. In the **Name** box, enter a name that you'll use to reference the CloudWatch agent configuration file in later steps. For example, **`AmazonCloudWatch-EC2Health-Configuration`**.
   c. (Optional) In the **Description** box, type a description for the parameter.
   d. For **Parameter tier**, choose **Standard**.
   e. For **Type**, choose **String**.
   f. For **Data type**, choose **text**.
   g. In the **Value** box, paste the agent configuration JSON provided earlier in this document.
   h. Choose **Create parameter**.

Step 3: Install the CloudWatch agent and apply the configuration using an CloudFormation template

You can use CloudFormation to install the agent and configure it to use the CloudWatch agent configuration that you created in the previous steps.

To install and configure the CloudWatch agent for this solution

1. Open the CloudFormation **Quick create stack** wizard using this link: https://console.aws.amazon.com/cloudformation/home?#/stacks/quickcreate?templateURL=https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/CloudWatchAgent/CFN/v1.0.0/cw-agent-installation-template-1.0.0.json .

2. Verify that the selected Region on the console is the Region where the EC2 instances are running.
3. For **Stack name**, enter a name to identity this stack, such as **`CWAgentInstallationStack`**.
4. In the **Parameters** section, specify the following:

   a. For **CloudWatchAgentConfigSSM**, enter the name of the Systems Manager parameter for the agent configuration that you created earlier, such as **`AmazonCloudWatch-EC2Health-Configuration`**.

   b. To select the target instances, you have two options.

      i. For **InstanceIds**, specify a comma-delimited list of instance IDs list of instance IDs where you want to install the CloudWatch agent with this configuration. You can list a single instance or several instances.

      ii. If you are deploying at scale, you can specify the **TagKey** and the corresponding **TagValue** to target all EC2 instances with this tag and value. If you specify a **TagKey**, you must specify a corresponding **TagValue**. (For an Auto Scaling group, specify **`aws:autoscaling:groupName`** for the **TagKey** and specify the Auto Scaling group name for the **TagValue** to deploy to all instances within the Auto Scaling group.)

   If you specify both the **InstanceIds** and the **TagKeys** parameters, the **InstanceIds** will take precedence and the tags will be ignored.
5. Review the settings, then choose **Create stack**.

If you want to edit the template file first to customize it, choose the **Upload a template file** option under **Create Stack Wizard** to upload the edited template. For more information, see Creating a stack on CloudFormation console. You can use the following link to download the template: https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/CloudWatchAgent/CFN/v1.0.0/cw-agent-installation-template-1.0.0.json .

> **Note**
>
> After this step is completed, this Systems Manager parameter will be associated with the CloudWatch agents running in the targeted instances. This means that:
>
> 1. If the Systems Manager parameter is deleted, the agent will stop.

2. If the Systems Manager parameter is edited, the configuration changes will automatically apply to the agent at the scheduled frequency which is 30 days by default.
3. If you want to immediately apply changes to this Systems Manager parameter, you must run this step again. For more information about associations, see Working with associations in AWS Systems Manager.

Step 4: Verify the agent setup is configured properly

You can verify whether the CloudWatch agent is installed by following the steps in Verify that the CloudWatch agent is running. If the CloudWatch agent is not installed and running, make sure you have set up everything correctly.

- Be sure you have attached a role with correct permissions for the EC2 instance as described in the section called "Step 1: Ensure the target EC2 instances have the required IAM permissions".
- Be sure you have correctly configured the JSON for the Systems Manager parameter. Follow the steps in Troubleshooting installation of the CloudWatch agent with CloudFormation.

To verify that EC2 health metrics are being published to CloudWatch

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Choose **Metrics**, **Classic metrics**.
3. Make sure you've selected the Region where you deployed the solution, and choose **Custom namespaces**, **CWAgent**.
4. Search for the metrics mentioned in the agent configuration section of this document, such as `mem_used_percent`. If you see results for these metrics, then the metrics are being published to CloudWatch.

Create the EC2 Health solution dashboard

This dashboard displays the newly emitted metrics, showing the EC2 Health metrics. This dashboard provides a top contributor view for the health of your EC2 instances in a single region. The top contributor view displays the top 10 per metric widget. This allows you to identify outliers at a glance.

To create the dashboard, you can use the following options:

- Use CloudWatch console to create the dashboard.
- Use AWS CloudFormation console to deploy the dashboard.
- Download the AWS CloudFormation infrastructure as code and integrate it as part of your continuous integration (CI) automation.

By using the CloudWatch console to create a dashboard, you can preview the dashboard before actually creating and being charged.

> **Note**
>
> The dashboard created with CloudFormation in this solution displays metrics from the Region where the solution is deployed. Be sure to create the CloudFormation stack in the Region where your EC2 metrics are published.
> If you've specified a custom namespace other than `CWAgent` in the CloudWatch agent configuration, you'll have to change the CloudFormation template for the dashboard to replace `CWAgent` with the customized namespace you are using.

To create the dashboard via CloudWatch Console

1. Open the CloudWatch Console **Create Dashboard** using this link: https://console.aws.amazon.com/cloudwatch/home?#dashboards?dashboardTemplate=Ec2LinuxMacOsHealth&referrer=os-catalog .
2. Verify that the selected Region on the console is the Region where the EC2 instances are running.
3. Enter the name of the dashboard, then choose **Create Dashboard**.

   To easily differentiate this dashboard from similar dashboards in other Regions, we recommend including the Region name in the dashboard name, such as **`EC2HealthDashboard-us-east-1`**.
4. Preview the dashboard and choose **Save** to create the dashboard.

To create the dashboard via CloudFormation

1. Open the CloudFormation **Quick create stack** wizard using this link: https://console.aws.amazon.com/cloudformation/home?#/stacks/quickcreate?templateURL=https://

aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/EC2_Health/CloudWatch/CFN/v1.0.0/dashboard-template-linux-macos-1.0.0.json .

2. Verify that the selected Region on the console is the Region where the EC2 instances are running.
3. For **Stack name**, enter a name to identity this stack, such as `EC2HealthDashboardStack`.
4. In the **Parameters** section, specify the name of the dashboard under the **DashboardName** parameter.

   To easily differentiate this dashboard from similar dashboards in other Regions, we recommend including the Region name in the dashboard name, such as **`EC2HealthDashboard-us-east-1`**.
5. Acknowledge access capabilities for transforms under **Capabilities and transforms**. Note that CloudFormation doesn't add any IAM resources.
6. Review the settings, then choose **Create stack**.
7. After the stack status is **CREATE_COMPLETE**, choose the **Resources** tab under the created stack and then choose the link under **Physical ID** to go to the dashboard. You can also access the dashboard in the CloudWatch console by choosing **Dashboards** in the left navigation pane of the console, and finding the dashboard name under **Custom Dashboards**.

If you want to edit the template file to customize it for any purpose, you can use the **Upload a template file** option under **Create Stack Wizard** to upload the edited template. For more information, see Creating a stack on CloudFormation console. You can use this link to download the template: https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/EC2_Health/CloudWatch/CFN/v1.0.0/dashboard-template-linux-macos-1.0.0.json

Get started with the EC2 Health solution dashboard

Here are a few tasks that you can try out with the new EC2 monitoring dashboard. These tasks allow you to validate that the dashboard is working correctly and provide you some hands-on experience using it to monitor EC2 instances. As you try these out, you'll get familiar with navigating the dashboard and interpreting the visualized metrics.

Monitor the various CPU utilization metrics

In the **CPU** section, examine the array of CPU usage metrics. These provide insight into how CPU resources are being utilized across different activities like user processes, system tasks, and I/

O operations. Look for instances with consistently high utilization or unusual patterns, which might indicate the need for scaling or optimization.

Analyze disk utilization across different devices

Navigate to the **Disk** section to find the storage usage and inode availability metrics. These help you identify instances that are running low on storage space or file system resources. Pay attention to any instances approaching high disk usage levels, as this could lead to performance issues or service disruptions.

Investigate memory utilization patterns

In the **Memory** section, observe the graph which plots memory utilization over time. This shows how much of the available memory is being used by each instance. Look for patterns or spikes in memory usage that might correlate with specific times or events. High memory utilization could indicate the need for instance resizing or application optimization.

Correlate patterns across core utilization metrics

Compare and watch out for related utilization patterns. For example, a workload running a log rotation process could present regular increases in **CPU** and **memory** utilization, followed by a decrease in **disk** utilization.

Inspect network activity

In the **Network** section, examine the inbound and outbound network traffic metrics, both in terms of data volume and packet count. These give you insight into the network activity for your EC2 instances. Look out for both regular or anomalous spikes in network traffic, or imbalances between inbound and outbound data.

Amazon CloudWatch solution: Prometheus metric collection on Amazon Amazon EC2

This solution helps you collect Prometheus-compatible metrics from your Amazon EC2 instances without running or scaling your own collection infrastructure. You run one or more Prometheus exporters on your instances, and a Amazon CloudWatch managed Prometheus collector discovers the targets in your VPC, scrapes their `/metrics` endpoints, and delivers the metrics to CloudWatch. For general information about all CloudWatch observability solutions, see CloudWatch observability solutions. For more information about managed collectors, see Amazon CloudWatch managed Prometheus collectors.

Topics

- Requirements
- Enable Prometheus exporters
- Step 1: Set up the scrape configuration
- Step 2: Set up the scraper
- Validate metrics collection
- Build a custom dashboard
- Costs

Requirements

This solution is relevant for the following conditions:

- Compute: Amazon EC2 instances that run one or more Prometheus exporters.
- Amazon VPC with DNS enabled, and at least two subnets in different Availability Zones for the collector.
- A security group that allows the collector to reach the exporter ports on your instances.
- If you deploy the collector in private subnets that have no internet access, an interface VPC endpoint for CloudWatch. For more information, see Configure VPC endpoints for private subnets.

Enable Prometheus exporters

A Prometheus exporter is a process that exposes metrics in Prometheus exposition format on an HTTP `/metrics` endpoint. You run an exporter that matches the workload you want to monitor. The following exporters are commonly used on Amazon EC2:

- **Node Exporter** — Host-level infrastructure metrics such as CPU, memory, disk, and network (default port 9100). For more information, see the Node Exporter repository on GitHub.
- **JMX Exporter** — JVM and Java application metrics for Java workloads. For more information, see the JMX Exporter repository on GitHub.
- **NGINX Prometheus Exporter** — NGINX web server and reverse proxy metrics. For more information, see the NGINX Prometheus Exporter repository on GitHub.

- **DCGM Exporter** — NVIDIA GPU metrics for GPU workloads such as machine learning training and inference (default port 9400). For more information, see the DCGM Exporter repository on GitHub.
- **HAProxy Exporter** — HAProxy load balancer metrics. For more information, see the HAProxy Exporter repository on GitHub.
- **Apache Exporter** — Apache HTTP Server metrics. For more information, see the Apache Exporter repository on GitHub.

Install and run each exporter on your instances by following its official documentation. Note the port that each exporter listens on, because you reference these ports in your scrape configuration. For a complete catalog of available exporters, see Exporters and integrations in the Prometheus documentation.

After you start an exporter, confirm that it exposes metrics by querying its endpoint from the instance:

```
curl http://localhost:port-number/metrics
```

Step 1: Set up the scrape configuration

The following example uses `static_configs` with the instance private DNS names to scrape a sample application (port 8080) and Node Exporter (port 9100) on your Amazon EC2 instances. The `relabel_configs` section adds consistent labels to your metrics so that you can query and filter across services. For the full set of supported configuration options, see Scraper configuration.

```
global:
  scrape_interval: 30s
  scrape_timeout: 10s

scrape_configs:
  - job_name: 'ec2-metrics'
    static_configs:
      - targets:
          - ip-ip-address.us-west-2.compute.internal:8080
    metrics_path: '/metrics'
    relabel_configs:
      - source_labels: [__address__]
        target_label: instance
```

```
        replacement: 'ec2-metrics-instance'
      - target_label: service
        replacement: 'ec2-metrics'
      - target_label: environment
        replacement: 'dev'
    metric_relabel_configs:
      - source_labels: [__name__]
        regex: '.*'
        action: keep

- job_name: ec2-node-exporter
  static_configs:
    - targets:
        - ip-ip-address.us-west-2.compute.internal:9100
```

Step 2: Set up the scraper

Create a VPC-connected managed collector that scrapes your instances and delivers metrics to your CloudWatch dataset. Provide the subnets and security group that allow the collector to reach your exporter ports:

You can use GetDefaultScraperConfiguration to retrieve a general-purpose scraper configuration, or provide your own.

AWS API

Use the `CreateScraper` API operation to create a scraper with a CloudWatch destination. Replace the subnet, security group, and dataset information with your own values.

```
POST /scrapers HTTP/1.1

{
  "alias": "ec2-payment-service-scraper",
  "source": {
    "vpcConfiguration": {
      "subnetIds": ["subnet-subnet-id-1", "subnet-subnet-id-2"],
      "securityGroupIds": ["sg-security-group-id"]
    }
  },
  "destination": {
    "cloudWatchConfiguration": {
      "datasetArn": "arn:aws:cloudwatch:us-west-2:123456789012:dataset/default"
```

```
    }
  },
  "scrapeConfiguration": {
    "configurationBlob": "base64-encoded-blob"
  }
}
```

AWS CLI

Use the `create-scraper` command to create a scraper with a CloudWatch destination. Replace the subnet, security group, and dataset information with your own values.

```
aws amp create-scraper \
  --alias "ec2-payment-service-scraper" \
  --source '{
    "vpcConfiguration": {
      "subnetIds": ["subnet-subnet-id-1", "subnet-subnet-id-2"],
      "securityGroupIds": ["sg-security-group-id"]
    }
  }' \
  --scrape-configuration configurationBlob=$(cat ec2-scraper.yml | base64 -w 0) \
  --destination '{
    "cloudWatchConfiguration": {
      "datasetArn": "arn:aws:cloudwatch:us-west-2:123456789012:dataset/default"
    }
  }'
```

When you create a managed collector, Amazon Managed Service for Prometheus automatically creates a service-linked role that grants the collector permission to access your VPC resources and write to your CloudWatch dataset.

Validate metrics collection

Within minutes, metrics begin flowing to your CloudWatch dataset. To confirm that your metrics arrive, run an ad-hoc query in CloudWatch using Query Studio. For example, the following query returns the metrics for the `ec2-metrics` job:

```
{job="ec2-metrics"}
```

Build a custom dashboard

After the collector begins delivering your Amazon EC2 metrics to CloudWatch, you can build a custom CloudWatch dashboard to visualize them. With custom dashboards, you can combine metrics from your Prometheus exporters into widgets, add PromQL-based queries, and organize the widgets to fit your monitoring needs. For more information, see Using CloudWatch dashboards.

Costs

We charge for Prometheus collectors by the hour, and CloudWatch OpenTelemetry metric ingestion pricing applies. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

Amazon CloudWatch solution: Prometheus metric collection on Amazon ECS

This solution helps you collect Prometheus-compatible metrics from your Amazon ECS tasks without running or scaling your own collection infrastructure. Your tasks expose metrics through Prometheus exporters, and a Amazon CloudWatch managed Prometheus collector discovers the tasks in your VPC through DNS-based service discovery, scrapes their `/metrics` endpoints, and delivers the metrics to CloudWatch. Because Amazon ECS tasks are ephemeral and their IP addresses change, this solution uses AWS Cloud Map service discovery so that the collector always scrapes the current set of tasks. For general information about all CloudWatch observability solutions, see CloudWatch observability solutions. For more information about managed collectors, see Amazon CloudWatch managed Prometheus collectors.

Topics

- Requirements
- Enable Prometheus exporters
- Step 1: Set up security groups
- Step 2: Set up the scrape configuration
- Step 3: Set up the scraper
- Validate metrics collection
- Build a custom dashboard
- Costs

Requirements

This solution is relevant for the following conditions:

- Compute: Amazon ECS tasks (on Amazon EC2 or AWS Fargate) that expose Prometheus-compatible metrics.
- Amazon ECS services that you register with AWS Cloud Map for DNS-based service discovery.
- Amazon VPC with DNS enabled, and at least two subnets in different Availability Zones for the collector.
- A security group that allows the collector to reach the metrics port on your tasks. If your tasks and the collector share a security group, add a self-referencing ingress rule for the metrics port.
- If you deploy the collector in private subnets that have no internet access, an interface VPC endpoint for CloudWatch. For more information, see Configure VPC endpoints for private subnets.

Enable Prometheus exporters

A Prometheus exporter is a process that exposes metrics in Prometheus exposition format on an HTTP `/metrics` endpoint. On Amazon ECS, you typically run an exporter as a sidecar container in the same task definition as your application, or instrument the application to expose metrics directly. The following exporters are commonly used:

- **Node Exporter** — Host-level infrastructure metrics for tasks on the Amazon EC2 launch type (default port 9100). For more information, see the Node Exporter repository on GitHub.
- **JMX Exporter** — JVM and Java application metrics for Java workloads. For more information, see the JMX Exporter repository on GitHub.
- **NGINX Prometheus Exporter** — NGINX web server and reverse proxy metrics. For more information, see the NGINX Prometheus Exporter repository on GitHub.
- **DCGM Exporter** — NVIDIA GPU metrics for GPU workloads (default port 9400). For more information, see the DCGM Exporter repository on GitHub.
- **HAProxy Exporter** — HAProxy load balancer metrics. For more information, see the HAProxy Exporter repository on GitHub.
- **Apache Exporter** — Apache HTTP Server metrics. For more information, see the Apache Exporter repository on GitHub.

Add the exporter to your task definition and expose its metrics port by following the exporter's official documentation. For a complete catalog of available exporters, see Exporters and integrations in the Prometheus documentation.

Step 1: Set up security groups

Confirm that the security group for your Amazon ECS tasks allows inbound traffic from the collector on the metrics port. When your tasks and the collector share a security group, add a self-referencing ingress rule so that resources in the same security group can communicate. The following command allows inbound traffic on port 80 from the same security group:

```
aws ec2 authorize-security-group-ingress \
  --group-id sg-security-group-id \
  --ip-permissions IpProtocol=tcp,FromPort=80,ToPort=80,UserIdGroupPairs='[{GroupId=sg-security-group-id}]'
```

Step 2: Set up the scrape configuration

For Amazon ECS tasks that you register with AWS Cloud Map, use DNS-based service discovery (`dns_sd_configs`) to automatically find and scrape your tasks as they start and stop. The `dns_sd_configs` section directs the collector to query the AWS Cloud Map DNS name and scrape all returned IP addresses. When Amazon ECS replaces a task, the collector picks up the change on its next DNS query. The `relabel_configs` section adds consistent labels to your metrics so that you can query and filter across services. For the full set of supported configuration options, see Scraper configuration.

```
global:
  scrape_interval: 30s
  scrape_timeout: 10s

scrape_configs:
  - job_name: 'ecs-payforadoption'
    dns_sd_configs:
      - names: ['payforadoption-go.Workshop-space']
        type: A
        port: 80
    metrics_path: '/metrics'
    relabel_configs:
      - target_label: service_name
        replacement: 'payforadoption-go'
      - target_label: cloudmap_namespace
```

```
        replacement: 'Workshop-space'
      - target_label: environment
        replacement: 'production'
      - target_label: compute_platform
        replacement: 'ecs-fargate'
```

Step 3: Set up the scraper

Create a VPC-connected managed collector that scrapes your Amazon ECS tasks and delivers metrics to your CloudWatch dataset:

You can use GetDefaultScraperConfiguration to retrieve a general-purpose scraper configuration, or provide your own.

AWS API

Use the `CreateScraper` API operation to create a scraper with a CloudWatch destination. Replace the subnet, security group, and dataset information with your own values.

```
POST /scrapers HTTP/1.1

{
  "alias": "ecs-payforadoption-scraper",
  "source": {
    "vpcConfiguration": {
      "subnetIds": ["subnet-subnet-id-1", "subnet-subnet-id-2"],
      "securityGroupIds": ["sg-security-group-id"]
    }
  },
  "destination": {
    "cloudWatchConfiguration": {
      "datasetArn": "arn:aws:cloudwatch:us-west-2:123456789012:dataset/default"
    }
  },
  "scrapeConfiguration": {
    "configurationBlob": "base64-encoded-blob"
  }
}
```

AWS CLI

Use the `create-scraper` command to create a scraper with a CloudWatch destination. Replace the subnet, security group, and dataset information with your own values.

```
aws amp create-scraper \
  --alias "ecs-payforadoption-scraper" \
  --source '{
    "vpcConfiguration": {
      "subnetIds": ["subnet-subnet-id-1", "subnet-subnet-id-2"],
      "securityGroupIds": ["sg-security-group-id"]
    }
  }' \
  --scrape-configuration configurationBlob=$(cat ecs-scraper.yml | base64 -w 0) \
  --destination '{
    "cloudWatchConfiguration": {
      "datasetArn": "arn:aws:cloudwatch:us-west-2:123456789012:dataset/default"
    }
  }'
```

Validate metrics collection

After the collector begins delivering metrics, run an ad-hoc query in CloudWatch using Query Studio to confirm that your metrics arrive. For example, the following query returns the average requests per second to the Amazon ECS task over the last five minutes:

```
rate(payforadoption_requests_total[5m])
```

Build a custom dashboard

After the collector begins delivering your Amazon ECS metrics to CloudWatch, you can build a custom CloudWatch dashboard to visualize them. With custom dashboards, you can combine metrics from your Prometheus exporters into widgets, add PromQL-based queries, and organize the widgets to fit your monitoring needs. For more information, see Using CloudWatch dashboards.

Costs

We charge for Prometheus collectors by the hour, and CloudWatch OpenTelemetry metric ingestion pricing applies. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

Amazon CloudWatch solution: Amazon MSK insights

This solution helps you monitor your Amazon MSK clusters in CloudWatch without running or scaling your own collection infrastructure. When you enable Open Monitoring on an Amazon MSK cluster, the cluster exposes Prometheus metrics through the JMX Exporter and Node Exporter, and an Amazon CloudWatch managed Prometheus collector scrapes those metrics and delivers them to CloudWatch. For general information about all CloudWatch observability solutions, see CloudWatch observability solutions. For the complete collector setup walkthrough, including scraper creation and the example scrape configuration, see Integrate Amazon MSK.

Topics

- Requirements
- Enable the managed collector
- Amazon MSK detailed monitoring levels
- View the automatic dashboard
- Costs

Requirements

This solution is relevant for the following conditions:

- An Amazon MSK cluster in provisioned mode. Managed collectors do not support Amazon MSK Serverless or Amazon MSK Express clusters.
- Open Monitoring enabled on the cluster, which exposes the JMX Exporter (port 11001) and Node Exporter (port 11002).
- Amazon VPC with DNS enabled, and at least two subnets in different Availability Zones for the collector.
- A security group that allows the collector to reach broker ports 11001 and 11002.

Enable the managed collector

To collect Amazon MSK metrics with a managed collector, you enable Open Monitoring on your cluster and then create a VPC-connected collector that scrapes the broker endpoints and delivers metrics to your CloudWatch dataset. The collector connects to your VPC and scrapes all brokers

using DNS-based service discovery, so your monitoring stays resilient to broker replacements and cluster scaling. For step-by-step instructions, see Integrate Amazon MSK.

> **Note**
>
> The `--open-monitoring` parameter alone exposes the Prometheus endpoints on ports 11001 and 11002. Enhanced monitoring tiers such as `PER_TOPIC_PER_PARTITION` are separate from Open Monitoring and can incur additional charges, so set them only if you need that level of Amazon MSK metrics.

Amazon MSK detailed monitoring levels

Separately from the Prometheus metrics that the collector scrapes, Amazon MSK publishes its own metrics to CloudWatch at several monitoring levels. Each level builds on the previous one and provides more granular operational visibility. You choose a monitoring level when you create or update the cluster. The following list summarizes the levels. For the complete list of metrics at each level, see Amazon MSK metrics for monitoring with CloudWatch in the *Amazon MSK Developer Guide*.

- **Basic monitoring** (`DEFAULT`) — The default level, available at no additional cost. Includes cluster-level and broker-level metrics such as the number of brokers, number of partitions, bytes and messages in and out, CPU utilization, and network I/O.
- **Enhanced broker-level monitoring** (`PER_BROKER`) — Includes basic monitoring plus more granular per-broker metrics, at an additional cost.
- **Enhanced topic-level monitoring** (`PER_TOPIC_PER_BROKER`) — Includes enhanced broker-level monitoring plus per-topic metrics for a more granular view of topic performance across brokers, at an additional cost.
- **Enhanced partition-level monitoring** (`PER_TOPIC_PER_PARTITION`) — The most detailed level. Includes enhanced topic-level monitoring plus fine-grained per-partition metrics such as offset lag, at an additional cost.

> **Note**
>
> Amazon MSK publishes detailed monitoring metrics to classic CloudWatch metrics, which you can query with the `GetMetricData` API. To make detailed monitoring metrics

available alongside the Open Monitoring Prometheus metrics, you need to enable OpenTelemetry enrichment. For more information, see OpenTelemetry metric enrichment.

View the automatic dashboard

After the collector begins delivering your Amazon MSK metrics to CloudWatch, the CloudWatch console provides an automatic dashboard named **MSK OTel**. To open it, sign in to the AWS Management Console, open the CloudWatch console, choose **Dashboards** in the navigation pane, choose **Automatic dashboards**, and then choose **MSK OTel**. You can start monitoring your clusters without building any widgets or dashboards yourself. If the automatic dashboard meets your needs, you can use it as is. To build a tailored monitoring experience, you can add any of its widgets to a custom dashboard. For more information about custom dashboards, see Using CloudWatch dashboards.

Costs

We charge for Prometheus collectors by the hour, and CloudWatch OpenTelemetry metric ingestion pricing applies. Higher Amazon MSK monitoring levels also incur additional monthly costs. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

Monitor across accounts and Regions

To enable unified monitoring across accounts, CloudWatch offers the following features:

- **CloudWatch cross-account observability**– facilitate observability within a single Region with the Observability Access Manager (OAM) service. You can link accounts and easily view metrics, logs, traces, and other telemetry between accounts. This helps you to unify observability in central monitoring accounts that view telemetry shared from source accounts, and operate on this shared telemetry as if it were native to the monitoring account.
- **Cross-account cross-Region CloudWatch console**– delivers a console experience that allows you to view dashboards, metrics, and alarms consoles of other accounts across Regions by toggling between accounts. After you set up the necessary permissions, you use an account selector integrated into the alarms, dashboards, and metrics consoles to view metrics, dashboards, and alarms in other accounts without having to log in and out of the accounts. By enabling this feature, you can also set up dashboards that contain cross-account cross-Region metrics for centralized visibility within an account.
- **Cross-account cross-Region centralization**– Amazon CloudWatch centralization capability streamlines log and metrics consolidation for improved centralized monitoring, analysis, and compliance across your entire AWS infrastructure. You define centralization rules that control what gets centralized, enabling unified monitoring, alarming, and analysis from a single destination. For more information, see Cross-account cross-Region log centralization and Cross-account cross-Region metrics centralization.

These features are complementary to each other and can be used independently or together. See the following table for a comparison of the features. We recommend that you use CloudWatch cross-account observability for the richest cross-account observability and discovery experience within a Region for your metrics, logs, and traces.

	CloudWatch cross-account observability	Cross-account cross-Region CloudWatch console	Cross-account cross-Region centralization
What is it?	Unified access to underlying telemetry and other observability resources across	A designated monitoring account assume a **CrossAccountSharingRole** defined in source	Amazon CloudWatch centralization capability streamlines log and metrics consolida

	CloudWatch cross-account observability	Cross-account cross-Region CloudWatch console	Cross-account cross-Region centralization
	multiple accounts. After this is configured, observability resources are seamlessly viewable between accounts, eliminating the need for role assumptions. The central monitoring account gains direct access to the telemetry data and resources from source accounts, streamlining the monitoring and observability process.	accounts from the CloudWatch console. By assuming this role, the monitoring account can invoke operations such as dashboard viewing on behalf of source accounts, directly from its console.	tion for improved centralized monitoring, analysis, and compliance across your entire AWS infrastructure.

	CloudWatch cross-account observability	Cross-account cross-Region CloudWatch console	Cross-account cross-Region centralization
How does it work?	A monitoring account, using the Observability Access Monitoring service, creates a *sink* and attaches a sink policy to it. The sink policy defines which resources they would like to view and which source accounts should share them. Then source accounts can create a link to the monitoring account sink, establishing what they actually want to share. After the link is created, the specified resources are visible in the monitoring account.	A source account initiates the configuration by setting up a **CrossAccountSharingRole**, allowing a monitoring account to run operations in the source account. Then, a monitoring account enables the cross-account cross-Region selector in the console by specifying the source account ID. This enables the monitoring account to be able to switch into the source account. When switching, the CloudWatch console checks for the existence of a service-linked role that allows CloudWatch to assume the **CrossAccountSharingRole** that was created in the source account.	Uses AWS Organizations trusted access. An administrator creates a centralization rule in the management or delegated administrator account that defines source accounts/OUs/Regions and a destination account/Region. Logs and metrics arriving in source accounts are automatically copied to the destination with source metadata (account ID and Region) added.
What telemetry is supported?	• Metrics • Traces • Logs	• Metrics • Traces	• Logs • Metrics

	CloudWatch cross-account observability	Cross-account cross-Region CloudWatch console	Cross-account cross-Region centralization
What functionality is supported?	• Dashboarding • Alarms • Metrics Insights • Anomaly Detection • CloudWatch Logs insights • Application Insights • Other functionalities. For more details see CloudWatch cross-account observability.	• Console switching between accounts and Regions in metrics, alarms, and traces consoles. • Custom dashboards with metrics and alarms from other accounts and Regions For more details, see Cross-account cross-Region CloudWatch console.	Logs: CloudWatch Logs Insights, Subscription filters, Metric filters Metrics: Custom via PutMetricData, Embedded Metric Format (EMF), OpenTelemetry (OTLP)
How many accounts can I use it with?	A monitoring account can see resources from as many as 100,000 source accounts at the same time. A source account can share their resources with as many as five different monitoring accounts.	By using the cross-account cross-Region selector in the console, a monitoring account can switch to one other account at a time but there is no limit on the number of accounts that can be linked. When defining cross-account dashboards and alarms, many source accounts can be referenced.	Works with AWS Organizations supported number of accounts

	CloudWatch cross-account observability	Cross-account cross-Region CloudWatch console	Cross-account cross-Region centralization
Does it move telemetry data?	No. Resources are shared between accounts with the exception of copied traces.	No. An IAM policy is configured to allow embedded account switching for cross-account cross-Region resource visibility.	Yes
How much does it cost?	No extra charges for shared logs and metrics, and the first trace copy is free. For more information about pricing, see Amazon CloudWatch pricing.	No additional charges for cross-account or cross-Region actions.	The first copy of centralized telemetry is free. An optional backup region (second copy) is a paid feature. For more information, see Amazon CloudWatch Pricing.
Does it support observability across Regions?	No	Yes	Yes, you can centralize data across Regions.
Does it support programmatic access?	Yes. the AWS CLI, AWS Cloud Development Kit (AWS CDK), and APIs are supported.	No	Yes
Does it support programmatic setup?	Yes	Yes	Yes

	CloudWatch cross-account observability	Cross-account cross-Region CloudWatch console	Cross-account cross-Region centralization
Does it support AWS Organizations?	Yes	Yes	Yes. AWS Organizations is required to use this feature.

- Cross-account cross-Region CloudWatch console
- Cross-account cross-Region metrics centralization

CloudWatch cross-account observability

With Amazon CloudWatch cross-account observability, you can monitor and troubleshoot applications that span multiple accounts within a Region. Seamlessly search, visualize, and analyze your metrics, logs, traces, Application Signals services and service level objectives (SLOs), Application Insights applications, and internet monitors in any of the linked accounts without account boundaries.

Set up one or more AWS accounts as *monitoring accounts* and link them with multiple *source accounts*. A monitoring account is a central AWS account that can view and interact with observability data generated from source accounts. A source account is an individual AWS account that generates observability data for the resources that reside in it. Source accounts share their observability data with the monitoring account. The shared observability data can include the following types of telemetry:

- Metrics in Amazon CloudWatch. You can choose to share the metrics from all namespaces with the monitoring account, or filter to a subset of namespaces.
- Log groups in Amazon CloudWatch Logs. You can choose to share all log groups with the monitoring account, or filter to a subset of log groups.
- Traces in AWS X-Ray
- Services and Service level objectives (SLOs) in Application Signals

- Applications in Amazon CloudWatch Application Insights
- Monitors in CloudWatch Internet Monitor

To create links between monitoring accounts and source accounts, you can use the CloudWatch console. Alternatively, use the *Observability Access Manager* commands in the AWS CLI and API. For more information, see Observability Access Manager API Reference.

A *sink* is a resource that represents an attachment point in a monitoring account. Source accounts can link to the sink to share observability data. Each account can have one sink per Region. Each sink is managed by the monitoring account where it is located. An *observability link* is a resource that represents the link established between a source account and a monitoring account. Links are managed by the source account.

The next topic explains how to set up CloudWatch cross-account observability in both monitoring accounts and source accounts. For information about the cross-account cross-Region CloudWatch dashboard, see Cross-account cross-Region CloudWatch console.

Use Organizations for source accounts

There are two options for linking source accounts to your monitoring account. You can use one or both options.

- Use AWS Organizations to link accounts in an organization or organizational unit to the monitoring account.
- Connect individual AWS accounts to the monitoring account.

We recommend that you use Organizations so that new AWS accounts created later in the organization are automatically onboarded to cross-account observability as source accounts.

Details about linking monitoring accounts and source accounts

- Each monitoring account can be linked to as many as 100,000 source accounts.
- Each source account can share data with as many as five monitoring accounts.
- You can set up a single account as both a monitoring account and a source account. If you do, this account sends only the observability data from itself to its linked monitoring account. It does not relay the data from its source accounts.
- A monitoring account specifies which telemetry types can be shared with it. A source account specifies which telemetry types it wants to share.

- If there are more telemetry types selected in the *monitoring account* than in the source account, the accounts are linked. Only the data types that are selected in both accounts are shared.
- If there are more telemetry types selected in the *source account* than in the monitoring account, the link creation fails and nothing is shared.
- A metric name doesn't appear in the monitoring account console until that metric emits new data points after the link is created.

- To remove a link between accounts, do so from the source account.
- To delete a sink in a monitoring account, you must first remove all links to that sink the monitoring account.

Pricing

Cross-account observability in CloudWatch comes with no extra cost for logs and metrics, Application Signals, and the first trace copy is free. For more information about pricing, see Amazon CloudWatch Pricing.

}
```

- **Source account, scoped to a specific monitoring account** – To create, update, and manage links for just one specified monitoring account, you must sign in to account with at least the following permissions. In this example, the monitoring account is 999999999999.

  If the link isn't going to share all seven resource types (metrics, logs, traces, Application Insights applications, Application Signals services and service level objectives (SLOs), and Internet Monitor monitors), you can omit `cloudwatch:Link`, `logs:Link`, `xray:Link`, `applicationinsights:Link`, `application-signals:Link`, or `internetmonitor:Link` as needed.

  JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Action": [
                "oam:CreateLink",
                "oam:UpdateLink",
                "oam:DeleteLink",
                "oam:GetLink",
```

```
                "oam:TagResource"
            ],
            "Effect": "Allow",
            "Resource": "arn:*:oam:*:*:link/*"
        },
        {
            "Action": [
                "oam:CreateLink",
                "oam:UpdateLink"
            ],
            "Effect": "Allow",
            "Resource": "arn:*:oam:*:*:sink/*",
            "Condition": {
                "StringEquals": {
                    "aws:ResourceAccount": [
                        "999999999999"
                    ]
                }
            }
        },
        {
            "Action": "oam:ListLinks",
            "Effect": "Allow",
            "Resource": "*"
        },
        {
            "Action": "cloudwatch:Link",
            "Effect": "Allow",
            "Resource": "*"
        },
        {
            "Action": "logs:Link",
            "Effect": "Allow",
            "Resource": "*"
        },
        {
            "Action": "xray:Link",
            "Effect": "Allow",
            "Resource": "*"
        },
        {
             "Action": "applicationinsights:Link",
             "Effect": "Allow",
             "Resource": "*"
```

```
         },
        {
             "Action": "internetmonitor:Link",
             "Effect": "Allow",
             "Resource": "*"
        },
        {
             "Action": "application-signals:Link",
             "Effect": "Allow",
             "Resource": "*"
        }
    ]
}
```

- **Source account, with permissions to link to any monitoring account** – To create a link to any existing monitoring account sink and share metrics, log groups, traces, Application Insights applications, and Internet Monitor monitors, you must sign in to the source account with full administrator permissions or sign in there with the following permissions

  If the link isn't going to share all seven resource types (metrics, logs, traces, Application Insights applications, Application Signals services and service level objectives (SLOs), and Internet Monitor monitors), you can omit `cloudwatch:Link`, `logs:Link`, `xray:Link`, `applicationinsights:Link`, `application-signals:Link`, or `internetmonitor:Link` as needed.

  JSON

```

    "Version":"2012-10-17",
    "Statement": [{
            "Effect": "Allow",
            "Action": [
                "oam:CreateLink",
                "oam:UpdateLink"
            ],
            "Resource": [
                "arn:aws:oam:*:*:link/*",
                "arn:aws:oam:*:*:sink/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
```

```
                "oam:List*",
                "oam:Get*"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "oam:DeleteLink",
                "oam:GetLink",
                "oam:TagResource"
            ],
            "Resource": "arn:aws:oam:*:*:link/*"
        },
        {
            "Action": "cloudwatch:Link",
            "Effect": "Allow",
            "Resource": "*"
        },
        {
            "Action": "xray:Link",
            "Effect": "Allow",
            "Resource": "*"
        },
        {
            "Action": "logs:Link",
            "Effect": "Allow",
            "Resource": "*"
        },
        {
             "Action": "applicationinsights:Link",
             "Effect": "Allow",
             "Resource": "*"
        },
        {
             "Action": "internetmonitor:Link",
             "Effect": "Allow",
             "Resource": "*"
        },
        {
             "Action": "application-signals:Link",
             "Effect": "Allow",
             "Resource": "*"
        }
```

```
    ]
}
```

Permissions needed to monitor across accounts

After a link has been created, to view source account information from a monitoring account, you must be signed in to an account with one of the following:

- Full administrator access in the monitoring account
- The following cross-account permissions, in addition to permissions to view the specific types of resources that you will be monitoring

```
{
   "Sid": "AllowReadOnly",
   "Effect": "Allow",
   "Action": [
     "oam:Get*",
     "oam:List*"
   ],
   "Resource": "*"
 }
```

Setup overview

The following high-level steps show you how to set up CloudWatch cross-account observability.

> **Note**
>
> We recommend creating a new AWS account to use as your organization's monitoring account.

1. Set up a dedicated monitoring account.
2. (Optional) Download an CloudFormation template or copy a URL to link source accounts.
3. Link source accounts to the monitoring account.

After completing these steps, you can use the monitoring account to view the observability data of the source accounts.

Step 1: Set up a monitoring account

Follow the steps in this section to set up an AWS account as a monitoring account for CloudWatch cross-account observability.

Prerequisites

- **If you're setting up accounts in an AWS Organizations organization as the source accounts** – Get the organization path or organization ID.
- **If you're not using Organizations for the source accounts** – Get the account IDs of the source accounts.

To set up an account as a monitoring account, you must have certain permissions. For more information, see Necessary permissions.

To set up a monitoring account

1. Sign in to the account that you want to use as a monitoring account.
2. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
3. In the left navigation pane, choose **Settings**.
4. By **Monitoring account configuration**, choose **Configure**.
5. For **Select data**, choose whether this monitoring account will be able to view **Logs**, **Metrics**, **Traces**, **Application Insights - Applications**, **Internet Monitor - Monitors**, and **Application Signals - Services, Service Level Objectives (SLOs)** data from the source accounts it is linked to.
6. For **List source accounts**, enter the source accounts that this monitoring account will view. To identify the source accounts, enter individual account IDs, organization paths, or organization IDs. If you enter an organization path or organization ID, this monitoring account is allowed to view observability data from all linked accounts in that organization.

   Separate the entries in this list with commas.

> **Important**
>
> When you enter an organization path, follow the exact format. The ou-id must end with a / (a slash character). For example: `o-a1b2c3d4e5/r-f6g7h8i9j0example/ou-def0-awsbbbb/`

7. For **Define a label to use to identify your source account**, you can define alabel that is used to create a CloudFormation template. The label is then applied to source accounts when that template is used to link the source accounts to this monitoring account.

   You can specify whether to use account names or email addresses in this label, and also use variables such as `$AccountName`, `$AcccountEmail`, and `$AcccountEmailNoDomain`.

   > **Note**
   >
   > In the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions, the only supported option is to use custom labels, and the `$AccountName`, `$AcccountEmail`, and `$AcccountEmailNoDomain` variables all resolve as *`account-id`* instead of the specified variable.

8. Choose **Configure**.

> **Important**
>
> The link between the monitoring and source accounts is not complete until you configure the source accounts. For more information, see the following sections.

Step 2: (Optional) Download an CloudFormation template or URL

To link source accounts to a monitoring account, we recommend using an AWS CloudFormation template or a URL.

- **If you are linking an entire organization** – CloudWatch provides an CloudFormation template.
- **If you are linking individual accounts** – Use either an CloudFormation template or a URL that CloudWatch provides.

To use an CloudFormation template, you must download it during these steps. After you link the monitoring account with at least one source account, the CloudFormation template is no longer available to download.

To download an CloudFormation template or copy a URL for linking source accounts to the monitoring account

1. Sign in to the account that you want to use as a monitoring account.
2. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
3. In the left navigation pane, choose **Settings**.
4. By **Monitoring account configuration**, choose **Resources to link accounts**.
5. Do one of the following:
   - Choose **AWS organization** to get a template to use to link accounts in an organization to this monitoring account.
   - Choose **Any account** to get a template or URL for setting up individual accounts as source accounts.
6. Do one of the following:
   - If you chose **AWS organization**, choose **Download CloudFormation template**.
   - If you chose **Any account**, choose either **Download CloudFormation template** or **Copy URL**.
7. (Optional) Repeat steps 5-6 to download both the CloudFormation template and the URL.

Step 3: Link the source accounts

Use the steps in these sections to link source accounts to a monitoring account.

To link monitoring accounts with source accounts, you must have certain permissions. For more information, see Necessary permissions.

Use an CloudFormation template to set up all accounts in an organization or an organizational unit as source accounts

These steps assume that you already downloaded the necessary CloudFormation template by performing the steps in Step 2: (Optional) Download an CloudFormation template or URL.

To use an CloudFormation template to link accounts in an organization or organizational unit to the monitoring account

1. Sign in to the organization's management account.
2. Open the CloudFormation console at https://console.aws.amazon.com/cloudformation.
3. In the left navigation bar, choose **StackSets**.
4. Check that you are signed in to the Region that you want, then choose **Create StackSet**.
5. Choose **Next**.
6. Choose **Template is ready** and choose **Upload a template file**.
7. Choose **Choose file**, choose the template that you downloaded from the monitoring account, and choose **Open**.
8. Choose **Next**.
9. For **Specify StackSet details**, enter a name for the StackSet and choose **Next**.
10. For **Add stacks to stack set**, choose **Deploy new stacks**.
11. For **Deployment targets**, choose whether to deploy to the entire organization or to specified organizational units.
12. For **Specify regions**, choose which Regions to deploy CloudWatch cross-account observability to.
13. Choose **Next**.
14. On the **Review** page, confirm your selected options and choose **Submit**.
15. In the **Stack instances** tab, refresh the screen until you see that your stack instances have the status **CREATE_COMPLETE**.

Use an CloudFormation template to set up individual source accounts

These steps assume that you already downloaded the necessary CloudFormation template by performing the steps in Step 2: (Optional) Download an CloudFormation template or URL.

To use an CloudFormation template to set up individual source accounts for CloudWatch cross-account observability

1. Sign in to the source account.
2. Open the CloudFormation console at https://console.aws.amazon.com/cloudformation.
3. In the left navigation bar, choose **Stacks**.

4. Check that you are signed in to the Region that you want, then choose **Create stack**, **With new resources (standard)**.
5. Choose **Next**.
6. Choose **Upload a template file**.
7. Choose **Choose file**, choose the template that you downloaded from the monitoring account, and choose **Open**.
8. Choose **Next**.
9. For **Specify stack details**, enter a name for the stack and choose **Next**.
10. On the **Configure stack options** page, choose **Next**.
11. On the **Review** page, choose **Submit**.
12. On the status page for your stack, refresh the screen until you see that your stack has the status **CREATE_COMPLETE**.
13. To use this same template to link more source accounts to this monitoring account, sign out of this account and sign in to the next source account. Then repeat steps 2-12.

Use a URL to set up individual source accounts

These steps assume that you already copied the necessary URL by performing the steps in Step 2: (Optional) Download an CloudFormation template or URL.

To use a URL to link individual source accounts to the monitoring account

1. Sign in to the account that you want to use as a source account.
2. Enter the URL that you copied from the monitoring account.

   You see the CloudWatch settings page, with some information filled in.
3. For **Select data**, choose whether this source account will share **Logs**, **Metrics**, **Traces**, **Application Insights - Applications**, and **Internet Monitor - Monitors** data to this monitoring account.

   For both **Logs** and **Metrics**, you can choose whether to share all resources or a subset with the monitoring account.

   a. (Optional) To share a subset of this account's log groups with the monitoring account, select **Logs** and choose **Filter Logs**. Then use the **Filter Logs** box to construct a query to

find the log groups that you want to share. The query will use the term `LogGroupName` and one or more of the following operands.

- = and `!=`
- `AND`
- `OR`
- `^` indicates LIKE and `!^` indicates NOT LIKE. These can be used only as prefix searches. Include a `%` at the end of the string that you want to search for and include.
- `IN` and `NOT IN`, using parentheses `(  )`

The complete query must be no more than 2000 characters and is limited to five conditional operands. Conditional operands are `AND` and `OR`. There isn't a limit on the number of other operands.

> **Tip**
>
> Choose **View sample queries** to see the correct syntax for common query formats.

b. (Optional) To share a subset of this account's metric namespaces with the monitoring account, select **Metrics** and choose **Filter Metrics**. Then use the **Filter Metrics** box to construct a query to find the metric namespaces that you want to share. Use the term `Namespace` and one or more of the following operands.

- = and `!=`
- `AND`
- `OR`
- `LIKE` and `NOT LIKE`. These can be used only as prefix searches. Include a `%` at the end of the string that you want to search for and include.
- `IN` and `NOT IN`, using parentheses `(  )`

The complete query must be no more than 2000 characters and is limited to five conditional operands. Conditional operands are `AND` and `OR`. There isn't a limit on the number of other operands.

> **Tip**
>
> Choose **View sample queries** to see the correct syntax for common query formats.

4. Do not change the ARN in **Enter monitoring account configuration ARN**.
5. The **Define a label to identify your source account** section is pre-filled with the label choice from the monitoring account, if there is one. Optionally, choose **Edit** to change it.

> **Note**
>
> In the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions, the only supported option is to use custom labels, and the `$AccountName`, `$AcccountEmail`, and `$AcccountEmailNoDomain` variables all resolve as *`account-id`* instead of the specified variable.

6. Choose **Link**.
7. Enter **`Confirm`** in the box and choose **Confirm**.
8. To use this same URL to link more source accounts to this monitoring account, sign out of this account and sign in to the next source account. Then repeat steps 2-7.

Manage monitoring accounts and source accounts

After you set up your monitoring accounts and source accounts, you can use the steps in these sections to manage them.

Contents

- Link more source accounts to an existing monitoring account
- Remove the link between a monitoring account and source account
- View information about a monitoring account

Link more source accounts to an existing monitoring account

Follow the steps in this section to add links from additional source accounts to an existing monitoring account.

Each source account can be linked to as many as five monitoring accounts. Each monitoring account can be linked to as many as 100,000 source accounts.

To manage a source account, you must have certain permissions. For more information, see Necessary permissions.

To add more source accounts to a monitoring account

1. Sign in to the monitoring account.
2. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
3. In the left navigation pane, choose **Settings**.
4. By **Monitoring account configuration**, choose **Manage source accounts**.
5. Choose the **Configuration policy** tab.
6. In the **Configuration policy** box, add the new source account ID in the **Principal** line.

   For example, suppose the **Principal** line is currently the following:

   ```
   "Principal": {"AWS": ["111111111111", "222222222222"]}
   ```

   To add 999999999999 as a third source account, edit the line to the following:

   ```
   "Principal": {"AWS": ["111111111111", "222222222222", "999999999999"]}
   ```
7. Choose **Update**.
8. Choose the **Configuration details** tab.
9. Choose the copy icon that is next to the monitoring account's sink ARN.
10. Sign in to the account that you want to use as a new source account.
11. Paste the monitoring account's sink ARN that you copied in Step 9.

    You see the CloudWatch settings page, with some information filled in.
12. For **Select data**, choose whether this source account will send **Logs**, **Metrics**, **Traces**, and **Application Insights - Applications**, **Internet Monitor - Monitors**, and **Application Signals - Services, Service Level Objectives (SLOs)** data to the monitoring accounts it is linked to.
13. Do not change the ARN in **Enter monitoring account configuration ARN**.
14. The **Define a label to identify your source account** section is pre-filled with the label choice from the monitoring account, if there is one. Optionally, choose **Edit** to change it.

> **Note**
>
> In the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions, the only supported option is to use custom labels, and the `$AccountName`, `$AcccountEmail`, and `$AcccountEmailNoDomain` variables all resolve as *`account-id`* instead of the specified variable.

15. Choose **Link**.
16. Enter **`Confirm`** in the box and choose **Confirm**.

Remove the link between a monitoring account and source account

Follow the steps in this section to stop sending data from one source account to a monitoring account.

> **Note**
>
> After the source account stops sharing the metrics with the *Monitoring* account, the *Source* account metrics data is not accessible to the monitoring account. Source metric names can be visible to the monitoring account for upto 14 days.

You must have the permissions required to manage a source account to complete this task. For more information, see Necessary permissions.

To remove the link between a source account and a monitoring account

1. Sign in to the source account.
2. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
3. In the left navigation pane, choose **Settings**.
4. By **Source account configuration**, choose **View linked monitoring accounts**.
5. Select the check box next to the monitoring account that you want to stop sharing data with.
6. Choose **Remove monitoring account**, **Confirm**.
7. Sign in to the monitoring account.
8. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

9. Choose **Settings**.
10. By **Monitoring account configuration**, choose **Manage monitoring account**.
11. In the **Configuration policy** box, delete the source account ID from the **Principal** line and choose **Update**.

View information about a monitoring account

Follow the steps in this section to view the cross-account settings for a monitoring account.

To manage a monitoring account, you must have certain permissions. For more information, see Necessary permissions.

To manage a monitoring account

1. Sign in to the monitoring account.
2. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
3. In the left navigation pane, choose **Settings**.
4. By **Monitoring account configuration**, choose **Manage monitoring accounts**.
5. To view the Observability Access Manager policy that enables this account to be a monitoring account, choose the **Configuration policy** tab.
6. To view the source accounts that are linked to this monitoring account, choose the **Linked source accounts** tab.
7. To view the monitoring account sink ARN, and the types of data that this monitoring account can view in linked source accounts, choose the **Linked source accounts** tab.

Cross-account cross-Region CloudWatch console

> **Note**
>
> We recommend that you use CloudWatch cross-account observability to get the richest cross-account observability and discovery experience for your metrics, logs, and traces within a Region. For more information, see CloudWatch cross-account observability.

The cross-account, cross-Region CloudWatch console allows you to easily switch between different accounts and Region by using selectors in the console to view the dashboards, alarms, and metrics

in other accounts and Regions. This feature also allows you to create cross-account, cross-Region dashboards which summarize your CloudWatch metrics from multiple AWS accounts and multiple Regions into a single dashboard, making them accessible without having to switch accounts or Regions.

Many organizations have their AWS resources deployed in multiple accounts, to provide billing and security boundaries. In this case, we recommend that you designate one or more of your accounts as your *monitoring accounts*, and build your cross-account cross-Region dashboards in these accounts. Cross-account cross-Region console functionality is integrated with AWS Organizations, to help you efficiently build your cross-account cross-Region dashboards.

The cross-account, cross-region CloudWatch console experience does not provide cross-account cross-Region visibility for logs. Additionally, it does not support the creation of alarms on metrics in other accounts or Regions from within a monitoring account.

Topics

- Enabling cross-account cross-Region functionality in CloudWatch
- (Optional) Integrate with AWS Organizations
- Troubleshooting your CloudWatch cross-account setup
- Monitoring account permissions for cross-account access
- Disabling and cleaning up after using cross-account

Enabling cross-account cross-Region functionality in CloudWatch

To set up cross-account cross-Region functionality in your CloudWatch console, use the CloudWatch console to set up your sharing accounts and monitoring accounts.

Set up a sharing account

You must enable sharing in each account that will make data available to the monitoring account.

This grants the read-only permissions that you choose in step 5 to all users that view a cross account dashboard in the account that you share with, if the user has corresponding permissions in the account that you share with.

To enable your account to share CloudWatch data with other accounts

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

2. In the navigation pane, choose **Settings**.
3. For **Share your CloudWatch data**, choose **Configure**.
4. For **Sharing**, choose **Specific accounts** and enter the IDs of the accounts that you want to share data with.

   Any accounts that you specify here can view your account's CloudWatch data. Specify the IDs only of accounts that you know and trust.
5. For **Permissions**, specify how to share your data with one of the following options:

   - **Provide read-only access to your CloudWatch metrics, dashboards, and alarms**. This option enables the monitoring accounts to create cross-account dashboards that include widgets that contain CloudWatch data from your account.
   - **Include CloudWatch automatic dashboards**. If you select this option, users in the monitoring account can also view the information in this account's automatic dashboards. For more information, see Getting started with CloudWatch automatic dashboards.
   - **Include X-Ray read-only access for the X-Ray Trace Map**. If you select this option, users in the monitoring account can also view the X-Ray trace map and X-Ray trace information in this account. For more information, see Using the X-Ray Trace Map.
   - **Include read-only access for Database Insights**. If you select this option, users in the monitoring account can also view Database Insights telemetry in this account. For more information, see Set up cross-account cross-region monitoring for CloudWatch Database Insights.
   - **Full read-only access to everything in your account**. This option enables the accounts that you use for sharing to create cross-account dashboards that include widgets that contain CloudWatch data from your account. It also enables those accounts to look deeper into your account and view your account's data in the consoles of other AWS services.
6. Choose **Launch CloudFormation template**.

   In the confirmation screen, type **`Confirm`**, and choose **Launch template**.
7. Select the **I acknowledge...** check box, and choose **Create stack**.

Sharing with an entire organization

Completing the preceding procedure creates an IAM role which enables your account to share data with one account. You can create or edit an IAM role that shares your data with all accounts in an organization. Do this only if you know and trust all accounts in the organization.

This grants the read-only permissions listed in the policies shown in step 5 of the previous procedure to all users that view a cross-account dashboard in the account that you share with, if the user has corresponding permissions in the account that you share with.

To share your CloudWatch account data with all accounts in an organization

1. If you haven't already, complete the preceding procedure to share your data with one AWS account.
2. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
3. In the navigation pane, choose **Roles**.
4. In the list of roles, choose **CloudWatch-CrossAccountSharingRole**.
5. Choose **Trust relationships**, **Edit trust relationship**.

   You see a policy like this:

   JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::123456789012:root"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

6. Change the policy to the following, replacing *org-id* with the ID of your organization.

   JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
```

```
      "Effect": "Allow",
      "Principal": {
        "AWS": "*"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:PrincipalOrgID": "org-id"
        }
      }

    }
  ]
}
```

7. Choose **Update Trust Policy**.

Set up a monitoring account

Enable each monitoring account to view cross-account CloudWatch data. You can enable a monitoring account by using the Amazon CloudWatch console or the AWS Cloud Development Kit (AWS CDK).

After you set up a monitoring account, you can create cross-account dashboards. For more information, see Creating a customized CloudWatch dashboard.

Enable a monitoring account by using the console

When you complete the following procedure, CloudWatch creates a service role that CloudWatch uses in the monitoring account to access data shared from your other accounts. This service role is called **ServiceRoleForCloudWatchCrossAccountV2**.

To enable your account to view cross-account CloudWatch data

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Settings**, and then, in the **Cross-account cross-region** section, choose **Configure**.
3. Under the **View cross-account cross-region** section, choose **Enable**, and then select the **Show selector in the console** checkbox to enable an account selector to appear in the CloudWatch console when you're graphing a metric or creating an alarm.
4. Under **View cross-account cross-region**, choose one of the following options:

- **Account Id Input**. This option prompts you to manually input an account ID each time that you want to switch accounts when you view cross-account data.
- **AWS Organization account selector**. This option causes the accounts that you specified when you completed your cross-account integration with Organizations to appear. When you next use the console, CloudWatch displays a dropdown list of these accounts for you to select from when you are viewing cross-account data.

  To do this, you must have first used your organization management account to allow CloudWatch to see a list of accounts in your organization. For more information, see (Optional) Integrate with AWS Organizations.
- **Custom account selector**. This option prompts you to enter a list of account IDs. When you next use the console, CloudWatch displays a dropdown list of these accounts for you to select from when you are viewing cross-account data.

  You can also enter a label for each of these accounts to help you identify them when choosing accounts to view.

  The account selector settings that a user makes here are retained only for that user, not for all other users in the monitoring account.

5. Choose **Enable**.

Enable a monitoring account by using the CDK

You can also set up a monitoring account without using the console. Define the **ServiceRoleForCloudWatchCrossAccountV2** role as infrastructure as code. Use this approach when you manage multiple monitoring accounts. It deploys the role consistently across all of them. The following example uses the AWS CDK in TypeScript to define the role with the required trust policy and an inline permissions policy:

```
import { Role, ServicePrincipal, PolicyDocument, PolicyStatement, Effect } from 'aws-
cdk-lib/aws-iam';

new Role(this, 'ServiceRoleForCloudWatchCrossAccountV2', {
  roleName: 'ServiceRoleForCloudWatchCrossAccountV2',
  path: '/service-role/',
  assumedBy: new ServicePrincipal('cloudwatch-crossaccount.amazonaws.com'),
  description: 'Allows CloudWatch to assume the CloudWatch-CrossAccountSharingRole in
 sharing accounts.',
```

```
  inlinePolicies: {
    CrossAccountAccess: new PolicyDocument({
      statements: [
        new PolicyStatement({
          effect: Effect.ALLOW,
          actions: ['sts:AssumeRole'],
          resources: ['arn:aws:iam::*:role/CloudWatch-CrossAccountSharingRole'],
        }),
      ],
    }),
  },
});
```

This example uses a wildcard resource, which is the least restrictive scope. To restrict the monitoring account to specific sharing accounts or to an organization, change the `resources` array. You can add a `conditions` property with an `aws:ResourceOrgID` condition. Either approach matches one of the inline policies in the following section.

To deploy the role to many accounts at once, use the synthesized template with CloudFormation StackSets. A stack set creates the role across multiple accounts and Regions in a single operation. A stack set also automatically deploys the role to new accounts that join your organization. For more information about CloudFormation StackSets, see Working with CloudFormation StackSets in the *CloudFormation User Guide*.

Scope of accounts the monitoring account can access

When you define the role with the AWS CDK, the inline permissions policy grants `sts:AssumeRole` permission. CloudWatch uses this permission to assume the **CloudWatch-CrossAccountSharingRole** in your sharing accounts. To follow the principle of least privilege, limit the `Resource` of the `sts:AssumeRole` action to only the accounts that the monitoring account needs. You can scope access in the following ways, from most restrictive to least restrictive:

- **An entire organization** – Allow the monitoring account to assume the sharing role only in accounts that belong to your organization. Replace *`org-id`* with the ID of your organization (for example, `o-a1b2c3d4e5`). Use the following JSON inline policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
```

```
      "Action": "sts:AssumeRole",
      "Resource": "arn:aws:iam::*:role/CloudWatch-CrossAccountSharingRole",
      "Condition": {
        "StringEquals": {
          "aws:ResourceOrgID": "org-id"
        }
      }
    }
  ]
}
```

- **A list of accounts** – Allow the monitoring account to assume the sharing role only in the accounts that you list. Replace each example account ID (such as 111122223333) with the ID of a sharing account. Use the following JSON inline policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "sts:AssumeRole",
      "Resource": [
        "arn:aws:iam::111122223333:role/CloudWatch-CrossAccountSharingRole",
        "arn:aws:iam::444455556666:role/CloudWatch-CrossAccountSharingRole"
      ]
    }
  ]
}
```

- **Any account** – Allow the monitoring account to assume the sharing role in any account. This matches the permissions of the role that CloudWatch creates for you, but it is the least restrictive option. Use the following JSON inline policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "sts:AssumeRole",
      "Resource": "arn:aws:iam::*:role/CloudWatch-CrossAccountSharingRole"
    }
  ]
```

```
}
```

Cross-Region functionality

This feature provides Cross-Region functionality automatically. You do not need to take any extra steps to display metrics from different Regions in a single account on the same graph or the same dashboard. Cross-Region functionality is not supported for alarms, so you cannot create an alarm in one Region that watches a metric in a different Region.

(Optional) Integrate with AWS Organizations

If you want to integrate cross-account functionality with AWS Organizations, you must make a list of all accounts in the organization available to the monitoring accounts.

To enable cross-account CloudWatch functionality to access a list of all accounts in your organization

1. Sign in to your organization's management account.
2. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
3. In the navigation pane, choose **Settings**, then choose **Configure**.
4. For **Grant permission to view the list of accounts in the organization**, choose **Specific accounts** to be prompted to enter a list of account IDs. The list of accounts in your organization are shared with only the accounts that you specify here.
5. Choose **Share organization account list**.
6. Choose **Launch CloudFormation template**.

   In the confirmation screen, type **`Confirm`**, and choose **Launch template**.

Troubleshooting your CloudWatch cross-account setup

This section contains troubleshooting tips for cross-account, console deployment in CloudWatch.

I am getting access denied errors displaying cross-account data

Check the following:

- Your monitoring account must have a role named **ServiceRoleForCloudWatchCrossAccountV2**. If it does not, create this role. For more information, see the section called “Set up a monitoring account”.
- Each sharing account must have a role named **CloudWatch-CrossAccountSharingRole**. If it does not, create this role. For more information, see the section called “Set up a sharing account”.
- The sharing role must trust the monitoring account.

To confirm that your roles are set up properly for the CloudWatch cross-account console

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**.
3. In the list of roles, make sure the needed role exists. In a sharing account, look for **CloudWatch-CrossAccountSharingRole**. In a monitoring account, look for **ServiceRoleForCloudWatchCrossAccountV2**.
4. If you are in a sharing account and **CloudWatch-CrossAccountSharingRole** already exists, choose **CloudWatch-CrossAccountSharingRole**.
5. Choose **Trust relationships**, **Edit trust relationship**.
6. Confirm that the policy lists either the account ID of the monitoring account, or the organization ID of an organization that contains the monitoring account.

I don't see an account dropdown in the console

First, check that you have created the correct IAM roles, as discussed in the preceding troubleshooting section. If those are set up correctly, make sure that you have enabled this account to view cross-account data, as described in Enable Your Account to View Cross-Account Data.

Monitoring account permissions for cross-account access

To access an action in source accounts successfully, the user in the monitoring account must have the equivalent permission for all resources (*) for that action in the monitoring account. This is a local permission requirement in the monitoring account and is unrelated to permissions in the cross-account sharing role in source accounts.

Example

To start a Logs query in a source account, you must have wildcard (*) access to StartQuery in the monitoring account. The source account's cross-account role can still restrict access to specific log groups.

Supported - wildcard resource:

```
{
  "Effect": "Allow",
  "Action": "logs:StartQuery",
  "Resource": "*"
}
```

Not supported - specific ARN:

```
{
  "Effect": "Allow",
  "Action": "logs:StartQuery",
  "Resource": "arn:aws:logs:us-east-1:123456789012:log-group:/aws/lambda/my-function:*"
}
```

Disabling and cleaning up after using cross-account

To disable cross-account functionality for CloudWatch, follow these steps.

Step 1: Remove the cross-account stacks or roles

The best method is to remove the CloudFormation stacks that were used to enable cross-account functionality.

- In each of the sharing accounts, remove the **CloudWatch-CrossAccountSharingRole** stack.
- If you used AWS Organizations to enable cross-account functionality with all accounts in an organization, remove the **CloudWatch-CrossAccountListAccountsRole** stack in the organization's management account.

If you didn't use the CloudFormation stacks to enable cross-account functionality, do the following:

- In each of the sharing accounts, delete the **CloudWatch-CrossAccountSharingRole** IAM role.

- If you used AWS Organizations to enable cross-account functionality with all accounts in an organization, delete the **CloudWatch-CrossAccountSharing-ListAccountsRole** IAM role in the organization's management account.

Step 2: Remove the service role

In the monitoring account, delete the **ServiceRoleForCloudWatchCrossAccountV2** IAM service role.

Cross-account cross-Region metrics centralization

Amazon CloudWatch Metrics centralization automatically centralizes metrics from multiple source accounts and Regions into a single destination account within your AWS Organizations organization. You define rules to control what gets centralized, enabling unified monitoring, alarming, and analysis across your entire AWS infrastructure.

CloudWatch Metrics centralization supports the full range of CloudWatch metrics query capabilities in the destination account, including GetMetricData, PromQL, Metric Math, Anomaly Detection, and Alarms.

Metrics centralization concepts

Before you begin using CloudWatch Metrics centralization, familiarize yourself with the following concepts:

- **Source account** – The AWS account where metric data originates.
- **Destination account** – The AWS account where centralized metric data is stored. This account serves as the centralized location for metric querying, alarming, and analysis.
- **Source metadata** – Centralized metrics are automatically tagged with source metadata so you can identify the origin of each metric in the destination account. For Metrics Insights querying, the dimensions `:@aws.account` and `:@aws.region` are added. For PromQL querying, the attributes `@aws.account` and `@aws.region` are added.
- **Backup region** – An optional secondary Region (see pricing) within the destination account where metric data can be centralized for increased resiliency and disaster recovery purposes.

Centralized metrics

When you enable metrics centralization, CloudWatch automatically centralizes metrics from your source accounts to the destination account. Once centralized, a copy of the metrics is now owned by your destination account. Metrics ingested via PutMetricData or EMF are queryable using GetMetricData. Metrics ingested via OpenTelemetry (OTLP) are queryable using PromQL.

Supported metric types

The following metric types are centralized:

- Custom metrics (PutMetricData)
- Embedded Metric Format (EMF) metrics
- OpenTelemetry (OTLP) metrics

Source metadata dimensions

Centralized metrics include additional source identification metadata. The format differs based on the query path:

Metrics Insights querying (GetMetricData)

Dimension	Description
`:@aws.account`	The AWS account ID where the metric originated
`:@aws.region`	The AWS Region where the metric originated

PromQL querying

Attribute	Description
`@aws.account`	The AWS account ID where the metric originated
`@aws.region`	The AWS Region where the metric originated

Setting up metrics centralization

To set up CloudWatch Metrics centralization, you need to configure centralization rules that define how metric data flows from source accounts to your destination account.

Prerequisites

- AWS Organizations must be set up and the source and destination accounts must both belong to the same organization.
- Trusted access must be enabled for CloudWatch so the management account and the destination account can access the metric data.

> **Note**
>
> It is recommended to enable trusted access through the console, which automatically creates the required service-linked role (SLR). If trusted access is enabled through other methods, the service-linked role will need to be created separately.

Creating a centralization rule

Use the following procedure to create a centralization rule that centralizes metric data from source accounts to your destination account.

To create a centralization rule

1. Navigate to the CloudWatch console in the Management or Delegated Administrator account of the organization.
2. Choose **Settings**.
3. Navigate to the **Organization** tab.
4. Choose **Configure rule**.
5. Specify source details by setting the following fields, then choose **Next**:
    a. **Centralization rule name**: Enter a unique name for the centralization rule.
    b. **Source accounts**: Define source selection criteria to pick accounts from which metric data will be centralized. The selection criteria can include:

- A list of member accounts in the organization
- A list of organization units in the organization
- The entire organization

You can provide the selection criteria in two modes:

- **Builder**: A click-based experience to generate the source selection criteria
- **Editor**: A free-form text box to provide the source selection criteria

Supported syntax for source selection criteria:

- **Supported Keys:**`OrganizationId` | `OrganizationUnitId` | `AccountId` | `*`
- **Supported Operators:**= | `IN` | `OR`

c. **Source regions**: Select a list of Regions to look for the metric data to centralize.

6. Specify destination details by setting the following fields, then choose **Next**:

a. **Metrics**: Ensure Metrics is selected (it is enabled by default). If you only want to centralize metrics, you can deselect Logs.

b. **Destination region**: Select a primary Region that stores a copy of the centralized metric data.

7. Specify telemetry data by setting the following fields, then choose **Next**:

a. **Metrics**: All metrics from the source accounts are centralized to the destination account. This includes custom metrics, Embedded Metric Format (EMF) metrics, and OpenTelemetry (OTLP) metrics.

b. **Backup region**: Optionally select a Region that stores a second copy of the centralized metric data. Logs and metrics can have separate backup region settings.

> **Note**
>
> Currently, all metrics from source accounts are centralized. Selective metric filtering is not supported at this time.

8. Review the centralization rule, optionally make any last-minute edits, and choose **Create centralization policy**.

Modifying a centralization rule

To modify a centralization rule

1. Navigate to the CloudWatch console in the Management or Delegated Administrator account of the organization.
2. Choose **Settings**.
3. Navigate to the **Organization** tab.
4. Choose **Manage rules**.
5. Select the rule to update and choose **Edit**.
6. Update the rule configuration as needed, choosing **Next** to proceed through each step.
7. In Step 4, Review and configure, choose **Update centralization policy**.

Viewing a centralization rule

To view a centralization rule

1. Navigate to the CloudWatch console in the Management or Delegated Administrator account of the organization.
2. Choose **Settings**.
3. Navigate to the **Organization** tab.
4. Choose **Manage rules**.
5. View a list of all existing centralization rules and choose a specific rule name to view its details.

Deleting a centralization rule

To delete a centralization rule

1. Navigate to the CloudWatch console in the Management or Delegated Administrator account of the organization.
2. Choose **Settings**.
3. Navigate to the **Organization** tab.

4. Choose **Manage rules**.
5. Select the rule to delete and choose **Delete**.
6. Confirm deletion and choose **Delete**.

Features supported with centralized metrics

The following CloudWatch features work with centralized metrics in the destination account:

> **Note**
>
> Resource-based automatic dashboards (such as EC2 and S3) have partial support. These dashboards may show incomplete data for centralized metrics because they depend on resource metadata that is not centralized from source accounts.

Fully supported features

Feature	Description
GetMetricData API	Query metric data points programmatically
GetMetricStatistics API	Query metric statistics
ListMetrics API	Discover available centralized metrics
Console Metric Browser	Browse and navigate centralized metrics
Metrics Insights (SQL queries)	Query metrics using SQL-like syntax
Query Studio	Unified query interface for PromQL and metrics
Search Expressions	Dynamic metric discovery via SEARCH()
Metric Math	Arithmetic, comparison, and logical operators on time series
Anomaly Detection	ML-based anomaly detection models and alarms
Metric Alarms	Standard threshold-based alarms
Composite Alarms	Boolean logic combining multiple alarm states

Feature	Description
PromQL Alarms	Alarms using PromQL expressions
Alarm Actions (SNS)	SNS notifications on alarm state changes
CloudWatch Dashboards	Add centralized metrics to dashboards
Metric Streams	Stream centralized metrics to Firehose, S3, or partners
PromQL Querying	Prometheus-compatible metric queries

Monitoring and troubleshooting centralization rules

You can monitor the status and performance of your centralization rules using CloudWatch metrics, the CloudWatch console, and AWS CloudTrail logs.

Monitoring centralization API calls with AWS CloudTrail

AWS CloudTrail logs API calls made to the centralization service. Key CloudTrail events include:

- `CreateCentralizationRuleForOrganization`: When a new centralization rule is created
- `UpdateCentralizationRuleForOrganization`: When an existing rule is modified
- `DeleteCentralizationRuleForOrganization`: When a rule is deleted
- `GetCentralizationRuleForOrganization`: When rule details are retrieved
- `ListCentralizationRulesForOrganization`: When rules are listed

Troubleshooting common issues

If metrics are not being centralized as expected, review the following common scenarios:

- **Historical metric data** – The centralization feature only processes new metric data that arrives after rule creation. Historical data is not centralized.
- **Trusted access not enabled** – Trusted access must be enabled for CloudWatch in AWS Organizations for the management account and the destination account.
- **Source selection criteria** – Verify that your centralization rule's source selection criteria includes the correct accounts and Regions.

- **Organization membership** – Both source and destination accounts must belong to the same AWS Organizations organization.
- **Metric quota limits** – If the destination account has reached its metric quota limits, new metrics cannot be ingested. Request a quota increase if needed.
- **Rule health status** – Check the centralization rule health status in the console or using the `GetCentralizationRuleForOrganization` API. Each centralization rule has a health status that indicates whether it is operating correctly. Rule health statuses include:
  - `HEALTHY`: The rule is operating normally and replicating metric data as configured.
  - `UNHEALTHY`: The rule has encountered issues and may not be replicating data correctly.
  - `PROVISIONING`: Centralization for the organization is in the process of being set up.

Pricing

The first copy of centralized metrics is free. Please see the Amazon CloudWatch Pricing page for more information.

Collect and send telemetry

CloudWatch provides multiple methods to collect and send telemetry data from your applications and infrastructure. Use the CloudWatch agent to collect metrics and logs from Amazon EC2 instances and on-premises servers, embedded metric format to generate metrics from structured log data, or CloudWatch Pipelines to transform and route telemetry at scale.

Topics

- Collect metrics, logs, and traces using the CloudWatch agent
- Embedding metrics within logs
- CloudWatch pipelines
- Amazon CloudWatch managed Prometheus collectors

Collect metrics, logs, and traces using the CloudWatch agent

The CloudWatch agent is a software component that collects metrics, logs, and traces from your Amazon EC2 instances, on-premises servers, and containerized applications. It enables you to monitor your infrastructure and applications more comprehensively than the basic monitoring provided by default.

The CloudWatch agent enables you to do the following:

- Collect internal system-level metrics from Amazon EC2 instances across operating systems. The metrics can include in-guest metrics, in addition to the metrics for Amazon EC2 instances. For a list of additional metrics that you can collect, see Metrics collected by the CloudWatch agent.
- Collect system-level metrics from on-premises servers. These can include servers in a hybrid environment as well as servers not managed by AWS.
- Retrieve custom metrics from your applications or services using the `StatsD` and `collectd` protocols. `StatsD` is supported on both Linux servers and servers running Windows Server. `collectd` is supported only on Linux servers.
- Collect logs from Amazon EC2 instances and on-premises servers, running either Linux or Windows Server.

> **Note**
>
> The CloudWatch agent does not support collecting logs from FIFO pipes.

- Send the metrics to either CloudWatch or Amazon Managed Service for Prometheus, or to both. The CloudWatch agent configuration file contains a `metrics_destinations` parameter in the `metrics` section. You can specify `cloudwatch`, `amp`, or both in this parameter.
- Version 1.300031.0 and later can be used to enable CloudWatch Application Signals. For more information, see Application Signals.
- Version 1.300025.0 and later can collect traces from OpenTelemetry or X-Ray client SDKs, and send them to X-Ray.

  Using the CloudWatch agent allows you to collect traces without needing to run a separate trace collection daemon, helping to reduce the number of agents that you run and manage.

Metrics sent to CloudWatch can be viewed in CloudWatch just as any other CloudWatch metrics. The default CloudWatch namespace for metrics collected by the CloudWatch agent is `CWAgent`, although you can specify a different namespace when you configure the agent.

The logs collected by the CloudWatch agent are processed and stored in Amazon CloudWatch Logs, just like logs collected by the older CloudWatch Logs agent. For information about CloudWatch Logs pricing, see Amazon CloudWatch Pricing.

Metrics collected by the CloudWatch agent are billed as custom metrics. For more information about CloudWatch metrics pricing, see Amazon CloudWatch Pricing.

The CloudWatch agent is open-source under the MIT license, and is hosted on GitHub. If you would like to build, customize or contribute to the CloudWatch agent, see the GitHub repository for the latest instructions. If you think you've found a potential security issue, do not post it on GitHub or any public forum. Instead, follow the instructions at Vulnerability Reporting or email AWS security directly.

You can download and install the CloudWatch agent manually using the command line, or you can integrate it with AWS Systems Manager. The general flow of installing the CloudWatch agent is as follows:

1. Create IAM roles or users that enable the agent to collect metrics from the server and optionally to integrate with AWS Systems Manager.

2. Download the agent package.
3. Modify the CloudWatch agent configuration file and specify the metrics that you want to collect.
4. Install and start the agent on your servers.

Contents

- Supported operating systems
- Prerequisites
- Download the CloudWatch agent package
- Verifying the signature of the CloudWatch agent package
- Installing the CloudWatch agent
- Set up the CloudWatch agent with security-enhanced Linux (SELinux)
- Create the CloudWatch agent configuration file
- Starting the CloudWatch agent
- Metrics collected by the CloudWatch agent
- Using the CloudWatch agent with related telemetry
- Common scenarios with the CloudWatch agent
- CloudWatch agent credentials preference
- Troubleshooting the CloudWatch agent

Supported operating systems

The CloudWatch agent is supported on the following operating systems:

x86-64 architecture

- Amazon Linux 2023
- Amazon Linux 2
- Ubuntu Server versions 25.04, 24.04, and 22.04
- Red Hat Enterprise Linux (RHEL) versions 10, 9, and 8
- Debian version 12
- SUSE Linux Enterprise Server (SLES) version 15
- Oracle Linux versions 9 and 8

- AlmaLinux versions 10, 9, and 8
- Rocky Linux versions 10, 9, and 8
- macOS computers: EC2 M1 Mac1 instances, and computers running macOS 14 (Sonoma), macOS 13 (Ventura), and macOS 12 (Monterey)
- Windows Server 2025, Windows Server 2022, Windows Server 2019, and Windows Server 2016
- Windows 11
- 64-bit Windows 10

ARM64 architecture

- Amazon Linux 2023
- Amazon Linux 2
- Ubuntu Server version 22.04
- Red Hat Enterprise Linux (RHEL) versions 9 and 8
- Debian version 12
- SUSE Linux Enterprise Server 15
- macOS computers: macOS 14 (Sonoma), macOS 13 (Ventura), and macOS 12 (Monterey)

Prerequisites

Make sure the following prerequisites are completed before installing the CloudWatch agent for the first time.

IAM roles and users for CloudWatch agent

Access to AWS resources requires permissions. You create an IAM role, an IAM user, or both to grant permissions that the CloudWatch agent needs to write metrics to CloudWatch.

Create an IAM role for Amazon EC2 instances

If you're going to run the CloudWatch agent on Amazon EC2 instances, create an IAM role with the necessary permissions.

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.

2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. Under **Trusted entity type**, verify that **AWS service** is selected. For **Use case**, choose **EC2**. Choose **Next**.
5. In the list of policies, select the check box next to **CloudWatchAgentServerPolicy**. If necessary, use the search box to find the policy.
6. Choose **Next**.
7. For **Role name**, enter a name for the role, such as `CloudWatchAgentServerRole`. Choose **Create role**.

(Optional) If the agent is going to send logs to CloudWatch Logs and you want the agent to be able to set retention policies for these log groups, you need to add the `logs:PutRetentionPolicy` permission to the role.

Create IAM user for on-premises servers

If you're going to run the CloudWatch agent on on-premises servers, create an IAM user with the necessary permissions.

> **Note**
>
> This scenario requires IAM users with programmatic access and long-term credentials, which presents a security risk. To help mitigate this risk, we recommend that you provide these users with only the permissions they require to perform the task and that you remove these users when they are no longer needed.

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Users** and then **Add users**.
3. Enter the user name for the new user. Select **Access key - Programmatic access** and choose **Next: Permissions**.
4. Choose **Attach existing policies directly**.
5. In the list of policies, select the check box next to **CloudWatchAgentServerPolicy**. If necessary, use the search box to find the policy. Choose **Next: Tags**.

6. (Optional) Create tags for the new IAM user. Choose **Next: Review**. Confirm that the correct policy is listed and choose **Create user**.
7. Next to the name of the new user, choose **Show**. Copy the access key and secret key to a file so that you can use them when installing the agent. Choose **Close**.

Attach an IAM role to an Amazon EC2 instance

To enable the CloudWatch agent to send data from an Amazon EC2 instance, you must attach the IAM role you created to the instance.

For more information about attaching an IAM role to an instance, see Attaching an IAM Role to an Instance in the Amazon Elastic Compute Cloud User Guide.

Allowing the CloudWatch agent to set log retention policy

You can configure the CloudWatch agent to set the retention policy for log groups that it sends log events to. If you do this, you must grant the `logs:PutRetentionPolicy` to the IAM role or user that the agent uses. The agent uses an IAM role to run on Amazon EC2 instances, and uses an IAM user for on-premises servers.

To grant log retention permissions to the agent's IAM role

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose **Roles**.
3. In the search box, enter the beginning of the name of the CloudWatch agent's IAM role. You chose this name when you created the role. It might be named `CloudWatchAgentServerRole`.

   When you see the role, choose the name of the role.
4. In the **Permissions** tab, choose **Add permissions**, **Create inline policy**.
5. Choose the **JSON** tab and copy the following policy into the box, replacing the default JSON in the box:

   JSON

```
{
  "Version":"2012-10-17",
```

```
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "logs:PutRetentionPolicy",
      "Resource": "*"
    }
  ]
}
```

6. Choose **Review policy**.
7. For **Name**, enter **`CloudWatchAgentPutLogsRetention`** or something similar, and choose **Create policy**.

To grant log retention permissions to the agent's IAM user

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose **Users**.
3. In the search box, enter the beginning of the name of the CloudWatch agent's IAM user. You chose this name when you created the user.

   When you see the user, choose the name of the user.
4. In the **Permissions** tab, choose **Add inline policy**.
5. Choose the **JSON** tab and copy the following policy into the box, replacing the default JSON in the box:

   JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "logs:PutRetentionPolicy",
      "Resource": "*"
    }
  ]
}
```

6. Choose **Review policy**.
7. For **Name**, enter **`CloudWatchAgentPutLogsRetention`** or something similar, and choose **Create policy**.

Network requirements

> **Note**
>
> When the server is in a public subnet make sure there is access to an internet gateway. When the server is in a private subnet, access is through the NAT gateways or VPC Endpoint. For more information about NAT gateways, see https://docs.aws.amazon.com/vpc/latest/userguide/vpc-nat-gateway.html.

Your Amazon EC2 instances must have outbound internet access to send data to CloudWatch or CloudWatch Logs. For more information about how to configure internet access, see Internet Gateways in the Amazon VPC User Guide.

Using VPC endpoints

If you're using a VPC and want to use CloudWatch agent without public internet access, you can configure VPC endpoints for CloudWatch and CloudWatch Logs.

The endpoints and ports to configure on your proxy are as follows:

- If you're using the agent to collect metrics, you must add the CloudWatch endpoints for the appropriate Regions to the allow list. These endpoints are listed in Amazon CloudWatch endpoints and quotas.
- If you're using the agent to collect logs, you must add the CloudWatch Logs endpoints for the appropriate Regions to the allow list. These endpoints are listed in Amazon CloudWatch Logs endpoints and quotas.
- If you're using Systems Manager to install the agent or Parameter Store to store your configuration file, you must add the Systems Manager endpoints for the appropriate Regions to the allow list. These endpoints are listed in AWS Systems Manager endpoints and quotas.

Download the CloudWatch agent package

> **Note**
>
> To download the CloudWatch agent, your connection must use TLS 1.2 or later.

The CloudWatch agent is available as a package in Amazon Linux 2023 and Amazon Linux 2. If you are using this operating system, you can install the package by entering the following command. You must also make sure that the IAM role attached to the instance has the **CloudWatchAgentServerPolicy** attached.

```
sudo yum install amazon-cloudwatch-agent
```

On all supported operating systems, you can download and install the CloudWatch agent using the command line.

For each download link, there is a general link as well as links for each AWS Region.

If you use the Region-specific links, replace the default Region (*us-east-1*) with the appropriate Region for your account. For example, for Amazon Linux 2023 and Amazon Linux 2 and the x86-64 architecture, three of the valid download links are:

- `https://amazoncloudwatch-agent.s3.amazonaws.com/amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm`
- `https://amazoncloudwatch-agent-us-east-1.s3.us-east-1.amazonaws.com/amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm`
- `https://amazoncloudwatch-agent-eu-central-1.s3.eu-central-1.amazonaws.com/amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm`

You can also download a README file about the latest changes to the agent, and a file that indicates the version number that is available for download. These files are in the following locations:

> **Note**
>
> If you use the Region-specific links, replace the default Region (*us-east-1*) with the appropriate Region for your account.

- `https://amazoncloudwatch-agent.s3.amazonaws.com/info/latest/RELEASE_NOTES` or `https://amazoncloudwatch-agent-us-east-1.s3.us-east-1.amazonaws.com/info/latest/RELEASE_NOTES`
- `https://amazoncloudwatch-agent.s3.amazonaws.com/info/latest/CWAGENT_VERSION` or `https://amazoncloudwatch-agent-us-east-1.s3.us-east-1.amazonaws.com/info/latest/CWAGENT_VERSION`

Verifying the signature of the CloudWatch agent package

GPG signature files are included for CloudWatch agent packages on Linux servers. You can use a public key to verify the agent download file is original and unmodified.

For Windows Server, you can use the MSI to verify the signature. For macOS computers, the signature is included in the agent download package.

To find the correct signature file, use the following table. For each architecture and operating system, you can see a general link and links for each Region.

If you use the Region-specific links, replace the default Region (*us-east-1*) with the appropriate Region for your account. For example, for Amazon Linux 2023 and Amazon Linux 2 and the x86-64 architecture, three of the valid links are:

- `https://amazoncloudwatch-agent.s3.amazonaws.com/amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm.sig`
- `https://amazoncloudwatch-agent-us-east-1.s3.us-east-1.amazonaws.com/amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm`
- `https://amazoncloudwatch-agent-eu-central-1.s3.eu-central-1.amazonaws.com/amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm`

Note

To download the CloudWatch agent, your connection must use TLS 1.2 or later.

ARM64	SUSE	https://amazoncloudwatch-agent.s3.amazonaws.com/suse/arm64/latest/amazon-cloudwatch-agent.rpm https://amazoncloudwatch-agent-*us-east-1* .s3.*us-east-1* .amazonaws.com/suse/arm64/latest/amazon-cloudwatch-agent.rpm	https://amazoncloudwatch-agent.s3.amazonaws.com/suse/arm64/latest/amazon-cloudwatch-agent.rpm.sig https://amazoncloudwatch-agent-*us-east-1* .s3.*us-east-1* .amazonaws.com/suse/arm64/latest/amazon-cloudwatch-agent.rpm.sig

To verify the CloudWatch agent package on a Linux server

1. Download the public key.

```
shell$ wget https://amazoncloudwatch-agent.s3.amazonaws.com/assets/amazon-
cloudwatch-agent.gpg
```

2. Import the public key into your keyring.

```
shell$  gpg --import amazon-cloudwatch-agent.gpg
gpg: key 3B789C72: public key "Amazon CloudWatch Agent" imported
gpg: Total number processed: 1
gpg: imported: 1 (RSA: 1)
```

   Make a note of the key value, as you need it in the next step. In the preceding example, the key value is 3B789C72.

3. Verify the fingerprint by running the following command, replacing *key-value* with the value from the preceding step:

```
shell$  gpg --fingerprint key-value
pub   2048R/3B789C72 2017-11-14
      Key fingerprint = 9376 16F3 450B 7D80 6CBD  9725 D581 6730 3B78 9C72
uid                  Amazon CloudWatch Agent
```

   The fingerprint string should be equal to the following:

   ```
   9376 16F3 450B 7D80 6CBD 9725 D581 6730 3B78 9C72
   ```

   If the fingerprint string doesn't match, don't install the agent. Contact Amazon Web Services.

   After you have verified the fingerprint, you can use it to verify the signature of the CloudWatch agent package.

4. Download the package signature file using **wget**. To determine the correct signature file, see the preceding table.

```
wget Signature File Link
```

5. To verify the signature, run **gpg --verify**.

```
shell$ gpg --verify signature-filename agent-download-filename
```

```
gpg: Signature made Wed 29 Nov 2017 03:00:59 PM PST using RSA key ID 3B789C72
gpg: Good signature from "Amazon CloudWatch Agent"
gpg: WARNING: This key is not certified with a trusted signature!
gpg:          There is no indication that the signature belongs to the owner.
Primary key fingerprint: 9376 16F3 450B 7D80 6CBD  9725 D581 6730 3B78 9C72
```

If the output includes the phrase BAD `signature`, check whether you performed the procedure correctly. If you continue to get this response, contact Amazon Web Services and avoid using the downloaded file.

Note the warning about trust. A key is trusted only if you or someone who you trust has signed it. This doesn't mean that the signature is invalid, only that you have not verified the public key.

To verify the CloudWatch agent package on a server running Windows Server

1. Download and install GnuPG for Windows from https://gnupg.org/download/. When installing, include the **Shell Extension (GpgEx)** option.

   You can perform the remaining steps in Windows PowerShell.

2. Download the public key.

   ```
   PS> wget https://amazoncloudwatch-agent.s3.amazonaws.com/assets/amazon-cloudwatch-
   agent.gpg -OutFile amazon-cloudwatch-agent.gpg
   ```

3. Import the public key into your keyring.

   ```
   PS>  gpg --import amazon-cloudwatch-agent.gpg
   gpg: key 3B789C72: public key "Amazon CloudWatch Agent" imported
   gpg: Total number processed: 1
   gpg: imported: 1 (RSA: 1)
   ```

   Make a note of the key value because you need it in the next step. In the preceding example, the key value is 3B789C72.

4. Verify the fingerprint by running the following command, replacing *`key-value`* with the value from the preceding step:

   ```
   PS>  gpg --fingerprint key-value
   pub   rsa2048 2017-11-14 [SC]
   ```

```
      9376 16F3 450B 7D80 6CBD  9725 D581 6730 3B78 9C72
uid           [ unknown] Amazon CloudWatch Agent
```

The fingerprint string should be equal to the following:

```
9376 16F3 450B 7D80 6CBD 9725 D581 6730 3B78 9C72
```

If the fingerprint string doesn't match, don't install the agent. Contact Amazon Web Services.

After you have verified the fingerprint, you can use it to verify the signature of the CloudWatch agent package.

5. Download the package signature file using wget. To determine the correct signature file, see CloudWatch Agent Download Links.
6. To verify the signature, run **gpg --verify**.

```
PS> gpg --verify sig-filename agent-download-filename
gpg: Signature made 11/29/17 23:00:45 Coordinated Universal Time
gpg:                using RSA key D58167303B789C72
gpg: Good signature from "Amazon CloudWatch Agent" [unknown]
gpg: WARNING: This key is not certified with a trusted signature!
gpg:          There is no indication that the signature belongs to the owner.
Primary key fingerprint: 9376 16F3 450B 7D80 6CBD  9725 D581 6730 3B78 9C72
```

If the output includes the phrase `BAD signature`, check whether you performed the procedure correctly. If you continue to get this response, contact Amazon Web Services and avoid using the downloaded file.

Note the warning about trust. A key is trusted only if you or someone who you trust has signed it. This doesn't mean that the signature is invalid, only that you have not verified the public key.

To verify the CloudWatch agent package on a macOS computer

- There are two methods for signature verification on macOS.
  - Verify the fingerprint by running the following command.

```
pkgutil --check-signature amazon-cloudwatch-agent.pkg
```

You should see a result similar to the following.

```
Package "amazon-cloudwatch-agent.pkg":
       Status: signed by a developer certificate issued by Apple for
 distribution

```

- Or, download and use the .sig file To use this method, follow these steps.
  - Install the GPG application to your macOS host by entering the following command.

    ```
    brew install GnuPG
    ```

- Download the package signature file using curl. To determine the correct signature file, see CloudWatch Agent Download Links.
- To verify the signature, run **gpg --verify**.

```
PS> gpg --verify sig-filename agent-download-filename
gpg: Signature made 11/29/17 23:00:45 Coordinated Universal Time
gpg:                using RSA key D58167303B789C72
gpg: Good signature from "Amazon CloudWatch Agent" [unknown]
gpg: WARNING: This key is not certified with a trusted signature!
```

```
gpg:          There is no indication that the signature belongs to the owner.
Primary key fingerprint: 9376 16F3 450B 7D80 6CBD  9725 D581 6730 3B78 9C72
```

If the output includes the phrase BAD `signature`, check whether you performed the procedure correctly. If you continue to get this response, contact Amazon Web Services and avoid using the downloaded file.

Note the warning about trust. A key is trusted only if you or someone who you trust has signed it. This doesn't mean that the signature is invalid, only that you have not verified the public key.

Installing the CloudWatch agent

You can install the CloudWatch agent on your Amazon EC2 instances, on-premises servers, and in containerized environments to collect metrics, logs, and traces. The agent supports Linux, Windows, and macOS operating systems. There are several ways to install the agent, including using Systems Manager, from the CloudWatch console, installing from the command line, or installing using a configuration file. Before installing, make sure you have the required IAM permissions and network access configured.

Topics

- Install and Configure Amazon CloudWatch Agent with Workload Detection in the CloudWatch console
- Manual installation on Amazon EC2
- Install the CloudWatch agent using AWS Systems Manager
- Install the CloudWatch agent on on-premises servers
- Install the CloudWatch agent on new instances using CloudFormation

Install and Configure Amazon CloudWatch Agent with Workload Detection in the CloudWatch console

Introduction

You can use the CloudWatch Getting Started console to install and configure the CloudWatch agent on Amazon EC2 instances. The Amazon CloudWatch agent is a lightweight software component that collects system-level metrics, logs, and traces from your Amazon EC2 instances. By

automating the collection and delivery of monitoring data to CloudWatch, the agent enables you to gain actionable insights, optimize resource utilization, and ensure your applications are running smoothly with minimal configuration effort.

Configure the CloudWatch agent with pre-defined, workload-specific configurations that leverage automatic workload detection to identify running applications and services on your instances. You can customize data collection with specific metrics, logs, and traces, enabling you to monitor application performance and troubleshoot issues effectively.

How it Works

The CloudWatch agent detects workloads running on your Amazon EC2 instances through automatic workload detection capabilities. This feature identifies running applications and services on your instances, enabling intelligent monitoring without manual configuration.

Observability solutions provide pre-defined, workload-specific configurations tailored to common applications such as Apache Kafka, Apache Tomcat, Java Virtual Machines (JVM), NGINX, and NVIDIA GPU workloads. These solutions streamline the monitoring setup by automatically collecting the right metrics, logs, and traces specific to each detected workload, eliminating the need for manual instrumentation and configuration.

When workload detection is enabled, the agent analyzes your instance environment and automatically selects relevant pre-configured monitoring templates. These configurations are optimized by AWS subject-matter experts to capture the most important telemetry data for each workload type, ensuring you have comprehensive observability from the start.

Prerequisites

SSM Agent installation (required)

You must have AWS Systems Manager (SSM) agent installed on your Amazon EC2 instances. SSM agent comes pre-installed on most AWS-supplied Amazon Machine Images (AMIs), If you need to manually install or update the SSM agent, refer to the Systems Manager documentation.

> **Note**
>
> Default Host Management Configuration (DHMC) is a Systems Manager feature that automatically grants Amazon EC2 instances permissions to connect to Systems Manager without requiring you to manually attach an IAM instance profile to each instance. If your Amazon EC2 instances are using DHMC and the CloudWatch agent installation process

attaches the CloudWatch policy to your instances, it can take up to 30 minutes for the new policy to take effect. This delay can postpone the publication of metrics, logs, and traces to CloudWatch. To mitigate, you can create your Amazon EC2 instances with an IAM role that contains the AmazonSSMManagedInstanceCore policy.

Workload Detection (Recommended)

Workload detection is an opt-in feature that automatically identifies running applications and services on your instances. We recommend turning on workload detection to take advantage of pre-configured, workload-specific monitoring templates. You can enable workload detection in the CloudWatch console settings.

Getting started

Open the Getting Started with Amazon CloudWatch agent page in the Amazon CloudWatch console: https://console.aws.amazon.com/cloudwatch/home#cloudwatch-agent

Manual instance deployment for CloudWatch Agent

Manually select up to 50 instances for CloudWatch agent installation and configuration. This targeted approach allows you to enhance monitoring for specific Amazon EC2 instances.

Tag-based deployment for CloudWatch Agent

Use tag-based deployment to install and configure the CloudWatch agent on fleets of Amazon EC2 instances. This method applies to all current and future instances with matching tags.

Tag-based configuration

Tag-based configurations allow you to efficiently organize, view, and modify configurations, helping you to manage CloudWatch agent and its configuration across fleets of Amazon EC2 instances.

CloudWatch agent installation

Install the CloudWatch agent to collect metrics, logs, and traces from Amazon EC2 instances and on-premises hosts. This telemetry provides important health and performance data about your infrastructure and applications.

CloudWatch agent configuration

Configure the CloudWatch agent with pre-defined, workload-specific configurations. You can customize data collection with specific metrics, logs, and traces, enabling you to monitor application performance and troubleshoot issues effectively.

Costs

Additional metrics that you add during this process are billed as custom metrics. For more information about CloudWatch metrics pricing, see Amazon CloudWatch Pricing.

Manual installation on Amazon EC2

> **Note**
>
> Make sure the prerequisites are completed before installing the CloudWatch agent for the first time.

Topics

- Installing on Amazon Linux using the package manager
- Installing on Amazon Linux using the command line
- Installing on Windows
- Installing on macOS

Installing on Amazon Linux using the package manager

The CloudWatch agent is available as a package in Amazon Linux 2023 and Amazon Linux 2. If you are using one of these operating systems, you can install the package by entering the following command:

```
sudo yum install amazon-cloudwatch-agent
```

You must also make sure that the IAM role attached to the instance has the **CloudWatchAgentServerPolicy** attached.

Installing on Amazon Linux using the command line

On all supported Linux operating systems, you can download and install the CloudWatch agent using the command line.

1. Download the CloudWatch agent. For a Linux server, enter the following command. For `download-link`, use the appropriate download link from the table below.

```
wget download-link
```

Architecture	Platform	Download link
x86-64	Amazon Linux 2023 and Amazon Linux 2	https://amazoncloudwatch-agent.s3.amazonaws.com/amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm
ARM64	Amazon Linux 2023 and Amazon Linux 2	https://amazoncloudwatch-agent.s3.amazonaws.com/amazon_linux/arm64/latest/amazon-cloudwatch-agent.rpm

2. After you have downloaded the package, you can optionally verify the package signature. For more information, see Verifying the signature of the CloudWatch agent package.
3. Install the package. If you downloaded an RPM package on a Linux server, change to the directory containing the package and enter the following:

```
sudo rpm -U ./amazon-cloudwatch-agent.rpm
```

If you downloaded a DEB package on a Linux server, change to the directory containing the package and enter the following:

```
sudo dpkg -i -E ./amazon-cloudwatch-agent.deb
```

Installing on Windows

On Windows Server, you can download and install the CloudWatch agent using the command line.

1. Download the following file:

```
https://amazoncloudwatch-agent.s3.amazonaws.com/windows/amd64/latest/amazon-
cloudwatch-agent.msi
```

2. After you have downloaded the package, you can optionally verify the package signature. For more information, see Verifying the signature of the CloudWatch agent package.
3. Install the package. Change to the directory containing the package and enter the following:

```
msiexec /i amazon-cloudwatch-agent.msi
```

   This command also works from within PowerShell. For more information about MSI command options, see Command-Line Options in the Microsoft Windows documentation.

Installing on macOS

On macOS computers, you can download and install the CloudWatch agent using the command line.

1. Download the appropriate package for your architecture:

```
https://amazoncloudwatch-agent.s3.amazonaws.com/darwin/amd64/latest/amazon-
cloudwatch-agent.pkg
```

   For ARM64 architecture:

```
https://amazoncloudwatch-agent.s3.amazonaws.com/darwin/arm64/latest/amazon-
cloudwatch-agent.pkg
```

2. After you have downloaded the package, you can optionally verify the package signature. For more information, see Verifying the signature of the CloudWatch agent package.
3. Install the package. Change to the directory containing the package and enter the following:

```
sudo installer -pkg ./amazon-cloudwatch-agent.pkg -target /
```

Install the CloudWatch agent using AWS Systems Manager

Using AWS Systems Manager makes it easier to install the CloudWatch agent on a fleet of Amazon EC2 instances. You can download the agent into one server and create your CloudWatch agent

configuration file for all servers in the fleet. Then you can use Systems Manager to install the agent on the other servers, using the configuration file that you created. Use the following topics to install and run the CloudWatch agent using AWS Systems Manager.

Topics

- Install or update the SSM Agent
- Verify Systems Manager prerequisites
- Verify internet access
- Download the CloudWatch agent package to your first instance
- Create and modify the agent configuration file
- Install and start the CloudWatch agent on additional EC2 instances using your agent configuration
- Install the CloudWatch agent on additional EC2 instances using your agent configuration
- (Optional) Modify the common configuration and named profile for CloudWatch agent

Install or update the SSM Agent

On an Amazon EC2 instance, the CloudWatch agent requires that the instance is running version 2.2.93.0 or later of the SSM Agent. Before you install the CloudWatch agent, update or install SSM Agent on the instance if you haven't already done so.

For information about installing or updating SSM Agent on an instance running Linux, see Installing and Configuring SSM Agent on Linux Instances in the *AWS Systems Manager User Guide*.

For information about installing or updating the SSM Agent, see Working with SSM Agent in the *AWS Systems Manager User Guide*.

Verify Systems Manager prerequisites

Before you use Systems Manager Run Command to install and configure the CloudWatch agent, verify that your instances meet the minimum Systems Manager requirements. For more information, see Systems Manager Prerequisites in the *AWS Systems Manager User Guide*.

Verify internet access

Your Amazon EC2 instances must be able to connect to CloudWatch endpoints. This can be by Internet Gateway, NAT gateway, or CloudWatch Interface VPC endpoints. For more information about how to configure internet access, see Internet Gateways in the *Amazon VPC User Guide*.

The endpoints and ports to configure on your proxy are as follows:

- If you're using the agent to collect metrics, you must allow list the CloudWatch endpoints for the appropriate Regions. These endpoints are listed in Amazon CloudWatch in the *Amazon Web Services General Reference*.
- If you're using the agent to collect logs, you must allow list the CloudWatch Logs endpoints for the appropriate Regions. These endpoints are listed in Amazon CloudWatch Logs in the *Amazon Web Services General Reference*.
- If you're using Systems Manager to install the agent or Parameter Store to store your configuration file, you must allow list the Systems Manager endpoints for the appropriate Regions. These endpoints are listed in AWS Systems Manager in the *Amazon Web Services General Reference*.

Download the CloudWatch agent package to your first instance

Use the following steps to download the CloudWatch agent package using Systems Manager.

To download the CloudWatch agent using Systems Manager

1. Open the Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.

   -or-

   If the AWS Systems Manager home page opens, scroll down and choose **Explore Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, choose **AWS-ConfigureAWSPackage**.
5. In the **Targets** area, choose the instance to install the CloudWatch agent on. If you don't see a specific instance, it might not be configured as a managed instance for use with Systems Manager. For more information, see Setting Up AWS Systems Manager for Hybrid Environments in the *AWS Systems Manager User Guide*.
6. In the **Action** list, choose **Install**.
7. In the **Name** field, enter `AmazonCloudWatchAgent`.
8. Keep **Version** set to **latest** to install the latest version of the agent.
9. Choose **Run**.

10. Optionally, in the **Targets and outputs** areas, select the button next to an instance name and choose **View output**. Systems Manager should show that the agent was successfully installed.

Create and modify the agent configuration file

After you have downloaded the CloudWatch agent, you must create the configuration file before you start the agent on any servers.

If you're going to save your agent configuration file in the Systems Manager Parameter Store, you must use an EC2 instance to save to the Parameter Store. Additionally, you must first attach to that instance the `CloudWatchAgentAdminRole` IAM role. For more information about attaching roles, see Attaching an IAM Role to an Instance in the *Amazon EC2 User Guide*.

For more information about creating the CloudWatch agent configuration file, see Create the CloudWatch agent configuration file.

Install and start the CloudWatch agent on additional EC2 instances using your agent configuration

After you have a CloudWatch agent configuration saved in Parameter Store, you can use it when you install the agent on other servers.

For each of these servers, follow the steps listed previously in this section to verify the Systems Manager prerequisites, the version of the SSM Agent, and internet access. Then use the following instructions to install the CloudWatch agent on the additional instances, using the CloudWatch agent configuration file that you have created.

Step 1: Download and install the CloudWatch agent

To be able to send the CloudWatch data to a different Region, make sure that the IAM role that you attached to this instance has permissions to write the CloudWatch data in that Region.

Following is an example of using the `aws configure` command to create a named profile for the CloudWatch agent. This example assumes that you are using the default profile name of `AmazonCloudWatchAgent`.

To create the AmazonCloudWatchAgent profile for the CloudWatch agent

- On Linux servers, type the following command and follow the prompts:

```
sudo aws configure --profile AmazonCloudWatchAgent
```

On Windows Server, open PowerShell as an administrator, type the following command and follow the prompts.

```
aws configure --profile AmazonCloudWatchAgent
```

Install the CloudWatch agent on additional EC2 instances using your agent configuration

After you have a CloudWatch agent configuration saved in Parameter Store, you can use it when you install the agent on other servers.

For each of these servers, follow the steps listed previously in this section to verify the Systems Manager prerequisites, the version of the SSM Agent, and internet access. Then use the following instructions to install the CloudWatch agent on the additional instances, using the CloudWatch agent configuration file that you have created.

Step 1: Download and install the CloudWatch agent

You need to install the agent on each server where you will run the agent. The CloudWatch agent is available as a package in Amazon Linux 2023 and Amazon Linux 2. If you are using this operating system, you can use Systems Manager to install the package by using the following steps.

> **Note**
>
> You must also make sure that the IAM role attached to the instance has the **CloudWatchAgentServerPolicy** attached. For more information, see Prerequisites.

To use Systems Manager to install the CloudWatch agent package

1. Open the Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.

   -or-

   If the AWS Systems Manager home page opens, scroll down and choose **Explore Run Command**.

3. Choose **Run command**.
4. In the **Command document** list, select **AWS-RunShellScript**. Then paste the following into **Command parameters**.

```
sudo yum install amazon-cloudwatch-agent
```

5. Choose **Run**

On all supported operating systems, you can download the CloudWatch agent package using either Systems Manager Run Command or an Amazon S3 download link.

> **Note**
>
> When you install or update the CloudWatch agent, only the **Uninstall and reinstall** option is supported. You can't use the **In-place update** option.

Systems Manager Run Command enables you to manage the configuration of your instances. You specify a Systems Manager document, specify parameters, and execute the command on one or more instances. SSM Agent on the instance processes the command and configures the instance as specified.

To download the CloudWatch agent using Run Command

1. Open the Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.

   -or-

   If the AWS Systems Manager home page opens, scroll down and choose **Explore Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, choose **AWS-ConfigureAWSPackage**.
5. In the **Targets** area, choose the instance on which to install the CloudWatch agent. If you do not see a specific instance, it might not be configured for Run Command. For more information, see Setting Up AWS Systems Manager for Hybrid Environments in the *AWS Systems Manager User Guide*.

6. In the **Action** list, choose **Install**.
7. In the **Name** box, enter *AmazonCloudWatchAgent*.
8. Keep **Version** set to **latest** to install the latest version of the agent.
9. Choose **Run**.
10. Optionally, in the **Targets and outputs** areas, select the button next to an instance name and choose **View output**. Systems Manager should show that the agent was successfully installed.

Step 2: Start the CloudWatch agent using your agent configuration file

Follow these steps to start the agent using Systems Manager Run Command.

For information about setting up the agent on a system that has security-enhanced Linux (SELinux) enabled, see Set up the CloudWatch agent with security-enhanced Linux (SELinux).

To start the CloudWatch agent using Run Command

1. Open the Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.

   -or-

   If the AWS Systems Manager home page opens, scroll down and choose **Explore Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, choose **AmazonCloudWatch-ManageAgent**.
5. In the **Targets** area, choose the instance where you installed the CloudWatch agent.
6. In the **Action** list, choose **configure**.
7. In the **Optional Configuration Source** list, choose **ssm**.
8. In the **Optional Configuration Location** box, enter the name of the Systems Manager parameter name of the agent configuration file that you created and saved to Systems Manager Parameter Store, as explained in Create the CloudWatch agent configuration file.
9. In the **Optional Restart** list, choose **yes** to start the agent after you have finished these steps.
10. Choose **Run**.
11. Optionally, in the **Targets and outputs** areas, select the button next to an instance name and choose **View output**. Systems Manager should show that the agent was successfully started.

(Optional) Modify the common configuration and named profile for CloudWatch agent

The CloudWatch agent includes a configuration file called `common-config.toml`. You can use this file to optionally specify proxy and Region information.

On a server running Linux, this file is in the `/opt/aws/amazon-cloudwatch-agent/etc` directory. On a server running Windows Server, this file is in the `C:\ProgramData\Amazon\AmazonCloudWatchAgent` directory.

The default `common-config.toml` is as follows:

```
# This common-config is used to configure items used for both ssm and cloudwatch access

## Configuration for shared credential.
## Default credential strategy will be used if it is absent here:
##            Instance role is used for EC2 case by default.
##            AmazonCloudWatchAgent profile is used for onPremise case by default.
# [credentials]
#    shared_credential_profile = "{profile_name}"
#    shared_credential_file= "{file_name}"

## Configuration for proxy.
## System-wide environment-variable will be read if it is absent here.
## i.e. HTTP_PROXY/http_proxy; HTTPS_PROXY/https_proxy; NO_PROXY/no_proxy
## Note: system-wide environment-variable is not accessible when using ssm run-command.
## Absent in both here and environment-variable means no proxy will be used.
# [proxy]
#    http_proxy = "{http_url}"
#    https_proxy = "{https_url}"
#    no_proxy = "{domain}"
```

All lines are commented out initially. To set the credential profile or proxy settings, remove the # from that line and specify a value. You can edit this file manually, or by using the `RunShellScript` Run Command in Systems Manager:

- `shared_credential_profile` – For on-premises servers, this line specifies the IAM user credential profile to use to send data to CloudWatch. If you keep this line commented out, `AmazonCloudWatchAgent` is used.

On an EC2 instance, you can use this line to have the CloudWatch agent send data from this instance to CloudWatch in a different AWS Region. To do so, specify a named profile that includes a `region` field specifying the name of the Region to send to.

If you specify a `shared_credential_profile`, you must also remove the # from the beginning of the `[credentials]` line.

- `shared_credential_file` – To have the agent look for credentials in a file located in a path other than the default path, specify that complete path and file name here. The default path is `/root/.aws` on Linux and is `C:\\Users\\Administrator\\.aws` on Windows Server.

  The first example below shows the syntax of a valid `shared_credential_file` line for Linux servers, and the second example is valid for Windows Server. On Windows Server, you must escape the \ characters.

  ```
  shared_credential_file= "/usr/username/credentials"
  ```

  ```
  shared_credential_file= "C:\\Documents and Settings\\username\\.aws\\credentials"
  ```

  If you specify a `shared_credential_file`, you must also remove the # from the beginning of the `[credentials]` line.

- Proxy settings – If your servers use HTTP or HTTPS proxies to contact AWS services, specify those proxies in the `http_proxy` and `https_proxy` fields. If there are URLs that should be excluded from proxying, specify them in the `no_proxy` field, separated by commas.

Install the CloudWatch agent on on-premises servers

If you downloaded the CloudWatch agent on a computer and created your agent configuration file, you can use that configuration file to install the agent in other on-premises servers.

Download the CloudWatch agent on an on-premises server

You can download the CloudWatch agent package using either Systems Manager Run Command or an Amazon S3 download link.

Download using Systems Manager

To use Systems Manager Run Command, you must register your on-premises server with Amazon EC2 Systems Manager. For more information, see Setting Up Systems Manager in Hybrid Environments in the *AWS Systems Manager User Guide*.

If you have already registered your server, update SSM Agent to the latest version.

For information about updating SSM Agent on a server running Linux, see Install SSM Agent for a Hybrid Environment (Linux) in the *AWS Systems Manager User Guide*.

For information about updating the SSM Agent on a server running Windows Server, see Install SSM Agent for a Hybrid Environment (Windows) in the *AWS Systems Manager User Guide*.

To use the SSM Agent to download the CloudWatch agent package on an on-premises server

1. Open the Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.

   -or-

   If the AWS Systems Manager home page opens, scroll down and choose **Explore Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, select the button next to **AWS-ConfigureAWSPackage**.
5. In the **Targets** area, select the server to install the CloudWatch agent on. If you don't see a specific server, it might not be configured for Run Command. For more information, see Setting Up AWS Systems Manager for Hybrid Environments in the *AWS Systems Manager User Guide*.
6. In the **Action** list, choose **Install**.
7. In the **Name** box, enter `AmazonCloudWatchAgent`.
8. Keep **Version** blank to install the latest version of the agent.
9. Choose **Run**.

   The agent package is downloaded, and the next steps are to configure and start it.

(Installing on an on-premises server) Specify IAM credentials and AWS Region

To enable the CloudWatch agent to send data from an on-premises server, you must specify the access key and secret key of the IAM user that you created earlier.

You also must specify the AWS Region to send the metrics to, using the `region` field.

Following is an example of this file.

```
[AmazonCloudWatchAgent]
aws_access_key_id=my_access_key
aws_secret_access_key=my_secret_key
region = us-west-1
```

For *my_access_key* and *my_secret_key*, use the keys from the IAM user that doesn't have the permissions to write to Systems Manager Parameter Store.

If you name this profile `AmazonCloudWatchAgent`, you don't need to do anything more. Optionally, you can give it a different name and specify that name as the value for `shared_credential_profile` in the `common-config.toml` file, which is explained in the following section.

Following is an example of using the **aws configure** command to create a named profile for the CloudWatch agent. This example assumes that you're using the default profile name of `AmazonCloudWatchAgent`.

To create the AmazonCloudWatchAgent profile for the CloudWatch agent

1. If you haven't already done so, install the AWS Command Line Interface on the server. For more information, see Installing the AWS CLI.
2. On Linux servers, enter the following command and follow the prompts:

   ```
   sudo aws configure --profile AmazonCloudWatchAgent
   ```

   On Windows Server, open PowerShell as an administrator, enter the following command, and follow the prompts.

   ```
   aws configure --profile AmazonCloudWatchAgent
   ```

(Optional) Modifying the common configuration and named profile for CloudWatch agent

The CloudWatch agent includes a configuration file called `common-config.toml`. You can optionally use this file to specify proxy and Region information.

On a server running Linux, this file is in the `/opt/aws/amazon-cloudwatch-agent/etc` directory. On a server running Windows Server, this file is in the `C:\ProgramData\Amazon\AmazonCloudWatchAgent` directory.

The default `common-config.toml` is as follows:

```
# This common-config is used to configure items used for both ssm and cloudwatch access

## Configuration for shared credential.
## Default credential strategy will be used if it is absent here:
##            Instance role is used for EC2 case by default.
##            AmazonCloudWatchAgent profile is used for onPremise case by default.
# [credentials]
#    shared_credential_profile = "{profile_name}"
#    shared_credential_file= "{file_name}"

## Configuration for proxy.
## System-wide environment-variable will be read if it is absent here.
## i.e. HTTP_PROXY/http_proxy; HTTPS_PROXY/https_proxy; NO_PROXY/no_proxy
## Note: system-wide environment-variable is not accessible when using ssm run-command.
## Absent in both here and environment-variable means no proxy will be used.
# [proxy]
#    http_proxy = "{http_url}"
#    https_proxy = "{https_url}"
#    no_proxy = "{domain}"
```

All lines are commented out initially. To set the credential profile or proxy settings, remove the # from that line and specify a value. You can edit this file manually, or by using the `RunShellScript` Run Command in Systems Manager:

- `shared_credential_profile` – For on-premises servers, this line specifies the IAM user credential profile to use to send data to CloudWatch. If you keep this line commented out, `AmazonCloudWatchAgent` is used. For more information about creating this profile, see (Installing on an on-premises server) Specify IAM credentials and AWS Region.

On an EC2 instance, you can use this line to have the CloudWatch agent send data from this instance to CloudWatch in a different AWS Region. To do so, specify a named profile that includes a `region` field specifying the name of the Region to send to.

If you specify a `shared_credential_profile`, you must also remove the # from the beginning of the `[credentials]` line.

- `shared_credential_file` – To have the agent look for credentials in a file located in a path other than the default path, specify that complete path and file name here. The default path is `/root/.aws` on Linux and is `C:\\Users\\Administrator\\.aws` on Windows Server.

  The first example below shows the syntax of a valid `shared_credential_file` line for Linux servers, and the second example is valid for Windows Server. On Windows Server, you must escape the \ characters.

  ```
  shared_credential_file= "/usr/username/credentials"
  ```

  ```
  shared_credential_file= "C:\\Documents and Settings\\username\\.aws\\credentials"
  ```

  If you specify a `shared_credential_file`, you must also remove the # from the beginning of the `[credentials]` line.

- Proxy settings – If your servers use HTTP or HTTPS proxies to contact AWS services, specify those proxies in the `http_proxy` and `https_proxy` fields. If there are URLs that should be excluded from proxying, specify them in the `no_proxy` field, separated by commas.

Install the CloudWatch agent on new instances using CloudFormation

This section describes how to install the CloudWatch agent on new Amazon EC2 instances using AWS CloudFormation.

> **Note**
>
> Amazon uploaded several CloudFormation templates to GitHub that can help you install and update the CloudWatch agent on new Amazon EC2 instances. For more information about using CloudFormation, see What is AWS CloudFormation?.

The template location is Deploy the Amazon CloudWatch agent to EC2 instances using CloudFormation. This location includes both `inline` and `ssm` directories. Each of these directories contains templates for both Linux and Windows instances.

- The templates in the `inline` directory have the CloudWatch agent configuration embedded into the CloudFormation template. By default, the Linux templates collect the metrics `mem_used_percent` and `swap_used_percent`, and the Windows templates collect `Memory % Committed Bytes In Use` and `Paging File % Usage`.

  To modify these templates to collect different metrics, modify the following section of the template. The following example is from the template for Linux servers. Follow the format and syntax of the agent configuration file to make these changes. For more information, see Manually create or edit the CloudWatch agent configuration file.

```
{
   "metrics":{
      "append_dimensions":{
         "AutoScalingGroupName":"${!aws:AutoScalingGroupName}",
         "ImageId":"${!aws:ImageId}",
         "InstanceId":"${!aws:InstanceId}",
         "InstanceType":"${!aws:InstanceType}"
      },
      "metrics_collected":{
         "mem":{
            "measurement":[
               "mem_used_percent"
            ]
         },
         "swap":{
            "measurement":[
               "swap_used_percent"
            ]
         }
      }
   }
}
```

> **Note**
>
> In the inline templates, all placeholder variables must have an exclamation mark (!) before them as an escape character. You can see this in the example template. If you add other placeholder variables, be sure to add an exclamation mark before the name.

- The templates in the `ssm` directory load an agent configuration file from Parameter Store. To use these templates, you must first create a configuration file and upload it to Parameter Store. You then provide the Parameter Store name of the file in the template. You can create the configuration file manually or by using the wizard. For more information, see Create the CloudWatch agent configuration file.

You can use both types of templates for installing the CloudWatch agent and for updating the agent configuration.

For information about setting up the agent on a system that has security-enhanced Linux (SELinux) enabled, see Set up the CloudWatch agent with security-enhanced Linux (SELinux).

Tutorial: Install and configure the CloudWatch agent using an CloudFormation inline template

This tutorial walks you through using CloudFormation to install the CloudWatch agent on a new Amazon EC2 instance. This tutorial installs on a new instance running Amazon Linux 2 using the inline templates, which don't require the use of the JSON configuration file or Parameter Store. The inline template includes the agent configuration in the template. In this tutorial, you use the default agent configuration contained in the template.

After the procedure for installing the agent, the tutorial continues with how to update the agent.

To use CloudFormation to install the CloudWatch agent on a new instance

1. Download the template from GitHub. In this tutorial, download the inline template for Amazon Linux 2 as follows:

   ```
   curl -O https://raw.githubusercontent.com/aws-cloudformation/aws-cloudformation-templates/main/Solutions/AmazonCloudWatchAgent/inline/amazon_linux.yaml
   ```

2. Open the CloudFormation console at https://console.aws.amazon.com/cloudformation.
3. Choose **Create stack**.

4. For **Choose a template**, select **Upload a template to Amazon S3**, choose the downloaded template, and choose **Next**.
5. On the **Specify Details** page, fill out the following parameters and choose **Next**:
   - **Stack name**: Choose a stack name for your CloudFormation stack.
   - **IAMRole**: Choose an IAM role that has permissions to write CloudWatch metrics, logs, and traces. For more information, see Prerequisites.
   - **InstanceAMI**: Choose an AMI that is valid in the Region where you're going to launch your stack.
   - **InstanceType**: Choose a valid instance type.
   - **KeyName**: To enable SSH access to the new instance, choose an existing Amazon EC2 key pair. If you don't already have an Amazon EC2 key pair, you can create one in the AWS Management Console. For more information, see Amazon EC2 Key Pairs in the *Amazon EC2 User Guide*.
   - **SSHLocation**: Specifies the IP address range that can be used to connect to the instance using SSH. The default allows access from any IP address.
6. On the **Options** page, you can choose to tag your stack resources. Choose **Next**.
7. On the **Review** page, review your information, acknowledge that the stack might create IAM resources, and then choose **Create**.

   If you refresh the console, you see that the new stack has the `CREATE_IN_PROGRESS` status.
8. When the instance is created, you can see it in the Amazon EC2 console. Optionally, you can connect to the host and check the progress.

   Use the following command to confirm that the agent is installed:

   ```
   rpm -qa amazon-cloudwatch-agent
   ```

   Use the following command to confirm that the agent is running:

   ```
   ps aux | grep amazon-cloudwatch-agent
   ```

The next procedure demonstrates using CloudFormation to update the CloudWatch agent using an inline template. The default inline template collects the `mem_used_percent` metric. In this tutorial, you change the agent configuration to stop collecting that metric.

To use CloudFormation to update the CloudWatch agent

1. In the template that you downloaded in the previous procedure, remove the following lines and then save the template:

```
"mem": {

     "measurement": [
         "mem_used_percent"
       ]
 },
```

2. Open the CloudFormation console at https://console.aws.amazon.com/cloudformation.
3. On the CloudFormation dashboard, select the stack that you created and choose **Update Stack**.
4. For **Select Template**, select **Upload a template to Amazon S3**, choose the template that you modified, and choose **Next**.
5. On the **Options** page, choose **Next** and then **Next**.
6. On the **Review** page, review your information and choose **Update**.

   After some time, you see `UPDATE_COMPLETE`.

Tutorial: Install the CloudWatch agent using CloudFormation and Parameter Store

This tutorial walks you through using CloudFormation to install the CloudWatch agent on a new Amazon EC2 instance. This tutorial installs on a new instance running Amazon Linux 2 using an agent configuration file that you create and save in Parameter Store.

After the procedure for installing the agent, the tutorial continues with how to update the agent.

To use CloudFormation to install the CloudWatch agent on a new instance using a configuration from Parameter Store

1. If you haven't done so already, download the CloudWatch agent package to one of your computers so that you can create the agent configuration file. For more information and downloading the agent using Parameter Store, see Download the CloudWatch agent package.
2. Create the agent configuration file and save it in Parameter Store. For more information, see Create the CloudWatch agent configuration file.

3. Download the template from GitHub as follows:

```
curl -O https://raw.githubusercontent.com/awslabs/aws-cloudformation-templates/
master/aws/solutions/AmazonCloudWatchAgent/ssm/amazon_linux.template
```

4. Open the CloudFormation console at https://console.aws.amazon.com/cloudformation.
5. Choose **Create stack**.
6. For **Choose a template**, select **Upload a template to Amazon S3**, choose the template that you downloaded, and choose **Next**.
7. On the **Specify Details** page, fill out the following parameters accordingly and choose **Next**:
   - **Stack name**: Choose a stack name for your CloudFormation stack.
   - **IAMRole**: Choose an IAM role that has permissions to write CloudWatch metrics, logs, and traces. For more information, see Prerequisites.
   - **InstanceAMI**: Choose an AMI that is valid in the Region where you're going to launch your stack.
   - **InstanceType**: Choose a valid instance type.
   - **KeyName**: To enable SSH access to the new instance, choose an existing Amazon EC2 key pair. If you don't already have an Amazon EC2 key pair, you can create one in the AWS Management Console. For more information, see Amazon EC2 Key Pairs in the *Amazon EC2 User Guide*.
   - **SSHLocation**: Specifies the IP address range that can be used to connect to the instance using SSH. The default allows access from any IP address.
   - **SSMKey**: Specifies the agent configuration file that you created and saved in Parameter Store.
8. On the **Options** page, you can choose to tag your stack resources. Choose **Next**.
9. On the **Review** page, review your information, acknowledge that the stack might create IAM resources, and then choose **Create**.

   If you refresh the console, you see that the new stack has the `CREATE_IN_PROGRESS` status.
10. When the instance is created, you can see it in the Amazon EC2 console. Optionally, you can connect to the host and check the progress.

    Use the following command to confirm that the agent is installed:

```
rpm -qa amazon-cloudwatch-agent
```

Use the following command to confirm that the agent is running:

```
ps aux | grep amazon-cloudwatch-agent
```

The next procedure demonstrates using CloudFormation to update the CloudWatch agent, using an agent configuration that you saved in Parameter Store.

To use CloudFormation to update the CloudWatch agent using a configuration in Parameter Store

1. Change the agent configuration file stored in Parameter Store to the new configuration that you want.
2. In the CloudFormation template that you downloaded in the the section called “Tutorial: Install the CloudWatch agent using CloudFormation and Parameter Store” topic, change the version number. For example, you might change `VERSION=1.0` to `VERSION=2.0`.
3. Open the CloudFormation console at https://console.aws.amazon.com/cloudformation.
4. On the CloudFormation dashboard, select the stack that you created and choose **Update Stack**.
5. For **Select Template**, select **Upload a template to Amazon S3**, select the template that you just modified, and choose **Next**.
6. On the **Options** page, choose **Next** and then **Next**.
7. On the **Review** page, review your information and choose **Update**.

   After some time, you see `UPDATE_COMPLETE`.

Troubleshooting installation of the CloudWatch agent with CloudFormation

This section helps you troubleshoot issues with installing and updating the CloudWatch agent using CloudFormation.

Detecting when an update fails

If you use CloudFormation to update your CloudWatch agent configuration, and use an invalid configuration, the agent stops sending any metrics to CloudWatch. A quick way to check whether

an agent configuration update succeeded is to look at the `cfn-init-cmd.log` file. On a Linux server, the file is located at `/var/log/cfn-init-cmd.log`. On a Windows instance, the file is located at `C:\cfn\log\cfn-init-cmd.log`.

Metrics are missing

If you don't see metrics that you expect to see after installing or updating the agent, confirm that the agent is configured to collect that metric. To do this, check the `amazon-cloudwatch-agent.json` file to make sure that the metric is listed, and check that you are looking in the correct metric namespace. For more information, see CloudWatch agent files and locations.

Set up the CloudWatch agent with security-enhanced Linux (SELinux)

If your system has security-enhanced Linux (SELinux) enabled, you must apply the appropriate security policies to ensure that the CloudWatch agent runs in a confined domain.

Prerequisites

Before you can configure SELinux for the agent, check the following **prerequisites**:

To complete the prerequisites for using the CloudWatch agent with SELinux

1. If you haven't done so, install the following SELinux policy development packages:

   ```
   sudo yum update
   sudo yum install -y selinux-policy-devel policycoreutils-devel rpm-build git
   ```

2. Run the following command to check your system's SELinux status:

   ```
   sestatus
   ```

   Example output:

   ```
   SELinux status:                 enabled
   SELinuxfs mount:                /sys/fs/selinux
   SELinux root directory:         /etc/selinux
   Loaded policy name:             targeted
   Current mode:                   permissive
   Mode from config file:          permissive
   Policy MLS status:              enabled
   ```

```
Policy deny_unknown status:     allowed
Memory protection checking:     actual (secure)
Max kernel policy version:      33
```

If you find that SELinux is currently disabled, do the following:

a. Open the SELinux file by entering the following command:

```
sudo vi /etc/selinux/config
```

b. Set the `SELINUX` parameter to either `permissive` or `enforcing`. For example:

```
SELINUX=enforcing
```

c. Save the file and reboot the system to apply the changes.

```
sudo reboot
```

3. Ensure that the CloudWatch agent is running as a `systemd` service. This is required to use it within a confined SELinux domain.

```
sudo systemctl status amazon-cloudwatch-agent
```

If the agent is correctly configured, the output should indicate that it is `active (running)` and `enabled` at startup.

Configure SELinux for the agent

After you complete the prerequisites, you can configure SELinux.

To configure SELinux for the CloudWatch agent

1. Clone the SELinux policy for the CloudWatch agent by entering the following command:

```
git clone https://github.com/aws/amazon-cloudwatch-agent-selinux.git
```

2. Navigate to the cloned repository and then update the script permissions by entering the following commands:

```
cd amazon-cloudwatch-agent-selinux
```

```
chmod +x amazon_cloudwatch_agent.sh
```

3. Use sudo to run the SELinux policy installation script by entering the following command. During execution, the script prompts you to enter y or n to allow automatic restart. This restart ensures that the agent transitions into the correct SELinux domain.

```
sudo ./amazon_cloudwatch_agent.sh
```

4. If the CloudWatch agent hasn't been restarted yet, restart it to ensure that it transitions to the correct SELinux domain:

```
sudo systemctl restart amazon-cloudwatch-agent
```

5. Verify that CloudWatch Agent is running in the confined domain by entering the following command:

```
ps -efZ | grep amazon-cloudwatch-agent
```

   If the agent is correctly confined, the output should indicate a SELinux-confined domain instead of `unconfined_service_t`.

   The following is an example of output when the agent is correctly confined.

```
system_u:system_r:confined_t:s0 root 1234 1 0 12:00 ? 00:00:10 /opt/aws/amazon-
cloudwatch-agent/bin/amazon-cloudwatch-agent
```

After SELinux is configured, you can proceed to configure the agent to collect metrics, logs, and traces. For more information, see Manually create or edit the CloudWatch agent configuration file.

Create the CloudWatch agent configuration file

Before running the CloudWatch agent on any servers, you must create one or more CloudWatch agent configuration files.

The agent configuration file is a JSON file that specifies the metrics, logs, and traces that the agent is to collect, including custom metrics. You can create it by using the wizard or by creating it yourself from scratch. You could also use the wizard to initially create the configuration file and then modify it manually. If you create or modify the file manually, the process is more complex, but

you have more control over the metrics collected and can specify metrics not available through the wizard.

Any time you change the agent configuration file, you must then restart the agent to have the changes take effect. To restart the agent, follow the instructions in (Optional) Modify the common configuration and named profile for CloudWatch agent.

After you have created a configuration file, you can save it manually as a JSON file and then use this file when installing the agent on your servers. Alternatively, you can store it in Systems Manager Parameter Store if you're going to use Systems Manager when you install the agent on servers.

The CloudWatch agent supports using multiple configuration files. For more information, see Creating multiple CloudWatch agent configuration files.

Metrics, logs, and traces collected by the CloudWatch agent incur charges. For more information about pricing, see Amazon CloudWatch Pricing.

Contents

- Create the CloudWatch agent configuration file with the wizard
- Creating multiple CloudWatch agent configuration files
- Manually create or edit the CloudWatch agent configuration file

Create the CloudWatch agent configuration file with the wizard

The agent configuration file wizard, `amazon-cloudwatch-agent-config-wizard`, asks a series of questions to help you configure the CloudWatch agent for your needs. This section describes the credentials required for the configuration file. It describes how to run the CloudWatch agent configuration wizard. It also describes the metrics that are predefined in the wizard.

Required credentials

The wizard can autodetect the credentials and AWS Region to use if you have the AWS credentials and configuration files in place before you start the wizard. For more information about these files, see Configuration and Credential Files in the *AWS Systems Manager User Guide*.

In the AWS credentials file, the wizard checks for default credentials and also looks for an `AmazonCloudWatchAgent` section such as the following:

```
[AmazonCloudWatchAgent]
```

```
aws_access_key_id = my_access_key
aws_secret_access_key = my_secret_key
```

The wizard displays the default credentials, the credentials from the `AmazonCloudWatchAgent`, and an `Others` option. You can select which credentials to use. If you choose `Others`, you can input credentials.

For *my_access_key* and *my_secret_key*, use the keys from the IAM user that has the permissions to write to Systems Manager Parameter Store.

In the AWS configuration file, you can specify the Region that the agent sends metrics to if it's different than the `[default]` section. The default is to publish the metrics to the Region where the Amazon EC2 instance is located. If the metrics should be published to a different Region, specify the Region here. In the following example, the metrics are published to the `us-west-1` Region.

```
[AmazonCloudWatchAgent]
region = us-west-1
```

Run the CloudWatch agent configuration wizard

To create the CloudWatch agent configuration file

1. Start the CloudWatch agent configuration wizard by entering the following:

   ```
   sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-config-wizard
   ```

   On a server running Windows Server, run the following commands to launch the wizard:

   ```
   cd "C:\Program Files\Amazon\AmazonCloudWatchAgent"
   ```

   ```
   .\amazon-cloudwatch-agent-config-wizard.exe
   ```

2. Answer the questions to customize the configuration file for your server.
3. If you're storing the configuration file locally, the configuration file `config.json` is stored in `/opt/aws/amazon-cloudwatch-agent/bin/` on Linux servers, and is stored in `C:\Program Files\Amazon\AmazonCloudWatchAgent` on Windows Server. You can then copy this file to other servers where you want to install the agent.

If you're going to use Systems Manager to install and configure the agent, be sure to answer **Yes** when prompted whether to store the file in Systems Manager Parameter Store. You can also choose to store the file in Parameter Store even if you aren't using the SSM Agent to install the CloudWatch agent. To be able to store the file in Parameter Store, you must use an IAM role with sufficient permissions.

CloudWatch agent predefined metric sets

The wizard is configured with predefined sets of metrics, with different detail levels. These sets of metrics are shown in the following tables. For more information about these metrics, see Metrics collected by the CloudWatch agent.

> **Note**
>
> Parameter Store supports parameters in Standard and Advanced tiers. These parameter tiers are not related to the Basic, Standard, and Advanced levels of metric details that are described in these tables.

Amazon EC2 instances running Linux

Detail level	Metrics included
Basic	**Mem:** mem_used_percent **Disk:** disk_used_percent The `disk` metrics such as `disk_used_percent` have a dimension for `Partition`, which means that the number of custom metrics generated is dependent on the number of partitions associated with your instance. The number of disk partitions you have depends on which AMI you are using and the number of Amazon EBS volumes you attach to the server.
Standard	**CPU:** `cpu_usage_idle`, `cpu_usage_iowait`, `cpu_usage_user`, `cpu_usage_system` **Disk:** `disk_used_percent`, `disk_inodes_free`

Detail level	Metrics included
	Diskio: diskio_io_time **Mem:** mem_used_percent **Swap:** swap_used_percent
Advanced	**CPU:** cpu_usage_idle ,cpu_usage_iowait ,cpu_usage_user , cpu_usage_system **Disk:** disk_used_percent ,disk_inodes_free **Diskio:** diskio_io_time ,diskio_write_bytes ,diskio_re ad_bytes ,diskio_writes ,diskio_reads **Mem:** mem_used_percent **Netstat:** netstat_tcp_established ,netstat_tcp_time_wait **Swap:** swap_used_percent

On-premises servers running Linux

Detail level	Metrics included
Basic	**Disk:** disk_used_percent **Diskio:** diskio_write_bytes ,diskio_read_bytes ,diskio_wr ites ,diskio_reads **Mem:** mem_used_percent **Net:** net_bytes_sent ,net_bytes_recv ,net_packets_sent , net_packets_recv **Swap:** swap_used_percent
Standard	**CPU:** cpu_usage_idle ,cpu_usage_iowait **Disk:** disk_used_percent ,disk_inodes_free

Detail level	Metrics included
	Diskio: `diskio_io_time` , `diskio_write_bytes` , `diskio_read_bytes` , `diskio_writes` , `diskio_reads` **Mem:** `mem_used_percent` **Net:** `net_bytes_sent` , `net_bytes_recv` , `net_packets_sent` , `net_packets_recv` **Swap:** `swap_used_percent`
Advanced	**CPU:** `cpu_usage_guest` , `cpu_usage_idle` , `cpu_usage_iowait` , `cpu_usage_steal` , `cpu_usage_user` , `cpu_usage_system` **Disk:** `disk_used_percent` , `disk_inodes_free` **Diskio:** `diskio_io_time` , `diskio_write_bytes` , `diskio_read_bytes` , `diskio_writes` , `diskio_reads` **Mem:** `mem_used_percent` **Net:** `net_bytes_sent` , `net_bytes_recv` , `net_packets_sent` , `net_packets_recv` **Netstat:** `netstat_tcp_established` , `netstat_tcp_time_wait` **Swap:** `swap_used_percent`

Amazon EC2 instances running Windows Server

> **Note**
>
> The metric names listed in this table display how the metric appears when viewed in the console. The actual metric name might not include the first word. For example, the actual metric name for `LogicalDisk % Free Space` is just `% Free Space`.

Detail level	Metrics included
Basic	**Memory:** `Memory % Committed Bytes In Use` **LogicalDisk:** `LogicalDisk % Free Space`
Standard	**Memory:** `Memory % Committed Bytes In Use` **Paging:** `Paging File % Usage` **Processor:** `Processor % Idle Time`, `Processor % Interrupt Time`, `Processor % User Time` **PhysicalDisk:** `PhysicalDisk % Disk Time` **LogicalDisk:** `LogicalDisk % Free Space`
Advanced	**Memory:** `Memory % Committed Bytes In Use` **Paging:** `Paging File % Usage` **Processor:** `Processor % Idle Time`, `Processor % Interrupt Time`, `Processor % User Time` **LogicalDisk:** `LogicalDisk % Free Space` **PhysicalDisk:** `PhysicalDisk % Disk Time` , `PhysicalDisk Disk Write Bytes/sec` , `PhysicalDisk Disk Read Bytes/sec` , `PhysicalDisk Disk Writes/sec` , `PhysicalDisk Disk Reads/sec` **TCP:** `TCPv4 Connections Established` , `TCPv6 Connections Established`

On-premises server running Windows Server

Note

The metric names listed in this table display how the metric appears when viewed in the console. The actual metric name might not include the first word. For example, the actual metric name for `LogicalDisk % Free Space` is just `% Free Space`.

Detail level	Metrics included
Basic	**Paging:** `Paging File % Usage` **Processor:** `Processor % Processor Time` **LogicalDisk:**`LogicalDisk % Free Space` **PhysicalDisk:** `PhysicalDisk Disk Write Bytes/sec ,PhysicalDisk Disk Read Bytes/sec ,PhysicalDisk Disk Writes/sec , PhysicalDisk Disk Reads/sec` **Memory:** `Memory % Committed Bytes In Use` **Network Interface:** `Network Interface Bytes Sent/sec, Network Interface Bytes Received/sec ,Network Interface Packets Sent/sec, Network Interface Packets Received/sec`
Standard	**Paging:** `Paging File % Usage` **Processor:** `Processor % Processor Time, Processor % Idle Time, Processor % Interrupt Time` **LogicalDisk:** `LogicalDisk % Free Space` **PhysicalDisk:** `PhysicalDisk % Disk Time ,PhysicalDisk Disk Write Bytes/sec ,PhysicalDisk Disk Read Bytes/sec , PhysicalDisk Disk Writes/sec ,PhysicalDisk Disk Reads/sec` **Memory:** `Memory % Committed Bytes In Use`

Detail level	Metrics included
	Network Interface: Network Interface Bytes Sent/sec, Network Interface Bytes Received/sec , Network Interface Packets Sent/sec, Network Interface Packets Received/sec
Advanced	**Paging:**Paging File % Usage **Processor:** Processor % Processor Time, Processor % Idle Time, Processor % Interrupt Time, Processor % User Time **LogicalDisk:** LogicalDisk % Free Space **PhysicalDisk:** PhysicalDisk % Disk Time , PhysicalDisk Disk Write Bytes/sec , PhysicalDisk Disk Read Bytes/sec , PhysicalDisk Disk Writes/sec , PhysicalDisk Disk Reads/sec **Memory:** Memory % Committed Bytes In Use **Network Interface:** Network Interface Bytes Sent/sec, Network Interface Bytes Received/sec , Network Interface Packets Sent/sec, Network Interface Packets Received/sec **TCP:** TCPv4 Connections Established , TCPv6 Connections Established

Examples of configuration files

Basic system metrics configuration

```
{
  "agent": {
    "metrics_collection_interval": 60,
    "region": "us-east-1"
  },
  "metrics": {
    "namespace": "MySystem",
    "metrics_collected": {
      "cpu": {
```

```
        "resources": ["*"],
        "measurement": ["usage_active", "usage_system", "usage_user"]
      },
      "mem": {
        "measurement": ["used_percent"]
      },
      "disk": {
        "resources": ["/"],
        "measurement": ["used_percent"]
      }
    },
    "append_dimensions": {
      "InstanceId": "${aws:InstanceId}"
    }
  }
}
```

Web server monitoring configuration

```
{
  "agent": {
    "metrics_collection_interval": 60,
    "region": "us-east-1"
  },
  "metrics": {
    "namespace": "WebServer",
    "metrics_collected": {
      "cpu": {
        "resources": ["*"],
        "measurement": ["usage_active"]
      },
      "mem": {
        "measurement": ["used_percent"]
      },
      "net": {
        "resources": ["eth0"],
        "measurement": ["bytes_sent", "bytes_recv"]
      }
    }
  },
  "logs": {
    "logs_collected": {
      "files": {
```

```
        "collect_list": [
          {
            "file_path": "/var/log/apache2/access.log",
            "log_group_name": "apache-access-logs",
            "log_stream_name": "{instance_id}-access"
          },
          {
            "file_path": "/var/log/apache2/error.log",
            "log_group_name": "apache-error-logs",
            "log_stream_name": "{instance_id}-error"
          }
        ]
      }
    }
  }
}
```

Database server configuration

```
{
  "agent": {
    "metrics_collection_interval": 30,
    "region": "us-east-1"
  },
  "metrics": {
    "namespace": "DatabaseServer",
    "metrics_collected": {
      "cpu": {
        "resources": ["*"],
        "measurement": ["usage_active", "usage_iowait"]
      },
      "mem": {
        "measurement": ["used_percent", "available_percent"]
      },
      "disk": {
        "resources": ["/", "/data"],
        "measurement": ["used_percent", "inodes_free"]
      },
      "diskio": {
        "resources": ["*"],
        "measurement": ["read_bytes", "write_bytes", "io_time"]
      }
```

```
    },
    "append_dimensions": {
      "InstanceId": "${aws:InstanceId}",
      "InstanceType": "${aws:InstanceType}",
      "AutoScalingGroupName": "${aws:AutoScalingGroupName}"
    }
  }
}
```

Creating multiple CloudWatch agent configuration files

On both Linux servers and Windows servers, you can set up the CloudWatch agent to use multiple configuration files. For example, you can use a common configuration file that collects a set of metrics, logs, and traces that you always want to collect from all servers in your infrastructure. You can then use additional configuration files that collect metrics from certain applications or in certain situations.

To set this up, first create the configuration files that you want to use. Any configuration files that will be used together on the same server must have different file names. You can store the configuration files on servers or in Parameter Store.

Start the CloudWatch agent using the `fetch-config` option and specify the first configuration file. To append the second configuration file to the running agent, use the same command but with the `append-config` option. All metrics, logs, and traces listed in either configuration file are collected. The following example commands illustrate this scenario using configurations stores as files. The first line starts the agent using the `infrastructure.json` configuration file, and the second line appends the `app.json` configuration file.

The following example commands are for Linux.

```
/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -m ec2
 -s -c file:/tmp/infrastructure.json
```

```
/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a append-config -m
 ec2 -s -c file:/tmp/app.json
```

The following example commands are for Windows Server.

```
& "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1"
 -a fetch-config -m ec2 -s -c file:"C:\Program Files\Amazon\AmazonCloudWatchAgent
\infrastructure.json"
```

```
& "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1"
 -a append-config -m ec2 -s -c file:"C:\Program Files\Amazon\AmazonCloudWatchAgent
\app.json"
```

The following example configuration files illustrate a use for this feature. The first configuration file is used for all servers in the infrastructure, and the second collects only logs from a certain application and is appended to servers running that application.

infrastructure.json

```
{
  "metrics": {
    "metrics_collected": {
      "cpu": {
        "resources": [
          "*"
        ],
        "measurement": [
          "usage_active"
        ],
        "totalcpu": true
      },
      "mem": {
         "measurement": [
           "used_percent"
        ]
      }
    }
  },
  "logs": {
    "logs_collected": {
      "files": {
        "collect_list": [
          {
            "file_path": "/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-
agent.log",
            "log_group_name": "amazon-cloudwatch-agent.log"
          },
```

```
          {
            "file_path": "/var/log/messages",
            "log_group_name": "/var/log/messages"
          }
        ]
      }
    }
  }
}
```

app.json

```
{
    "logs": {
        "logs_collected": {
            "files": {
                "collect_list": [
                    {
                        "file_path": "/app/app.log*",
                        "log_group_name": "/app/app.log"
                    }
                ]
            }
        }
    }
}
```

Any configuration files appended to the configuration must have different file names from each other and from the initial configuration file. If you use `append-config` with a configuration file with the same file name as a configuration file that the agent is already using, the append command overwrites the information from the first configuration file instead of appending to it. This is true even if the two configuration files with the same file name are on different file paths.

The preceding example shows the use of two configuration files, but there is no limit to the number of configuration files that you can append to the agent configuration. You can also mix the use of configuration files located on servers and configurations located in Parameter Store.

Manually create or edit the CloudWatch agent configuration file

The CloudWatch agent configuration file is a JSON file with four sections: `agent`, `metrics`, `logs`, and `traces`.

- The `agent` section includes fields for the overall configuration of the agent.
- The `metrics` section specifies the custom metrics for collection and publishing to CloudWatch. If you're using the agent only to collect logs, you can omit the `metrics` section from the file.
- The `logs` section specifies what log files are published to CloudWatch Logs. This can include events from the Windows Event Log if the server runs Windows Server.
- The `traces` section specifies the sources for traces that are collected and sent to AWS X-Ray.

This section explains the structure and fields of the CloudWatch agent configuration file. You can view the schema definition for this configuration file. The schema definition is located at *`installation-directory`*`/doc/amazon-cloudwatch-agent-schema.json` on Linux servers and at *`installation-directory`*`/amazon-cloudwatch-agent-schema.json` on servers running Windows Server.

If you create or edit the agent configuration file manually, you can give it any name. For simplicity in troubleshooting, we recommend that you name it `/opt/aws/amazon-cloudwatch-agent/etc/cloudwatch-agent.json` on a Linux server and `$Env:ProgramData\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent.json` on servers running Windows Server. After you have created the file, you can copy it to other servers where you want to install the agent.

When the agent is started, it creates a copy of each configuration file in `/opt/aws/amazon-cloudwatch-agent/etc/amazon-cloudwatch-agent.d` directory, with the filename prefixed with either `file_` (for local file sources) or `ssm_` (for Systems Manager parameter store sources) to indicate the configuration origin.

> **Note**
>
> Metrics, logs, and traces collected by the CloudWatch agent incur charges. For more information about pricing, see Amazon CloudWatch Pricing.

CloudWatch agent configuration file: Agent section

The `agent` section can include the following fields. The wizard doesn't create an `agent` section. Instead, the wizard omits it and uses the default values for all fields in this section.

- `metrics_collection_interval` – Optional. Specifies how often all metrics specified in this configuration file are to be collected. You can override this value for specific types of metrics.

This value is specified in seconds. For example, specifying 10 causes metrics to be collected every 10 seconds, and setting it to 300 specifies metrics to be collected every 5 minutes.

If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-resolution metrics.

The default value is 60.

- `region` – Specifies the Region to use for the CloudWatch endpoint when an Amazon EC2 instance is being monitored. The metrics collected are sent to this Region, such as `us-west-1`. If you omit this field, the agent sends metrics to the Region where the Amazon EC2 instance is located.

  If you are monitoring an on-premises server, this field isn't used, and the agent reads the Region from the `AmazonCloudWatchAgent` profile of the AWS configuration file.

- `credentials` – Specifies an IAM role to use when sending metrics, logs, and traces to a different AWS account. If specified, this field contains one parameter, `role_arn`.
  - `role_arn` – Specifies the Amazon Resource Name (ARN) of an IAM role to use for authentication when sending metrics, logs, and traces to a different AWS account. For more information, see Sending metrics, logs, and traces to a different account.
- debug – Optional. Specifies running the CloudWatch agent with debug log messages. The default value is `false`.
- `aws_sdk_log_level` – Optional. Supported only in versions 1.247350.0 and later of the CloudWatch agent.

  You can specify this field to have the agent perform logging for AWS SDK endpoints. The value for this field can include one or more of the following options. Separate multiple options with the `|` character.
  - `LogDebug`
  - `LogDebugWithSigning`
  - `LogDebugWithHTTPBody`
  - `LogDebugRequestRetries`
  - `LogDebugWithEventStreamBody`

  For more information about these options, see LogLevelType.

- `logfile` – Specifies the location where the CloudWatch agent writes log messages. If you specify an empty string, the log goes to stderr. If you don't specify this option, the default locations are the following:
  - Linux: `/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-agent.log`
  - Windows Server: `c:\\ProgramData\\Amazon\\CloudWatchAgent\\Logs\\amazon-cloudwatch-agent.log`

  The CloudWatch agent automatically rotates the log file that it creates. A log file is rotated out when it reaches 100 MB in size. The agent keeps the rotated log files for up to seven days, and it keeps as many as five backup log files that have been rotated out. Backup log files have a timestamp appended to their filename. The timestamp shows the date and time that the file was rotated out: for example, `amazon-cloudwatch-agent-2018-06-08T21-01-50.247.log.gz`.
- `omit_hostname` – Optional. By default, the hostname is published as a dimension of metrics that are collected by the agent, unless you are using the `append_dimensions` field in the `metrics` section. Set `omit_hostname` to `true` to prevent the hostname from being published as a dimension even if you are not using `append_dimensions`. The default value is `false`.
- `run_as_user` – Optional. Specifies a user to use to run the CloudWatch agent. If you don't specify this parameter, the root user is used. This option is valid only on Linux servers.

  If you specify this option, the user must exist before you start the CloudWatch agent. For more information, see Running the CloudWatch agent as a different user.
- `user_agent` – Optional. Specifies the `user-agent` string that is used by the CloudWatch agent when it makes API calls to the CloudWatch backend. The default value is a string consisting of the agent version, the version of the Go programming language that was used to compile the agent, the runtime operating system and architecture, the build time, and the plugins enabled.
- `usage_data` – Optional. By default, the CloudWatch agent sends health and performance data about itself to CloudWatch whenever it publishes metrics or logs to CloudWatch. This data incurs no costs to you. You can prevent the agent from sending this data by specifying `false` for `usage_data`. If you omit this parameter, the default of `true` is used and the agent sends the health and performance data.

  If you set this value to `false`, you must stop and restart the agent for it to take effect.
- `service.name` – Optional. Specifies the service name to be used to populate the entity for finding related telemetry.

- `deployment.environment` – Optional. Specifies the environment name to be used to populate the entity for finding related telemetry.
- `use_dualstack_endpoint` – Optional. If this is `true`, the CloudWatch agent will use dual stack endpoints for all API calls.

The following is an example of an `agent` section.

```
"agent": {
   "metrics_collection_interval": 60,
   "region": "us-west-1",
   "logfile": "/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-agent.log",
   "debug": false,
   "run_as_user": "cwagent"
  }
```

CloudWatch agent configuration file: Metrics section

Fields common to Linux and Windows

On servers running either Linux or Windows Server, the `metrics` section includes the following fields:

- `namespace` – Optional. The namespace to use for the metrics collected by the agent. The default value is `CWAgent`. The maximum length is 255 characters. The following is an example:

  ```
  {
    "metrics": {
      "namespace": "Development/Product1Metrics",
     ......
     },
  }
  ```

- `append_dimensions` – Optional. Adds Amazon EC2 metric dimensions to all metrics collected by the agent. This also causes the agent to not publish the hostname as a dimension.

  The only supported key-value pairs for `append_dimensions` are shown in the following list. Any other key-value pairs are ignored. The agent supports these key-value pairs exactly as they are shown in the following list. You can't change the key values to publish different dimension names for them.

- `"ImageId":"${aws:ImageId}"` sets the instance's AMI ID as the value of the `ImageId` dimension.
- `"InstanceId":"${aws:InstanceId}"` sets the instance's instance ID as the value of the `InstanceId` dimension.
- `"InstanceType":"${aws:InstanceType}"` sets the instance's instance type as the value of the `InstanceType` dimension.
- `"AutoScalingGroupName":"${aws:AutoScalingGroupName}"` sets the instance's Auto Scaling group name as the value of the `AutoScalingGroupName` dimension.

If you want to append dimensions to metrics with arbitrary key-value pairs, use the `append_dimensions` parameter in the field for that particular type of metric.

If you specify a value that depends on Amazon EC2 metadata and you use proxies, you must make sure that the server can access the endpoint for Amazon EC2. For more information about these endpoints, see Amazon Elastic Compute Cloud (Amazon EC2) in the *Amazon Web Services General Reference*.

- `aggregation_dimensions` – Optional. Specifies the dimensions that collected metrics are to be aggregated on. For example, if you roll up metrics on the `AutoScalingGroupName` dimension, the metrics from all instances in each Auto Scaling group are aggregated and can be viewed as a whole.

  You can roll up metrics along single or multiple dimensions. For example, specifying `[["InstanceId"], ["InstanceType"], ["InstanceId","InstanceType"]]` aggregates metrics for instance ID singly, instance type singly, and for the combination of the two dimensions.

  You can also specify `[]` to roll up all metrics into one collection, disregarding all dimensions.

- `endpoint_override` – Specifies a FIPS endpoint or private link to use as the endpoint where the agent sends metrics. Specifying this and setting a private link enables you to send the metrics to an Amazon VPC endpoint. For more information, see What Is Amazon VPC?.

  The value of `endpoint_override` must be a string that is a URL.

  For example, the following part of the metrics section of the configuration file sets the agent to use a VPC Endpoint when sending metrics.

```
{
```

```
  "metrics": {
    "endpoint_override": "vpce-XXXXXXXXXXXXXXXXXXXXXXXX.monitoring.us-
east-1.vpce.amazonaws.com",
   ......
   },
}
```

- `metrics_collected` – Required. Specifies which metrics are to be collected, including custom metrics collected through `StatsD` or `collectd`. This section includes several subsections.

  The contents of the `metrics_collected` section depend on whether this configuration file is for a server running Linux or Windows Server.

- `metrics_destinations` – Optional. Specifies one or more destinations for all metrics defined in `metrics_collected`. If specified here, it overrides the default destination of `cloudwatch`.
  - `cloudwatch` – Amazon CloudWatch.
  - amp – Amazon Managed Service for Prometheus.
    - `workspace_id` – The ID corresponding to the Amazon Managed Service for Prometheus workspace.

```
{
  "metrics": {
    "metrics_destinations": {
      "cloudwatch": {},
      "amp": {
        "workspace_id": "ws-abcd1234-ef56-7890-ab12-example"
      }
    }
  }
}
```

- `force_flush_interval` – Specifies in seconds the maximum amount of time that metrics remain in the memory buffer before being sent to the server. No matter the setting for this, if the size of the metrics in the buffer reaches 1 MB or 1000 different metrics, the metrics are immediately sent to the server.

  The default value is 60.

- `credentials` – Specifies an IAM role to use when sending metrics to a different account. If specified, this field contains one parameter, `role_arn`.

- `role_arn` – Specifies the ARN of an IAM role to use for authentication when sending metrics to a different account. For more information, see Sending metrics, logs, and traces to a different account. If specified here, this value overrides the `role_arn` specified in the `agent` section of the configuration file, if any.
- `service.name` – Optional. Specifies the service name to be used to populate the entity for finding related telemetry.
- `deployment.environment` – Optional. Specifies the environment name to be used to populate the entity for finding related telemetry.

Linux section

On servers running Linux, the `metrics_collected` section of the configuration file can also contain the following fields.

Many of these fields can include a `measurement` sections that lists the metrics you want to collect for that resource. These `measurement` sections can either specify the complete metric name such as `swap_used`, or just the part of the metric name that will be appended to the type of resource. For example, specifying `reads` in the `measurement` section of the `diskio` section causes the `diskio_reads` metric to be collected.

- `collectd` – Optional. Specifies that you want to retrieve custom metrics using the `collectd` protocol. You use `collectd` software to send the metrics to the CloudWatch agent. For more information about the configuration options available for collectd, see Retrieve custom metrics with collectd.
- `cpu` – Optional. Specifies that CPU metrics are to be collected. This section is valid only for Linux instances. You must include at least one of the `resources` and `totalcpu` fields for any CPU metrics to be collected. This section can include the following fields:
  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

- `resources` – Optional. Specify this field with a value of `*` to cause per-cpu metrics to be collected. The only allowed value is `*`.
- `totalcpu` – Optional. Specifies whether to report cpu metrics aggregated across all cpu cores. The default is true.
- `measurement` – Specifies the array of cpu metrics to be collected. Possible values are `time_active`, `time_guest`, `time_guest_nice`, `time_idle`, `time_iowait`, `time_irq`, `time_nice`, `time_softirq`, `time_steal`, `time_system`, `time_user`, `usage_active`, `usage_guest`, `usage_guest_nice`, `usage_idle`, `usage_iowait`, `usage_irq`, `usage_nice`, `usage_softirq`, `usage_steal`, `usage_system`, and `usage_user`. This field is required if you include `cpu`.

  By default, the unit for `cpu_usage_*` metrics is `Percent`, and `cpu_time_*` metrics don't have a unit.

  Within the entry for each individual metric, you might optionally specify one or both of the following:

  - `rename` – Specifies a different name for this metric.
  - `unit` – Specifies the unit to use for this metric, overriding the default unit of `None` for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.
- `metrics_collection_interval` – Optional. Specifies how often to collect the cpu metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds. For example, specifying 10 causes metrics to be collected every 10 seconds, and setting it to 300 specifies metrics to be collected every 5 minutes.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-resolution metrics.
- `append_dimensions` – Optional. Additional dimensions to use for only the cpu metrics. If you specify this field, it's used in addition to dimensions specified in the global `append_dimensions` field that is used for all types of metrics that the agent collects.

- `disk` – Optional. Specifies that disk metrics are to be collected. Collects metrics only for mounted volumes. This section is valid only for Linux instances. This section can include the following fields:

- `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.
- `resources` – Optional. Specifies an array of disk mount points. This field limits CloudWatch to collect metrics from only the listed mount points. You can specify `*` as the value to collect metrics from all mount points. The default value is to collect metrics from all mount points.
- `measurement` – Specifies the array of disk metrics to be collected. Possible values are `free`, `total`, `used`, `used_percent`, `inodes_free`, `inodes_used`, and `inodes_total`. This field is required if you include `disk`.

  > **Note**
  >
  > The `disk` metrics have a dimension for `Partition`, which means that the number of custom metrics generated is dependent on the number of partitions associated with your instance. The number of disk partitions you have depends on which AMI you are using and the number of Amazon EBS volumes you attach to the server.

  To see the default units for each `disk` metric, see Metrics collected by the CloudWatch agent on Linux and macOS instances.

  Within the entry for each individual metric, you might optionally specify one or both of the following:

  - `rename` – Specifies a different name for this metric.
  - `unit` – Specifies the unit to use for this metric, overriding the default unit of None of None for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.
- `ignore_file_system_types` – Specifies file system types to exclude when collecting disk metrics. Valid values include `sysfs`, `devtmpfs`, and so on.
- `drop_device` – Setting this to `true` causes `Device` to not be included as a dimension for disk metrics.

Preventing `Device` from being used as a dimension can be useful on instances that use the Nitro system because on those instances the device names change for each disk mount when the instance is rebooted. This can cause inconsistent data in your metrics and cause alarms based on these metrics to go to `INSUFFICIENT DATA` state.

The default is `false`.

- `metrics_collection_interval` – Optional. Specifies how often to collect the disk metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information, see High-resolution metrics.

- `append_dimensions` – Optional. Specify key-value pairs to use as additional dimensions for only the disk metrics. If you specify this field, it is used in addition to dimensions specified in the `append_dimensions` field that is used for all types of metrics collected by the agent.

  One key-value pair that you can use is the following. You can also specify other custom key-value pairs.

  - `"VolumeId":"${aws:VolumeId}"` adds a `VolumeId` dimension to your block device disk metrics. For Amazon EBS volumes, this will be the Amazon EBS Volume ID. For EC2 instance store, this will be the device serial. Using this requires the `drop_device` parameter to be set to `false`.

- `diskio` – Optional. Specifies that disk i/o metrics are to be collected. This section is valid only for Linux instances. This section can include the following fields:

  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

- `resources` – Optional. If you specify an array of devices, CloudWatch collects metrics from only those devices. Otherwise, metrics for all devices are collected. You can also specify * as the value to collect metrics from all devices.
- `measurement` – Specifies the array of diskio and AWS NVMe driver metrics to be collected for Amazon EBS volumes and instance store volumes attached to Amazon EC2 instances. Possible diskio values are `reads`, `writes`, `read_bytes`, `write_bytes`, `read_time`, `write_time`, `io_time`, and `iops_in_progress`. For a list of the NVMe driver metrics for Amazon EBS volumes and Amazon EC2 instance store volumes, see Collect Amazon EBS NVMe driver metrics and Collect Amazon EC2 instance store volume NVMe driver metrics. This field is required if you include `diskio`.

  Within the entry for each individual metric, you might optionally specify one or both of the following:

  - `rename` – Specifies a different name for this metric.
  - `unit` – Specifies the unit to use for this metric, overriding the default unit of None of None for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

  For information on default units and description of the metrics, see Collect Amazon EBS NVMe driver metrics.
- `metrics_collection_interval` – Optional. Specifies how often to collect the diskio metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-resolution metrics.
- `append_dimensions` – Optional. Additional dimensions to use for only the diskio metrics. If you specify this field, it is used in addition to dimensions specified in the `append_dimensions` field that is used for all types of metrics collected by the agent.

- `swap` – Optional. Specifies that swap memory metrics are to be collected. This section is valid only for Linux instances. This section can include the following fields:
  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value

of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

- `measurement` – Specifies the array of swap metrics to be collected. Possible values are `free`, `used`, and `used_percent`. This field is required if you include `swap`.

  To see the default units for each `swap` metric, see Metrics collected by the CloudWatch agent on Linux and macOS instances.

  Within the entry for each individual metric, you might optionally specify one or both of the following:

  - `rename` – Specifies a different name for this metric.
  - `unit` – Specifies the unit to use for this metric, overriding the default unit of None of None for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

- `metrics_collection_interval` – Optional. Specifies how often to collect the swap metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-resolution metrics.

- `append_dimensions` – Optional. Additional dimensions to use for only the swap metrics. If you specify this field, it is used in addition to dimensions specified in the global `append_dimensions` field that is used for all types of metrics collected by the agent. It's collected as a high-resolution metric.

- `mem` – Optional. Specifies that memory metrics are to be collected. This section is valid only for Linux instances. This section can include the following fields:

  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter

don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

- `measurement` – Specifies the array of memory metrics to be collected. Possible values are `active`, `available`, `available_percent`, `buffered`, `cached`, `free`, `inactive`, `shared`, `total`, `used`, and `used_percent`. This field is required if you include `mem`.

  To see the default units for each `mem` metric, see Metrics collected by the CloudWatch agent on Linux and macOS instances.

  Within the entry for each individual metric, you might optionally specify one or both of the following:

  - `rename` – Specifies a different name for this metric.
  - `unit` – Specifies the unit to use for this metric, overriding the default unit of `None` for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

- `metrics_collection_interval` – Optional. Specifies how often to collect the mem metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-resolution metrics.

- `append_dimensions` – Optional. Additional dimensions to use for only the mem metrics. If you specify this field, it's used in addition to dimensions specified in the `append_dimensions` field that is used for all types of metrics that the agent collects.

- `net` – Optional. Specifies that networking metrics are to be collected. This section is valid only for Linux instances. This section can include the following fields:

  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated

metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

- `resources` – Optional. If you specify an array of network interfaces, CloudWatch collects metrics from only those interfaces. Otherwise, metrics for all devices are collected. You can also specify `*` as the value to collect metrics from all interfaces.
- `measurement` – Specifies the array of networking metrics to be collected. Possible values are `bytes_sent`, `bytes_recv`, `drop_in`, `drop_out`, `err_in`, `err_out`, `packets_sent`, and `packets_recv`. This field is required if you include `net`.

  To see the default units for each `net` metric, see Metrics collected by the CloudWatch agent on Linux and macOS instances.

  Within the entry for each individual metric, you might optionally specify one or both of the following:

  - `rename` – Specifies a different name for this metric.
  - `unit` – Specifies the unit to use for this metric, overriding the default unit of `None` for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.
- `metrics_collection_interval` – Optional. Specifies how often to collect the net metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds. For example, specifying 10 causes metrics to be collected every 10 seconds, and setting it to 300 specifies metrics to be collected every 5 minutes.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-resolution metrics.
- `append_dimensions` – Optional. Additional dimensions to use for only the net metrics. If you specify this field, it's used in addition to dimensions specified in the `append_dimensions` field that is used for all types of metrics collected by the agent.

- `netstat` – Optional. Specifies that TCP connection state and UDP connection metrics are to be collected. This section is valid only for Linux instances. This section can include the following fields:
  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value

of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

- `measurement` – Specifies the array of netstat metrics to be collected. Possible values are `tcp_close`, `tcp_close_wait`, `tcp_closing`, `tcp_established`, `tcp_fin_wait1`, `tcp_fin_wait2`, `tcp_last_ack`, `tcp_listen`, `tcp_none`, `tcp_syn_sent`, `tcp_syn_recv`, `tcp_time_wait`, and `udp_socket`. This field is required if you include `netstat`.

  To see the default units for each `netstat` metric, see Metrics collected by the CloudWatch agent on Linux and macOS instances.

  Within the entry for each individual metric, you might optionally specify one or both of the following:

  - `rename` – Specifies a different name for this metric.
  - `unit` – Specifies the unit to use for this metric, overriding the default unit of `None` for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.
- `metrics_collection_interval` – Optional. Specifies how often to collect the netstat metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-resolution metrics.
- `append_dimensions` – Optional. Additional dimensions to use for only the netstat metrics. If you specify this field, it's used in addition to dimensions specified in the `append_dimensions` field that is used for all types of metrics collected by the agent.

- `processes` – Optional. Specifies that process metrics are to be collected. This section is valid only for Linux instances. This section can include the following fields:
  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can

specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

- `measurement` – Specifies the array of processes metrics to be collected. Possible values are `blocked`, `dead`, `idle`, `paging`, `running`, `sleeping`, `stopped`, `total`, `total_threads`, `wait`, and `zombies`. This field is required if you include `processes`.

  For all `processes` metrics, the default unit is None.

  Within the entry for each individual metric, you might optionally specify one or both of the following:

  - `rename` – Specifies a different name for this metric.
  - `unit` – Specifies the unit to use for this metric, overriding the default unit of None for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.
- `metrics_collection_interval` – Optional. Specifies how often to collect the processes metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds. For example, specifying 10 causes metrics to be collected every 10 seconds, and setting it to 300 specifies metrics to be collected every 5 minutes.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information, see High-resolution metrics.
- `append_dimensions` – Optional. Additional dimensions to use for only the process metrics. If you specify this field, it's used in addition to dimensions specified in the `append_dimensions` field that is used for all types of metrics collected by the agent.

- `nvidia_gpu` – Optional. Specifies that NVIDIA GPU metrics are to be collected. This section is valid only for Linux instances on hosts that are configured with a NVIDIA GPU accelerator and have the NVIDIA System Management Interface (nvidia-smi) installed.

  The NVIDIA GPU metrics that are collected are prefixed with the string `nvidia_smi_` to distinguish them from the metrics collected for other accelerator types. This section can include the following fields:

  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent

sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

- `measurement` – Specifies the array of NVIDIA GPU metrics to be collected. For a list of the possible values to use here, see the **Metric** column in the table in Collect NVIDIA GPU metrics.

  Within the entry for each individual metric, you can optionally specify one or both of the following:

  - `rename` – Specifies a different name for this metric.
  - `unit` – Specifies the unit to use for this metric, overriding the default unit of `None` for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.
- `metrics_collection_interval` – Optional. Specifies how often to collect the NVIDIA GPU metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

- `jmx` – Optional. Specifies that you want to retrieve Java Management Extensions (JMX) metrics from the instance. For more information about the parameters that you can use in this section and the metrics that you can collect, see Collect Java Management Extensions (JMX) metrics.
- `otlp` – Optional. Specifies that you want to collect metrics from the OpenTelemetry SDK. For more information about the fields that you can use in this section, see Collect metrics and traces with OpenTelemetry.
- `procstat` – Optional. Specifies that you want to retrieve metrics from individual processes. For more information about the configuration options available for procstat, see Collect process metrics with the procstat plugin.
- `statsd` – Optional. Specifies that you want to retrieve custom metrics using the `StatsD` protocol. The CloudWatch agent acts as a daemon for the protocol. You use any standard `StatsD` client to send the metrics to the CloudWatch agent. For more information about the configuration options available for StatsD, see Retrieve custom metrics with StatsD.
- `ethtool` – Optional. Specifies that you want to retrieve network metrics using the `ethtool` plugin. This plugin can import both the metrics collected by the standard ethtool utility, as well as network performance metrics from Amazon EC2 instances. For more information about the configuration options available for ethtool, see Collect network performance metrics.

- `efa` – Optional. Specifies that Elastic Fabric Adapter (EFA) metrics are to be collected. This section is valid only for Linux instances that have EFA devices attached. The agent collects EFA metrics from the `/sys/class/infiniband/` sysfs interface.

  This section can include the following fields:

  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.
  - `measurement` – Specifies the array of EFA metrics to be collected. This field is required. If you don't specify this field, the agent returns an error. You can specify metric names with or without the `efa_` prefix. For example, both `efa_tx_bytes` and `tx_bytes` are valid.

    For a list of the possible values to use here, see the **Metric** column in the table in Collect EFA metrics.
  - `metrics_collection_interval` – Optional. Specifies how often to collect the EFA metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file. The default value is 60 seconds.

  Each EFA metric is emitted with `device`, `port`, and `eniId` dimensions. To append the `InstanceId` dimension, use the `append_dimensions` field in the `metrics` section.

The following is an example of a `metrics` section for a Linux server. In this example, three CPU metrics, three netstat metrics, three process metrics, and one disk metric are collected, and the agent is set up to receive additional metrics from a `collectd` client.

```
"metrics": {
    "aggregation_dimensions" : [["AutoScalingGroupName"], ["InstanceId",
 "InstanceType"],[]],
    "metrics_collected": {
      "collectd": {},
      "cpu": {
        "resources": [
          "*"
```

```
        ],
        "measurement": [
          {"name": "cpu_usage_idle", "rename": "CPU_USAGE_IDLE", "unit": "Percent"},
          {"name": "cpu_usage_nice", "unit": "Percent"},
          "cpu_usage_guest"
        ],
        "totalcpu": false,
        "drop_original_metrics": [ "cpu_usage_guest" ],
        "metrics_collection_interval": 10,
        "append_dimensions": {
          "test": "test1",
          "date": "2017-10-01"
        }
      },
      "netstat": {
        "measurement": [
          "tcp_established",
          "tcp_syn_sent",
          "tcp_close"
        ],
        "metrics_collection_interval": 60
      },
       "disk": {
        "measurement": [
          "used_percent"
        ],
        "resources": [
          "*"
        ],
        "drop_device": true
      },
      "processes": {
        "measurement": [
          "running",
          "sleeping",
          "dead"
        ]
      }
    },
    "append_dimensions": {
      "ImageId": "${aws:ImageId}",
      "InstanceId": "${aws:InstanceId}",
      "InstanceType": "${aws:InstanceType}",
      "AutoScalingGroupName": "${aws:AutoScalingGroupName}"
```

```
    }
  }
```

Windows Server

In the `metrics_collected` section for Windows Server, you can have subsections for each Windows performance object, such as `Memory`, `Processor`, and `LogicalDisk`. For information about what objects and counters are available, see Performance Counters in the Microsoft Windows documentation.

Within the subsection for each object, you specify a `measurement` array of the counters to collect. The `measurement` array is required for each object that you specify in the configuration file. You can also specify a `resources` field to name the instances to collect metrics from. You can also specify `*` for `resources` to collect separate metrics for every instance. If you omit `resources` for counters that have instances, the data for all instances is aggregated into one set. If you omit `resources` for counters that don't have instances, the counters are not collected by the CloudWatch agent. To determine whether counters have instances, you can use one of the following commands.

Powershell:

```
Get-Counter -ListSet *
```

Command line (not Powershell):

```
TypePerf.exe -q
```

Within each object section, you can also specify the following optional fields:

- `metrics_collection_interval` – Optional. Specifies how often to collect the metrics for this object, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds. For example, specifying 10 causes metrics to be collected every 10 seconds, and setting it to 300 specifies metrics to be collected every 5 minutes.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information, see High-resolution metrics.

- `append_dimensions` – Optional. Specifies additional dimensions to use for only the metrics for this object. If you specify this field, it's used in addition to dimensions specified in the global `append_dimensions` field that is used for all types of metrics collected by the agent.
- `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

Within each counter section, you can also specify the following optional fields:

- `rename` – Specifies a different name to be used in CloudWatch for this metric.
- `unit` – Specifies the unit to use for this metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

There are other optional sections that you can include in `metrics_collected`:

- `statsd` – Enables you to retrieve custom metrics using the `StatsD` protocol. The CloudWatch agent acts as a daemon for the protocol. You use any standard `StatsD` client to send the metrics to the CloudWatch agent. For more information, see Retrieve custom metrics with StatsD.
- `procstat` – Enables you to retrieve metrics from individual processes. For more information, see Collect process metrics with the procstat plugin.
- `jmx` – Optional. Specifies that you want to retrieve Java Management Extensions (JMX) metrics from the instance. For more information about the fields that you can use in this section and the metrics that you can collect, see Collect Java Management Extensions (JMX) metrics.
- `otlp` – Optional. Specifies that you want to collect metrics from the OpenTelemetry SDK. For more information about the fields that you can use in this section, see Collect metrics and traces with OpenTelemetry.

The following is an example `metrics` section for use on Windows Server. In this example, many Windows metrics are collected, and the computer is also set to receive additional metrics from a `StatsD` client.

```
"metrics": {
    "metrics_collected": {
      "statsd": {},
      "Processor": {
        "measurement": [
          {"name": "% Idle Time", "rename": "CPU_IDLE", "unit": "Percent"},
          "% Interrupt Time",
          "% User Time",
          "% Processor Time"
        ],
        "resources": [
          "*"
        ],
        "append_dimensions": {
          "d1": "win_foo",
          "d2": "win_bar"
        }
      },
      "LogicalDisk": {
        "measurement": [
          {"name": "% Idle Time", "unit": "Percent"},
          {"name": "% Disk Read Time", "rename": "DISK_READ"},
          "% Disk Write Time"
        ],
        "resources": [
          "*"
        ]
      },
      "Memory": {
        "metrics_collection_interval": 5,
        "measurement": [
          "Available Bytes",
          "Cache Faults/sec",
          "Page Faults/sec",
          "Pages/sec"
        ],
        "append_dimensions": {
          "d3": "win_bo"
        }
      },
      "Network Interface": {
        "metrics_collection_interval": 5,
        "measurement": [
```

```
          "Bytes Received/sec",
          "Bytes Sent/sec",
          "Packets Received/sec",
          "Packets Sent/sec"
        ],
        "resources": [
          "*"
        ],
        "append_dimensions": {
          "d3": "win_bo"
        }
      },
      "System": {
        "measurement": [
          "Context Switches/sec",
          "System Calls/sec",
          "Processor Queue Length"
        ],
        "append_dimensions": {
          "d1": "win_foo",
          "d2": "win_bar"
        }
      }
    },
    "append_dimensions": {
      "ImageId": "${aws:ImageId}",
      "InstanceId": "${aws:InstanceId}",
      "InstanceType": "${aws:InstanceType}",
      "AutoScalingGroupName": "${aws:AutoScalingGroupName}"
    },
    "aggregation_dimensions" : [["ImageId"], ["InstanceId", "InstanceType"], ["d1"],[]]
    }
  }
```

CloudWatch agent configuration file: Logs section

The `logs` section includes the following fields:

- `service.name` – Optional. Specifies the service name to be used to populate the entity for finding related telemetry.
- `deployment.environment` – Optional. Specifies the environment name to be used to populate the entity for finding related telemetry.

- `backpressure_mode` – Optional. Specifies the behavior when the CloudWatch agent is ingesting logs faster than it can send to CloudWatch Logs, resulting in backpressure. Backpressure can happen from network issues, API throttling, or high log volume.

  The agent supports the following values:

  - `fd_release` – Releases file descriptors for deleted files during backpressure conditions. This option can help prevent disk space exhaustion when external log rotation or cleanup processes remove files while the agent maintains open file descriptors. The `auto_removal` option takes precedence over the `backpressure_mode` option being set to `fd_release`. When `auto_removal` is enabled, the CloudWatch agent processes the file to completion without releasing the file descriptor.

    > **Important**
    >
    > Using `fd_release` can result in the CloudWatch agent being unable to read log files to completion, causing log loss.

- `concurrency` – Optional. Specifies the number of shared log publishers used to concurrently publish log files to CloudWatch Logs.

  If you omit this field, each log file destination (log group, stream combination) has a single shared log publisher, which can lead to bottlenecks for large files or when writing multiple files to the same destination. Enabling concurrency can help with throughput.

- `logs_collected` – Required if the `logs` section is included. Specifies which log files and Windows event logs are to be collected from the server. It can include two fields, `files` and `windows_events`.
  - `files` – Specifies which regular log files the CloudWatch agent is to collect. It contains one field, `collect_list`, which further defines these files.
    - `collect_list` – Required if `files` is included. Contains an array of entries, each of which specifies one log file to collect. Each of these entries can include the following fields:
      - `file_path` – Specifies the path of the log file to upload to CloudWatch Logs. Standard Unix glob matching rules are accepted, with the addition of `**` as a *super asterisk*. For example, specifying `/var/log/**.log` causes all `.log` files in the `/var/log` directory tree to be collected. For more examples, see Glob Library.

You can also use the standard asterisk as a standard wildcard. For example, `/var/log/system.log*` matches files such as `system.log_1111`, `system.log_2222`, and so on in `/var/log`.

Only the latest file is pushed to CloudWatch Logs based on file modification time. We recommend that you use wildcards to specify a series of files of the same type, such as `access_log.2018-06-01-01` and `access_log.2018-06-01-02`, but not multiple kinds of files, such as `access_log_80` and `access_log_443`. To specify multiple kinds of files, add another log stream entry to the agent configuration file so that each kind of log file goes to a different log stream.

- `auto_removal` – Optional. If this is `true`, the CloudWatch agent automatically deletes this log file after reading it and it has been rotated. Usually the log files are deleted after their entire contents are uploaded to CloudWatch Logs, but if the agent reaches the EOF (end of file) and also detects another newer log file that matches the same `file_path`, the agent deletes the OLD file, so you must make sure that you are done writing to the OLD file before creating the NEW file. The RUST tracing library has a known incompatibility because it will potentially create a NEW log file and then still attempt to write to the OLD log file.

  The agent only removes complete files from logs that create multiple files, such as logs that create separate files for each date. If a log continuously writes to a single file, it is not removed.

  If you already have a log file rotation or removal method in place, we recommend that you omit this field or set it to `false`.

  If you omit this field, the default value of `false` is used.

- `log_group_name` – Optional. Specifies what to use as the log group name in CloudWatch Logs.

  We recommend that you use this field to specify a log group name to prevent confusion. If you omit `log_group_name`, the value of `file_path` up to the final dot is used as the log group name. For example, if the file path is `/tmp/TestLogFile.log.2017-07-11-14`, the log group name is `/tmp/TestLogFile.log`.

  If you specify a log group name, you can use `{instance_id}`, `{hostname}`, `{local_hostname}`, and `{ip_address}` as variables within the name. `{hostname}`

retrieves the hostname from the EC2 metadata, and {local_hostname} uses the hostname from the network configuration file.

If you use these variables to create many different log groups, keep in mind the limit of 1,000,000 log groups per Region per account.

Allowed characters include a–z, A–Z, 0–9, '_' (underscore), '-' (hyphen), '/' (forward slash), and '.' (period).

- log_group_class – Optional. Specifies which log group class to use for the new log group. For more information about log group classes, see Log classes.

  Valid values are STANDARD and INFREQUENT_ACCESS. If you omit this field, the default of STANDARD is used.

  > **Important**
  >
  > After a log group is created, its class can't be changed.

- log_stream_name – Optional. Specifies what to use as the log stream name in CloudWatch Logs. As part of the name, you can use {instance_id}, {hostname}, {local_hostname}, and {ip_address} as variables within the name. {hostname} retrieves the hostname from the EC2 metadata, and {local_hostname} uses the hostname from the network configuration file.

  If you omit this field, the value of the log_stream_name parameter in the global logs section is used. If that is also omitted, the default value of {instance_id} is used.

  If a log stream doesn't already exist, it's created automatically.

- retention_in_days – Optional. Specifies the number of days to retain the log events in the specified log group.
  - If the agent is creating this log group now, and you omit this field, the retention of this new log group is set to never expire.
  - If this log group already exists and you specify this field, the new retention that you specify is used. If you omit this field for a log group that already exists, the log group's retention is not changed.

    The CloudWatch agent wizard uses -1 as the default value for this field when it is used to create the agent configuration file and you don't specify a value for log retention.

This `-1` value set by the wizard specifies that the events in the log group will never expire. However, manually editing this value to `-1` has no effect.

Valid values are 1, 3, 5, 7, 14, 30, 60, 90, 120, 150, 180, 365, 400, 545, 731, 1827, 2192, 2557, 2922, 3288, and 3653.

If you configure the agent to write multiple log streams to the same log group, specifying the `retention_in_days` in one place will set the log retention for the entire log group. If you specify `retention_in_days` for the same log group in multiple places, the retention is set if all of those values are equal. However, if different `retention_in_days` values are specified for the same log group in multiple places, the log retention will not be set and the agent will stop, returning an error.

> **Note**
>
> The agent's IAM role or IAM user must have the `logs:PutRetentionPolicy` for it to be able to set retention policies.

> **Warning**
>
> If you set `retention_in_days` for a log group that already exists, all logs in that log group that were published before the number of days that you specify are deleted. For example, setting it to 3 would cause all logs from 3 days ago and before to be deleted.

- `filters` – Optional. Can contain an array of entries, each of which specifies a regular expression and a filter type to specify whether to publish or drop log entries that match the filter. If you omit this field, all logs in the log file are published to CloudWatch Logs. If you include this field, the agent processes each log message with all of the filters that you specify, and only the log events that pass all of the filters are published to CloudWatch Logs. The log entries that don't pass all of the filters will still remain in the host's log file, but will not be sent to CloudWatch Logs.

  Each entry in the filters array can include the following fields:

  - `type`– Denotes the type of filter. Valid values are `include` and `exclude`. With `include`, the log entry must match the expression to be published to CloudWatch Logs. With `exclude`, each log entry that matches the filter is not sent to CloudWatch Logs.

- `expression`– A regular expression string that follows the RE2 Syntax.

> **Note**
>
> The CloudWatch agent doesn't check the performance of any regular expression that you supply, or restrict the run time of the evaluation of the regular expressions. We recommend that you are careful not to write an expression that is expensive to evaluate. For more information about possible issues, see Regular expression Denial of Service - ReDoS

For example, the following excerpt of the CloudWatch agent configuration file publishes logs that are PUT and POST requests to CloudWatch Logs, but excluding logs that come from Firefox.

```
"collect_list": [
  {
    "file_path": "/opt/aws/amazon-cloudwatch-agent/logs/test.log",
    "log_group_name": "test.log",
    "log_stream_name": "test.log",
    "filters": [
      {
        "type": "exclude",
        "expression": "Firefox"
      },
      {
        "type": "include",
        "expression": "P(UT|OST)"
      }
    ]
  },
  .....
]
```

> **Note**
>
> The order of the filters in the configuration file matters for performance. In the preceding example, the agent drops all the logs that match `Firefox` before it starts evaluating the second filter. To cause fewer log entries to be evaluated by

more than one filter, put the filter that you expect to rule out more logs first in the configuration file.

- `timezone` – Optional. Specifies the time zone to use when putting timestamps on log events. The valid values are `UTC` and `Local`. The default value is `Local`.

  This parameter is ignored if you don't specify a value for `timestamp_format`.

- `timestamp_format` – Optional. Specifies the timestamp format, using plaintext and special symbols that start with %. If you omit this field, the current time is used. If you use this field, you can use the symbols in the following list as part of the format.

  Note

  This parameter is not considered when the `file_path` is set to `amazon-cloudwatch-agent.log`

  If a single log entry contains two time stamps that match the format, the first time stamp is used.

  This list of symbols is different than the list used by the older CloudWatch Logs agent. For a summary of these differences, see Timestamp differences between the CloudWatch agent and the earlier CloudWatch Logs agent

  %y

  Year without century as a zero-padded decimal number. For example, 19 to represent 2019.

  %Y

  Year with century as a decimal number. For example, 2019.

  %b

  Month as the locale's abbreviated name

  %B

  Month as the locale's full name

`%m`

Month as a zero-padded decimal number

`%-m`

Month as a decimal number (not zero-padded)

`%d`

Day of the month as a zero-padded decimal number

`%-d`

Day of the month as a decimal number (not zero-padded)

`%A`

Full name of weekday, such as `Monday`

`%a`

Abbreviation of weekday, such as `Mon`

`%H`

Hour (in a 24-hour clock) as a zero-padded decimal number

`%I`

Hour (in a 12-hour clock) as a zero-padded decimal number

`%-I`

Hour (in a 12-hour clock) as a decimal number (not zero-padded)

`%p`

AM or PM

`%M`

Minutes as a zero-padded decimal number

`%-M`

Minutes as a decimal number (not zero-padded)

`%S`

Seconds as a zero-padded decimal number

`%-S`

Seconds as a decimal number (not zero padded)

`%f`

Fractional seconds as a decimal number (1-9 digits), zero-padded on the left.

`%Z`

Time zone, for example PST

`%z`

Time zone, expressed as the offset between the local time zone and UTC. For example, `-0700`. Only this format is supported. For example, `-07:00` isn't a valid format.

- `multi_line_start_pattern` – Specifies the pattern for identifying the start of a log message. A log message is made of a line that matches the pattern and any subsequent lines that don't match the pattern.

  If you omit this field, multi-line mode is disabled, and any line that begins with a non-whitespace character closes the previous log message and starts a new log message.

  If you include this field, you can specify `{timestamp_format}` to use the same regular expression as your timestamp format. Otherwise, you can specify a different regular expression for CloudWatch Logs to use to determine the start lines of multi-line entries.

- `encoding` – Specified the encoding of the log file so that it can be read correctly. If you specify an incorrect coding, there might be data loss because characters that can't be decoded are replaced with other characters.

  The default value is `utf-8`. The following are all possible values:

  ```
  ascii, big5, euc-jp, euc-kr, gbk, gb18030, ibm866, iso2022-jp,
  iso8859-2, iso8859-3, iso8859-4, iso8859-5, iso8859-6, iso8859-7,
  iso8859-8, iso8859-8-i, iso8859-10, iso8859-13, iso8859-14,
  iso8859-15, iso8859-16, koi8-r, koi8-u, macintosh, shift_jis, utf-8,
  utf-16, utf-16le, UTF-16, UTF-16LE, windows-874, windows-1250,
  ```

`windows-1251, windows-1252, windows-1253, windows-1254, windows-1255, windows-1256, windows-1257, windows-1258, x-mac-cyrillic`

- `service.name` – Optional. Specifies the service name to be used to populate the entity for finding related telemetry.
- `deployment.environment` – Optional. Specifies the environment name to be used to populate the entity for finding related telemetry.
- `trim_timestamp` – Optional. If this is true, the CloudWatch agent will remove the timestamp matched by `timestamp_format` from the line before sending it to CloudWatch Logs. The LogEvent will still contain the `timestamp` field.

  If you omit this field, the default value of `false` is used.

- The `windows_events` section specifies the type of Windows events to collect from servers running Windows Server. It includes the following fields:
  - `collect_list` – Required if `windows_events` is included. Specifies the types and levels of Windows events to be collected. Each log to be collected has an entry in this section, which can include the following fields:
    - `event_name` – Specifies the type of Windows events to log. This is equivalent to the Windows event log channel name: for example, `System`, `Security`, `Application`, and so on. This field is required for each type of Windows event to log.

      > **Note**
      >
      > When CloudWatch retrieves messages from a Windows log channel, it looks up the log channel based on its `Full Name` property. Meanwhile, the Windows Event Viewer navigation pane displays the `Log Name` property of log channels. The `Full Name` and `Log Name` do not always match. To confirm the `Full Name` of a channel, right-click on it in the Windows Event viewer and open **Properties**.

    - `event_levels` – Optional. Specifies the levels of event to log. You must specify each level to log. Possible values include `INFORMATION`, `WARNING`, `ERROR`, `CRITICAL`, and `VERBOSE`. This field is optional for each type of Windows event to log. and can be used with other filtering option like `event_ids` and `filters`.
    - `event_ids` – Optional. Contains an array of Windows Event IDs to specify which events to collect from the Windows Event Log. When this field is excluded, all events from the

specified event log are collected. When this field is included, the agent only collects events that match the specified Event IDs.

Each entry in the `event_ids` array should be a numeric Event ID value and can be used with other filtering options. See the third entry in the config sample below.

> **Note**
>
> Using `event_ids` for filtering is recommended over regex expressions when you need to filter by Event ID, as it provides better performance.

- `filters` – Optional. Contains an array of entries. Each entry specifies a regular expression and a filter type to specify whether to publish or drop the log entries that match the filter. When the field is included, the agent processes each log message with all of the filters that you specify, and only the log events that pass all filters are published to CloudWatch Logs. The windows event logs that doesn't pass all of the filters will be dropped and not sent to CloudWatch Logs. The filters section can also be used with other filtering mechanisms like event ids [4624, 4625] and system levels (Information, Error, or Critical) to effectively filter logs and push to CloudWatch.

  Each entry in the filters array can include the following fields:

  - `type` – Specifies the type of filter. Valid values are `include` and `exclude`. With include, the windows events entry must match the expression to be published to CloudWatch Logs. With exclude, each windows event log entry that matches the filter is not sent to CloudWatch Logs.
  - `expression` – A regular expression string that follows the RE2 Syntax.

  > **Note**
  >
  > The CloudWatch agent does not validate regular expressions that you provide. It also does not limit their evaluation time. Write your expressions carefully to avoid performance issues. For more information about security risks, see Regular expression Denial of Service - ReDoS .

  In the example agent configuration below:

For the first entry, the agent pushes logs that contain database failure messages, any authentication related activities, and all login events (both successful and failed attempts) to CloudWatch. Any log that doesn't match this pattern is dropped.

In the second entry, initial filtering is done based on event ids for windows event subscription. The agent collects all logs that contain the string user, discarding logs that don't match these patterns. The agent then drops logs containing `successful` before sending the remaining logs to CloudWatch Logs. Every filter type is applied to each windows event log before sending to CloudWatch.

```
"collect_list": [
  {
        "event_name": "Application",
        "log_group_name": "ApplicationEvents",
        "log_stream_name": "ApplicationEvents",
        "filters": [
            {
                "type": "include",
                "expression": "Database.*failed|Authentication.*|login.*"
            }
        ]
    },
    {
        "event_name": "System",
        "log_group_name": "SystemEvents",
        "log_stream_name": "Logon-events",
        "event_ids": [
            4624,
            4625
         ],
        "filters": [
            {
                "type": "include",
                "expression": ".*user.*"
            },
            {
                "type": "exclude",
                "expression": ".*successful.*"
            }
         ]
     }
```

```
  .....
]
```

> **Note**
>
> The order of the filters in the configuration will impact the performance. In the second entry, the agent drops all the logs that does not match the user before it starts evaluating the second filter expression. For optimal performance, order filters from highest to lowest exclusion rate.

While you can filter out logs on event ids and system levels in the filter expression, it is recommended to use the `event_ids` and `log_level` as shown in the second entry for improved performance.

> **Warning**
>
> Even though all filtering mechanisms (event_levels, event_ids, filters) are optional, at least one is required during agent configuration to filter logs.

- `log_group_name` – Required. Specifies what to use as the log group name in CloudWatch Logs.
- `log_stream_name` – Optional. Specifies what to use as the log stream name in CloudWatch Logs. As part of the name, you can use `{instance_id}`, `{hostname}`, `{local_hostname}`, and `{ip_address}` as variables within the name. `{hostname}` retrieves the hostname from the EC2 metadata, and `{local_hostname}` uses the hostname from the network configuration file.

  If you omit this field, the value of the `log_stream_name` parameter in the global `logs` section is used. If that is also omitted, the default value of `{instance_id}` is used.

  If a log stream doesn't already exist, it's created automatically.
- `event_format` – Optional. Specifies the format to use when storing Windows events in CloudWatch Logs. `xml` uses the XML format as in Windows Event Viewer. `text` uses the legacy CloudWatch Logs agent format.
- `retention_in_days` – Optional. Specifies the number of days to retain the Windows events in the specified log group.

- If the agent is creating this log group now, and you omit this field, the retention of this new log group is set to never expire.
- If this log group already exists and you specify this field, the new retention that you specify is used. If you omit this field for a log group that already exists, the log group's retention is not changed.

  The CloudWatch agent wizard uses `-1` as the default value for this field when it is used to create the agent configuration file and you don't specify a value for log retention. This `-1` value set by the wizard specifies that the events in the log group don't expire. However, manually editing this value to `-1` has no effect.

Valid values are 1, 3, 5, 7, 14, 30, 60, 90, 120, 150, 180, 365, 400, 545, 731, 1827, 2192, 2557, 2922, 3288, and 3653.

If you configure the agent to write multiple log streams to the same log group, specifying the `retention_in_days` in one place will set the log retention for the entire log group. If you specify `retention_in_days` for the same log group in multiple places, the retention is set if all of those values are equal. However, if different `retention_in_days` values are specified for the same log group in multiple places, the log retention will not be set and the agent will stop, returning an error.

> **Note**
>
> The agent's IAM role or IAM user must have the `logs:PutRetentionPolicy` for it to be able to set retention policies.

> **Warning**
>
> If you set `retention_in_days` for a log group that already exists, all logs in that log group that were published before the number of days that you specify are deleted. For example, setting it to 3 would cause all logs from 3 days ago and before to be deleted.

- `log_stream_name` – Optional. Specifies the default log stream name to be used for any logs or Windows events that don't have individual log stream names defined in the `log_stream_name` parameter within their entry in `collect_list`.

- `endpoint_override` – Specifies a FIPS endpoint or private link to use as the endpoint where the agent sends logs. Specifying this field and setting a private link enables you to send the logs to an Amazon VPC endpoint. For more information, see What Is Amazon VPC?.

  The value of `endpoint_override` must be a string that is a URL.

  For example, the following part of the logs section of the configuration file sets the agent to use a VPC Endpoint when sending logs.

  ```
  {
    "logs": {
      "endpoint_override": "vpce-XXXXXXXXXXXXXXXXXXXXXXXX.logs.us-
  east-1.vpce.amazonaws.com",
     ......
     },
  }
  ```

- `force_flush_interval` – Specifies in seconds the maximum amount of time that logs remain in the memory buffer before being sent to the server. No matter the setting for this field, if the size of the logs in the buffer reaches 1 MB, the logs are immediately sent to the server. The default value is 5.

  If you are using the agent to report high-resolution metrics in embedded metric format, and you are setting alarms on those metrics, keep this parameter set to the default value of 5. Otherwise, the metrics are reported with a delay that can cause alarming on partial or incomplete data.

- `credentials` – Specifies an IAM role to use when sending logs to a different AWS account. If specified, this field contains one parameter, `role_arn`.
  - `role_arn` – Specifies the ARN of an IAM role to use for authentication when sending logs to a different AWS account. For more information, see Sending metrics, logs, and traces to a different account. If specified here, this overrides the `role_arn` specified in the `agent` section of the configuration file, if any.
- `metrics_collected` – This field can contain sections to specify that the agent is to collect logs to enable use cases such as CloudWatch Application Signals and Container Insights with enhanced observability for Amazon EKS.
  - `application_signals` (Optional) Specifies that you want to enable CloudWatch Application Signals For more information about this configuration, see Enable CloudWatch Application Signals.

- `kubernetes` – This field can contain an `enhanced_container_insights` parameter, which you can use to enable Container Insights with enhanced observability for Amazon EKS.
  - `enhanced_container_insights` – Set this to `true` to enable Container Insights with enhanced observability for Amazon EKS. For more information, see Amazon EKS.
  - `accelerated_compute_metrics` – Set this to `false` to opt out of collecting Nvidia GPU metrics on Amazon EKS clusters. For more information, see NVIDIA GPU metrics.
- `emf` – To collect metrics embedded in logs, it is no longer necessary to add this `emf` field. This is a legacy field that specified that the agent is to collect logs that are in embedded metric format. You can generate metric data from these logs. For more information, see Embedding metrics within logs.
- `otlp` – Optional. Specifies that you want to collect metrics from the OpenTelemetry SDK. For more information about the fields that you can use in this section, see Collect metrics and traces with OpenTelemetry.

The following is an example of a `logs` section.

```
"logs":{
    "logs_collected": {
    "files": {
            "collect_list": [
                   {
                        "file_path": "c:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\
\Logs\\amazon-cloudwatch-agent.log",
                       "log_group_name": "amazon-cloudwatch-agent.log",
                       "log_stream_name": "my_log_stream_name_1"
                   },
                   {
                       "file_path": "c:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\
\Logs\\test.log",
                       "log_group_name": "test.log",
                       "log_stream_name": "my_log_stream_name_2"
                   }
               ]
          },
      "windows_events": {
                "collect_list": [
                                {
                       "event_name": "System",
                       "event_ids": [
```

```
                        1001,
                        1008
                    ],
                    "log_group_name": "System",
                    "log_stream_name": "System"
                },
                {
                    "event_name": "CustomizedName",
                    "event_levels": [
                        "INFORMATION",
                        "ERROR"
                    ],
                    "log_group_name": "CustomizedLogGroup",
                    "log_stream_name": "CustomizedLogStream"
                },
                {
                    "event_name": "Application",
                    "event_levels": [
                        "INFORMATION",
                        "ERROR"
                    ],
                    "event_ids":[
                         7369,
                         5624
                    ],
                    "log_group_name": "CustomizedLogGroup",
                    "log_stream_name": "CustomizedLogStream"
                }
            ]
        }
     },
     "log_stream_name": "my_log_stream_name",
     "metrics_collected": {
      "kubernetes": {
      "enhanced_container_insights": true
    }
  }
}
```

CloudWatch agent configuration file: Traces section

By adding a `traces` section to the CloudWatch agent configuration file, you can enable CloudWatch Application Signals or collect traces from X-Ray and from the OpenTelemetry instrumentation SDK and send them to X-Ray.

> **Important**
>
> The agent's IAM role or IAM user must have the **AWSXrayWriteOnlyAccess** policy to send trace data to X-Ray.

For a quick start for collecting traces, you can add just the following to the CloudWatch agent configuration file.

```
"traces_collected": {
        "xray": {
        },
        "otlp": {
        }
      }
```

If you add the previous section to the CloudWatch agent configuration file and restart the agent, this causes the agent to start collecting traces using the following default options and values. For more information about these parameters, see the parameter definitions later in this section.

```
"traces_collected": {
        "xray": {
            "bind_address": "127.0.0.1:2000",
            "tcp_proxy": {
              "bind_address": "127.0.0.1:2000"
            }
        },
        "otlp": {
            "grpc_endpoint": "127.0.0.1:4317",
            "http_endpoint": "127.0.0.1:4318"
        }
      }
```

The `traces` section can include the following fields:

- `traces_collected` – Required if the `traces` section is included. Specifies which SDKs to collect traces from. It can include the following fields:
  - `application_signals` – Optional. Specifies that you want to enable CloudWatch Application Signals For more information about this configuration, see Enable CloudWatch Application Signals.
  - `xray` – Optional. Specifies that you want to collect traces from the X-Ray SDK. This section can include the following fields:
    - `bind_address` – Optional. Specifies the UDP address for the CloudWatch agent to use to listen for X-Ray traces. The format is `ip:port`. This address must match the address set in the X-Ray SDK.

      If you omit this field, the default of `127.0.0.1:2000` is used.
    - `tcp_proxy` – Optional. Configures the address for a proxy used to support X-Ray remote sampling. For more information, see Configuring sampling rules in the X-Ray documentation.

      This section can contain the following field.
      - `bind_address` – Optional. Specifies the TCP address to which the CloudWatch agent should set up the proxy. The format is `ip:port`. This address must match the address set in the X-Ray SDK.

        If you omit this field, the default of `127.0.0.1:2000` is used.
  - `otlp` – Optional. Specifies that you want to collect traces from the OpenTelemetry SDK. For more information about the fields that you can use in this section, see Collect metrics and traces with OpenTelemetry). For more information about the AWS Distro for OpenTelemetry, see AWS Distro for OpenTelemetry. For more information about the AWS Distro for OpenTelemetry SDKs, see Introduction.

    This section can include the following fields:
    - `grpc_endpoint` – Optional. Specifies the address for the CloudWatch agent to use to listen for OpenTelemetry traces sent using gRPC Remote Procedure Calls. The format is `ip:port`. This address must match the address set for the gRPC exporter in the OpenTelemetry SDK.

      If you omit this field, the default of `127.0.0.1:4317` is used.

  - `http_endpoint` – Optional. Specifies the address for the CloudWatch agent to use to listen for OTLP traces sent over HTTP. The format is `ip:port`. This address must match the address set for the HTTP exporter in the OpenTelemetry SDK.

    If you omit this field, the default of `127.0.0.1:4318` is used.

- `concurrency` – Optional. Specifies the maximum number of concurrent calls to X-Ray that can be used to upload traces. The default value is 8
- `local_mode` – Optional. If `true`, the agent doesn't collect Amazon EC2 instance metadata. The default is `false`
- `endpoint_override` – Optional. Specifies a FIPS endpoint or private link to use as the endpoint where the CloudWatch agent sends traces. Specifying this field and setting a private link enables you to send the traces to an Amazon VPC endpoint. For more information, see What is Amazon VPC

  The value of `endpoint_override` must be a string that is a URL.
- `region_override` – Optional. Specifies the Region to use for the X-Ray endpoint. The CloudWatch agent sends the traces to X-Ray in the specified Region. If you omit this field, the agent sends the traces to the Region where the Amazon EC2 instance is located.

  If you specify a Region here, it takes precedence over the setting of the `region` parameter in the `agent` section of the configuration file.
- `proxy_override` – Optional. Specifies the proxy server address for the CloudWatch agent to use when sending requests to X-Ray. The proxy server's protocol must be specified as part of this address.
- `credentials` – Specifies an IAM role to use when sending traces to a different AWS account. If specified, this field contains one parameter, `role_arn`.
  - `role_arn` – Specifies the ARN of an IAM role to use for authentication when sending traces to a different AWS account. For more information, see Sending metrics, logs, and traces to a different account. If specified here, this overrides the `role_arn` specified in the `agent` section of the configuration file, if any.
- `transit_spans_in_otlp_format` – Optional. If `true`, sends traces to X-Ray in the OpenTelemetry Protocol format, which supports span events in Transaction Search. For more information, see Adding custom attributes. The default is `false`.

CloudWatch agent configuration file: Complete examples

The following is an example of a complete CloudWatch agent configuration file for a Linux server.

The items listed in the `measurement` sections for the metrics you want to collect can either specify the complete metric name such or just the part of the metric name that will be appended to the type of resource. For example, specifying either `reads` or `diskio_reads` in the `measurement` section of the `diskio` section will cause the `diskio_reads` metric to be collected.

This example includes both ways of specifying metrics in the `measurement` section.

```
   {
     "agent": {
       "metrics_collection_interval": 10,
       "logfile": "/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-agent.log"
     },
     "metrics": {
       "namespace": "MyCustomNamespace",
       "metrics_collected": {
         "cpu": {
           "resources": [
             "*"
           ],
           "measurement": [
             {"name": "cpu_usage_idle", "rename": "CPU_USAGE_IDLE", "unit":
"Percent"},
             {"name": "cpu_usage_nice", "unit": "Percent"},
             "cpu_usage_guest"
           ],
           "totalcpu": false,
           "metrics_collection_interval": 10,

  }
```

Save the CloudWatch agent configuration file manually

If you create or edit the CloudWatch agent configuration file manually, you can give it any name. After you have created the file, you can copy it to other servers where you want to run the agent.

Uploading the CloudWatch agent configuration file to Systems Manager Parameter Store

If you plan to use the SSM Agent to install the CloudWatch agent on servers, after you manually edit the CloudWatch agent configuration file, you can upload it to Systems Manager Parameter Store. To do so, use the Systems Manager `put-parameter` command.

To be able to store the file in Parameter Store, you must use an IAM role with sufficient permissions.

Use the following command, where *`parameter name`* is the name to be used for this file in Parameter Store and *`configuration_file_pathname`* is the path and file name of the configuration file that you edited.

```
aws ssm put-parameter --name "parameter name" --type "String" --value
 file://configuration_file_pathname
```

Enable CloudWatch Application Signals

Use CloudWatch Application Signals to automatically instrument your applications on AWS so that you can track application performance against your business objectives. Application Signals provides you a unified, application-centric view of your Java applications, their dependencies, and their edges. For more information, see Application Signals.

CloudWatch Application Signals leverages the CloudWatch agent to receive metrics and traces from your auto-instrumented applications, optionally apply rules to reduce high cardinality, and then publish the processed telemetry to CloudWatch. You can provide custom configuration to the CloudWatch agent specifically for Application Signals using the agent configuration file. To start with, the presence of an `application_signals` section under the `metrics_collected` section within the `logs` section of the agent configuration file specifies that the CloudWatch agent will receive metrics from your auto-instrumented applications. Similarly, the presence of an `application_signals` section under the `traces_collected` section within the `traces` section of the agent configuration file specifies that the CloudWatch agent is enabled to receive traces from your auto-instrumented applications. In addition, you can optionally pass in custom configuration rules to reduce publishing high-cardinality telemetry as outlined in this section.

- For Amazon EKS clusters, when you install the Amazon CloudWatch Observability EKS add-on, the CloudWatch agent is by default enabled to receive both metrics and traces from your auto-instrumented applications. If you would like to optionally pass in custom configuration rules, you can do so by passing in a custom agent configuration to the Amazon EKS add-on when you create or update it by using additional configuration, as outlined in (Optional) Additional configuration.
- For RedHat for OpenShift on AWS (ROSA), when you install the CloudWatch agent operator using helm charts, the CloudWatch agent is by default enabled to receive both metrics and traces from your auto-instrumented applications. If you would like to optionally pass in custom configuration rules, you can do so by passing in a custom agent configuration by using the Helm chart, as outlined in (Optional) Additional configuration.
- For other supported platforms including Amazon EC2, you must start the CloudWatch agent with an agent configuration that enables Application Signals by specifying the `application_signals` sections and optionally any custom configuration rules as outlined later in this section.

The following is an overview of the fields in the CloudWatch agent configuration file that are related to CloudWatch Application Signals.

- `logs`
  - `metrics_collected` – This field can contain sections to specify that the agent is to collect logs to enable use cases such as CloudWatch Application Signals and Container Insights with enhanced observability for Amazon EKS.

    > **Note**
    >
    > Previously this section was also used to specify that the agent is to collect logs that are in embedded metric format. Those settings are no longer needed.

    - `application_signals` (Optional) Specifies that you want to enable CloudWatch Application Signals to receive metrics from your auto-instrumented applications to facilitate CloudWatch Application Signals.
      - `rules` (Optional) An array of rules to conditionally select metrics and traces and apply actions to handle high-cardinality scenarios. Each rule can contain the following fields:
        - `rule_name` (Optional) The name of the rule.
        - `selectors` (Optional) An array of metrics and traces dimension matchers. Each selector must provide the following fields:
          - `dimension` Required if `selectors` is not empty. This specifies the dimension of metrics and traces to use as a filter.
          - `match` Required if `selectors` is not empty. A wildcard pattern used for matching values of the specified dimension.
        - `action` (Optional) The action to be applied to metrics and traces that match the specified selectors. The value of `action` must be one of the following keywords:
          - `keep` Specifies to send only the metrics and traces to CloudWatch if matched by the `selectors`.
          - `drop` Specifies to drop the metric and traces that match the `selectors`.
          - `replace` Specifies to replace the dimensions of the metrics and traces that match `selectors`. They are replaced according to the `replacements` section.

- `replacements` Required if `action` is `replace`. An array of dimension and value pairs that will be applied to metrics and traces that match the specified `selectors` when the `action` is `replace`. Each replacement must provide the following fields:
  - `target_dimension` Required if `replacements` is not empty. Specifies the dimension that needs to be replace.
  - `value` Required if `replacements` is not empty. The value to replace the original value of `target_dimension` with.
- `limiter` (Optional) Use this section to limit how many metrics and dimensions Application Signals sends to CloudWatch, to optimize your costs.
  - `disabled` (Optional) If `true`, the metric limiting feature is disabled. The default is `false`
  - `drop_threshold` (Optional) The maximum number of distinct metrics per service in one rotation interval that can be exported by one CloudWatch agent. The default is 500.
  - `rotation_interval` (Optional) The interval at which the limiter resets the metric records for distinction counting. This is expressed as a string with a sequence of numbers and a unit suffix. Fractions are supported. The supported unit suffixes are `s`, `m`, `h`, `ms`, `us`, and `ns`. The default is `1h` for one hour.
  - `log_dropped_metrics` (Optional) Specifies whether the agent should write logs to the CloudWatch agent logs when Application Signals metrics are dropped. The default is `false`.

    > **Note**
    >
    > To activate this logging, the `debug` parameter in the `agent` section must also be set to `true`.

- `traces`
  - `traces_collected`
    - `application_signals` Optional. Specify this to enable the CloudWatch agent to receive traces from your auto-instrumented applications for facilitating CloudWatch Application Signals.

Note

Even though the custom `application_signals` rules are specified under the `metrics_collected` section that is contained in the `logs` section, they also implicitly apply to the `traces_collected` section as well. The same set of rules will apply to both metrics and traces.

When there are multiple rules with different actions, they apply in the following sequence: `keep`, then `drop`, then `replace`.

The following is an example of a full CloudWatch agent configuration file that applies custom rules.

```
{
  "logs": {
    "metrics_collected": {
      "application_signals": {
        "rules": [
          {
            "rule_name": "keep01",
            "selectors": [
              {
                "dimension": "Service",
                "match": "pet-clinic-frontend"
              },
              {
                "dimension": "RemoteService",
                "match": "customers-service"
              }
            ],
            "action": "keep"
          },
          {
            "rule_name": "drop01",
            "selectors": [
              {
                "dimension": "Operation",
                "match": "GET /api/customer/owners/*"
              }
            ],
            "action": "drop"
```

```
          },
          {
            "rule_name": "replace01",
            "selectors": [
              {
                "dimension": "Operation",
                "match": "PUT /api/customer/owners/*/pets/*"
              },
              {
                "dimension": "RemoteOperation",
                "match": "PUT /owners"
              }
            ],
            "replacements": [
              {
                "target_dimension": "Operation",
                "value": "PUT /api/customer/owners/{ownerId}/pets{petId}"
              }
            ],
            "action": "replace"
          }
        ]
      }
    }
  },
  "traces": {
    "traces_collected": {
      "application_signals": {}
    }
  }
}
```

For the previous example configuration file, the `rules` are processed as follows:

1. Rule `keep01` ensures that any metrics and traces with the dimension `Service` as `pet-clinic-frontend` and the dimension `RemoteService` as `customers-service` are kept.
2. For the processed metrics and traces after applying `keep01`, the `drop01` rule ensures that metrics and traces with the dimension `Operation` as `GET /api/customer/owners/*` are dropped.
3. For the processed metrics and traces after applying `drop01`, the `replace01` rule updates metrics and traces that have the dimension `Operation` as `PUT /api/customer/owners/*/`

`pets/*` and the dimension `RemoteOperation` as `PUT /owners` such that their `Operation` dimension is now replaced to be `PUT /api/customer/owners/{ownerId}/pets{petId}`.

The following is a complete example of a CloudWatch configuration file that manages cardinality in Application Signals by changing the metric limit to 100, enabling the logging of dropped metrics, and setting the rotation interval to two hours.

```
{
    "logs": {
        "metrics_collected": {
            "application_signals": {
                "limiter": {
                    "disabled": false,
                    "drop_threshold": 100,
                    "rotation_interval": "2h",
                    "log_dropped_metrics": true
                }
            }
        },
        "traces": {
            "traces_collected": {
                "application_signals": {}
            }
        }
    }
}
```

Collect network performance metrics

EC2 instances running on Linux that use the Elastic Network Adapter (ENA) publish network performance metrics. Version 1.246396.0 and later of the CloudWatch agent enable you to import these network performance metrics into CloudWatch. When you import these network performance metrics into CloudWatch, they are charged as CloudWatch custom metrics.

For more information about the ENA driver, see Enabling enhanced networking with the Elastic Network Adapter (ENA) on Linux instances and Enabling enhanced networking with the Elastic Network Adapter (ENA) on Windows instances.

How you set up the collection of network performance metrics differs on Linux servers and Windows servers.

The following table lists these network performance metrics enabled by the ENA adapter. When the CloudWatch agent imports these metrics into CloudWatch from Linux instances, it prepends `ethtool_` at the beginning of each of these metric names.

Metric	Description
Name on Linux servers: **`bw_in_allowance_exceeded`** Name on Windows servers: **`Aggregate inbound BW allowance exceeded`**	The number of packets queued and/or dropped because the inbound aggregate bandwidth exceeded the maximum for the instance. This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None
Name on Linux servers: **`bw_out_allowance_exceeded`** Name on Windows servers: **`Aggregate outbound BW allowance exceeded`**	The number of packets queued and/or dropped because the outbound aggregate bandwidth exceeded the maximum for the instance. This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None
Name on Linux servers:**`conntrack_allowance_available`** Name on Windows servers: **`Available connection tracking allowance`**	Reports the number of tracked connections that can be established by the instance before hitting the Connections Tracked allowance of that instance type. This metric is available only on Nitro-based EC2 instances using the Linux driver for Elastic Network Adapter (ENA) starting from version 2.8.1, and on computers using the Windows driver for Elastic Network Adapter (ENA) starting from version 2.6.0.

Metric	Description
	This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None
Name on Linux servers:**`ena_srd_mode`** Name on Windows servers: **`ena srd mode`**	Describes which ENA Express features are enabled. For more information about ENA Express, see Improve network performance with ENA Express on Linux instances Values are as follows: • `0` = ENA Express off, UDP off • 1 = ENA Express on, UDP off • 2 = ENA Express off, UDP on **Note** This happens only when ENA Express was originally enabled, and UDP was configured to use it. The prior value is retained for UDP traffic. • 3 = ENA Express on, UDP on

Metric	Description
Name on Linux servers:**ena_srd_eligible_tx_pkts** Name on Windows servers: **ena srd eligible tx pkts**	The number of network packets sent within a given time period that meet AWS Scalable Reliable Datagram (SRD) requirements for eligibility, as follows: • Both sending and receiving instance types are supported. • Both sending and receiving instances must have ENA Express configured. • The sending and receiving instances must be on the same subnet. • The network path between the instances must not include middleware boxes. ENA Express doesn't currently support middleware boxes.
Name on Linux servers:**ena_srd_tx_pkts** Name on Windows servers: **ena srd tx pkts**	The number of SRD packets transmitted within a given time period.
Name on Linux servers:**ena_srd_rx_pkts** Name on Windows servers: **ena srd rx pkts**	The number of SRD packets received within a given time period.
Name on Linux servers:**ena_srd_resource_utilization** Name on Windows servers: **ena srd resource utilization**	The percentage of the maximum allowed memory utilization for concurrent SRD connections that the instance has consumed.

Metric	Description
Name on Linux servers: **`linklocal_allowance_exceeded`** Name on Windows servers: **`Link local packet rate allowance exceeded`**	The number of packets dropped because the PPS of the traffic to local proxy services exceeded the maximum for the network interface. This impacts traffic to the DNS service, the Instance Metadata Service, and the Amazon Time Sync Service, but does not impact traffic to custom DNS resolvers. This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None
Name on Linux servers: **`pps_allowance_exceeded`** Name on Windows servers: **`PPS allowance exceeded`**	The number of packets queued and/or dropped because the bidirectional PPS exceeded the maximum for the instance. This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None

Linux setup

On Linux servers, the *ethtool plugin* enables you to import the network performance metrics into CloudWatch.

ethtool is a standard Linux utility that can collect statistics about Ethernet devices on Linux servers. The statistics it collects depend on the network device and driver. Examples of these statistics include `tx_cnt`, `rx_bytes`, `tx_errors`, and `align_errors`. When you use the ethtool plugin

with the CloudWatch agent, you can also import these statistics into CloudWatch, along with the EC2 network performance metrics listed earlier in this section.

> **Tip**
>
> To find the statistics available on our operating system and network device, use the `ethtool -S` command.

When the CloudWatch agent imports metrics into CloudWatch, it adds an `ethtool_` prefix to the names of all imported metrics. So the standard ethtool statistic `rx_bytes` is called `ethtool_rx_bytes` in CloudWatch, and the EC2 network performance metric `bw_in_allowance_exceeded` is called `ethtool_bw_in_allowance_exceeded` in CloudWatch.

On Linux servers, to import ethtool metrics, add an `ethtool` section to the `metrics_collected` section of the CloudWatch agent configuration file. The `ethtool` section can include the following subsections:

- **interface_include**— Including this section causes the agent to collect metrics from only the interfaces that have names listed in this section. If you omit this section, metrics are collected from all Ethernet interfaces that aren't listed in `interface_exclude`.

  The default ethernet interface is `eth0`.
- **interface_exclude**— If you include this section, list the Ethernet interfaces that you don't want to collect metrics from.

  The ethtool plugin always ignores loopback interfaces.
- **metrics_include**— This section lists the metrics to import into CloudWatch. It can include both standard statistics collected by ethtool and Amazon EC2 high-resolution network metrics.

The following example displays part of the CloudWatch agent configuration file. This configuration collects the standard ethtool metrics `rx_packets` and `tx_packets`, and the Amazon EC2 network performance metrics from only the `eth1` interface.

For more information about the CloudWatch agent configuration file, see Manually create or edit the CloudWatch agent configuration file.

```
{
```

```
"metrics": {
    "append_dimensions": {
      "InstanceId": "${aws:InstanceId}"
    },
    "metrics_collected": {
      "ethtool": {
        "interface_include": [
          "eth1"
        ],
        "metrics_include": [
          "bw_in_allowance_exceeded",
          "bw_out_allowance_exceeded",
          "conntrack_allowance_exceeded",
          "linklocal_allowance_exceeded",
          "pps_allowance_exceeded"
         ]
      }
   }
}
}
```

Windows setup

On Windows servers, the network performance metrics are available through Windows Performance Counters, which the CloudWatch agent already collects metrics from. So you do not need a plugin to collect these metrics from Windows servers.

The following is a sample configuration file to collect network performance metrics from Windows. For more information about editing the CloudWatch agent configuration file, see Manually create or edit the CloudWatch agent configuration file.

```
{
    "metrics": {
        "append_dimensions": {
            "InstanceId": "${aws:InstanceId}"
        },
        "metrics_collected": {
            "ENA Packets Shaping": {
                "measurement": [
                    "Aggregate inbound BW allowance exceeded",
                    "Aggregate outbound BW allowance exceeded",
                    "Connection tracking allowance exceeded",
                    "Link local packet rate allowance exceeded",
```

```
                    "PPS allowance exceeded"
                ],
                "metrics_collection_interval": 60,
                "resources": [
                    "*"
                ]
            }
        }
    }
}
```

Viewing network performance metrics

After importing network performance metrics into CloudWatch, you can view these metrics as time series graphs, and create alarms that can watch these metrics and notify you if they breach a threshold that you specify. The following procedure shows how to view ethtool metrics as a time series graph. For more information about setting alarms, see Using Amazon CloudWatch alarms.

Because all of these metrics are aggregate counters, you can use CloudWatch metric math functions such as `RATE(METRICS())` to calculate the rate for these metrics in graphs or use them to set alarms. For more information about metric math functions, see Math expressions with metrics.

To view network performance metrics in the CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the namespace for the metrics collected by the agent. By default, this is **CWAgent**, but you may have specified a different namespace in the CloudWatch agent configuration file.
4. Choose a metric dimension (for example, **Per-Instance Metrics**).
5. The **Browse** tab displays all metrics for that dimension in the namespace. You can do the following:

    a. To graph a metric, select the check box next to the metric. To select all metrics, select the check box in the heading row of the table.

    b. To sort the table, use the column heading.

    c. To filter by resource, choose the resource ID, and then choose **Add to search**.

    d. To filter by metric, choose the metric name, and then choose **Add to search**.

6. (Optional) To add this graph to a CloudWatch dashboard, choose **Actions**, and then choose **Add to dashboard**.

Collect Amazon EBS NVMe driver metrics

For CloudWatch agent to collect AWS NVMe driver metrics for Amazon EBS volumes attached to an Amazon EC2 instance, add the `diskio` section inside the `metrics_collected` section of the CloudWatch agent configuration file.

Additionally, the CloudWatch agent binary requires `ioctl` permissions for NVMe driver devices to collect metrics from attached Amazon EBS volumes.

The following metrics can be collected.

Metric	Metric name in CloudWatch	Description
`ebs_total_read_ops`	`diskio_ebs_total_read_ops`	The total number of completed read operations.
`ebs_total_write_ops`	`diskio_ebs_total_write_ops`	The total number of completed write operations.
`ebs_total_read_bytes`	`diskio_ebs_total_read_bytes`	The total number of read bytes transferred.
`ebs_total_write_bytes`	`diskio_ebs_total_write_bytes`	The total number of write bytes transferred.
`ebs_total_read_time`	`diskio_ebs_total_read_time`	The total time spent, in microseconds, by all completed read operations.
`ebs_total_write_time`	`diskio_ebs_total_write_time`	The total time spent, in microseconds, by all completed write operations.

Metric	Metric name in CloudWatch	Description
ebs_volume_performance_exceeded_iops	diskio_ebs_volume_performance_exceeded_iops	The total time, in microseconds, that IOPS demand exceeded the volume's provisioned IOPS performance.
ebs_volume_performance_exceeded_tp	diskio_ebs_volume_performance_exceeded_tp	The total time, in microseconds, that throughput demand exceeded the volume's provisioned throughput performance.
ebs_ec2_instance_performance_exceeded_iops	diskio_ebs_ec2_instance_performance_exceeded_iops	The total time, in microseconds, that the EBS volume exceeded the attached Amazon EC2 instance's maximum IOPS performance.
ebs_ec2_instance_performance_exceeded_tp	diskio_ebs_ec2_instance_performance_exceeded_tp	The total time, in microseconds, that the EBS volume exceeded the attached Amazon EC2 instance's maximum throughput performance.
ebs_volume_queue_length	diskio_ebs_volume_queue_length	The number of read and write operations waiting to be completed.

Collect Amazon EC2 instance store volume NVMe driver metrics

For CloudWatch agent to collect AWS NVMe driver metrics for instance store volumes attached to an Amazon EC2 instance, add the `diskio` section inside the `metrics_collected` section of the CloudWatch agent configuration file.

Additionally, the CloudWatch agent binary requires `ioctl` permissions for NVMe driver devices to collect metrics from attached instance store volumes.

The following metrics can be collected.

Metric	Metric name in CloudWatch	Description
instance_store_total_read_ops	diskio_instance_store_total_read_ops	The total number of completed read operations.
instance_store_total_write_ops	diskio_instance_store_total_write_ops	The total number of completed write operations.
instance_store_total_read_bytes	diskio_instance_store_total_read_bytes	The total number of read bytes transferred.
instance_store_total_write_bytes	diskio_instance_store_total_write_bytes	The total number of write bytes transferred.
instance_store_total_read_time	diskio_instance_store_total_read_time	The total time spent, in microseconds, by all completed read operations.
instance_store_total_write_time	diskio_instance_store_total_write_time	The total time spent, in microseconds, by all completed write operations.
instance_store_performance_exceeded_iops	diskio_instance_store_performance_exceeded_iops	The total time, in microseconds, that IOPS demand exceeded the volume's IOPS maximum performance.

Metric	Metric name in CloudWatch	Description
instance_store_performance_exceeded_tp	diskio_instance_store_performance_exceeded_tp	The total time, in microseconds, that throughput demand exceeded the volume's maximum throughput performance.
instance_store_volume_queue_length	diskio_instance_store_volume_queue_length	The number of read and write operations waiting to be completed.

Collect NVIDIA GPU metrics

You can use the CloudWatch agent to collect NVIDIA GPU metrics from Linux servers. To set this up, add a `nvidia_gpu` section inside the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Linux section.

Additionally, the instance must have an NVIDIA driver installed. NVIDIA drivers on pre-installed on some Amazon Machine Images (AMIs). Otherwise, you can manually install the driver. For more information, see Install NVIDIA drivers on Linux instances.

The following metrics can be collected. All of these metrics are collected with no CloudWatch `Unit`, but you can specify a unit for each metric by adding a parameter to the CloudWatch agent configuration file. For more information, see Linux section.

Metric	Metric name in CloudWatch	Description
utilization_gpu	nvidia_smi_utilization_gpu	The percentage of time over the past sample period during which one or more kernals on the GPU was running.
temperature_gpu	nvidia_smi_temperature_gpu	The core GPU temperature in degrees Celsius.

Metric	Metric name in CloudWatch	Description
power_draw	nvidia_smi_power_draw	The last measured power draw for the entire board, in watts.
utilization_memory	nvidia_smi_utilization_memory	The percentage of time over the past sample period during which global (device) memory was being read or written.
fan_speed	nvidia_smi_fan_speed	The percentage of maximum fan speed that the device's fan is currently intended to run at.
memory_total	nvidia_smi_memory_total	Reported total memory, in MB.
memory_used	nvidia_smi_memory_used	Memory used, in MB.
memory_free	nvidia_smi_memory_free	Memory free, in MB.
pcie_link_gen_current	nvidia_smi_pcie_link_gen_current	The current link generation.
pcie_link_width_current	nvidia_smi_pcie_link_width_current	The current link width.
encoder_stats_session_count	nvidia_smi_encoder_stats_session_count	Current number of encoder sessions.
encoder_stats_average_fps	nvidia_smi_encoder_stats_average_fps	The moving average of the encode frames per second.

Metric	Metric name in CloudWatch	Description
encoder_stats_average_latency	nvidia_smi_encoder_stats_average_latency	The moving average of the encode latency in microseconds.
clocks_current_graphics	nvidia_smi_clocks_current_graphics	The current frequency of the graphics (shader) clock.
clocks_current_sm	nvidia_smi_clocks_current_sm	The current frequency of the Streaming Multiprocessor (SM) clock.
clocks_current_memory	nvidia_smi_clocks_current_memory	The current frequency of the memory clock.
clocks_current_video	nvidia_smi_clocks_current_video	The current frequency of the video (encoder plus decoder) clocks.

All of these metrics are collected with the following dimensions:

Dimension	Description
index	A unique identifier for the GPU on this server. Represents the NVIDIA Management Library (NVML) index of the device.

Dimension	Description
`name`	The type of GPU. For example, `NVIDIA Tesla A100`
`arch`	The server architecture.

Collect EFA metrics

You can use the CloudWatch agent to collect Elastic Fabric Adapter (EFA) metrics from Linux servers that have EFA devices attached. To set this up, add an `efa` section inside the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Linux section.

> **Note**
>
> All EFA metrics are reported as delta values. The agent automatically applies cumulative-to-delta conversion.

The following metrics can be collected.

Metric	Description
`efa_tx_bytes`	Bytes transmitted on the EFA device.
`efa_rx_bytes`	Bytes received on the EFA device.
`efa_tx_pkts`	Packets transmitted on the EFA device.
`efa_rx_pkts`	Packets received on the EFA device.
`efa_rx_dropped`	Received packets dropped on the EFA device.
`efa_send_bytes`	Bytes sent via EFA send operations.

Metric	Description
efa_send_wrs	Send work requests completed.
efa_recv_bytes	Bytes received via EFA receive operations.
efa_recv_wrs	Receive work requests completed.
efa_rdma_read_bytes	Bytes transferred via RDMA read operations.
efa_rdma_read_resp_bytes	Bytes received in RDMA read responses.
efa_rdma_read_wrs	RDMA read work requests completed.
efa_rdma_read_wr_err	RDMA read work request errors.
efa_rdma_write_bytes	Bytes transferred via RDMA write operations.
efa_rdma_write_recv_bytes	Bytes received via RDMA write operations.
efa_rdma_write_wrs	RDMA write work requests completed.
efa_rdma_write_wr_err	RDMA write work request errors.
efa_retrans_bytes	Bytes retransmitted.
efa_retrans_pkts	Packets retransmitted.
efa_retrans_timeout_events	Retransmission timeout events.
efa_impaired_remote_conn_events	Impaired remote connection events.
efa_unresponsive_remote_events	Unresponsive remote endpoint events.

Dimensions

Each EFA metric is emitted with the following dimensions by default:

- `device` – The EFA device name.
- `port` – The EFA port number.
- `eniId` – The ENI ID of the EFA NIC.

To append additional dimensions such as `InstanceId`, use the `append_dimensions` field in the `metrics` section of the agent configuration file.

Example configuration

The following example configuration collects a subset of EFA metrics every 60 seconds and appends the `InstanceId` dimension to each metric.

```
{
  "metrics": {
    "append_dimensions": {
      "InstanceId": "${aws:InstanceId}"
    },
    "metrics_collected": {
      "efa": {
        "measurement": [
          "efa_tx_bytes",
          "efa_rx_bytes",
          "efa_tx_pkts",
          "efa_rx_pkts",
          "efa_rx_dropped",
          "efa_rdma_read_bytes",
          "efa_rdma_write_bytes"
        ],
        "metrics_collection_interval": 60
      }
    }
  }
}
```

Collect Java Management Extensions (JMX) metrics

You can use the CloudWatch agent to collect Java Management Extensions (JMX) metrics from your Java applications.

The CloudWatch agent supports collecting these metrics from the following versions:

- JVM 8 and later
- Kafka 0.8.2.x and later
- Tomcat 9, 10.1, and 11 (beta)

Amazon EC2

To enable JMX in your JVM instance

For the CloudWatch agent to be able to collect JMX metrics, your application's JVM must bind to a port using the `com.sun.management.jmxremote.port` system property.

```
java -Dcom.sun.management.jmxremote.port=port-number -jar example.jar
```

For more information and other configurations, see the JMX documentation.

Amazon EKS

To enable JMX on your Java application pods

When using the CloudWatch Observability EKS add-on, add the following annotations to the workload manifest file under the `PodTemplate` section to enable JMX metrics collection:

- `instrumentation.opentelemetry.io/inject-java: "true"`
- One or more of the following:
  - For JVM metrics: `cloudwatch.aws.amazon.com/inject-jmx-jvm: "true"`
  - For Kafka broker metrics: `cloudwatch.aws.amazon.com/inject-jmx-kafka: "true"`
  - For Kafka consumer metrics: `cloudwatch.aws.amazon.com/inject-jmx-kafka-consumer: "true"`
  - For Kafka producer metrics: `cloudwatch.aws.amazon.com/inject-jmx-kafka-producer: "true"`
  - For Tomcat metrics: `cloudwatch.aws.amazon.com/inject-jmx-tomcat: "true"`

You must also configure a `jmx` section in the CloudWatch agent configuration as described below. For more information about providing a custom agent configuration with the EKS add-on, see Use a custom CloudWatch agent configuration.

Fields common to Amazon EC2 and Amazon EKS

To start collecting JMX metrics, add a `jmx` section inside the `metrics_collected` section of the CloudWatch agent configuration file. The `jmx` section must include at least one of the following target subsections.

- `jvm` – Optional. Specifies that you want to retrieve Java Virtual Machine (JVM) metrics from the instance. For more information, see Collect JVM metrics.

  This section can include the following fields:

  - `measurement` – Specifies the array of JVM metrics to be collected. For a list of the possible values to use here, see the **Metric** column in the table in Collect JVM metrics.

    Within the entry for each individual metric, you can optionally specify one or both of the following:

    - `rename` – Specifies a different name for this metric.
    - `unit` – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.
- `kafka` – Optional. Specifies that you want to retrieve Apache Kafka broker metrics from the instance. For more information, see Collect Kafka metrics.

  This section can include the following fields:

  - `measurement` – Specifies the array of Kafka broker metrics to be collected. For a list of the possible values to use here, see the **Metric** column in the first table in Collect Kafka metrics.

    Within the entry for each individual metric, you can optionally specify one or both of the following:

    - `rename` – Specifies a different name for this metric.
    - `unit` – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

- `kafka-consumer` – Optional. Specifies that you want to retrieve Apache Kafka consumer metrics from the instance. For more information, see Collect Kafka metrics.

  This section can include the following fields:

  - `measurement` – Specifies the array of Kafka consumer metrics to be collected. For a list of the possible values to use here, see the **Metric** column in the second metrics table in Collect Kafka metrics.

    Within the entry for each individual metric, you can optionally specify one or both of the following:

    - `rename` – Specifies a different name for this metric.
    - `unit` – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.
- `kafka-producer` – Optional. Specifies that you want to retrieve Apache Kafka producer metrics from the instance. For more information, see Collect Kafka metrics.

  This section can include the following fields:

  - `measurement` – Specifies the array of Kafka producer metrics to be collected. For a list of the possible values to use here, see the **Metric** column in the third metrics table in Collect Kafka metrics.

    Within the entry for each individual metric, you can optionally specify one or both of the following:

    - `rename` – Specifies a different name for this metric.
    - `unit` – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.
- `tomcat` – Optional. Specifies that you want to retrieve Apache Tomcat metrics from the instance. For more information, see Collect Tomcat metrics.

  This section can include the following fields:

  - `measurement` – Specifies the array of Tomcat metrics to be collected. For a list of the possible values to use here, see the **Metric** column in the table in Collect Tomcat metrics.

    Within the entry for each individual metric, you can optionally specify one or both of the following:

- `rename` – Specifies a different name for this metric.
- `unit` – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

The `jmx` section can also include the optional `append_dimensions` field:

- `append_dimensions` – Optional. Additional dimensions to use for only the process metrics. If you specify this field, it's used in addition to dimensions specified in the `append_dimensions` field that is used for all types of metrics collected by the agent.

Fields only on Amazon EC2

The following fields apply only when running the CloudWatch agent on Amazon EC2 instances.

- `endpoint` – The address for the JMX client to connect to. The format is `ip:port`. If the endpoint is not localhost, both password authentication and SSL must be enabled.
- `metrics_collection_interval` – Optional. Specifies how often to collect the processes metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds. For example, specifying 10 causes metrics to be collected every 10 seconds, and setting it to 300 specifies metrics to be collected every 5 minutes.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information, see High-resolution metrics.

If JMX was enabled with password authentication or SSL for remote access, you can use the following fields.

- `password_file` – Optional. Specifies a Java properties file of keys to passwords. The file must be read-only and restricted to the user running the CloudWatch agent. If password authentication is enabled, this requires the same username and password pair as the entry in the JMX password file provided in the `com.sun.management.jmxremote.password.file` property. If SSL is enabled, it requires entries for `keystore` and `truststore` and corresponds to the `javax.net.ssl.keyStorePassword` and `javax.net.ssl.trustStorePassword` respectively.

- `username` – If password authentication is enabled, specify the username that matches the username in the provided password file.
- `keystore_path` – If SSL is enabled, specify the full path to the Java keystore, which consists of a private key and a certificate to the public key. Corresponds to the `javax.net.ssl.keyStore` property.
- `keystore_type` – If SSL is enabled, specify the type of keystore being used. Corresponds to the `javax.net.ssl.keyStoreType` property.
- `truststore_path` – If SSL is enabled, specify the full path to the Java truststore, which must contain the remote JMX server's public certificate. Corresponds to the `javax.net.ssl.trustStore` property.
- `truststore_type` – If SSL is enabled, specify the type of truststore being used. Corresponds to the `javax.net.ssl.trustStoreType` property.
- `remote_profile` – Optional. Supported JMX remote profiles are TLS in combination with SASL profiles: `SASL/PLAIN`, `SASL/DIGEST-MD5`, and `SASL/CRAM-MD5`. Should be one of:`SASL/PLAIN`, `SASL/DIGEST-MD5`, `SASL/CRAM-MD5`, `TLS SASL/PLAIN`, `TLS SASL/DIGEST-MD5`, or `TLS SASL/CRAM-MD5`
- `realm` – Optional. The realm as required by the remote profile `SASL/DIGEST-MD5`.
- `registry_ssl_enabled` – If RMI registry authentication is enabled. Set to true if the JVM was configured with `com.sun.management.jmxremote.registry.ssl=true`.
- `insecure` – Optional. Set to `true` to opt out of the validation required if the agent is configured for a non-localhost endpoint.

The following is an example of the `jmx` section of the CloudWatch agent configuration file.

```
{
  "metrics": {
    "metrics_collected": {
      "jmx": [
        {
          "endpoint": "remotehost:1314",
          "jvm": {
            "measurement": [
              "jvm.memory.heap.init",
              "jvm.memory.nonheap.used"
            ]
          },
          "kafka": {
```

```
            "measurement": [
              "kafka.request.count",
              {
                "name": "kafka.message.count",
                "rename": "KAFKA_MESSAGE_COUNT",
                "unit": "Count"
              }
            ]
          },
          "username": "cwagent",
          "keystore_path": "/path/to/keystore",
          "keystore_type": "PKCS12",
          "truststore_path": "/path/to/truststore",
          "truststore_type": "PKCS12"
        },
        {
          "endpoint": "localhost:1315",
          "kafka-producer": {
            "measurement": [
              "kafka.producer.request-rate"
            ]
          },
          "append_dimensions": {
            "service.name": "kafka/1"
          }
        }
      ]
    }
  }
}
```

Collect JVM metrics

You can use the CloudWatch agent to collect Java Virtual Machine (JVM) metrics. To set this up, add a `jvm` section inside the `jmx`section of the CloudWatch agent configuration file.

The following metrics can be collected.

Metric	Dimensions	Description
`jvm.classes.loaded`	[DEFAULT]	The total number of loaded classes.

Metric	Dimensions	Description
		Unit: None **Meaningful statistics:** Minimum, Maximum, Average
`jvm.gc.collections.count`	[DEFAULT], `name`	The total number of garbage collections that have occurred. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
`jvm.gc.collections.elapsed`	[DEFAULT], `name`	The approximate accumulated garbage collection elapsed time. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
jvm.memory.heap.init	[DEFAULT]	The initial amount of memory that the JVM requests from the operating system for the heap. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
jvm.memory.heap.max	[DEFAULT]	The maximum amount of memory that can be used for the heap. **Unit:** Bytes **Meaningful statistics:** Maximum

Metric	Dimensions	Description
jvm.memory.heap.used	[DEFAULT]	The current heap memory usage. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
jvm.memory.heap.committed	[DEFAULT]	The amount of memory that is guaranteed to be available for the heap. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
jvm.memory.nonheap.init	[DEFAULT]	The initial amount of memory that the JVM requests from the operating system for non-heap purposes. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
jvm.memory.nonheap.max	[DEFAULT]	The maximum amount of memory that can be used for non-heap purposes. **Unit:** Bytes **Meaningful statistics:** Maximum

Metric	Dimensions	Description
jvm.memory.nonheap.used	[DEFAULT]	The current non-heap memory usage. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
jvm.memory.nonheap.committed	[DEFAULT]	The amount of memory that is guaranteed to be available for non-heap purposes. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
jvm.memory.pool.init	[DEFAULT], name	The initial amount of memory that the JVM requests from the operating system for the memory pool. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
jvm.memory.pool.max	[DEFAULT], name	The maximum amount of memory that can be used for the memory pool. **Unit:** Bytes **Meaningful statistics:** Maximum

Metric	Dimensions	Description
jvm.memory.pool.used	[DEFAULT], name	The current memory pool memory usage. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
jvm.memory.pool.committed	[DEFAULT], name	The amount of memory that is guaranteed to be available for the memory pool. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`jvm.threads.count`	[DEFAULT]	The current number of threads. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

The JVM metrics are collected with the following dimensions:

Dimension	Description
[DEFAULT]	On Amazon EC2 by default, the host is also published as a dimension of metrics that are collected by the CloudWatch agent, unless you are using the `append_dimensions` field in the `metrics` section. See `omit_hostname` in the agent section of Manually create or edit the CloudWatch agent configuration file for more information. On Amazon EKS by default, k8s related context is also published as dimensions of metrics (`k8s.container.name`, `k8s.deployment.name`, `k8s.namespace.name`, `k8s.node.name`, `k8s.pod.name`, and `k8s.replicaset.name`). These can be filtered down using the `aggregation_dimensions` field.

Dimension	Description
name	For jvm.gc.collections metrics, the value is the garbage collector name. For jvm.memory.pool metrics, the value is the memory pool name.

Collect Kafka metrics

You can use the CloudWatch agent to collect Apache Kafka metrics. To set this up, add one or more of the following subsections inside the jmx section of the CloudWatch agent configuration file.

- Use a kafka section to collect Kafka broker metrics.
- Use a kafka-consumer section to collect Kafka consumer metrics.
- Use a kafka-producer section to collect Kafka producer metrics.

Kafka broker metrics

The following metrics can be collected for Kafka brokers.

Metric	Dimensions	Description
kafka.message.count	[DEFAULT]	The number of messages received by the Kafka broker. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`kafka.request.count`	[DEFAULT], `type`	The number of requests received by the Kafka broker. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
`kafka.request.failed`	[DEFAULT], `type`	The number of requests to the Kafka broker that resulted in a failure. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`kafka.request.time.total`	[DEFAULT], `type`	The total time that the Kafka broker has taken to service requests. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average
`kafka.request.time.50p`	[DEFAULT], `type`	The 50th percentile time that the Kafka broker has taken to service requests. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`kafka.request.time.99p`	[DEFAULT], `type`	The 99th percentile time that the Kafka broker has taken to service requests. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average
`kafka.request.time.avg`	[DEFAULT], `type`	The average time that the Kafka broker has taken to service requests. **Unit:** Milliseconds **Meaningful statistics:** Average

Metric	Dimensions	Description
kafka.network.io	[DEFAULT], state	The number of bytes received by or sent by the Kafka broker. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
kafka.purgatory.size	[DEFAULT], type	The number of requests waiting in purgatory. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
kafka.partition.count	[DEFAULT]	The number of partitions on the Kafka broker. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
kafka.partition.offline	[DEFAULT]	The number of partitions that are offline. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
kafka.partition.under_replicated	[DEFAULT]	The number of under-replicated partitions. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`kafka.isr.operation.count`	[DEFAULT], `operation`	The number of in-sync replica shrink and expand operations. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
`kafka.max.lag`	[DEFAULT]	The maximum lag in messages between follower and leader replicas. **Unit:** None **Meaningful statistics:** Maximum

Metric	Dimensions	Description
kafka.controller.active.count	[DEFAULT]	The number of active controllers on the broker. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
kafka.leader.election.rate	[DEFAULT]	Leader election rate. If this increases, it indicates broker failures. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
kafka.unclean.election.rate	[DEFAULT]	Unclean leader election rate. If this increases, it indicates broker failures. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
kafka.request.queue	[DEFAULT]	The size of the request queue. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
kafka.logs.flush.time.count	[DEFAULT]	The logs flush count. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
kafka.logs.flush.time.median	[DEFAULT]	The 50th percentile value of the logs flush count. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average
kafka.logs.flush.time.99p	[DEFAULT]	The 99th percentile value of the logs flush count. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average

The Kafka broker metrics are collected with the following dimensions:

Dimension	Description
[DEFAULT]	On Amazon EC2 by default, the host is also published as a dimension of metrics that are

Dimension	Description
	collected by the CloudWatch agent, unless you are using the `append_dimensions` field in the `metrics` section. See `omit_hostname` in the agent section of Manually create or edit the CloudWatch agent configuration file for more information. On Amazon EKS by default, k8s related context is also published as dimension s of metrics (`k8s.container.name`, `k8s.deployment.name`, `k8s.namespace.name`, `k8s.node.name`, `k8s.pod.name`, and `k8s.replicaset.name`). These can be filtered down using the `aggregation_dimensions` field.
`type`	The request type. Possible values are `produce`, `fetch`, `fetchconsumer`, and `fetchfollower`.
`state`	The direction of network traffic. Possible values are `in` and `out`.
`operation`	The operation type for the in-sync replica. Possible values are `shrink` and `expand`.

Kafka consumer metrics

The following metrics can be collected for Kafka consumers.

Metric	Dimensions	Description
`kafka.consumer.fetch-rate`	[DEFAULT], `client-id`	The number of fetch requests

Metric	Dimensions	Description
		for all topics per second. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
`kafka.consumer.records-lag-max`	[DEFAULT], `client-id`	The number of messages that the consumer lags behind the producer. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
`kafka.consumer.total.bytes-consumed-rate`	[DEFAULT], `client-id`	The average number of bytes consumed for all topics per second. **Unit:** Bytes **Meaningful statistics:** Average

Metric	Dimensions	Description
kafka.consumer.total.fetch-size-avg	[DEFAULT], client-id	The number of bytes fetched per request for all topics. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
kafka.consumer.total.records-consumed-rate	[DEFAULT], client-id	The average number of records consumed for all topics per second. **Unit:** None **Meaningful statistics:** Average
kafka.consumer.bytes-consumed-rate	[DEFAULT], client-id , topic	The average number of bytes consumed per second. **Unit:** Bytes **Meaningful statistics:** Average

Metric	Dimensions	Description
`kafka.consumer.fetch-size-avg`	[DEFAULT], `client-id` , `topic`	The number of bytes fetched per request. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
`kafka.consumer.records-consumed-rate`	[DEFAULT], `client-id` , `topic`	The average number of records consumed per second. **Unit:** None **Meaningful statistics:** Average

The Kafka consumer metrics are collected with the following dimensions:

Dimension	Description
[DEFAULT]	On Amazon EC2 by default, the host is also published as a dimension of metrics that are collected by the CloudWatch agent, unless you are using the `append_dimensions` field in the `metrics` section. See `omit_hostname` in the agent section of Manually create or edit the CloudWatch agent configuration file for more information.

Dimension	Description
	On Amazon EKS by default, k8s related context is also published as dimension s of metrics (`k8s.container.name` , `k8s.deployment.name` , `k8s.namespace.name` , `k8s.node.name` , `k8s.pod.name` , and `k8s.replicaset.name`). These can be filtered down using the `aggregation_dimensions` field.
`client-id`	The ID of the client.
`topic`	The Kafka topic.

Kafka producer metrics

The following metrics can be collected for Kafka producers.

Metric	Dimensions	Description
`kafka.producer.io-wait-time-ns-avg`	[DEFAULT], `client-id`	The average length of time the I/O thread spent waiting for a socket ready for reads or writes. **Unit:** None **Meaningful statistics:** Average
`kafka.producer.out`	[DEFAULT], `client-id`	The average number of

Metric	Dimensions	Description
`going-byte-rate`		outgoing bytes sent per second to all servers. **Unit:** Bytes **Meaningful statistics:** Average
`kafka.producer.request-latency-avg`	[DEFAULT], `client-id`	The average request latency. **Unit:** Milliseconds **Meaningful statistics:** Average
`kafka.producer.request-rate`	[DEFAULT], `client-id`	The average number of requests sent per second. **Unit:** None **Meaningful statistics:** Average

Metric	Dimensions	Description
kafka.producer.response-rate	[DEFAULT], client-id	The number of responses received per second. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
kafka.producer.byte-rate	[DEFAULT], client-id , topic	The average number of bytes sent per second for a topic. **Unit:** Bytes **Meaningful statistics:** Average
kafka.producer.compression-rate	[DEFAULT], client-id , topic	The average compression rate of record batches for a topic. **Unit:** None **Meaningful statistics:** Average

Metric	Dimensions	Description
`kafka.producer.record-error-rate`	[DEFAULT], `client-id` , `topic`	The average per-second number of record sends that resulted in errors for a topic. **Unit:** None **Meaningful statistics:** Average
`kafka.producer.record-retry-rate`	[DEFAULT], `client-id` , `topic`	The average per-second number of retried record sends for a topic. **Unit:** None **Meaningful statistics:** Average

Metric	Dimensions	Description
`kafka.producer.record-send-rate`	[DEFAULT], `client-id` , `topic`	The average number of records sent per second for a topic. **Unit:** None **Meaningful statistics:** Average

Kafka producer metrics are collected with the following dimensions:

Dimension	Description
[DEFAULT]	On Amazon EC2 by default, the host is also published as a dimension of metrics that are collected by the CloudWatch agent, unless you are using the `append_dimensions` field in the `metrics` section. See `omit_hostname` in the agent section of Manually create or edit the CloudWatch agent configuration file for more information. On Amazon EKS by default, k8s related context is also published as dimensions of metrics (`k8s.container.name` , `k8s.deployment.name` , `k8s.namespace.name` , `k8s.node.name` , `k8s.pod.name` , and `k8s.replicaset.name`). These can be filtered down using the `aggregation_dimensions` field.

Dimension	Description
client-id	The ID of the client.
topic	The Kafka topic.

Collect Tomcat metrics

You can use the CloudWatch agent to collect Apache Tomcat metrics. To set this up, add a `tomcat` section inside the `jmx` section of the CloudWatch agent configuration file.

The following metrics can be collected.

Metric	Dimensions	Description
tomcat.sessions	[DEFAULT]	The number of active sessions. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
tomcat.errors	[DEFAULT], proto_handler	The number of errors encountered. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`tomcat.processing_time`	[DEFAULT], `proto_handler`	The total processing time. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average
`tomcat.traffic`	[DEFAULT], `proto_handler`	The number of bytes received and sent. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
`tomcat.threads`	[DEFAULT], `proto_handler`	The number of threads. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`tomcat.max_time`	[DEFAULT], `proto_handler` , `direction`	Maximum time to process a request. **Unit:** Milliseconds **Meaningful statistics:** Maximum
`tomcat.request_count`	[DEFAULT], `proto_handler`	The total requests. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Tomcat metrics are collected with the following dimensions:

Dimension	Description
[DEFAULT]	On Amazon EC2 by default, the host is also published as a dimension of metrics that are collected by the CloudWatch agent, unless you are using the `append_dimensions` field in the `metrics` section. See `omit_hostname` in the agent section of Manually create or edit the CloudWatch agent configuration file for more information.

Dimension	Description
	On Amazon EKS by default, k8s related context is also published as dimension s of metrics (`k8s.container.name` , `k8s.deployment.name` , `k8s.namespace.name` , `k8s.node.name` , `k8s.pod.name` , and `k8s.replicaset.name`). These can be filtered down using the `aggregation_dimensions` field.
`proto_handler`	The `proto_handler` is an identifier for a connector, which is provided in the `<protocol>-<type>-<port>` format (for example, `http-nio-8080`).
`direction`	The traffic direction. Possible values are `received` and `sent`.

Collect metrics and traces with OpenTelemetry

You can collect metrics and traces from your applications or services using the CloudWatch agent with the OpenTelemetry Protocol (OTLP), which is a popular open source solution. You can use any OpenTelemetry SDK to send metrics and traces to the CloudWatch agent. For more information about the available OpenTelemetry SDKs, see OpenTelemetry Supported Language APIs & SDKs..

To collect OpenTelemetry metrics and traces, add an `otlp` section to the CloudWatch agent configuration file. The section has the following fields:

- `grpc_endpoint` – Optional. Specifies the address for the CloudWatch agent to use to listen for OpenTelemetry metrics or traces sent using gRPC Remote Procedure Calls. The format is `ip:port`. This address must match the address set for the gRPC exporter in the OpenTelemetry SDK. If you omit this field, the default of `127.0.0.1:4317` is used.
- `http_endpoint` – Optional. Specifies the address for the CloudWatch agent to use to listen for OpenTelemetry metrics or traces sent over HTTP. The format is `ip:port`. This address must match the address set for the HTTP exporter in the OpenTelemetry SDK. If you omit this field, the default of `127.0.0.1:4318` is used.

- `tls` – Optional. Specifies that the server should be configured with TLS.
  - `cert_file` – Path to the TLS certificate to use for TLS required connections.
  - `key_file` – Path to the TLS key to use for TLS required connections.

The `otlp` section can be placed in multiple sections within the CloudWatch agent configuration file depending on how and where you want to send the metrics and traces.

> **Important**
>
> Each `otlp` section requires a unique endpoint and port. For detailed information about splitting the metrics and traces endpoints, see OTLP Exporter Configuration in the OpenTelemetry SDK documentation.

To send metrics to CloudWatch or Amazon Managed Service for Prometheus, add the `otlp` section under `metrics_collected` within the `metrics` section. For more information about sending metrics to different destinations, see Manually create or edit the CloudWatch agent configuration file. The following example shows a configuration that sends metrics to CloudWatch:

> **Note**
>
> If you are running the agent in containerized environments and sending telemetry from outside the agent container's network, make sure to specify the endpoint as `0.0.0.0` instead of the default endpoint `127.0.0.1`.

```
{
  "metrics": {
    "metrics_collected": {
      "otlp": {
        "grpc_endpoint": "127.0.0.1:4317",
        "http_endpoint": "127.0.0.1:4318"
      }
    }
  }
}
```

To send metrics to Amazon CloudWatch Logs using the Embedded metric format (EMF), add the `otlp` section under `metrics_collected` within the `logs` section. This sends the EMF logs by default to the `/aws/cwagent` log group and a generated log stream. The metrics are extracted into the `CWAgent` namespace by default. The following example shows a configuration that sends metrics as EMF logs to CloudWatch Logs:

```
{
  "logs": {
    "metrics_collected": {
      "otlp": {
        "grpc_endpoint": "127.0.0.1:4317",
        "http_endpoint": "127.0.0.1:4318"
      }
    }
  }
}
```

To send traces to AWS X-Ray, add the `otlp` section under `traces_collected` within the `traces` section. The following example shows a configuration that sends traces to X-Ray:

```
{
  "traces": {
    "traces_collected": {
      "otlp": {
        "grpc_endpoint": "127.0.0.1:4317",
        "http_endpoint": "127.0.0.1:4318"
      }
    }
  }
}
```

Collect process metrics with the procstat plugin

The *procstat* plugin enables you to collect metrics from individual processes. The plugin is supported on Linux servers and on servers running supported version of Windows Server. This section describes how to configure the CloudWatch agent for procstat and view metrics the CloudWatch agent imports. It also lists the metrics that procstat collects.

> **Note**
>
> The `procstat` plugin is not supported for the Fargate launch type in Amazon ECS environments.

Topics

- Configure the CloudWatch agent for procstat
- Metrics collected by procstat
- Viewing process metrics imported by the CloudWatch agent

Configure the CloudWatch agent for procstat

To use the procstat plugin, add a `procstat` section in the `metrics_collected` section of the CloudWatch agent configuration file. There are three ways to specify the processes to monitor. You can use only one of these methods, but you can use that method to specify one or more processes to monitor.

- `pid_file`: Selects processes by the names of the process identification number (PID) files they create.
- `exe`: Selects the processes that have process names that match the string that you specify, using regular expression matching rules. The match is a "contains" match, meaning that if you specify `agent` as the term to match, processes with names like `cloudwatchagent` match the term. For more information, see Syntax.
- `pattern`: Selects processes by the command lines used to start the processes. All processes are selected that have command lines matching the specified string using regular expression matching rules. The entire command line is checked, including parameters and options used with the command.

  The match is a "contains" match, meaning that if you specify `-c` as the term to match, processes with parameters like `-config` match the term.

The CloudWatch agent uses only one of these methods, even if you include more than one of the above sections. If you specify more than one section, the CloudWatch agent uses the `pid_file` section if it is present. If not, it uses the `exe` section.

On Linux servers, the strings that you specify in an `exe` or `pattern` section are evaluated as regular expressions. On servers running Windows Server, these strings are evaluated as WMI queries. An example would be `pattern: "%apache%"`. For more information, see LIKE Operator.

Whichever method you use, you can include an optional `metrics_collection_interval` parameter, which specifies how often in seconds to collect those metrics. If you omit this parameter, the default value of 60 seconds is used.

In the examples in the following sections, the `procstat` section is the only section included in the `metrics_collected` section of the agent configuration file. Actual configuration files can also include other sections in `metrics_collected`. For more information, see Manually create or edit the CloudWatch agent configuration file.

Configure with pid_file

The following example `procstat` section monitors the processes that create the PID files `example1.pid` and `example2.pid`. Different metrics are collected from each process. Metrics collected from the process that creates `example2.pid` are collected every 10 seconds, and the metrics collected from the `example1.pid` process are collected every 60 seconds, the default value.

```
{
    "metrics": {
        "metrics_collected": {
            "procstat": [
                {
                    "pid_file": "/var/run/example1.pid",
                    "measurement": [
                        "cpu_usage",
                        "memory_rss"
                    ]
                },
                {
                    "pid_file": "/var/run/example2.pid",
                    "measurement": [
                        "read_bytes",
                        "read_count",
                        "write_bytes"
                    ],
                    "metrics_collection_interval": 10
                }
            ]
```

```
        }
    }
}
```

Configuring with exe

The following example `procstat` section monitors all processes with names that match the strings `agent` or `plugin`. The same metrics are collected from each process.

```
{
    "metrics": {
        "metrics_collected": {
            "procstat": [
                {
                    "exe": "agent",
                    "measurement": [
                        "cpu_time",
                        "cpu_time_system",
                        "cpu_time_user"
                    ]
                },
                {
                    "exe": "plugin",
                    "measurement": [
                        "cpu_time",
                        "cpu_time_system",
                        "cpu_time_user"
                    ]
                }
            ]
        }
    }
}
```

Configuring with pattern

The following example `procstat` section monitors all processes with command lines that match the strings `config` or `-c`. The same metrics are collected from each process.

```
{
    "metrics": {
        "metrics_collected": {
```

```
            "procstat": [
                {
                    "pattern": "config",
                    "measurement": [
                        "rlimit_memory_data_hard",
                        "rlimit_memory_data_soft",
                        "rlimit_memory_stack_hard",
                        "rlimit_memory_stack_soft"
                    ]
                },
                {
                    "pattern": "-c",
                    "measurement": [
                        "rlimit_memory_data_hard",
                        "rlimit_memory_data_soft",
                        "rlimit_memory_stack_hard",
                        "rlimit_memory_stack_soft"
                    ]
                }
            ]
        }
    }
}
```

Metrics collected by procstat

The following table lists the metrics that you can collect with the `procstat` plugin.

The CloudWatch agent adds `procstat` to the beginning of the following metric names. There is a different syntax depending on whether it was collected from a Linux server or a server running Windows Server. For example, the `cpu_time` metric appears as `procstat_cpu_time` when collected from Linux and as `procstat cpu_time` when collected from Windows Server.

Metric name	Available on	Description
`cpu_time`	Linux	The amount of time that the process uses the CPU. This metric is measured in

Metric name	Available on	Description
		hundredths of a second. Unit: Count
cpu_time_guest	Linux	The amount of time that the process is in guest mode. This metric is measured in hundredths of a second. Type: Float Unit: None
cpu_time_guest_nice	Linux	The amount of time that the process is running in a nice guest. This metric is measured in hundredths of a second. Type: Float Unit: None

Metric name	Available on	Description
cpu_time_idle	Linux	The amount of time that the process is in idle mode. This metric is measured in hundredths of a second. Type: Float Unit: None
cpu_time_iowait	Linux	The amount of time that the process is waiting for I/O operations to complete. This metric is measured in hundredths of a second. Type: Float Unit: None

Metric name	Available on	Description
cpu_time_irq	Linux	The amount of time that the process is servicing interrupts. This metric is measured in hundredths of a second. Type: Float Unit: None
cpu_time_nice	Linux	The amount of time that the process is in nice mode. This metric is measured in hundredths of a second. Type: Float Unit: None

Metric name	Available on	Description
cpu_time_soft_irq	Linux	The amount of time that the process is servicing software interrupts. This metric is measured in hundredths of a second. Type: Float Unit: None
cpu_time_steal	Linux	The amount of time spent running in other operating systems when running in a virtualized environment. This metric is measured in hundredths of a second. Type: Float Unit: None

Metric name	Available on	Description
cpu_time_stolen	Linux, Windows Server	The amount of time that the process is in *stolen time*, which is time spent in other operating systems in a virtualized environment. This metric is measured in hundredths of a second. Type: Float Unit: None
cpu_time_system	Linux, Windows Server, macOS	The amount of time that the process is in system mode. This metric is measured in hundredths of a second. Type: Float Unit: Count

Metric name	Available on	Description
cpu_time_user	Linux, Windows Server, macOS	The amount of time that the process is in user mode. This metric is measured in hundredths of a second. Unit: Count
cpu_usage	Linux, Windows Server, macOS	The percentage of time that the process is active in any capacity. Unit: Percent
memory_data	Linux, macOS	The amount of memory that the process uses for data. Unit: Bytes
memory_locked	Linux, macOS	The amount of memory that the process has locked. Unit: Bytes

Metric name	Available on	Description
memory_rss	Linux, Windows Server, macOS	The amount of real memory (resident set) that the process is using. Unit: Bytes
memory_stack	Linux, macOS	The amount of stack memory that the process is using. Unit: Bytes
memory_swap	Linux, macOS	The amount of swap memory that the process is using. Unit: Bytes
memory_vms	Linux, Windows Server, macOS	The amount of virtual memory that the process is using. Unit: Bytes

Metric name	Available on	Description
num_fds	Linux	The number of file descriptors that this process has open. Unit: None
num_threads	Linux, Windows, macOS	The number of threads in this process. Unit: None
pid	Linux, Windows Server, macOS	Process identifier (ID). Unit: None

Metric name	Available on	Description
`pid_count`	Linux, Windows Server. macOS	The number of process IDs associated with the process. On Linux servers and macOS computers the full name of this metric is `procstat_lookup_pid_count` and on Windows Server it is `procstat_lookup pid_count` . Unit: None
`read_bytes`	Linux, Windows Server	The number of bytes that the process has read from disks. Unit: Bytes

Metric name	Available on	Description
write_bytes	Linux, Windows Server	The number of bytes that the process has written to disks. Unit: Bytes
read_count	Linux, Windows Server	The number of disk read operations that the process has executed. Unit: None
rlimit_realtime_priority_hard	Linux	The hard limit on the real-time priority that can be set for this process. Unit: None
rlimit_realtime_priority_soft	Linux	The soft limit on the real-time priority that can be set for this process. Unit: None

Metric name	Available on	Description
rlimit_signals_pending_hard	Linux	The hard limit on maximum number of signals that can be queued by this process. Unit: None
rlimit_signals_pending_soft	Linux	The soft limit on maximum number of signals that can be queued by this process. Unit: None
rlimit_nice_priority_hard	Linux	The hard limit on the maximum nice priority that can be set by this process. Unit: None

Metric name	Available on	Description
rlimit_nice_priority_soft	Linux	The soft limit on the maximum nice priority that can be set by this process. Unit: None
rlimit_num_fds_hard	Linux	The hard limit on the maximum number of file descriptors that this process can have open. Unit: None
rlimit_num_fds_soft	Linux	The soft limit on the maximum number of file descriptors that this process can have open. Unit: None

Metric name	Available on	Description
write_count	Linux, Windows Server	The number of disk write operations that the process has executed. Unit: None
involuntary_context_switches	Linux	The number of times that the process was involuntarily context-switched. Unit: None
voluntary_context_switches	Linux	The number of times that the process was context-switched voluntarily. Unit: None
realtime_priority	Linux	The current usage of real-time priority for the process. Unit: None

Metric name	Available on	Description
nice_priority	Linux	The current usage of nice priority for the process. Unit: None
signals_pending	Linux	The number of signals pending to be handled by the process. Unit: None
rlimit_cpu_time_hard	Linux	The hard CPU time resource limit for the process. Unit: None
rlimit_cpu_time_soft	Linux	The soft CPU time resource limit for the process. Unit: None
rlimit_file_locks_hard	Linux	The hard file locks resource limit for the process. Unit: None

Metric name	Available on	Description
rlimit_file_locks_soft	Linux	The soft file locks resource limit for the process. Unit: None
rlimit_memory_data_hard	Linux	The hard resource limit on the process for memory used for data. Unit: Bytes
rlimit_memory_data_soft	Linux	The soft resource limit on the process for memory used for data. Unit: Bytes
rlimit_memory_locked_hard	Linux	The hard resource limit on the process for locked memory. Unit: Bytes

Metric name	Available on	Description
rlimit_memory_locked_soft	Linux	The soft resource limit on the process for locked memory. Unit: Bytes
rlimit_memory_rss_hard	Linux	The hard resource limit on the process for physical memory. Unit: Bytes
rlimit_memory_rss_soft	Linux	The soft resource limit on the process for physical memory. Unit: Bytes
rlimit_memory_stack_hard	Linux	The hard resource limit on the process stack. Unit: Bytes
rlimit_memory_stack_soft	Linux	The soft resource limit on the process stack. Unit: Bytes

Metric name	Available on	Description
`rlimit_memory_vms_hard`	Linux	The hard resource limit on the process for virtual memory. Unit: Bytes
`rlimit_memory_vms_soft`	Linux	The soft resource limit on the process for virtual memory. Unit: Bytes

Viewing process metrics imported by the CloudWatch agent

After importing process metrics into CloudWatch, you can view these metrics as time series graphs, and create alarms that can watch these metrics and notify you if they breach a threshold that you specify. The following procedure shows how to view process metrics as a time series graph. For more information about setting alarms, see Using Amazon CloudWatch alarms.

To view process metrics in the CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the namespace for the metrics collected by the agent. By default, this is **CWAgent**, but you may have specified a different namespace in the CloudWatch agent configuration file.
4. Choose a metric dimension (for example, **Per-Instance Metrics**).
5. The **Browse** tab displays all metrics for that dimension in the namespace. You can do the following:

    a. To graph a metric, select the check box next to the metric. To select all metrics, select the check box in the heading row of the table.

b. To sort the table, use the column heading.

c. To filter by resource, choose the resource ID and then choose **Add to search**.

d. To filter by metric, choose the metric name and then choose **Add to search**.

6. (Optional) To add this graph to a CloudWatch dashboard, choose **Actions**, **Add to dashboard**.

Retrieve custom metrics with StatsD

You can retrieve additional custom metrics from your applications or services using the CloudWatch agent with the `StatsD` protocol. StatsD is a popular open-source solution that can gather metrics from a wide variety of applications. StatsD is especially useful for instrumenting your own metrics. For an example of using the CloudWatch agent and StatsD together, see How to better monitor your custom application metrics using Amazon CloudWatch Agent.

`StatsD` is supported on both Linux servers and servers running Windows Server. CloudWatch supports the following `StatsD` format:

```
MetricName:value|type|@sample_rate|#tag1:
  value,tag1...
```

- `MetricName` – A string with no colons, bars, # characters, or @ characters.
- `value` – This can be either integer or float.
- `type` – Specify `c` for counter, `g` for gauge, `ms` for timer, `h` for histogram, or `s` for set.
- `sample_rate` – (Optional) A float between 0 and 1, inclusive. Use only for counter, histogram, and timer metrics. The default value is 1 (sampling 100% of the time).
- `tags` – (Optional) A comma-separated list of tags. `StatsD` tags are similar to dimensions in CloudWatch. Use colons for key/value tags, such as `env:prod`.

You can use any `StatsD` client that follows this format to send the metrics to the CloudWatch agent. For more information about some of the available `StatsD` clients, see the StatsD client page on GitHub.

To collect these custom metrics, add a `"statsd": {}` line to the `metrics_collected` section of the agent configuration file. You can add this line manually. If you use the wizard to create the configuration file, it's done for you. For more information, see Create the CloudWatch agent configuration file.

The `StatsD` default configuration works for most users. There are optional fields that you can add to the **statsd** section of the agent configuration file as needed:

- `service_address` – The service address to which the CloudWatch agent should listen. The format is *`ip`*`:`*`port`*. If you omit the IP address, the agent listens on all available interfaces. Only the UDP format is supported, so you don't need to specify a UDP prefix.

  The default value is `:8125`.
- `metrics_collection_interval` – How often in seconds that the `StatsD` plugin runs and collects metrics. The default value is 10 seconds. The range is 1–172,000.
- `metrics_aggregation_interval` – How often in seconds CloudWatch aggregates metrics into single data points. The default value is 60 seconds.

  For example, if `metrics_collection_interval` is 10 and `metrics_aggregation_interval` is 60, CloudWatch collects data every 10 seconds. After each minute, the six data readings from that minute are aggregated into a single data point, which is sent to CloudWatch.

  The range is 0–172,000. Setting `metrics_aggregation_interval` to 0 disables the aggregation of `StatsD` metrics.
- `allowed_pending_messages` – The number of UDP messages that are allowed to queue up. When the queue is full, the StatsD server starts dropping packets. The default value is 10000.
- `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

The following is an example of the **statsd** section of the agent configuration file, using the default port and custom collection and aggregation intervals.

```
{
   "metrics":{
      "metrics_collected":{
         "statsd":{
```

```
            "service_address":":8125",
            "metrics_collection_interval":60,
            "metrics_aggregation_interval":300
         }
      }
   }
}
```

Viewing StatsD metrics imported by the CloudWatch agent

After importing StatsD metrics into CloudWatch, you can view these metrics as time series graphs, and create alarms that can watch these metrics and notify you if they breach a threshold that you specify. The following procedure shows how to view StatsD metrics as a time series graph. For more information about setting alarms, see Using Amazon CloudWatch alarms.

To view StatsD metrics in the CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the namespace for the metrics collected by the agent. By default, this is **CWAgent**, but you may have specified a different namespace in the CloudWatch agent configuration file.
4. Choose a metric dimension (for example, **Per-Instance Metrics**).
5. The **Browse** tab displays all metrics for that dimension in the namespace. You can do the following:

    a. To graph a metric, select the check box next to the metric. To select all metrics, select the check box in the heading row of the table.

    b. To sort the table, use the column heading.

    c. To filter by resource, choose the resource ID and then choose **Add to search**.

    d. To filter by metric, choose the metric name and then choose **Add to search**.
6. (Optional) To add this graph to a CloudWatch dashboard, choose **Actions**, **Add to dashboard**.

Retrieve custom metrics with collectd

You can retrieve additional metrics from your applications or services using the CloudWatch agent with the collectd protocol, which is supported only on Linux servers. collectd is a popular open-source solution with plugins that can gather system statistics for a wide variety of applications. By combining the system metrics that the CloudWatch agent can already collect with the additional

metrics from collectd, you can better monitor, analyze, and troubleshoot your systems and applications. For more information about collectd, see collectd - The system statistics collection daemon.

You use the collectd software to send the metrics to the CloudWatch agent. For the collectd metrics, the CloudWatch agent acts as the server while the collectd plugin acts as the client.

The collectd software is not installed automatically on every server. On a server running Amazon Linux 2, follow these steps to install collectd

```
sudo amazon-linux-extras install collectd
```

For information about installing collectd on other systems, see the Download page for collectd.

To collect these custom metrics, add a **"collectd": {}** line to the **metrics_collected** section of the agent configuration file. You can add this line manually. If you use the wizard to create the configuration file, it is done for you. For more information, see Create the CloudWatch agent configuration file.

Optional parameters are also available. If you are using collectd and you do not use `/etc/collectd/auth_file` as your **collectd_auth_file**, you must set some of these options.

- **service_address:** The service address to which the CloudWatch agent should listen. The format is `"udp://`*`ip`*`:`*`port`*. The default is `udp://127.0.0.1:25826`.
- **name_prefix:** A prefix to attach to the beginning of the name of each collectd metric. The default is `collectd_`. The maximum length is 255 characters.
- **collectd_security_level:** Sets the security level for network communication. The default is **encrypt**.

  encrypt specifies that only encrypted data is accepted. **sign** specifies that only signed and encrypted data is accepted. **none** specifies that all data is accepted. If you specify a value for **collectd_auth_file**, encrypted data is decrypted if possible.

  For more information, see Client setup and Possible interactions in the collectd Wiki.
- **collectd_auth_file** Sets a file in which user names are mapped to passwords. These passwords are used to verify signatures and to decrypt encrypted network packets. If given, signed data is verified and encrypted packets are decrypted. Otherwise, signed data is accepted without checking the signature and encrypted data cannot be decrypted.

The default is `/etc/collectd/auth_file`.

If **collectd_security_level** is set to **none**, this is optional. If you set **collectd_security_level** to `encrypt` or **sign**, you must specify **collectd_auth_file**.

For the format of the auth file, each line is a user name followed by a colon and any number of spaces followed by the password. For example:

```
user1: user1_password

user2: user2_password
```

- **collectd_typesdb:** A list of one or more files that contain the dataset descriptions. The list must be surrounded by brackets, even if there is just one entry in the list. Each entry in the list must be surrounded by double quotes. If there are multiple entries, separate them with commas. The default on Linux servers is `["/usr/share/collectd/types.db"]`. The default on macOs computers depends on the version of collectd. For example, `["/usr/local/Cellar/collectd/5.12.0/share/collectd/types.db"]`.

  For more information, see https://www.collectd.org/documentation/manpages/types.db.html.
- **metrics_aggregation_interval:** How often in seconds CloudWatch aggregates metrics into single data points. The default is 60 seconds. The range is 0 to 172,000. Setting it to 0 disables the aggregation of collectd metrics.

The following is an example of the collectd section of the agent configuration file.

```
{
   "metrics":{
      "metrics_collected":{
         "collectd":{
            "name_prefix":"My_collectd_metrics_",
            "metrics_aggregation_interval":120
         }
      }
   }
}
```

Viewing collected metrics imported by the CloudWatch agent

After importing collectd metrics into CloudWatch, you can view these metrics as time series graphs, and create alarms that can watch these metrics and notify you if they breach a threshold that you specify. The following procedure shows how to view collectd metrics as a time series graph. For more information about setting alarms, see Using Amazon CloudWatch alarms.

To view collectd metrics in the CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the namespace for the metrics collected by the agent. By default, this is **CWAgent**, but you may have specified a different namespace in the CloudWatch agent configuration file.
4. Choose a metric dimension (for example, **Per-Instance Metrics**).
5. The **Browse** tab displays all metrics for that dimension in the namespace. You can do the following:
    a. To graph a metric, select the check box next to the metric. To select all metrics, select the check box in the heading row of the table.
    b. To sort the table, use the column heading.
    c. To filter by resource, choose the resource ID and then choose **Add to search**.
    d. To filter by metric, choose the metric name and then choose **Add to search**.
6. (Optional) To add this graph to a CloudWatch dashboard, choose **Actions**, **Add to dashboard**.

Set up and configure Prometheus metrics collection on Amazon EC2 instances

The following sections explain how to install the CloudWatch agent with Prometheus monitoring on EC2 instances, and how to configure the agent to scrape additional targets. It also provides tutorials for setting up sample workloads to use testing with Prometheus monitoring.

Both Linux and Windows instances are supported.

For information about the operating systems supported by the CloudWatch agent, see Collect metrics, logs, and traces using the CloudWatch agent

VPC security group requirements

If you are using a VPC, the following requirements apply.

- The ingress rules of the security groups for the Prometheus workloads must open the Prometheus ports to the CloudWatch agent for scraping the Prometheus metrics by the private IP.
- The egress rules of the security group for the CloudWatch agent must allow the CloudWatch agent to connect to the Prometheus workloads' port by private IP.

Topics

- Step 1: Install the CloudWatch agent
- Step 2: Scrape Prometheus sources and import metrics
- Example: Set up Java/JMX sample workloads for Prometheus metric testing

Step 1: Install the CloudWatch agent

The first step is to install the CloudWatch agent on the EC2 instance. For instructions, see Installing the CloudWatch agent.

Step 2: Scrape Prometheus sources and import metrics

The CloudWatch agent with Prometheus monitoring needs two configurations to scrape the Prometheus metrics. One is for the standard Prometheus configurations as documented in <scrape_config>in the Prometheus documentation. The other is for the CloudWatch agent configuration.

Prometheus scrape configuration

The CloudWatch agent supports the standard Prometheus scrape configurations as documented in <scrape_config> in the Prometheus documentation. You can edit this section to update the configurations that are already in this file, and add additional Prometheus scraping targets. A sample configuration file contains the following global configuration lines:

```
PS C:\ProgramData\Amazon\AmazonCloudWatchAgent> cat prometheus.yaml
global:
  scrape_interval: 1m
  scrape_timeout: 10s
scrape_configs:
- job_name: MY_JOB
  sample_limit: 10000
  file_sd_configs:
```

```
    - files: ["C:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\\prometheus_sd_1.yaml",
"C:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\\prometheus_sd_2.yaml"]
```

The `global` section specifies parameters that are valid in all configuration contexts. They also serve as defaults for other configuration sections. It contains the following parameters:

- `scrape_interval`— Defines how frequently to scrape targets.
- `scrape_timeout`— Defines how long to wait before a scrape request times out.

The `scrape_configs` section specifies a set of targets and parameters that define how to scrape them. It contains the following parameters:

- `job_name`— The job name assigned to scraped metrics by default.
- `sample_limit`— Per-scrape limit on the number of scraped samples that will be accepted.
- `file_sd_configs`— List of file service discovery configurations. It reads a set of files containing a list of zero or more static configs. The `file_sd_configs` section contains a `files` parameter which defines patterns for files from which target groups are extracted.

The CloudWatch agent supports the following service discovery configuration types.

`static_config` Allows specifying a list of targets and a common label set for them. It is the canonical way to specify static targets in a scrape configuration.

The following is a sample static config to scrape Prometheus metrics from a local host. Metrics can also be scraped from other servers if the Prometheus port is open to the server where the agent runs.

```
PS C:\ProgramData\Amazon\AmazonCloudWatchAgent> cat prometheus_sd_1.yaml
- targets:
    - 127.0.0.1:9404
  labels:
    key1: value1
    key2: value2
```

This example contains the following parameters:

- `targets`— The targets scraped by the static config.
- `labels`— Labels assigned to all metrics that are scraped from the targets.

`ec2_sd_config` Allows retrieving scrape targets from Amazon EC2 instances. The following is a sample `ec2_sd_config` to scrape Prometheus metrics from a list of EC2 instances. The Prometheus ports of these instances have to open to the server where the CloudWatch agent runs. The IAM role for the EC2 instance where the CloudWatch agent runs must include the `ec2:DescribeInstance` permission. For example, you could attach the managed policy **AmazonEC2ReadOnlyAccess** to the instance running the CloudWatch agent.

```
PS C:\ProgramData\Amazon\AmazonCloudWatchAgent> cat prometheus.yaml
global:
  scrape_interval: 1m
  scrape_timeout: 10s
scrape_configs:
  - job_name: MY_JOB
    sample_limit: 10000
    ec2_sd_configs:
      - region: us-east-1
        port: 9404
        filters:
          - name: instance-id
            values:
              - i-98765432109876543
              - i-12345678901234567
```

This example contains the following parameters:

- `region`— The AWS Region where the target EC2 instance is. If you leave this blank, the Region from the instance metadata is used.
- `port`— The port to scrape metrics from.
- `filters`— Optional filters to use to filter the instance list. This example filters based on EC2 instance IDs. For more criteria that you can filter on, see DescribeInstances.

CloudWatch agent configuration for Prometheus

The CloudWatch agent configuration file includes `prometheus` sections under both `logs` and `metrics_collected`. It includes the following parameters.

- **cluster_name**— specifies the cluster name to be added as a label in the log event. This field is optional.
- **log_group_name**— specifies the log group name for the scraped Prometheus metrics.

- **prometheus_config_path**— specifies the Prometheus scrape configuration file path.
- **emf_processor**— specifies the embedded metric format processor configuration. For more information about embedded metric format, see Embedding metrics within logs.

  The `emf_processor` section can contain the following parameters:

  - **metric_declaration_dedup**— It set to true, the de-duplication function for the embedded metric format metrics is enabled.
  - **metric_namespace**— Specifies the metric namespace for the emitted CloudWatch metrics.
  - **metric_unit**— Specifies the metric name:metric unit map. For information about supported metric units, see MetricDatum.
  - **metric_declaration**— are sections that specify the array of logs with embedded metric format to be generated. There are `metric_declaration` sections for each Prometheus source that the CloudWatch agent imports from by default. These sections each include the following fields:
    - `source_labels` specifies the value of the labels that are checked by the `label_matcher` line.
    - `label_matcher` is a regular expression that checks the value of the labels listed in `source_labels`. The metrics that match are enabled for inclusion in the embedded metric format sent to CloudWatch.
    - `metric_selectors` is a regular expression that specifies the metrics to be collected and sent to CloudWatch.
    - `dimensions` is the list of labels to be used as CloudWatch dimensions for each selected metric.

The following is an example CloudWatch agent configuration for Prometheus.

```
{
   "logs":{
      "metrics_collected":{
         "prometheus":{
            "cluster_name":"prometheus-cluster",
            "log_group_name":"Prometheus",
            "prometheus_config_path":"C:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\
\prometheus.yaml",
            "emf_processor":{
               "metric_declaration_dedup":true,
               "metric_namespace":"CWAgent-Prometheus",
```

```
                "metric_unit":{
                   "jvm_threads_current": "Count",
                   "jvm_gc_collection_seconds_sum": "Milliseconds"
                },
                "metric_declaration":[
                   {
                      "source_labels":[
                         "job", "key2"
                      ],
                      "label_matcher":"MY_JOB;^value2",
                      "dimensions":[
                         [
                            "key1", "key2"
                         ],
                         [
                            "key2"
                         ]
                      ],
                      "metric_selectors":[
                         "^jvm_threads_current$",
                         "^jvm_gc_collection_seconds_sum$"
                      ]
                   }
                ]
             }
          }
       }
    }
}
```

The previous example configures an embedded metric format section to be sent as a log event if the following conditions are met:

- The value of the label `job` is `MY_JOB`
- The value of the label `key2` is `value2`
- The Prometheus metrics `jvm_threads_current` and `jvm_gc_collection_seconds_sum` contains both `job` and `key2` labels.

The log event that is sent includes the following highlighted section.

```
{
```

```
    "CloudWatchMetrics": [
        {
            "Metrics": [
                {
                    "Unit": "Count",
                    "Name": "jvm_threads_current"
                },
                {
                    "Unit": "Milliseconds",
                    "Name": "jvm_gc_collection_seconds_sum"
                }
            ],
            "Dimensions": [
                [
                    "key1",
                    "key2"
                ],
                [
                    "key2"
                ]
            ],
            "Namespace": "CWAgent-Prometheus"
        }
    ],
    "ClusterName": "prometheus-cluster",
    "InstanceId": "i-0e45bd06f196096c8",
    "Timestamp": "1607966368109",
    "Version": "0",
    "host": "EC2AMAZ-PDDOIUM",
    "instance": "127.0.0.1:9404",
    "jvm_threads_current": 2,
    "jvm_gc_collection_seconds_sum": 0.006000000000000002,
    "prom_metric_type": "gauge",
    ...
}
```

Example: Set up Java/JMX sample workloads for Prometheus metric testing

JMX Exporter is an official Prometheus exporter that can scrape and expose JMX mBeans as Prometheus metrics. For more information, see prometheus/jmx_exporter.

The CloudWatch agent can collect predefined Prometheus metrics from Java Virtual Machine (JVM), Hjava, and Tomcat (Catalina), from a JMX exporter on EC2 instances.

Step 1: Install the CloudWatch agent

The first step is to install the CloudWatch agent on the EC2 instance. For instructions, see Installing the CloudWatch agent.

Step 2: Start the Java/JMX workload

The next step is to start the Java/JMX workload.

First, download the latest JMX exporter jar file from the following location: prometheus/jmx_exporter.

Use the jar for your sample application

The example commands in the following sections use `SampleJavaApplication-1.0-SNAPSHOT.jar` as the jar file. Replace these parts of the commands with the jar for your application.

Prepare the JMX exporter configuration

The `config.yaml` file is the JMX exporter configuration file. For more information, see Configuration in the JMX exporter documentation.

Here is a sample configuration for Java and Tomcat.

```
---
lowercaseOutputName: true
lowercaseOutputLabelNames: true

rules:
- pattern: 'java.lang<type=OperatingSystem><>(FreePhysicalMemorySize|
TotalPhysicalMemorySize|FreeSwapSpaceSize|TotalSwapSpaceSize|SystemCpuLoad|

  name: catalina_session_$3_total
  labels:
    context: "$2"
    host: "$1"
  help: Catalina session $3 total
  type: COUNTER

- pattern: ".*"
```

Start the Java application with the Prometheus exporter

Start the sample application. This will emit Prometheus metrics to port 9404. Be sure to replace the entry point `com.gubupt.sample.app.App` with the correct information for your sample java application.

On Linux, enter the following command.

```
$ nohup java -javaagent:./jmx_prometheus_javaagent-0.14.0.jar=9404:./config.yaml -cp
  ./SampleJavaApplication-1.0-SNAPSHOT.jar com.gubupt.sample.app.App &
```

On Windows, enter the following command.

```
PS C:\> java -javaagent:.\jmx_prometheus_javaagent-0.14.0.jar=9404:.\config.yaml -cp  .
\SampleJavaApplication-1.0-SNAPSHOT.jar com.gubupt.sample.app.App
```

Verify the Prometheus metrics emission

Verify that Prometheus metrics are being emitted.

On Linux, enter the following command.

```
$ curl localhost:9404
```

On Windows, enter the following command.

```
PS C:\> curl  http://localhost:9404
```

Sample output on Linux:

```
StatusCode        : 200
StatusDescription : OK
Content           : # HELP jvm_classes_loaded The number of classes that are currently
 loaded in the JVM
                    # TYPE jvm_classes_loaded gauge
                    jvm_classes_loaded 2526.0

```
Links             : {}
ParsedHtml        : System.__ComObject
RawContentLength  : 71908
```

Step 3: Configure the CloudWatch agent to scrape Prometheus metrics

Next, set up the Prometheus scrape configuration in the CloudWatch agent configuration file.

To set up the Prometheus scrape configuration for the Java/JMX example

1. Set up the configuration for `file_sd_config` and `static_config`.

   On Linux, enter the following command.

   ```
   $ cat /opt/aws/amazon-cloudwatch-agent/var/prometheus.yaml
   global:
     scrape_interval: 1m
     scrape_timeout: 10s
   scrape_configs:
     - job_name: jmx
       sample_limit: 10000
       file_sd_configs:
         - files: [ "/opt/aws/amazon-cloudwatch-agent/var/prometheus_file_sd.yaml" ]
   ```

   On Windows, enter the following command.

   ```
   PS C:\ProgramData\Amazon\AmazonCloudWatchAgent> cat prometheus.yaml
   global:
     scrape_interval: 1m
     scrape_timeout: 10s
   scrape_configs:
     - job_name: jmx
       sample_limit: 10000
       file_sd_configs:
         - files: [ "C:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\
   \prometheus_file_sd.yaml" ]
   ```

2. Set up the scrape targets configuration.

   On Linux, enter the following command.

   ```
   $ cat /opt/aws/amazon-cloudwatch-agent/var/prometheus_file_sd.yaml
   ```

```
- targets:
  - 127.0.0.1:9404
  labels:
    application: sample_java_app
    os: linux
```

On Windows, enter the following command.

```
PS C:\ProgramData\Amazon\AmazonCloudWatchAgent> cat prometheus_file_sd.yaml
- targets:
  - 127.0.0.1:9404
  labels:
    application: sample_java_app
    os: windows
```

3. Set up the Prometheus scrape configuration by `ec2_sc_config`. Replace *your-ec2-instance-id* with the correct EC2 instance ID.

   On Linux, enter the following command.

```
$ cat .\prometheus.yaml
global:
  scrape_interval: 1m
  scrape_timeout: 10s
scrape_configs:
  - job_name: jmx
    sample_limit: 10000
    ec2_sd_configs:
      - region: us-east-1
        port: 9404
        filters:
          - name: instance-id
            values:
              - your-ec2-instance-id
```

   On Windows, enter the following command.

```
PS C:\ProgramData\Amazon\AmazonCloudWatchAgent> cat prometheus_file_sd.yaml
- targets:
  - 127.0.0.1:9404
  labels:
    application: sample_java_app
```

```
    os: windows
```

4. Set up the CloudWatch agent configuration. First, navigate to the correct directory. On Linux, it is `/opt/aws/amazon-cloudwatch-agent/var/cwagent-config.json`. On Windows, it is `C:\ProgramData\Amazon\AmazonCloudWatchAgent\cwagent-config.json`.

   The following is a sample configuration with Java/JHX Prometheus metrics defined. Be sure to replace *`path-to-Prometheus-Scrape-Configuration-file`* with the correct path.

```
{
  "agent": {
    "region": "us-east-1"
  },
  "logs": {
    "metrics_collected": {
      "prometheus": {
        "cluster_name": "my-cluster",
        "log_group_name": "prometheus-test",
        "prometheus_config_path": "path-to-Prometheus-Scrape-Configuration-file",
        "emf_processor": {
          "metric_declaration_dedup": true,
          "metric_namespace": "PrometheusTest",
          "metric_unit":{
            "jvm_threads_current": "Count",
            "jvm_classes_loaded": "Count",
            "java_lang_operatingsystem_freephysicalmemorysize": "Bytes",
            "catalina_manager_activesessions": "Count",
            "jvm_gc_collection_seconds_sum": "Seconds",
            "catalina_globalrequestprocessor_bytesreceived": "Bytes",
            "jvm_memory_bytes_used": "Bytes",
            "jvm_memory_pool_bytes_used": "Bytes"
          },
          "metric_declaration": [
            {
              "source_labels": ["job"],
              "label_matcher": "^jmx$",
              "dimensions": [["instance"]],
              "metric_selectors": [
                "^jvm_threads_current$",
                "^jvm_classes_loaded$",
                "^java_lang_operatingsystem_freephysicalmemorysize$",
                "^catalina_manager_activesessions$",
                "^jvm_gc_collection_seconds_sum$",
```

```
                "^catalina_globalrequestprocessor_bytesreceived$"
              ]
            },
            {
              "source_labels": ["job"],
              "label_matcher": "^jmx$",
              "dimensions": [["area"]],
              "metric_selectors": [
                "^jvm_memory_bytes_used$"
              ]
            },
            {
              "source_labels": ["job"],
              "label_matcher": "^jmx$",
              "dimensions": [["pool"]],
              "metric_selectors": [
                "^jvm_memory_pool_bytes_used$"
              ]
            }
          ]
        }
      }
    },
    "force_flush_interval": 5
  }
}
```

5. Restart the CloudWatch agent by entering one of the following commands.

   On Linux, enter the following command.

   ```
   sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
   config -m ec2 -s -c file:/opt/aws/amazon-cloudwatch-agent/var/cwagent-config.json
   ```

   On Windows, enter the following command.

   ```
   & "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1"
    -a fetch-config -m ec2 -s -c file:C:\ProgramData\Amazon\AmazonCloudWatchAgent
   \cwagent-config.json
   ```

Viewing the Prometheus metrics and logs

You can now view the Java/JMX metrics being collected.

To view the metrics for your sample Java/JMX workload

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the Region where your cluster is running, choose **Metrics** in the left navigation pane. Find the **PrometheusTest** namespace to see the metrics.
3. To see the CloudWatch Logs events, choose **Log groups** in the navigation pane. The events are in the log group **prometheus-test**.

Configure CloudWatch agent service and environment names for related entities

The CloudWatch agent can send metrics and logs with entity data to support the Explore related pane in the CloudWatch console. The service name or environment name can be configured by the CloudWatch Agent JSON configuration.

> **Note**
>
> The agent configuration may be overridden. For details about how the agent decides what data to send for related entities, see Using the CloudWatch agent with related telemetry.

For metrics, it can be configured at the agent, metrics, or plugin level. For logs it can be configured at the agent, logs, or file level. The most specific configuration is always used. For example if the configuration exists at the agent level and metrics level, then metrics will use the metric configuration, and anything else (logs) will use the agent configuration. The following example shows different ways to configure the service name and environment name.

```
{
  "agent": {
    "service.name": "agent-level-service",
    "deployment.environment": "agent-level-environment"
  },

  "metrics": {
    "service.name": "metric-level-service",
     "deployment.environment": "metric-level-environment",
```

```
    "metrics_collected": {
      "statsd": {
        "service.name": "statsd-level-service",
        "deployment.environment": "statsd-level-environment",
      },
      "collectd": {
        "service.name": "collectdd-level-service",
        "deployment.environment": "collectd-level-environment",
      }
    }

  },

  "logs": {
    "service.name": "log-level-service",
    "deployment.environment": "log-level-environment",

    "logs_collected": {
      "files": {
        "collect_list": [
          {
            "file_path": "/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-
agent.log",
            "log_group_name": "amazon-cloudwatch-agent.log",
            "log_stream_name": "amazon-cloudwatch-agent.log",

            "service.name": "file-level-service",
            "deployment.environment": "file-level-environment"
          }
        ]
      }
    }

  }
}
```

Starting the CloudWatch agent

You can start the CloudWatch agent using either Systems Manager Run Command or the command line.

For information about setting up the agent on a system that has security-enhanced Linux (SELinux) enabled, see Set up the CloudWatch agent with security-enhanced Linux (SELinux).

Start the CloudWatch agent using the command line on Amazon EC2

Follow these steps to use the command line to start the CloudWatch agent on on Amazon EC2.

For information about setting up the agent on a system that has security-enhanced Linux (SELinux) enabled, see Set up the CloudWatch agent with security-enhanced Linux (SELinux).

To use the command line to start the CloudWatch agent on on Amazon EC2

1. Copy the agent configuration file that you want to use to the server where you're going to run the agent. Note the pathname where you copy it to.
2. In this command, `-a fetch-config` causes the agent to load the latest version of the CloudWatch agent configuration file, and `-s` starts the agent.

   Enter one of the following commands. Replace *`configuration-file-path`* with the path to the agent configuration file. This file is called `config.json` if you created it with the wizard, and might be called `amazon-cloudwatch-agent.json` if you created it manually.

   On an EC2 instance running Linux, enter the following command.

   ```
   sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
   config -m ec2 -s -c file:configuration-file-path
   ```

   On an on-premises server running Linux, enter the following:

   ```
   sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
   config -m onPremise -s -c file:configuration-file-path
   ```

   On an EC2 instance running Windows Server, enter the following from the PowerShell console:

   ```
   & "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1" -
   a fetch-config -m ec2 -s -c file:configuration-file-path
   ```

   On an on-premises server running Windows Server, enter the following from the PowerShell console:

   ```
   & "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1" -
   a fetch-config -m onPremise -s -c file:configuration-file-path
   ```

Start the CloudWatch agent on an on-premises server

Follow these steps to start the CloudWatch agent on an on-premises server.

To use SSM Agent to start the CloudWatch agent on an on-premises server

1. Open the Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.

   -or-

   If the AWS Systems Manager home page opens, scroll down and choose **Explore Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, select the button next to **AmazonCloudWatch-ManageAgent**.
5. In the **Targets** area, select the instance where you installed the agent.
6. In the **Action** list, choose **configure**.
7. In the **Mode** list, choose **onPremise**.
8. In the **Optional Configuration Location** box, enter the name of the agent configuration file that you created with the wizard and stored in the Parameter Store.
9. Choose **Run**.

   The agent starts with the configuration you specified in the configuration file.

To use the command line to start the CloudWatch agent on an on-premises server

- In this command, `-a fetch-config` causes the agent to load the latest version of the CloudWatch agent configuration file, and `-s` starts the agent.

  Linux: If you saved the configuration file in the Systems Manager Parameter Store, enter the following:

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -m onPremise -s -c ssm:configuration-parameter-store-name
```

Linux: If you saved the configuration file on the local computer, enter the following command. Replace *configuration-file-path* with the path to the agent configuration file. This file is called `config.json` if you created it with the wizard, and might be called `amazon-cloudwatch-agent.json` if you created it manually.

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
config -m onPremise -s -c file:configuration-file-path
```

Windows Server: If you saved the agent configuration file in Systems Manager Parameter Store, enter the following from the PowerShell console:

```
& "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1" -
a fetch-config -m onPremise -s -c ssm:configuration-parameter-store-name
```

Windows Server: If you saved the agent configuration file on the local computer, enter the following from the PowerShell console. Replace *configuration-file-path* with the path to the agent configuration file. This file is called `config.json` if you created it with the wizard, and might be called `amazon-cloudwatch-agent.json` if you created it manually.

```
& "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1" -
a fetch-config -m onPremise -s -c file:configuration-file-path
```

Metrics collected by the CloudWatch agent

You can collect metrics from servers by installing the CloudWatch agent on the server. You can install the agent on both Amazon EC2 instances and on-premises servers. You can also install the agent on computers running Linux, Windows Server, or macOS. If you install the agent on an Amazon EC2 instance, the metrics the agent collects are in addition to the metrics enabled by default on Amazon EC2 instances. For information about installing the CloudWatch agent on an instance, see Collect metrics, logs, and traces using the CloudWatch agent. You can use this section to learn about metrics the CloudWatch agent collects.

Metrics collected by the CloudWatch agent on Windows Server instances

On a server running Windows Server, installing the CloudWatch agent enables you to collect the metrics associated with the counters in Windows Performance Monitor. The CloudWatch metric names for these counters are created by putting a space between the object name and the counter

name. For example, the `% Interrupt Time` counter of the `Processor` object is given the metric name `Processor % Interrupt Time` in CloudWatch. For more information about Windows Performance Monitor counters, see the Microsoft Windows Server documentation.

The default namespace for metrics collected by the CloudWatch agent is `CWAgent`, although you can specify a different namespace when you configure the agent.

Metrics collected by the CloudWatch agent on Linux and macOS instances

The following table lists the metrics that you can collect with the CloudWatch agent on Linux servers and macOS computers.

Metric	Description
`cpu_time_active`	The amount of time that the CPU is active in any capacity. This metric is measured in hundredths of a second. Unit: None
`cpu_time_guest`	The amount of time that the CPU is running a virtual CPU for a guest operating system. This metric is measured in hundredths of a second. Unit: None
`cpu_time_guest_nice`	The amount of time that the CPU is running a virtual CPU for a guest operating system, which is low-priority and can be interrupted by other processes. This metric is measured in hundredths of a second. Unit: None
`cpu_time_idle`	The amount of time that the CPU is idle. This metric is measured in hundredths of a second. Unit: None

Metric	Description
cpu_time_iowait	The amount of time that the CPU is waiting for I/O operations to complete. This metric is measured in hundredths of a second. Unit: None
cpu_time_irq	The amount of time that the CPU is servicing interrupts. This metric is measured in hundredths of a second. Unit: None
cpu_time_nice	The amount of time that the CPU is in user mode with low-priority processes, which can easily be interrupted by higher-priority processes. This metric is measured in hundredths of a second. Unit: None
cpu_time_softirq	The amount of time that the CPU is servicing software interrupts. This metric is measured in hundredths of a second. Unit: None
cpu_time_steal	The amount of time that the CPU is in *stolen time*, which is time spent in other operating systems in a virtualized environment. This metric is measured in hundredths of a second. Unit: None
cpu_time_system	The amount of time that the CPU is in system mode. This metric is measured in hundredths of a second. Unit: None

Metric	Description
cpu_time_user	The amount of time that the CPU is in user mode. This metric is measured in hundredths of a second. Unit: None
cpu_usage_active	The percentage of time that the CPU is active in any capacity. Unit: Percent
cpu_usage_guest	The percentage of time that the CPU is running a virtual CPU for a guest operating system. Unit: Percent
cpu_usage_guest_nice	The percentage of time that the CPU is running a virtual CPU for a guest operating system, which is low-priority and can be interrupted by other processes. Unit: Percent
cpu_usage_idle	The percentage of time that the CPU is idle. Unit: Percent
cpu_usage_iowait	The percentage of time that the CPU is waiting for I/O operations to complete. Unit: Percent
cpu_usage_irq	The percentage of time that the CPU is servicing interrupts. Unit: Percent

Metric	Description
cpu_usage_nice	The percentage of time that the CPU is in user mode with low-priority processes, which higher-priority processes can easily interrupt. Unit: Percent
cpu_usage_softirq	The percentage of time that the CPU is servicing software interrupts. Unit: Percent
cpu_usage_steal	The percentage of time that the CPU is in *stolen time*, or time spent in other operating systems in a virtualized environment. Unit: Percent
cpu_usage_system	The percentage of time that the CPU is in system mode. Unit: Percent
cpu_usage_user	The percentage of time that the CPU is in user mode. Unit: Percent
disk_free	Free space on the disks. Unit: Bytes
disk_inodes_free	The number of available index nodes on the disk. Unit: Count
disk_inodes_total	The total number of index nodes reserved on the disk. Unit: Count

Metric	Description
`disk_inodes_used`	The number of used index nodes on the disk. Unit: Count
`disk_total`	Total space on the disks, including used and free. Unit: Bytes
`disk_used`	Used space on the disks. Unit: Bytes
`disk_used_percent`	The percentage of total disk space that is used. Unit: Percent
`diskio_iops_in_progress`	The number of I/O requests that have been issued to the device driver but have not yet completed. Unit: Count
`diskio_io_time`	The amount of time that the disk has had I/O requests queued. Unit: Milliseconds The only statistic that should be used for this metric is `Sum`. Do not use `Average`.
`diskio_reads`	The number of disk read operations. Unit: Count The only statistic that should be used for this metric is `Sum`. Do not use `Average`.

Metric	Description
diskio_read_bytes	The number of bytes read from the disks. Unit: Bytes The only statistic that should be used for this metric is Sum. Do not use Average.
diskio_read_time	The amount of time that read requests have waited on the disks. Multiple read requests waiting at the same time increase the number. For example, if 5 requests all wait for an average of 100 milliseconds, 500 is reported. Unit: Milliseconds The only statistic that should be used for this metric is Sum. Do not use Average.
diskio_writes	The number disk write operations. Unit: Count The only statistic that should be used for this metric is Sum. Do not use Average.
diskio_write_bytes	The number of bytes written to the disks. Unit: Bytes The only statistic that should be used for this metric is Sum. Do not use Average.

Metric	Description
diskio_write_time	The amount of time that write requests have waited on the disks. Multiple write requests waiting at the same time increase the number. For example, if 8 requests all wait for an average of 1000 milliseconds, 8000 is reported. Unit: Milliseconds The only statistic that should be used for this metric is Sum. Do not use Average.
ethtool_bw_in_allowance_exceeded	The number of packets queued and/or dropped because the inbound aggregate bandwidth exceeded the maximum for the instance. This metric is collected only if you have listed it in the ethtool subsection of the metrics_collected section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None
ethtool_bw_out_allowance_exceeded	The number of packets queued and/or dropped because the outbound aggregate bandwidth exceeded the maximum for the instance. This metric is collected only if you have listed it in the ethtool subsection of the metrics_collected section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None

Metric	Description
ethtool_conntrack_allowance_exceeded	The number of packets dropped because connection tracking exceeded the maximum for the instance and new connections could not be established. This can result in packet loss for traffic to or from the instance. This metric is collected only if you have listed it in the ethtool subsection of the metrics_collected section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None
ethtool_linklocal_allowance_exceeded	The number of packets dropped because the PPS of the traffic to local proxy services exceeded the maximum for the network interface. This impacts traffic to the DNS service, the Instance Metadata Service, and the Amazon Time Sync Service. This metric is collected only if you have listed it in the ethtool subsection of the metrics_collected section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None

Metric	Description
ethtool_pps_allowance_exceeded	The number of packets queued and/or dropped because the bidirectional PPS exceeded the maximum for the instance. This metric is collected only if you have listed it in the ethtool subsection of the metrics_collected section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics. Unit: None
mem_active	The amount of memory that has been used in some way during the last sample period. Unit: Bytes
mem_available	The amount of memory that is available and can be given instantly to processes. Unit: Bytes
mem_available_percent	The percentage of memory that is available and can be given instantly to processes. Unit: Percent
mem_buffered	The amount of memory that is being used for buffers. Unit: Bytes
mem_cached	The amount of memory that is being used for file caches. Unit: Bytes

Metric	Description
mem_free	The amount of memory that isn't being used. Unit: Bytes
mem_inactive	The amount of memory that hasn't been used in some way during the last sample period Unit: Bytes
mem_shared	The amount of memory that is being shared between processes. Unit: Bytes
mem_total	The total amount of memory. Unit: Bytes
mem_used	The amount of memory currently in use. Unit: Bytes
mem_used_percent	The percentage of memory currently in use. Unit: Percent
net_bytes_recv	The number of bytes received by the network interface. Unit: Bytes The only statistic that should be used for this metric is Sum. Do not use Average.
net_bytes_sent	The number of bytes sent by the network interface. Unit: Bytes The only statistic that should be used for this metric is Sum. Do not use Average.

Metric	Description
net_drop_in	The number of packets received by this network interface that were dropped. Unit: Count The only statistic that should be used for this metric is Sum. Do not use Average.
net_drop_out	The number of packets transmitted by this network interface that were dropped. Unit: Count The only statistic that should be used for this metric is Sum. Do not use Average.
net_err_in	The number of receive errors detected by this network interface. Unit: Count The only statistic that should be used for this metric is Sum. Do not use Average.
net_err_out	The number of transmit errors detected by this network interface. Unit: Count The only statistic that should be used for this metric is Sum. Do not use Average.
net_packets_sent	The number of packets sent by this network interface. Unit: Count The only statistic that should be used for this metric is Sum. Do not use Average.

Metric	Description
net_packets_recv	The number of packets received by this network interface. Unit: Count The only statistic that should be used for this metric is Sum. Do not use Average.
netstat_tcp_close	The number of TCP connections with no state. Unit: Count
netstat_tcp_close_wait	The number of TCP connections waiting for a termination request from the client. Unit: Count
netstat_tcp_closing	The number of TCP connections that are waiting for a termination request with acknowledgment from the client. Unit: Count
netstat_tcp_established	The number of TCP connections established. Unit: Count
netstat_tcp_fin_wait1	The number of TCP connections in the FIN_WAIT1 state during the process of closing a connection. Unit: Count
netstat_tcp_fin_wait2	The number of TCP connections in the FIN_WAIT2 state during the process of closing a connection. Unit: Count

Metric	Description
netstat_tcp_last_ack	The number of TCP connections waiting for the client to send acknowledgment of the connectio n termination message. This is the last state right before the connection is closed down. Unit: Count
netstat_tcp_listen	The number of TCP ports currently listening for a connection request. Unit: Count
netstat_tcp_none	The number of TCP connections with inactive clients. Unit: Count
netstat_tcp_syn_sent	The number of TCP connections waiting for a matching connection request after having sent a connection request. Unit: Count
netstat_tcp_syn_recv	The number of TCP connections waiting for connection request acknowledgment after having sent and received a connection request. Unit: Count
netstat_tcp_time_wait	The number of TCP connections currently waiting to ensure that the client received the acknowledgment of its connection termination request. Unit: Count
netstat_udp_socket	The number of current UDP connections. Unit: Count

Metric	Description
processes_blocked	The number of processes that are blocked. Unit: Count
processes_dead	The number of processes that are dead, indicated by the X state code on Linux. This metric is not collected on macOS computers. Unit: Count
processes_idle	The number of processes that are idle (sleeping for more than 20 seconds). Available only on FreeBSD instances. Unit: Count
processes_paging	The number of processes that are paging, indicated by the W state code on Linux. This metric is not collected on macOS computers. Unit: Count
processes_running	The number of processes that are running, indicated by the R state code. Unit: Count
processes_sleeping	The number of processes that are sleeping, indicated by the S state code. Unit: Count
processes_stopped	The number of processes that are stopped, indicated by the T state code. Unit: Count

Metric	Description
processes_total	The total number of processes on the instance. Unit: Count
processes_total_threads	The total number of threads making up the processes. This metric is available only on Linux instances. This metric is not collected on macOS computers. Unit: Count
processes_wait	The number of processes that are paging, indicated by the W state code on FreeBSD instances. This metric is available only on FreeBSD instances, and is not available on Linux, Windows Server, or macOS instances. Unit: Count
processes_zombies	The number of zombie processes, indicated by the Z state code. Unit: Count
swap_free	The amount of swap space that isn't being used. Unit: Bytes
swap_used	The amount of swap space currently in use. Unit: Bytes
swap_used_percent	The percentage of swap space currently in use. Unit: Percent

Definitions of memory metrics collected by the CloudWatch agent

When the CloudWatch agent collects memory metrics, the source is the host's memory management subsystem. For example, the Linux kernel exposes OS-maintained data in `/proc`. For memory, the data is in `/proc/meminfo`.

Each different operating system and architecture has different calculations of the resources that are used by processes. For more information, see the following sections.

During each collection interval, the CloudWatch agent on each instance collects the instance resources and calculates the resources being used by all processes which are running in that instance. This information is reported back to CloudWatch metrics. You can configure the length of the collection interval in the CloudWatch agent configuration file. For more information, see CloudWatch agent configuration file: Agent section.

The following list explains how the memory metrics that the CloudWatch agent collects are defined.

- **Active Memory**– Memory that is being used by a process. In other words, the memory used by current running apps.
- **Available Memory**– The memory that can be instantly given to the processes without the system going into swap (also known as virtual memory).
- **Buffer Memory**– The data area shared by hardware devices or program processes that operate at different speeds and priorities.
- **Cached Memory**– Stores program instructions and data that are used repeatedly in the operation of programs that the CPU is likely to need next.
- **Free Memory**– Memory that is not being used at all and is readily available. It is completely free for the system to be used when needed.
- **Inactive Memory**– Pages that have not been accessed "recently".
- **Total Memory**– The size of the actual physical memory RAM.
- **Used Memory**– Memory that is currently in use by programs and processes.

Topics

- Linux: Metrics collected and calculations used
- macOS: Metrics collected and calculations used
- Windows: Metrics collected

- Example: Calculating memory metrics on Linux

Linux: Metrics collected and calculations used

Metrics collected and units:

- Active (Bytes)
- Available (Bytes)
- Available Percent (Percent)
- Buffered (Bytes)
- Cached (Bytes)
- Free (Bytes)
- Inactive (Bytes)
- Total (Bytes)
- Used (Bytes)
- Used Percent (Percent)

Used memory = Total Memory - Free Memory - Cached memory - Buffer memory

Total memory = Used Memory + Free Memory + Cached memory + Buffer memory

macOS: Metrics collected and calculations used

Metrics collected and units:

- Active (Bytes)
- Available (Bytes)
- Available Percent (Percent)
- Free (Bytes)
- Inactive (Bytes)
- Total (Bytes)
- Used (Bytes)
- Used Percent (Percent)

Available memory = Free Memory + Inactive memory

Used memory = Total Memory - Available memory

Total memory = Available Memory + Used Memory

Windows: Metrics collected

The metrics collected on Windows hosts are listed below. All of these metrics have `None` for `Unit`.

- Available bytes
- Cache Faults/sec
- Page Faults/sec
- Pages/sec

There are no calculations used for Windows metrics because the CloudWatch agent parses events from performance counters.

Example: Calculating memory metrics on Linux

As an example, suppose that entering the **`cat /proc/meminfo`** command on a Linux host shows the following results:

```
MemTotal:       3824388 kB
MemFree:         462704 kB
MemAvailable:   2157328 kB
Buffers:         126268 kB
Cached:         1560520 kB
SReclaimable:    289080 kB>
```

In this example, the CloudWatch agent will collect the following values. All the values that the CloudWatch agent collects and reports are in bytes.

- `mem_total`: 3916173312 bytes
- `mem_available`: 2209103872 bytes (MemFree + Cached)
- `mem_free`: 473808896 bytes
- `mem_cached`: 1893990400 bytes (`cached` + `SReclaimable`
- `mem_used`: 1419075584 bytes (`MemTotal` – (`MemFree` + `Buffers` + (`Cached` + `SReclaimable`)))
- `mem_buffered`: 129667072 bytes

- `mem_available_percent`: 56.41%
- `mem_used_percent`: 36.24% (`mem_used` / `mem_total`) * 100

Using the CloudWatch agent with related telemetry

Metrics and logs that are sent to CloudWatch can include an optional entity to correlate telemetry. Entities are used in the Explore related pane. The CloudWatch agent sends entities with a service name and environment name included.

The agent chooses the service name and environment name from the following data.

Service name

The agent chooses the service name from the following options, in priority order:

- **Application Signals instrumentation** – The agent sends the service name used by Application Signals. This can be overwritten by changing the `OTEL_SERVICE_NAME` environment variable used by supported OpenTelemetry instrumentation libraries.
- **CloudWatch agent configuration** – You can configure the agent to use a specific service name. This can be configured at the agent, plugin, metrics, logs, or log file level.
- **Kubernetes workload name** – For Kubernetes workloads, the agent sends the name of the workload for the corresponding pod, in the following priority order.
  - Deployment name
  - ReplicaSet name
  - StatefulSet name
  - DaemonSet name
  - CronJob name
  - Job name
  - Pod name
  - Container name
- **Resource tags from instance metadata** – For Amazon EC2 workloads, the agent sends the a name from tags, in the following order.
  - service
  - application
  - app

You must setup instance metadata for the agent to be able to access tags.

- **Default** – If no other service name is found, the agent will send the name `Unknown`.

Environment name

The agent chooses the environment name from the following options, in priority order:

- **Application Signals instrumentation** – The agent sends the environment name used by Application Signals. This can be overwritten by setting a `deployment.environment` environment variable used by supported OpenTelemetry instrumentation libraries. For example, applications may set the environment variable `OTEL_RESOURCE_ATTRIBUTES=deployment.environment=MyEnvironment`.
- **CloudWatch agent configuration** – You can configure the agent to use a specific environment name. This can be configured at the agent, plugin, metrics, logs, or log file level.
- **Cluster name and workspace** – For Amazon EKS, `eks:`*`cluster-name`*`/`*`Namespace`*. For native Kubernetes running on Amazon EC2, `k8s:`*`cluster-name`*`/`*`Namespace`*.
- **Resource tags from instance metadata** – For Amazon EC2 workloads, the agent can will use the `AutoScalingGroup` tag.

  You must setup instance metadata for the agent to be able to access tags.
- By default, Amazon EC2 instances that aren't running Kubernetes will get the environment name `ec2:default`.

Common scenarios with the CloudWatch agent

This section provides you with different scenarios that outline how to complete common configuration and customization tasks for the CloudWatch agent.

Topics

- Running the CloudWatch agent as a different user
- How the CloudWatch agent handles sparse log files
- Adding custom dimensions to metrics collected by the CloudWatch agent
- Aggregating or rolling up metrics collected by the CloudWatch agent
- Collecting high-resolution metrics with the CloudWatch agent

- Sending metrics, logs, and traces to a different account
- Timestamp differences between the CloudWatch agent and the earlier CloudWatch Logs agent
- Appending OpenTelemetry collector configuration files

Running the CloudWatch agent as a different user

On Linux servers, the CloudWatch runs as the root user by default. To have the agent run as a different user, use the `run_as_user` parameter in the `agent` section in the CloudWatch agent configuration file. This option is available only on Linux servers.

If you're already running the agent with the root user and want to change to using a different user, use one of the following procedures.

To run the CloudWatch agent as a different user on an EC2 instance running Linux

1. Download and install a new CloudWatch agent package.
2. Create a new Linux user or use the default user named `cwagent` that the RPM or DEB file created.
3. Provide credentials for this user in one of these ways:
   - If the file `.aws/credentials` exists in the home directory of the root user, you must create a credentials file for the user you are going to use to run the CloudWatch agent. This credentials file will be /home/*username*/`.aws/credentials`. Then set the value of the `shared_credential_file` parameter in `common-config.toml` to the pathname of the credential file. For more information, see Install the CloudWatch agent using AWS Systems Manager.
   - If the file `.aws/credentials` does not exist in the home directory of the root user, you can do one of the following:
     - Create a credentials file for the user you are going to use to run the CloudWatch agent. This credentials file will be /home/*username*/`.aws/credentials`. Then set the value of the `shared_credential_file` parameter in `common-config.toml` to the pathname of the credential file. For more information, see Install the CloudWatch agent using AWS Systems Manager.
     - Instead of creating a credentials file, attach an IAM role to the instance. The agent uses this role as the credential provider.
4. In the CloudWatch agent configuration file, add the following line in the `agent` section:

```
"run_as_user": "username"
```

Make other modifications to the configuration file as needed. For more information, see Create the CloudWatch agent configuration file

5. Give the user the required permissions. The user must have Read (r) permissions for the log files to be collected, and must have Execute (x) permission on every directory in the log files' path.
6. Start the agent with the configuration file that you just modified.

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
config -m ec2 -s -c file:configuration-file-path
```

To run the CloudWatch agent as a different user on an on-premises server running Linux

1. Download and install a new CloudWatch agent package.
2. Create a new Linux user or use the default user named `cwagent` that the RPM or DEB file created.
3. Store the credentials of this user to a path that the user can access, such as `/home/username/.aws/credentials`.
4. Set the value of the `shared_credential_file` parameter in `common-config.toml` to the pathname of the credential file. For more information, see Install the CloudWatch agent using AWS Systems Manager.
5. In the CloudWatch agent configuration file, add the following line in the `agent` section:

```
"run_as_user": "username"
```

Make other modifications to the configuration file as needed. For more information, see Create the CloudWatch agent configuration file

6. Give the user required permissions. The user must have Read (r) permissions for the log files to be collected, and must have Execute (x) permission on every directory in the log files' path.
7. Start the agent with the configuration file that you just modified.

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
config -m ec2 -s -c file:configuration-file-path
```

How the CloudWatch agent handles sparse log files

Sparse files are files with both empty blocks and real contents. A sparse file uses disk space more efficiently by writing brief information representing the empty blocks to disk instead of the actual null bytes which makes up the block. This makes the actual size of a sparse file usually much smaller than its apparent size.

However, the CloudWatch agent doesn't treat sparse files differently than it treats normal files. When the agent reads a sparse file, the empty blocks are treated as "real" blocks filled with null bytes. Because of this, the CloudWatch agent publishes as many bytes as the apparent size of a sparse file to CloudWatch.

Configuring the CloudWatch agent to publish a sparse file can cause higher than expected CloudWatch costs, so we recommend not to do so. For example, `/var/logs/lastlog` in Linux is usually a very sparse file, and we recommend that you don't publish it to CloudWatch.

Adding custom dimensions to metrics collected by the CloudWatch agent

To add custom dimensions such as tags to metrics collected by the agent, add the `append_dimensions` field to the section of the agent configuration file that lists those metrics.

For example, the following example section of the configuration file adds a custom dimension named `stackName` with a value of `Prod` to the `cpu` and `disk` metrics collected by the agent.

```
"cpu":{
  "resources":[
    "*"
  ],
  "measurement":[
    "cpu_usage_guest",
    "cpu_usage_nice",
    "cpu_usage_idle"
  ],
  "totalcpu":false,
  "append_dimensions":{
    "stackName":"Prod"
  }
},
"disk":{
  "resources":[
    "/",
    "/tmp"
```

```
  ],
  "measurement":[
    "total",
    "used"
  ],
  "append_dimensions":{
    "stackName":"Prod"
  }
}
```

Remember that any time you change the agent configuration file, you must restart the agent to have the changes take effect.

Aggregating or rolling up metrics collected by the CloudWatch agent

To aggregate or roll up metrics collected by the agent, add an `aggregation_dimensions` field to the section for that metric in the agent configuration file.

For example, the following configuration file snippet rolls up metrics on the `AutoScalingGroupName` dimension. The metrics from all instances in each Auto Scaling group are aggregated and can be viewed as a whole.

```
"metrics": {
  "cpu":{...}
  "disk":{...}
  "aggregation_dimensions" : [["AutoScalingGroupName"]]
}
```

To roll up along the combination of each `InstanceId` and `InstanceType` dimensions in addition to rolling up on the Auto Scaling group name, add the following.

```
"metrics": {
  "cpu":{...}
  "disk":{...}
  "aggregation_dimensions" : [["AutoScalingGroupName"], ["InstanceId", "InstanceType"]]
}
```

To roll up metrics into one collection instead, use `[]`.

```
"metrics": {
  "cpu":{...}
```

```
  "disk":{...}
  "aggregation_dimensions" : [[]]
}
```

Remember that any time you change the agent configuration file, you must restart the agent to have the changes take effect.

Collecting high-resolution metrics with the CloudWatch agent

The `metrics_collection_interval` field specifies the time interval for the metrics collected, in seconds. By specifying a value of less than 60 for this field, the metrics are collected as high-resolution metrics.

For example, if your metrics should all be high-resolution and collected every 10 seconds, specify 10 as the value for `metrics_collection_interval` under the `agent` section as a global metrics collection interval.

```
"agent": {
  "metrics_collection_interval": 10
}
```

Alternatively, the following example sets the `cpu` metrics to be collected every second, and all other metrics are collected every minute.

```
"agent":{
  "metrics_collection_interval": 60
},
"metrics":{
  "metrics_collected":{
    "cpu":{
      "resources":[
        "*"
      ],
      "measurement":[
        "cpu_usage_guest"
      ],
      "totalcpu":false,
      "metrics_collection_interval": 1
    },
    "disk":{
      "resources":[
        "/",
```

```
        "/tmp"
      ],
      "measurement":[
        "total",
        "used"
      ]
    }
  }
}
```

Remember that any time you change the agent configuration file, you must restart the agent to have the changes take effect.

Sending metrics, logs, and traces to a different account

To have the CloudWatch agent send the metrics, logs, or traces to a different account, specify a `role_arn` parameter in the agent configuration file on the sending server. The `role_arn` value specifies an IAM role in the target account that the agent uses when sending data to the target account. This role enables the sending account to assume a corresponding role in the target account when delivering the metrics or logs to the target account.

You can also specify separate `role_arn` strings in the agent configuration file: one to use when sending metrics, another for sending logs, and another for sending traces.

The following example of part of the `agent` section of the configuration file sets the agent to use `CrossAccountAgentRole` when sending data to a different account.

```
{
  "agent": {
    "credentials": {
      "role_arn": "arn:aws:iam::123456789012:role/CrossAccountAgentRole"
    }
  },
  .....
}
```

Alternatively, the following example sets different roles for the sending account to use for sending metrics, logs, and traces:

```
"metrics": {
    "credentials": {
```

```
     "role_arn": "RoleToSendMetrics"
    },
    "metrics_collected": {....
```

```
"logs": {
    "credentials": {
    "role_arn": "RoleToSendLogs"
    },
    ....
```

Policies needed

When you specify a `role_arn` in the agent configuration file, you must also make sure the IAM roles of the sending and target accounts have certain policies. The roles in both the sending and target accounts should have `CloudWatchAgentServerPolicy`. For more information about assigning this policy to a role, see Prerequisites.

The role in the sending account also must include the following policy. You add this policy on the **Permissions** tab in the IAM console when you edit the role.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "sts:AssumeRole"
            ],
            "Resource": [
                "arn:aws:iam::111122223333:role/agent-role-in-target-account"
            ]
        }
    ]
}
```

The role in the target account must include the following policy so that it recognizes the IAM role used by the sending account. You add this policy on the **Trust relationships** tab in the IAM console

when you edit the role. This role is the role specified in *agent-role-in-target-account* in the policy used by the sending account.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::111122223333:role/role-in-sender-account"
                ]
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

Timestamp differences between the CloudWatch agent and the earlier CloudWatch Logs agent

The CloudWatch agent supports a different set of symbols for timestamp formats, compared to the earlier CloudWatch Logs agent. These differences are shown in the following table.

Symbols supported by both agents	Symbols supported only by CloudWatch agent	Symbols supported only by earlier CloudWatch Logs agent
%A, %a, %b, %B, %d, %f, %H, %l, %m, %M, %p, %S, %y, %Y, %Z, %z	%-d, %-l, %-m, %-M, %-S	%c,%j, %U, %W, %w

For more information about the meanings of the symbols supported by the new CloudWatch agent, see CloudWatch Agent Configuration File: Logs Section in the *Amazon CloudWatch User*

Guide. For information about symbols supported by the CloudWatch Logs agent, see Agent Configuration File in the *Amazon CloudWatch Logs User Guide*.

Appending OpenTelemetry collector configuration files

The CloudWatch agent supports supplemental OpenTelemetry collector configuration files alongside its own configuration files. This feature allows you to use CloudWatch agent features such as CloudWatch Application Signals or Container Insights through the CloudWatch agent configuration and bring in your existing OpenTelemetry collector configuration with a single agent.

To prevent merge conflicts with pipelines automatically created by CloudWatch agent, we recommend that you add a custom suffix to each of the components and pipelines in your OpenTelemetry collector configuration.

```
receivers:
  otlp/custom-suffix:
    protocols:
      http:

exporters:
  awscloudwatchlogs/custom-suffix:
    log_group_name: "test-group"
    log_stream_name: "test-stream"

service:
  pipelines:
    logs/custom-suffix:
      receivers: [otlp/custom-suffix]
      exporters: [awscloudwatchlogs/custom-suffix]
```

To configure the CloudWatch agent, start the CloudWatch agent using the `fetch-config` option and specify the CloudWatch agent's configuration file. CloudWatch agent requires at least one CloudWatch agent configuration file.

```
/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -c
 file:/tmp/agent.json -s
```

Next, use the `append-config` option while specifying the OpenTelemetry collector configuration file.

```
/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a append-config -c
 file:/tmp/otel.yaml -s
```

The agent merges the two configuration files on start up and logs the resolved configuration.

CloudWatch agent credentials preference

This section outlines the credentials provider chain the CloudWatch agent uses to obtain credentials when communicating with other AWS services and APIs. The ordering is as follows:

> **Note**
>
> The preferences listed in numbers two through five are the same preference order as defined in the AWS SDK. For more information, see Specifying Credentials in the SDK documentation.

1. Shared config and credentials files as defined in the CloudWatch agent's `common-config.toml` file. For more information, see Install the CloudWatch agent using AWS Systems Manager.
2. AWS SDK environment variables

   > **Important**
   >
   > On Linux, if you run the CloudWatch agent using the `amazon-cloudwatch-agent-ctl` script, the script starts the agent as a `systemd` service. In this case, environment variables such as `HOME`, `AWS_ACCESS_KEY_ID`, and `AWS_SECRET_ACCESS_KEY` are not accessible by the agent.

3. Shared configuration and credentials files found in `$HOME/%USERPROFILE%`

   > **Note**
   >
   > The CloudWatch agent looks for `.aws/credentials` in `$HOME` on Linux and macOS and in `%USERPROFILE%` on Windows. These environment variables resolve to the home directory of the user the agent runs as: `root` on Linux and macOS (or the `run_as_user` if configured), and `LocalSystem` on Windows.
   > Unlike the AWS SDK, the CloudWatch agent does not have fallback methods to determine the home directory if the environment variables are inaccessible.

This difference in behavior is to maintain backwards compatibility with earlier implementations of the AWS SDK.
Furthermore, unlike with the shared credentials found in `common-config.toml`, if the AWS SDK-derived shared credentials expire and are rotated, the renewed credentials are not automatically picked up by the CloudWatch agent and require a restart of the agent to do so.

4. An AWS Identity and Access Management role for tasks if an application is present that uses an Amazon Elastic Container Service task definition or a RunTask API operation.
5. An instance profile attached to an Amazon EC2 instance.

As a best practice, we recommend that you specify credentials in the following order when you use the CloudWatch agent.

1. Use IAM roles for tasks if your application uses an Amazon Elastic Container Service task definition or a RunTask API operation.
2. Use IAM roles if your application runs on an Amazon EC2 instance.
3. Use the CloudWatch agent `common-config.toml` file to specify the credentials file. This credentials file is the same one used by other AWS SDKs and the AWS CLI. If you're already using a shared credentials file, you can also use it for this purpose. If you provide it by using the CloudWatch agent's `common-config.toml` file, you ensure that the agent will consume rotated credentials when they expire and get replaced without requiring you to restart the agent.
4. Use environment variables. Setting environment variables is useful if you're doing development work on a computer other than an Amazon EC2 instance.

Note

If you send telemetry to a different account as explained in Sending metrics, logs, and traces to a different account, the CloudWatch agent uses the credentials provider chain described in this section to obtain the initial set of credentials. It then uses those credentials when assuming the IAM role specified by `role_arn` in the CloudWatch agent configuration file.

Troubleshooting the CloudWatch agent

You can use the information in this section to troubleshoot issues you might encounter with the CloudWatch agent.

When encountering issues with the CloudWatch agent, you can use the `AWSSupport-TroubleshootCloudWatchAgent` automation runbook. The AWS troubleshooting tool can:

- Verify IAM permissions and instance profiles
- Check agent status and analyze logs
- Test endpoint connectivity
- Automatically collect and upload relevant logs to Amazon S3

For detailed information on the AWS troubleshooting tool, see Support Automation Workflow (SAW) Runbook - Troubleshoot CloudWatch agent.

Topics

- CloudWatch agent command line parameters
- Install the CloudWatch agent using Run Command fails
- The CloudWatch agent won't start
- Verify that the CloudWatch agent is running
- The CloudWatch agent won't start, and the error mentions an Amazon EC2 Region
- The CloudWatch agent won't start on Windows Server
- Where are the metrics?
- The CloudWatch agent takes a long time to run in a container or logs a hop limit error
- I updated my agent configuration but don't see the new metrics or logs in the CloudWatch console
- The CloudWatch agent is using the wrong credentials
- CloudWatch agent files and locations
- Finding information about CloudWatch agent versions
- Logs generated by the CloudWatch agent
- Stopping and restarting the CloudWatch agent

CloudWatch agent command line parameters

To see the full list of parameters supported by the CloudWatch agent, enter the following at the command line at a computer where you have it installed:

```
amazon-cloudwatch-agent-ctl -help
```

Install the CloudWatch agent using Run Command fails

To install the CloudWatch agent using Systems Manager Run Command, the SSM Agent on the target server must be version 2.2.93.0 or later of the SSM Agent agent. If your SSM Agent isn't the correct version, you might see errors that include the following messages:

```
no latest version found for package AmazonCloudWatchAgent on platform linux
```

```
failed to download installation package reliably
```

For information about updating your SSM Agent version, see Installing and Configuring SSM Agent in the *AWS Systems Manager User Guide*.

The CloudWatch agent won't start

If the CloudWatch agent fails to start, there might be an issue in your configuration. Configuration information is logged in the `configuration-validation.log` file. This file is located in `/opt/aws/amazon-cloudwatch-agent/logs/configuration-validation.log` on Linux servers and in `$Env:ProgramData\Amazon\AmazonCloudWatchAgent\Logs\configuration-validation.log` on servers running Windows Server.

Verify that the CloudWatch agent is running

You can query the CloudWatch agent to find whether it's running or stopped. You can use AWS Systems Manager to do this remotely. You can also use the command line, but only to check the local server.

To query the status of the CloudWatch agent using Run Command

1. Open the Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.

-or-

If the AWS Systems Manager home page opens, scroll down and choose **Explore Run Command**.

3. Choose **Run command**.
4. In the **Command document** list, choose the button next to **AmazonCloudWatch-ManageAgent**.
5. In the **Action** list, choose **status**.
6. For **Optional Configuration Source** choose **default** and keep **Optional Configuration Location** blank.
7. In the **Target** area, choose the instance to check.
8. Choose **Run**.

If the agent is running, the output resembles the following.

```
{
       "status": "running",
       "starttime": "2017-12-12T18:41:18",
       "version": "1.73.4"
}
```

If the agent is stopped, the `"status"` field displays `"stopped"`.

To query the status of the CloudWatch agent locally using the command line

- On a Linux server, enter the following:

  ```
  sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -m ec2 -a
   status
  ```

  On a server running Windows Server, enter the following in PowerShell as an administrator:

  ```
  & $Env:ProgramFiles\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1 -m
   ec2 -a status
  ```

The CloudWatch agent won't start, and the error mentions an Amazon EC2 Region

If the agent doesn't start and the error message mentions an Amazon EC2 Region endpoint, you might have configured the agent to need access to the Amazon EC2 endpoint without granting that access.

For example, if you specify a value for the `append_dimensions` parameter in the agent configuration file that depends on Amazon EC2 metadata and you use proxies, you must make sure that the server can access the endpoint for Amazon EC2. For more information about these endpoints, see Amazon Elastic Compute Cloud (Amazon EC2) in the *Amazon Web Services General Reference*.

The CloudWatch agent won't start on Windows Server

On Windows Server, you might see the following error:

```
Start-Service : Service 'Amazon CloudWatch Agent (AmazonCloudWatchAgent)' cannot be
 started due to the following
error: Cannot start service AmazonCloudWatchAgent on computer '.'.
At C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1:113
 char:12
+     $svc | Start-Service
+            ~~~~~~~~~~~~~
    + CategoryInfo          : OpenError:
 (System.ServiceProcess.ServiceController:ServiceController) [Start-Service],
   ServiceCommandException
    + FullyQualifiedErrorId :
 CouldNotStartService,Microsoft.PowerShell.Commands.StartServiceCommand
```

To fix this, first make sure that the server service is running. This error can be seen if the agent tries to start when the server service isn't running.

If the server service is already running, the following may be the issue. On some Windows Server installations, the CloudWatch agent takes more than 30 seconds to start. Because Windows Server, by default, allows only 30 seconds for services to start, this causes the agent to fail with an error similar to the following:

To fix this issue, increase the service timeout value. For more information, see A service does not start, and events 7000 and 7011 are logged in the Windows event log.

Where are the metrics?

If the CloudWatch agent has been running but you can't find metrics collected by it in the AWS Management Console or the AWS CLI, confirm that you're using the correct namespace. By default, the namespace for metrics collected by the agent is `CWAgent`. You can customize this namespace using the `namespace` field in the `metrics` section of the agent configuration file. If you don't see the metrics that you expect, check the configuration file to confirm the namespace being used.

When you first download the CloudWatch agent package, the agent configuration file is `amazon-cloudwatch-agent.json`. This file is in the directory where you ran the configuration wizard, or you might have moved it to a different directory. If you use the configuration wizard, the agent configuration file output from the wizard is named `config.json`. For more information about the configuration file, including the `namespace` field, see CloudWatch agent configuration file: Metrics section.

The CloudWatch agent takes a long time to run in a container or logs a hop limit error

When you run the CloudWatch agent as a container service and want to add Amazon EC2 metric dimensions to all metrics collected by the agent, you might see the following errors in version v1.247354.0 of the agent:

```
2022-06-07T03:36:11Z E! [processors.ec2tagger] ec2tagger: Unable to retrieve Instance
 Metadata Tags. This plugin must only be used on an EC2 instance.
2022-06-07T03:36:11Z E! [processors.ec2tagger] ec2tagger: Please increase hop limit
 to 2 by following this document https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/
configuring-instance-metadata-options.html#configuring-IMDS-existing-instances.
2022-06-07T03:36:11Z E! [telegraf] Error running agent: could not initialize processor
 ec2tagger: EC2MetadataRequestError: failed to get EC2 instance identity document
caused by: EC2MetadataError: failed to make EC2Metadata request
        status code: 401, request id:
caused by:
```

You might see this error if the agent tries to get metadata from IMDSv2 inside a container without an appropriate hop limit. In versions of the agent earlier than v1.247354.0, you can experience this issue without seeing the log message.

To solve this, increase the hop limit to 2 by following the instructions in Configure the instance metadata options.

I updated my agent configuration but don't see the new metrics or logs in the CloudWatch console

If you update your CloudWatch agent configuration file, the next time that you start the agent, you need to use the **`fetch-config`** option. For example, if you stored the updated file on the local computer, enter the following command:

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -s -m ec2 -c file:configuration-file-path
```

The CloudWatch agent is using the wrong credentials

If the CloudWatch agent is using unexpected credentials, the agent may be resolving credentials from a different source than you expect. The agent follows a credentials provider chain that differs from the AWS SDK in some cases. For more information, see CloudWatch agent credentials preference.

CloudWatch agent files and locations

The following table lists the files installed by and used with the CloudWatch agent, along with their locations on servers running Linux or Windows Server.

File	Linux location	Windows Server location
The control script that controls starting, stopping, and restarting the agent.	`/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl` or `/usr/bin/amazon-cloudwatch-agent-ctl`	`$Env:ProgramFiles\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1`
The log file the agent writes to. You might need to attach this when contacting AWS Support.	`/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-agent.log` or `/var/log/amazon/amazon-cloudwatch-agent/`	`$Env:ProgramData\Amazon\AmazonCloudWatchAgent\Logs\amazon-cloudwatch-agent.log`

File	Linux location	Windows Server location
	amazon-cloudwatch-agent.log	
Agent configuration validation file.	/opt/aws/amazon-cloudwatch-agent/logs/configuration-validation.log or /var/log/amazon/amazon-cloudwatch-agent/configuration-validation.log	$Env:ProgramData\Amazon\AmazonCloudWatchAgent\Logs\configuration-validation.log
The JSON file used to configure the agent immediately after the wizard creates it. For more information, see Create the CloudWatch agent configuration file.	/opt/aws/amazon-cloudwatch-agent/bin/config.json	$Env:ProgramFiles\Amazon\AmazonCloudWatchAgent\config.json
The JSON file used to configure the agent if this configuration file has been downloaded from Parameter Store.	/opt/aws/amazon-cloudwatch-agent/etc/amazon-cloudwatch-agent.json or /etc/amazon/amazon-cloudwatch-agent/amazon-cloudwatch-agent.json	$Env:ProgramData\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent.json
The TOML file used to specify Region and credential information to be used by the agent, overriding system defaults.	/opt/aws/amazon-cloudwatch-agent/etc/common-config.toml or /etc/amazon/amazon-cloudwatch-agent/common-config.toml	$Env:ProgramData\Amazon\AmazonCloudWatchAgent\common-config.toml

File	Linux location	Windows Server location
The TOML file that contains the converted contents of the JSON configuration file. The amazon-cloudwatch-agent-ctl script generates this file. Users should not directly modify this file. It can be useful for verifying that JSON to TOML translation was successful.	/opt/aws/amazon-cloudwatch-agent/etc/amazon-cloudwatch-agent.toml or /etc/amazon/amazon-cloudwatch-agent/amazon-cloudwatch-agent.toml	$Env:ProgramData\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent.toml
The YAML file that contains the converted contents of the JSON configuration file. The amazon-cloudwatch-agent-ctl script generates this file. You should not directly modify this file. This file can be useful for verifying that the JSON to YAML translation was successful.	/opt/aws/amazon-cloudwatch-agent/etc/amazon-cloudwatch-agent.yaml or /etc/amazon/amazon-cloudwatch-agent/amazon-cloudwatch-agent.yaml	$Env:ProgramData\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent.yaml

Finding information about CloudWatch agent versions

To find the version number of the CloudWatch agent on a Linux server, enter the following command:

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a status
```

To find the version number of the CloudWatch agent on Windows Server, enter the following command:

```
& $Env:ProgramFiles\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1 -m ec2
 -a status
```

> **Note**
>
> Using this command is the correct way to find the version of the CloudWatch agent. If you use **Programs and Features** in the Control Panel, you will see an incorrect version number.

You can also download a README file about the latest changes to the agent, and a file that indicates the version number that is currently available for download. These files are in the following locations:

- `https://amazoncloudwatch-agent.s3.amazonaws.com/info/latest/RELEASE_NOTES` or `https://amazoncloudwatch-agent-us-east-1.s3.us-east-1.amazonaws.com/info/latest/RELEASE_NOTES`
- `https://amazoncloudwatch-agent.s3.amazonaws.com/info/latest/CWAGENT_VERSION` or `https://amazoncloudwatch-agent-us-east-1.s3.us-east-1.amazonaws.com/info/latest/CWAGENT_VERSION`

Logs generated by the CloudWatch agent

The agent generates a log while it runs. This log includes troubleshooting information. This log is the `amazon-cloudwatch-agent.log` file. This file is located in `/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-agent.log` on Linux servers and in `$Env:ProgramData\Amazon\AmazonCloudWatchAgent\Logs\amazon-cloudwatch-agent.log` on servers running Windows Server.

You can configure the agent to log additional details in the `amazon-cloudwatch-agent.log` file. In the agent configuration file, in the `agent` section, set the `debug` field to `true`, then reconfigure and restart the CloudWatch agent. To disable the logging of this extra information, set the `debug` field to `false`. Then, reconfigure and restart the agent. For more information, see Manually create or edit the CloudWatch agent configuration file.

In versions 1.247350.0 and later of the CloudWatch agent, you can optionally set the `aws_sdk_log_level` field in the `agent` section of the agent configuration file to one or more of the following options. Separate multiple options with the `|` character.

- `LogDebug`
- `LogDebugWithSigning`
- `LogDebugWithHTTPBody`
- `LogDebugRequestRetries`
- `LogDebugWithEventStreamBody`

For more information about these options, see LogLevelType.

Stopping and restarting the CloudWatch agent

You can manually stop the CloudWatch agent using either AWS Systems Manager or the command line.

To stop the CloudWatch agent using Run Command

1. Open the Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. In the navigation pane, choose **Run Command**.

   -or-

   If the AWS Systems Manager home page opens, scroll down and choose **Explore Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, choose **AmazonCloudWatch-ManageAgent**.
5. In the **Targets** area, choose the instance where you installed the CloudWatch agent.
6. In the **Action** list, choose **stop**.
7. Keep **Optional Configuration Source** and **Optional Configuration Location** blank.
8. Choose **Run**.

To stop the CloudWatch agent locally using the command line

- On a Linux server, enter the following:

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -m ec2 -a
 stop
```

On a server running Windows Server, enter the following in PowerShell as an administrator:

```
& $Env:ProgramFiles\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1 -m
 ec2 -a stop
```

To restart the agent, follow the instructions in (Optional) Modify the common configuration and named profile for CloudWatch agent.

Embedding metrics within logs

The CloudWatch embedded metric format allows you to generate custom metrics asynchronously in the form of logs written to CloudWatch Logs. You can embed custom metrics alongside detailed log event data, and CloudWatch automatically extracts the custom metrics so that you can visualize and alarm on them, for real-time incident detection. Additionally, the detailed log events associated with the extracted metrics can be queried using CloudWatch Logs Insights to provide deep insights into the root causes of operational events.

Embedded metric format helps you generate actionable custom metrics from ephemeral resources such as Lambda functions and containers. By using the embedded metric format to send logs from these ephemeral resources, you can now easily create custom metrics without having to instrument or maintain separate code, while gaining powerful analytical capabilities on your log data.

No setup is required to use the embedded metric format. Either structure your logs by following the Embedded metric format specification, or generate them using our client libraries and send them to CloudWatch Logs using the PutLogEvents API or the CloudWatch agent.

To generate metrics from logs with embedded metric format, you need the `logs:PutLogEvents` permission but you don't need to also have the `cloudwatch:PutMetricData` permission.

Charges are incurred for logs ingestion and archival, and custom metrics that are generated. For more information, see Amazon CloudWatch Pricing.

> **Note**
>
> Be careful when configuring your metric extraction as it impacts your custom metric usage and corresponding bill. If you unintentionally create metrics based on high-cardinality dimensions (such as `requestId`), the embedded metric format will by design

create a custom metric corresponding to each unique dimension combination. For more information, see Dimensions.

The following topics describe how to publish logs using the embedded metric format, view your metrics and logs in the console, and set alarms on metrics created with the embedded metric format.

Topics

- Publishing logs with the embedded metric format
- Viewing your metrics and logs in the console
- Setting alarms on metrics created with the embedded metric format

Publishing logs with the embedded metric format

You can generate embedded metric format logs using the following methods:

- Generate and send the logs by using the open-sourced client libraries.
- Manually generate the logs using the embedded metric format specification, and then use the CloudWatch agent or the PutLogEvents API to send the logs.

The following topics provide more information about embedded metrics.

Topics

- Creating logs in embedded metric format using the client libraries
- Specification: Embedded metric format
- Using the PutLogEvents API to send manually-created embedded metric format logs
- Using the CloudWatch agent to send embedded metric format logs
- Using the embedded metric format with AWS Distro for OpenTelemetry

Creating logs in embedded metric format using the client libraries

You can use the open-sourced client libraries that Amazon provides to create embedded metric format logs. Full examples for different setups can be found in our client libraries under **/ examples**. The libraries and the instructions for how to use them are located on Github.

- Node.Js

> **Note**
>
> For Node.js, versions 4.1.1+, 3.0.2+, 2.0.7+ are required for use with the Lambda JSON log format. Using previous versions in such Lambda environments will lead to metric loss. For more information, see Accessing Amazon CloudWatch logs for AWS Lambda.

- Python
- Java
- C#

Client libraries are meant to work out of the box with the CloudWatch agent. Generated embedded metric format logs are sent to the CloudWatch agent, which then aggregates and publishes them to CloudWatch Logs for you.

> **Note**
>
> When using Lambda, no agent is required to send the logs to CloudWatch. Anything logged to STDOUT is sent to CloudWatch Logs via the Lambda Logging Agent.

Specification: Embedded metric format

The CloudWatch embedded metric format is a JSON specification used to instruct CloudWatch Logs to automatically extract metric values embedded in structured log events. You can use CloudWatch to graph and create alarms on the extracted metric values. This section describes embedded metric format specification conventions and the embedded metric format document structure.

Embedded metric format specification conventions

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this format specification are to be interpreted as described in Key Words RFC2119.

The terms "JSON", "JSON text", "JSON value", "member", "element", "object", "array", "number", "string", "boolean", "true", "false", and "null" in this format specification are to be interpreted as defined in JavaScript Object Notation RFC8259.

> **Note**
>
> If you plan to create alarms on metrics created using embedded metric format, see Setting alarms on metrics created with the embedded metric format for recommendations.

Embedded metric format document structure

This section describes the structure of an embedded metric format document. Embedded metric format documents are defined in JavaScript Object Notation RFC8259.

Unless otherwise noted, objects defined by this specification MUST NOT contain any additional members. Members not recognized by this specification MUST be ignored. Members defined in this specification are case-sensitive.

The embedded metric format is subject to the same limits as standard CloudWatch Logs events and are limited to a maximum size of 1 MB.

With the embedded metric format, you can track the processing of your EMF logs by metrics that are published in the `AWS/Logs` namespace of your account. These can be used to track failed metric generation from EMF, as well as whether failures happen due to parsing or validation. For more details see Monitoring with CloudWatch metrics.

Root node

The LogEvent message MUST be a valid JSON object with no additional data at the beginning or end of the LogEvent message string. For more information about the LogEvent structure, see InputLogEvent.

Embedded metric format documents MUST contain the following top-level member on the root node. This is a Metadata object object.

```
{
 "_aws": {
    "CloudWatchMetrics": [ ... ]
  }
}
```

The root node MUST contain all Target members members defined by the references in the MetricDirective object.

The root node MAY contain any other members that are not included in the above requirements. The values of these members MUST be valid JSON types.

Metadata object

The `_aws` member can be used to represent metadata about the payload that informs downstream services how they should process the LogEvent. The value MUST be an object and MUST contain the following members:

- **CloudWatchMetrics**— An array of MetricDirective object used to instruct CloudWatch to extract metrics from the root node of the LogEvent.

```
{
  "_aws": {
    "CloudWatchMetrics": [ ... ]
  }
}
```

- **Timestamp**— A number representing the time stamp used for metrics extracted from the event. Values MUST be expressed as the number of milliseconds after Jan 1, 1970 00:00:00 UTC.

```
{
  "_aws": {
    "Timestamp": 1559748430481
  }
}
```

MetricDirective object

The MetricDirective object instructs downstream services that the LogEvent contains metrics that will be extracted and published to CloudWatch. MetricDirectives MUST contain the following members:

- **Namespace**— A string representing the CloudWatch namespace for the metric.
- **Dimensions**— A DimensionSet array.
- **Metrics**— An array of MetricDefinition objects. This array MUST NOT contain more than 100 MetricDefinition objects.

DimensionSet array

A DimensionSet is an array of strings containing the dimension keys that will be applied to all metrics in the document. The values within this array MUST also be members on the root-node—referred to as the Target members

A DimensionSet MUST NOT contain more than 30 dimension keys. A DimensionSet MAY be empty.

The target member MUST have a string value. This value MUST NOT contain more than 1024 characters. The target member defines a dimension that will be published as part of the metric identity. Every DimensionSet used creates a new metric in CloudWatch. For more information about dimensions, see Dimension and Dimensions.

```
{
 "_aws": {
   "CloudWatchMetrics": [
     {
       "Dimensions": [ [ "functionVersion" ] ],
       ...
     }
   ]
 },
 "functionVersion": "$LATEST"
}
```

> **Note**
>
> Be careful when configuring your metric extraction as it impacts your custom metric usage and corresponding bill. If you unintentionally create metrics based on high-cardinality dimensions (such as `requestId`), the embedded metric format will by design create a custom metric corresponding to each unique dimension combination. For more information, see Dimensions.

MetricDefinition object

A MetricDefinition is an object that MUST contain the following member:

- **Name**— A string Reference values to a metric Target members. Metric targets MUST be either a numeric value or an array of numeric values.

A MetricDefinition object MAY contain the following members:

- **Unit**— An OPTIONAL string value representing the unit of measure for the corresponding metric. Values SHOULD be valid CloudWatch metric units. For information about valid units, see MetricDatum. If a value is not provided, then a default value of NONE is assumed.
- **StorageResolution**— An OPTIONAL integer value representing the storage resolution for the corresponding metric. Setting this to 1 specifies this metric as a high-resolution metric, so that CloudWatch stores the metric with sub-minute resolution down to one second. Setting this to 60 specifies this metric as standard-resolution, which CloudWatch stores at 1-minute resolution. Values SHOULD be valid CloudWatch supported resolutions, 1 or 60. If a value is not provided, then a default value of 60 is assumed.

  For more information about high-resolution metrics, see High-resolution metrics.

> **Note**
>
> If you plan to create alarms on metrics created using embedded metric format, see Setting alarms on metrics created with the embedded metric format for recommendations.

```
{
  "_aws": {
    "CloudWatchMetrics": [
      {
        "Metrics": [
          {
            "Name": "Time",
            "Unit": "Milliseconds",
            "StorageResolution": 60
          }
        ],
        ...
      }
    ]
  },
  "Time": 1
}
```

Reference values

Reference values are string values that reference Target members members on the root node. These references should NOT be confused with the JSON Pointers described in RFC6901. Target values cannot be nested.

Target members

Valid targets MUST be members on the root node and cannot be nested objects. For example, a _reference_ value of `"A.a"` MUST match the following member:

```
{ "A.a" }
```

It MUST NOT match the nested member:

```
{ "A": { "a" } }
```

Valid values of target members depend on what is referencing them. A metric target MUST be a numeric value or an array of numeric values. Numeric array metric targets MUST NOT have more than 100 members. A dimension target MUST have a string value.

Embedded metric format example and JSON schema

The following is a valid example of embedded metric format.

```
{
  "_aws": {
    "Timestamp": 1574109732004,
    "CloudWatchMetrics": [
      {
        "Namespace": "lambda-function-metrics",
        "Dimensions": [["functionVersion"]],
        "Metrics": [
          {
            "Name": "time",
            "Unit": "Milliseconds",
            "StorageResolution": 60
          }
        ]
      }
    ]
```

```
  },
  "functionVersion": "$LATEST",
  "time": 100,
  "requestId": "989ffbf8-9ace-4817-a57c-e4dd734019ee"
}
```

You can use the following schema to validate embedded metric format documents.

```
{
    "type": "object",
    "title": "Root Node",
    "required": [
        "_aws"
    ],
    "properties": {
        "_aws": {
            "$id": "#/properties/_aws",
            "type": "object",
            "title": "Metadata",
            "required": [
                "Timestamp",
                "CloudWatchMetrics"
            ],
            "properties": {

Second|Gigabits\\/Second|Terabits\\/Second|Count\\/Second|None)$"
                                        },
                                        "StorageResolution": {
                                            "$id": "#/properties/_aws/properties/
CloudWatchMetrics/items/properties/Metrics/items/properties/StorageResolution",
                                            "type": "integer",
                                            "title": "StorageResolution",
```

```
                                        "examples": [
                                            60
                                        ]
                                    }
                                }
                            }
                        }
                    }
                }
            }
        }
    }
}
```

Entity information in EMF format

When you publish logs to Amazon CloudWatch using Embedded Metric Format (EMF), you can include entity information in the log event. This section describes how to specify entity information and how CloudWatch processes this information.

Entity types

When no Entity is specified with the `PutLogEvents` request, CloudWatch will look for entity information in the EMF log content:

- **Service-type entities**

  Required fields: `Service` and `Environment`
- **Resource-type entities**

  Required fields: `ResourceType` and `Identifier`

Platform attributes

CloudWatch automatically determines the platform type based on these attributes:

- **Kubernetes (K8s):**

  Required: `K8s.Cluster`

Optional: `K8s.Namespace`, `K8s.Workload`, `K8s.Node`, `K8s.Pod`, `EC2.InstanceId`, `EC2.AutoScalingGroup`

- **Amazon EKS**

  Required: `EKS.Cluster`

  Optional: `K8s.Namespace`, `K8s.Workload`, `K8s.Node`, `K8s.Pod`, `EC2.InstanceId`
- **Amazon ECS:**

  Required: `ECS.Cluster`

  Optional: `ECS.Service`, `ECS.Task`
- **Amazon EC2**

  Required: `EC2.InstanceId`

  Optional: `EC2.AutoScalingGroup`
- **Lambda:**

  Required: `Lambda.Function`
- **Generic hosts:**

  Required: `Host`

Example EMF log format

```
{
    "_aws": {
        "CloudWatchMetrics": [
            {
                "Metrics": [
                    {"Name": "RequestLatency", "Unit": "Milliseconds"}
                ],
                "Namespace": "MyApplication"
            }
        ]
    },
    "Service": "PaymentService",
    "Environment": "Production",
```

```
    "K8s.Cluster": "main-cluster",
    "K8s.Namespace": "payment-ns",
    "K8s.Pod": "payment-pod-123",
    "K8s.Node": "worker-node-1",
    "K8s.Workload": "payment-deployment",
    "RequestLatency": 135.5,
    "timestamp": 1622163600000
}
```

Generated Entity

The above EMF log will generate the following Entity:

```
{
    "KeyAttributes": {
        "Type": "Service",
        "Name": "PaymentService",
        "Environment": "Production"
    },
    "Attributes": {
        "PlatformType": "K8s",
        "K8s.Cluster": "main-cluster",
        "K8s.Namespace": "payment-ns",
        "K8s.Pod": "payment-pod-123",
        "K8s.Node": "worker-node-1",
        "K8s.Workload": "payment-deployment"
    }
}
```

Entity processing

CloudWatch processes the entity information as follows:

- **KeyAttributes:**
  - Determines entity type based on required fields
  - For Service-type, extracts Service name and Environment
  - These become the primary identifiers for the entity
- **Attributes:**
  - Sets PlatformType based on included platform attributes
  - Includes all relevant platform-specific information

- Maintains relationship context for the telemetry data

CloudWatch uses this entity information to establish relationships between different pieces of telemetry data, enabling enhanced observability and contextual analysis of your applications and infrastructure. For more information, see How to add related information to custom telemetry sent to CloudWatch .

> **Note**
>
> Entity information helps CloudWatch create a complete picture of your application's telemetry data and its relationships within your infrastructure.

Using the PutLogEvents API to send manually-created embedded metric format logs

You can send embedded metric format logs to CloudWatch Logs using the CloudWatch Logs PutLogEvents API. When calling PutLogEvents, you have the option to include the following HTTP header, which tells CloudWatch Logs the metrics should be extracted, but it's not required.

```
x-amzn-logs-format: json/emf
```

The following is a full example using the AWS SDK for Java 2.x:

```
package org.example.basicapp;

import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cloudwatchlogs.CloudWatchLogsClient;
import software.amazon.awssdk.services.cloudwatchlogs.model.DescribeLogStreamsRequest;
import software.amazon.awssdk.services.cloudwatchlogs.model.DescribeLogStreamsResponse;
import software.amazon.awssdk.services.cloudwatchlogs.model.InputLogEvent;
import software.amazon.awssdk.services.cloudwatchlogs.model.PutLogEventsRequest;

import java.util.Collections;

public class EmbeddedMetricsExample {
        public static void main(String[] args) {

                final String usage = "To run this example, supply a Region code (eg.
 us-east-1), log group, and stream name as command line arguments"
```

```
                                + "Ex: PutLogEvents <region-id> <log-group-name>
 <stream-name>";

                if (args.length != 3) {
                        System.out.println(usage);
                        System.exit(1);
                }

                String regionId = args[0];
                String logGroupName = args[1];
                String logStreamName = args[2];

                CloudWatchLogsClient logsClient =
 CloudWatchLogsClient.builder().region(Region.of(regionId)).build();

                // Build a JSON log using the EmbeddedMetricFormat.
                long timestamp = System.currentTimeMillis();
                String message = "{" +
                                "  \"_aws\": {" +
                                "    \"Timestamp\": " + timestamp  + "," +
                                "    \"CloudWatchMetrics\": [" +
                                "      {" +
                                "        \"Namespace\": \"MyApp\"," +
                                "        \"Dimensions\": [[\"Operation\"], [\"Operation
\", \"Cell\"]]," +
                                "        \"Metrics\": [{ \"Name\": \"ProcessingLatency
\", \"Unit\": \"Milliseconds\", \"StorageResolution\": 60 }]" +
                                "      }" +
                                "    ]" +
                                "  }," +
                                "  \"Operation\": \"Aggregator\"," +
                                "  \"Cell\": \"001\"," +
                                "  \"ProcessingLatency\": 100" +
                                "}";
                InputLogEvent inputLogEvent = InputLogEvent.builder()
                        .message(message)
                        .timestamp(timestamp)
                        .build();

                // Specify the request parameters.
                PutLogEventsRequest putLogEventsRequest = PutLogEventsRequest.builder()
                        .logEvents(Collections.singletonList(inputLogEvent))
                        .logGroupName(logGroupName)
                        .logStreamName(logStreamName)
```

```
                        .build();

                logsClient.putLogEvents(putLogEventsRequest);

                System.out.println("Successfully put CloudWatch log event");
        }

}
```

> **Note**
>
> With the embedded metric format, you can track the processing of your EMF logs by metrics that are published in the AWS/Logs namespace of your account. These can be used to track failed metric generation from EMF, as well as whether failures happen due to parsing or validation. For more details see Monitoring with CloudWatch metrics.

Using the CloudWatch agent to send embedded metric format logs

This section describes how to install and use the CloudWatch agent. The first part of this section describes how to install the CloudWatch agent. The the second part of this section describes how to use the CloudWatch agent to send embedded metric format logs. If you want to use this method, you must install the CloudWatch agent for the AWS services you want to send embedded metric format logs from. Then you can begin sending the events. The CloudWatch agent must be version 1.230621.0 or later.

> **Note**
>
> You do not need to install the CloudWatch agent to send logs from Lambda functions. Lambda function timeouts are not handled automatically. This means that if your function times out before the metrics get flushed, then the metrics for that invocation will not be captured.

Installing the CloudWatch agent

Install the CloudWatch agent for each service which is to send embedded metric format logs.

Installing the CloudWatch agent on EC2

First, install the CloudWatch agent on the instance. For more information, see Installing the CloudWatch agent.

Once you have installed the agent, configure the agent to listen on a UDP or TCP port for the embedded metric format logs. The following is an example of this configuration that listens on the default socket `tcp:25888`. For more information about agent configuration, see Manually create or edit the CloudWatch agent configuration file.

```
{
  "logs": {
    "metrics_collected": {
      "emf": { }
    }
  }
}
```

Installing the CloudWatch agent on Amazon ECS

The easiest way to deploy the CloudWatch agent on Amazon ECS is to run it as a sidecar, defining it in the same task definition as your application.

Create agent configuration file

Create your CloudWatch agent configuration file locally. In this example, the relative file path will be `amazon-cloudwatch-agent.json`.

For more information about agent configuration, see Manually create or edit the CloudWatch agent configuration file.

```
{
  "logs": {
    "metrics_collected": {
      "emf": { }
    }
  }
}
```

Push configuration to SSM Parameter Store

Enter the following command to push the CloudWatch agent configuration file to the AWS Systems Manager (SSM) Parameter Store.

```
aws ssm put-parameter \
    --name "cwagentconfig" \
    --type "String" \
    --value "`cat amazon-cloudwatch-agent.json`" \
    --region "{{region}}"
```

Configure the task definition

Configure your task definition to use the CloudWatch Agent and expose the TCP or UDP port. The sample task definition that you should use depends on your networking mode.

Notice that the `webapp` specifies the `AWS_EMF_AGENT_ENDPOINT` environment variable. This is used by the library and should point to the endpoint that the agent is listening on. Additionally, the `cwagent` specifies the `CW_CONFIG_CONTENT` as a "valueFrom" parameter that points to the SSM configuration that you created in the previous step.

This section contains one example for bridge mode and one example for host or awsvpc mode. For more examples of how you can configure the CloudWatch agent on Amazon ECS, see the Github samples repository

The following is an example for bridge mode. When bridge mode networking is enabled, the agent needs to be linked to your application using the `links` parameter and must be addressed using the container name.

```
{
  "containerDefinitions": [
          {
              "name": "webapp",
              "links": [ "cwagent" ],
              "image": "my-org/web-app:latest",
              "memory": 256,
              "cpu": 256,
              "environment": [{
                "name": "AWS_EMF_AGENT_ENDPOINT",
                "value": "tcp://cwagent:25888"
              }],
          },
          {
```

```
            "name": "cwagent",
            "mountPoints": [],
            "image": "public.ecr.aws/cloudwatch-agent/cloudwatch-agent:latest",
            "memory": 256,
            "cpu": 256,
            "portMappings": [{
                "protocol": "tcp",
                "containerPort": 25888
            }],
            "environment": [{
              "name": "CW_CONFIG_CONTENT",
              "valueFrom": "cwagentconfig"
            }],
        }
    ],
}
```

The following is an example for host mode or awsvpc mode. When running on these network modes, the agent can be addressed over `localhost`.

```
{
  "containerDefinitions": [
          {
              "name": "webapp",
              "image": "my-org/web-app:latest",
              "memory": 256,
              "cpu": 256,
              "environment": [{
                "name": "AWS_EMF_AGENT_ENDPOINT",
                "value": "tcp://127.0.0.1:25888"
              }],
          },
          {
              "name": "cwagent",
              "mountPoints": [],
              "image": "public.ecr.aws/cloudwatch-agent/cloudwatch-agent:latest",
              "memory": 256,
              "cpu": 256,
              "portMappings": [{
                  "protocol": "tcp",
                  "containerPort": 25888
              }],
              "environment": [{
```

```
                "name": "CW_CONFIG_CONTENT",
                "valueFrom": "cwagentconfig"
            }],
        }
    ],
}
```

Note

In awsvpc mode, you must either give a public IP address to the VPC (Fargate only), set up a NAT gateway, or set up a CloudWatch Logs VPC endpoint. For more information about setting up a NAT, see NAT Gateways. For more information about setting up a CloudWatch Logs VPC endpoint, see Using CloudWatch Logs with Interface VPC Endpoints.
The following is an example of how to assign a public IP address to a task that uses the Fargate launch type.

```
aws ecs run-task \
--cluster {{cluster-name}} \
--task-definition cwagent-fargate \
--region {{region}} \
--launch-type FARGATE \
--network-configuration
 "awsvpcConfiguration={subnets=[{{subnetId}}],securityGroups=[{{sgId}}],assignPublicIp=ENA
```

Ensure permissions

Ensure the IAM role executing your tasks has permission to read from the SSM Parameter Store. You can add this permission by attaching the **AmazonSSMReadOnlyAccess** policy. To do so, enter the following command.

```
aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/AmazonSSMReadOnlyAccess
 \
--role-name CWAgentECSExecutionRole
```

Installing the CloudWatch agent on Amazon EKS

Parts of this process can be skipped if you have already installed CloudWatch Container Insights on this cluster.

Permissions

If you have not already installed Container Insights, then first ensure that your Amazon EKS nodes have the appropriate IAM permissions. They should have the **CloudWatchAgentServerPolicy** attached. For more information, see Setup guide (AWS CLI).

Create ConfigMap

Create a ConfigMap for the agent. The ConfigMap also tells the agent to listen on a TCP or UDP port. Use the following ConfigMap.

```
# cwagent-emf-configmap.yaml
apiVersion: v1
data:
  # Any changes here must not break the JSON format
  cwagentconfig.json: |
    {
      "agent": {
        "omit_hostname": true
      },
      "logs": {
        "metrics_collected": {
          "emf": { }
        }
      }
    }
kind: ConfigMap
metadata:
  name: cwagentemfconfig
  namespace: default
```

If you have already installed Container Insights, add the following `"emf": { }` line to your existing ConfigMap.

Apply the ConfigMap

Enter the following command to apply the ConfigMap.

```
kubectl apply -f cwagent-emf-configmap.yaml
```

Deploy the agent

To deploy the CloudWatch agent as a sidecar, add the agent to your pod definition, as in the following example.

```
apiVersion: v1
kind: Pod
metadata:
  name: myapp
  namespace: default
spec:
  containers:
    # Your container definitions go here
    - name: web-app
      image: my-org/web-app:latest
    # CloudWatch Agent configuration
    - name: cloudwatch-agent
      image: public.ecr.aws/cloudwatch-agent/cloudwatch-agent:latest
      imagePullPolicy: Always
      resources:
        limits:
          cpu: 200m
          memory: 100Mi
        requests:
          cpu: 200m
          memory: 100Mi
      volumeMounts:
        - name: cwagentconfig
          mountPath: /etc/cwagentconfig
      ports:
  # this should match the port configured in the ConfigMap
        - protocol: TCP
          hostPort: 25888
          containerPort: 25888
  volumes:
    - name: cwagentconfig
      configMap:
        name: cwagentemfconfig
```

Using the CloudWatch agent to send embedded metric format logs

When you have the CloudWatch agent installed and running, you can send the embedded metric format logs over TCP or UDP. There are two requirements when sending the logs over the agent:

- The logs must contain a `LogGroupName` key that tells the agent which log group to use.

- Each log event must be on a single line. In other words, a log event cannot contain the newline (\n) character.

The log events must also follow the embedded metric format specification. For more information, see Specification: Embedded metric format.

If you plan to create alarms on metrics created using embedded metric format, see Setting alarms on metrics created with the embedded metric format for recommendations.

The following is an example of sending log events manually from a Linux bash shell. You can instead use the UDP socket interfaces provided by your programming language of choice.

```
echo '{"_aws":{"Timestamp":1574109732004,"LogGroupName":"Foo","CloudWatchMetrics":
[{"Namespace":"MyApp","Dimensions":[["Operation"]],"Metrics":
[{"Name":"ProcessingLatency","Unit":"Milliseconds","StorageResolution":60}]}]},"Operation":"Agg
 \
> /dev/udp/0.0.0.0/25888
```

Note

With the embedded metric format, you can track the processing of your EMF logs by metrics that are published in the AWS/Logs namespace of your account. These can be used to track failed metric generation from EMF, as well as whether failures happen due to parsing or validation. For more details see Monitoring with CloudWatch metrics.

Using the embedded metric format with AWS Distro for OpenTelemetry

OpenTelemetry is an open-source initiative that removes boundaries and restrictions between vendor-specific formats for tracing, logs, and metrics by offering a single set of specifications and APIs. For more information, see OpenTelemetry. You can use the embedded metric format as a part of the OpenTelemetry project. Using the embedded metric format with OpenTelemetry requires two components: an OpenTelemetry-compliant data source and the AWS Distro for OpenTelemetry Collector enabled for use with CloudWatch embedded metric format logs.

We have preconfigured redistributions of the OpenTelemetry components, which AWS maintains, to make onboarding as easy as possible. For more information about using OpenTelemetry with the embedded metric format, in addition to other AWS services, see AWS Distro for

OpenTelemetry. For additional information regarding language support and usage, see AWS Observability on Github.

Viewing your metrics and logs in the console

After you generate embedded metric format logs that extract metrics, you can use the CloudWatch console to view the metrics. Embedded metrics have the dimensions that you specified when you generated the logs. Also, the embedded metrics that you generated using the client libraries have the following default dimensions:

- ServiceType
- ServiceName
- LogGroup

This section describes how to view these metrics in the CloudWatch console and query your extracted metrics using CloudWatch Logs Insights.

To view metrics that were generated from embedded metric format logs

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Select a namespace that you specified for your embedded metrics when you generated them. If you used the client libraries to generate the metrics and did not specify a namespace, then select **aws-embedded-metrics**. This is the default namespace for embedded metrics generated using the client libraries.
4. Select a metric dimension (for example, **ServiceName**).
5. The **Browse** tab displays all metrics for that dimension in the namespace. You can do the following:

    a. To sort the table, use the column heading.

    b. To graph a metric, select the check box next to the metric. To select all metrics, select the check box in the heading row of the table.

    c. To filter by resource, choose the resource ID and then choose **Add to search**.

    d. To filter by metric, choose the metric name and then choose **Add to search**.

Querying logs using CloudWatch Logs Insights

You can query the detailed log events associated with the extracted metrics by using CloudWatch Logs Insights to provide deep insights into the root causes of operational events. One of the benefits of extracting metrics from your logs is that you can filter your logs later by the unique metric (metric name plus unique dimension set) and metric values, to get context on the events that contributed to the aggregated metric value

For example, to get an impacted request id or x-ray trace id, you could run the following query in CloudWatch Logs Insights.

```
filter Latency > 1000 and Operation = "Aggregator"
| fields RequestId, TraceId
```

You can also perform query-time aggregation on high-cardinality keys, such as finding the customers impacted by an event. The following example illustrates this.

```
filter Latency > 1000 and Operation = "Aggregator"
| stats count() by CustomerId
```

For more information, see Analyzing Log Data with CloudWatch Logs Insights

Setting alarms on metrics created with the embedded metric format

In general, creating alarms on metrics generated by the embedded metric format follows the same pattern as creating alarms on any other metrics. For more information, see Using Amazon CloudWatch alarms. Embedded metric format metric generation depends on your log publishing flow because CloudWatch Logs needs to process logs so they can be transformed into metrics. It's important to publish logs in a timely manner, so that metric datapoints are created within the period of time that alarms are evaluated.

If you plan on using the embedded metric format to send high-resolution metrics and create alarms on these metrics, we recommended that you flush logs to CloudWatch Logs at an interval of 5 seconds or less to avoid introducing an additional delay, which can cause alarming on partial or missing data. If you are using the CloudWatch agent, you can adjust the flush interval by setting the `force_flush_interval` parameter in the CloudWatch agent configuration file. This value defaults to 5 seconds. If you are using Lambda on other platforms where you can't control the log flush interval, consider using "M out of N" alarms to control the number of datapoints used to alarm. For more information, see Alarm evaluation.

CloudWatch pipelines

CloudWatch pipelines is a fully managed data collector that ingests, transforms, and routes telemetry data—including logs and metrics—from AWS services, third-party applications, and custom sources to CloudWatch. Built-in processors let you enrich, filter, and standardize logs into formats like OCSF—without managing infrastructure or third-party tools. For metrics, CloudWatch pipelines processes and enriches OpenTelemetry (OTel) metrics inline during ingestion into CloudWatch.

CloudWatch pipelines is fully integrated with the logs management experience, enabling you to consistently process and enrich log data across related log groups via data-source and data-type specification. This unlocks use cases such as:

- **Automatic log categorization** – Logs processed through pipelines are automatically tagged with data source information, enabling service-centric discovery and querying across your infrastructure
- **Expanding third-party support** – Aggregate and normalize logs from a growing library of third-party sources for unified analytics and compliance

For metrics, CloudWatch pipelines enables the following use cases:

- **Enrichment** – Add business context such as team, cost center, or environment to metrics from sources you cannot modify
- **Cost optimization** – Strip high-cardinality attributes to reduce storage costs
- **Standardization** – Rename metrics and attributes to enforce naming conventions

Output from pipelines is fully compatible with CloudWatch Logs features including Logs Insights queries, Logs Anomaly Detection, and Live Tail. CloudWatch pipelines works with both Standard and Infrequent Access log classes and is backwards compatible with Log Transformers.

For metrics pipelines, processed metrics are fully queryable via PromQL in Query Studio and compatible with CloudWatch Alarms and Anomaly Detection.

To get started with CloudWatch pipelines, visit pipelines within the CloudWatch ingestion page in the CloudWatch console.

Note

Be aware of the following limits that apply to CloudWatch pipelines

- Logs pipelines per account: 330
  - Up to 300 pipelines for collecting data from CloudWatch Logs
  - Up to 30 pipelines for collecting data from other sources
- Metrics pipelines per account: up to 300
- Up to 20 processors per pipeline (logs and metrics)
- Metrics pipelines supported ingestion path: OTLP only

Pipeline components

Each pipeline consists of the following components:

- **Source** – Defines where data originates from (Amazon S3 buckets, CloudWatch Logs, CloudWatch Metrics (OTel), third-party integration). Each pipeline must have exactly one source. Metrics pipelines process OTel metrics on the OTLP ingestion path.
- **Processors** (optional) – Transform, parse, and enrich telemetry data as it flows through the pipeline. Processors are applied sequentially in the order they are defined. Metrics pipelines support a distinct set of processors optimized for OTel metric attributes.
- **Sink** – Defines the destination where processed data is sent. Supported sink types include `cloudwatch_logs` and `cloudwatch_metrics`. Each pipeline must have exactly one sink.
- **Extensions** (optional) – Provide additional functionality such as AWS Secrets Manager integration for credential management.

Throughout the entire pipeline, your data remains protected with transport layer encryption so that your data meets security and compliance requirements.

Note

Pipeline definitions are not encrypted with customer-provided keys and must never include sensitive data, such as passwords, API keys, or personally identifiable information (PII).

> **Note**
>
> Adding processors leads to mutation of the log events and original (raw) logs are not retained.

Pricing

CloudWatch pipelines is included with CloudWatch Logs at no additional cost. Standard log ingestion rates based on log class (vended or custom) and storage class (Standard or Infrequent Access) still apply. Metering occurs at time of first ingestion into CloudWatch. CloudWatch Logs sources are metered before pipeline processing. Third-party and S3 bucket sources are classified as Custom logs and metered after processing. For pricing details, see CloudWatch Pricing.

For metrics pipelines, standard CloudWatch OTel metrics ingestion and storage charges apply. There is no additional charge for pipeline processing.

Region availability

CloudWatch pipelines is available in the following AWS Regions:

- US East (N. Virginia)
- US East (Ohio)
- US West (N. California)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Hyderabad)
- Asia Pacific (Jakarta)
- Asia Pacific (Malaysia)
- Asia Pacific (Melbourne)
- Asia Pacific (Mumbai)
- Asia Pacific (New Zealand)
- Asia Pacific (Osaka)

- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Taipei)
- Asia Pacific (Thailand)
- Asia Pacific (Tokyo)
- Canada (Central)
- Canada West (Calgary)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)
- Europe (Milan)
- Europe (Paris)
- Europe (Spain)
- Europe (Stockholm)
- Europe (Zurich)
- Israel (Tel Aviv)
- Mexico (Central)
- South America (São Paulo)

Note

Third-party data source collection is available in regions where OpenSearch Ingestion has API endpoints.

For more details, see Amazon CloudWatch endpoints and quotas in the *AWS General Reference*.

Creating pipelines

CloudWatch pipelines supports creating pipelines for both logs and metrics data. The following sections describe how to create each type of pipeline.

Creating a logs pipeline

The pipeline configuration wizard guides you through creating your logs data pipeline.

1. Under **General settings**, provide the data source details including source name and type. You can also specify pipeline tags and the name of your pipeline.
2. Under **Destination**, specify the destination details. For logs pipelines, CloudWatch Logs is the only supported destination. For metrics pipelines, CloudWatch Metrics is the only supported destination.
3. Under **Processor**, add the desired processors and parsers. A parser is a required first step for certain data types. You can perform custom parsing using processors like Grok or CSV. You can use the lookup processor to enrich log events with data from an Amazon CloudWatch Logs lookup table. Processors that are not supported by the data type are disabled.

   To configure processors using natural language, enable the **AI-assisted** toggle. Enter a description of the log transformations you need, and CloudWatch pipelines generates the processor configuration automatically. For AWS vended logs, a sample log event is also generated so you can verify the output before deploying. You can review and edit the generated configuration before creating the pipeline.

   > **Important**
   >
   > To use AI-assisted processor configuration, you must have the `logs:GeneratePipeline` IAM permission. For more information, see the section called “AI-assisted processor configuration permissions”.

   You can also add conditional processing rules to supported processors using the `when` parameter. Conditional processing lets you control which log entries a processor acts on. For the expression syntax and supported processors, see the section called “Expression syntax for conditional processing”.

   To preserve unmodified copies of your log data for audit or compliance purposes, enable the **Keep original log** toggle. When enabled, CloudWatch pipelines automatically stores a copy of each raw log event before any transformation takes place in the `@original_message` system field of the event. This ensures that original data is always available for audits or investigations, even after processors modify the log events. The **Keep original log** toggle is only available for pipelines with a CloudWatch vended log source.

4. Under **Review and create**, review the pipeline configuration. If you're satisfied with the configuration, choose **Create pipeline** to start deployment and creation of pipeline resources. Pipeline creation completion takes up to 5 minutes depending on the source type. Upon completion, you'll be taken to the Pipelines tab in the Ingestion Console.

> **Important**
>
> Pipeline processor configurations are logged in AWS CloudTrail events for auditing and compliance purposes. To protect sensitive information, do not include passwords, API keys, or other sensitive information in processor configurations.

Creating a metrics pipeline

You can create a metrics pipeline by using the CloudWatch console or the AWS CLI. With a metrics pipeline, you can process CloudWatch metrics data, apply transformations, and forward the processed metrics to CloudWatch.

To create a metrics pipeline (console)

Use the following procedure to create a metrics pipeline in the CloudWatch console.

1. Open the CloudWatch console and in the navigation pane, choose **Ingestion**, **Pipelines**.
2. Choose **Create pipeline**.
3. For the source type, select **CloudWatch Metrics (OTel)**.
4. Configure the selection criteria to specify which metrics the pipeline processes. Selection criteria use OTel attribute paths such as `resource.attributes`, `metric.name`, and `datapoint.attributes`. All criteria use AND semantics (all must match).
5. Under **Processor**, add up to 20 processors to transform your metrics data.
6. Under **Review and create**, review the pipeline configuration and choose **Create pipeline**.

To create a metrics pipeline (AWS CLI)

Use the `create-telemetry-pipeline` command to create a metrics pipeline from the AWS CLI.

```
aws observabilityadmin create-telemetry-pipeline \
```

```
    --pipeline-configuration-body file://config.yaml
```

The following example shows a YAML configuration file that defines a metrics pipeline with a source, processor, and sink.

```
pipeline:
  source:
    cloudwatch_metrics:
      format: otlp
      selection_criteria:
        - match_all:
            - 'resource.attributes["service.name"] == "payment-service"'
            - 'metric.name == "http.server.request.duration"'
  processor:
    - add_attributes:
        attributes:
          - key: resource.attributes["team"]
            value: "platform-engineering"
  sink:
    - cloudwatch_metrics: {}
```

When the pipeline is created, it returns an ARN in the following format:

```
arn:aws:observabilityadmin:region:accountId:telemetry-pipeline/pipelineID
```

> **Note**
>
> CloudWatch Metrics is the only supported destination for metrics pipelines.

Supported API operations

The following table lists the API operations that you can use to manage metrics pipelines.

Operation	Description
`CreateTelemetryPipeline`	Creates a new metrics pipeline.
`GetTelemetryPipeline`	Retrieves details about a specific metrics pipeline.

Operation	Description
`ListTelemetryPipelines`	Lists all metrics pipelines in your account.
`DeleteTelemetryPipeline`	Deletes a metrics pipeline.
`ValidateTelemetryPipelineConfiguration`	Validates a pipeline configuration before creation.
`UpdateTelemetryPipeline`	Updates an existing metrics pipeline configuration.

Managing pipelines

After creating pipelines, you can monitor their performance and manage their configuration through the Pipelines tab.

Pipeline status monitoring

Each pipeline displays real-time status information including:

- Pipeline status: Active, Creating, Updating, Deleting, Create Failed, Update Failed, or Delete Failed.
- Data throughput metrics
- Error rates and failure details

Pipeline operations

You can perform the following operations on existing pipelines:

- **View details** – Review pipeline configuration and status
- **Edit pipeline** – Edit pipeline configuration including processors, parsing, and source selection criteria
- **Delete pipeline** – Remove pipelines that are no longer needed

> **Note**
>
> To programmatically manage metrics pipelines, use the Observability Admin APIs including `CreateTelemetryPipeline`, `UpdateTelemetryPipeline`, and `DeleteTelemetryPipeline`.

Supported data sources for CloudWatch

CloudWatch collects and processes telemetry data from a wide range of sources to provide unified observability and security insights. Data sources fall into four categories: AWS native services, third-party platforms, custom sources, and CloudWatch Metrics (OTel).

You can automate the enablement of AWS data sources using telemetry configuration. For more information, see Telemetry discovery and enablement.

AWS service data sources

CloudWatch provides native integration with 90+ AWS services for automatic data collection. When an AWS service source is selected, CloudWatch pipelines intercepts logs ingested into CloudWatch Logs for processing. To get started, enable logging for the supported AWS services using the service's console, then select the data source and type in the CloudWatch pipelines creation wizard.

The following table highlights key AWS service data sources. For the complete list of 90+ supported services, see Supported AWS services for data sources.

Key AWS service data sources

AWS service	Data type	Description
Amazon Amazon VPC	Flow Logs	Network traffic metadata for Amazon VPCs, subnets, and network interfaces
Amazon Amazon EKS	Control Plane Logs	Kubernetes API server, audit, authenticator, controller manager, and scheduler logs

AWS service	Data type	Description
AWS WAF	Web ACL Logs	Web request inspection logs including rule match details and actions taken
Amazon Route 53	Resolver Query Logs	DNS query logs for Amazon VPC resources routed through Route 53 Resolver
CloudTrail	Management and Data Events	API activity and resource-level operations across AWS services
Amazon Amazon EC2	Detailed Metrics	Instance-level performance metrics at 1-minute granularity
AWS Security Hub	CSPM Findings	Cloud security posture managemen t findings from AWS and third-party providers
Amazon Bedrock AgentCore	Runtime, Browser, CodeInterpreter, Gateway, Memory	Agent runtime execution, browser interaction, code execution, gateway, and memory operation logs
Amazon CloudFront	Distribution Logs	CDN access logs for content delivery distributions
Network Load Balancer	Access Logs	Network Load Balancer connection and TLS negotiation logs
Amazon RDS	Aurora MySQL and Aurora PostgreSQL Logs	Audit, error, general, slow query, IAM DB authentication error, proxy, and enhanced monitoring logs

For more information about CloudWatch Logs data sources, see Data source discovery and management.

Third-party data sources

CloudWatch extends monitoring capabilities beyond AWS with direct integrations for 38 third-party security, identity, and endpoint platforms. These integrations consolidate security events, audit logs, and telemetry data from external sources into CloudWatch Logs for unified analysis.

The following table lists the supported direct third-party integrations:

Direct third-party integrations

Source	Integration pattern	Category
Akamai DataStream 2	S3 Delivery	CDN and edge security
Check Point NGFW	S3 Delivery	Network security
Cisco Duo	API	Identity and access management
Cisco Meraki	API	Network security
Cisco Umbrella	S3 Delivery	DNS and network security
CrowdStrike Falcon	S3 Delivery	Endpoint security
Drupal Core	API	Content management
Entrust IDaaS	API	Identity and access management
F5 BIG-IP	S3 Delivery	Network security
GitHub	API	Source code and audit logs
GitLab	API	DevSecOps and source code
HashiCorp Vault	S3 Delivery	Secrets management
Jamf Protect	S3 Delivery	Endpoint security
Microsoft Entra ID	API	Identity and access management
Microsoft Office 365	API	Productivity and audit logs
Microsoft Windows Event Logs	API	Operating system events

Source	Integration pattern	Category
Netskope	API	Network security and CASB
Okta Auth0	API	Identity and access management
Okta SSO	API	Identity and access management
OneLogin Identity	API	Identity and access management
Palo Alto Networks NGFW	API	Network security
Palo Alto Prisma Cloud	API	Cloud security
PingIdentity PingAccess	S3 Delivery	Access management
PingIdentity PingFederate	S3 Delivery	Identity federation
PingIdentity PingOne	API	Identity and access management
Proofpoint TAP	API	Email security
Slack Audit Log	API	Collaboration and audit logs
SentinelOne	S3 Delivery	Endpoint security
ServiceNow CMDB	API	IT service management
Tanium Endpoint Management	S3 Delivery	Endpoint security and management
Tenable Vulnerability Managemen t	API	Vulnerability management
Wazuh Platform	API	Security monitoring and threat detection
Box	API	Content management and file sharing
Jamf Pro	API	Device management (Apple)

Source	Integration pattern	Category
Broadcom Carbon Black	S3 Delivery	Endpoint detection and response
Wiz CNAPP	API	Cloud security
Zeek	S3 Delivery	Network security monitoring
Zscaler ZIA/ZPA	S3 Delivery	Network security

For detailed setup procedures, prerequisites, and configuration steps for each integration, see Third-party data sources integration.

Additional third-party sources through Security Hub CSPM

Beyond the 34 direct integrations, 49+ additional third-party sources are available through AWS Security Hub CSPM integration. Security Hub CSPM partner providers that send findings to Security Hub are automatically available as data sources. For the full list of supported partners, see the Security Hub CSPM partner providers documentation.

Additional third-party sources through Security Hub

AWS Security Hub (distinct from Security Hub CSPM) provides its own set of third-party integrations. These integrations that send findings to Security Hub are automatically available as data sources. For the full list of supported integrations, see the Security Hub third-party integrations documentation.

Custom data sources

For logs that are not covered by AWS service or third-party integrations, CloudWatch pipelines can process custom logs stored in CloudWatch Logs or Amazon S3 buckets. Custom sources accommodate unique organizational requirements:

- **Application-specific logs** – Custom application telemetry from Amazon EC2 instances with specialized logging formats

- **File-based ingestion** – Amazon S3-based log files from legacy systems or batch processing workflows
- **Serverless integration** – Lambda function logs and custom serverless application telemetry

For more details, see Custom log data from CloudWatch Logs or an Amazon S3 bucket.

CloudWatch Metrics (OTel) source

The CloudWatch Metrics (OTel) source processes OpenTelemetry (OTel) metrics on the OTLP ingestion path based on selection criteria. This source enables you to transform metrics data through CloudWatch pipelines before the metrics are persisted in CloudWatch Metrics.

The following metric types are supported:

- **Custom OTel metrics** – Metrics that your applications emit through OpenTelemetry instrumentation and send to the OTLP endpoint
- **AWS vended OTel metrics** – Metrics that AWS services emit via OTLP

> **Note**
>
> The CloudWatch Metrics (OTel) source only supports metrics ingested through the OTLP endpoint. Metrics sent through other ingestion paths, such as the `PutMetricData` API, are not processed by this source.

You define which metrics to process by configuring metrics pipeline selection criteria. Selection criteria let you target specific metrics based on OTel attributes such as resource attributes, metric name, and datapoint attributes. For more information, see the section called “CloudWatch Metrics (OTel)”.

For information about sending OTel metrics to CloudWatch, see Using OpenTelemetry with CloudWatch.

Topics

- CloudWatch Metrics (OTel)
- Third-party data sources integration
- Custom log data from CloudWatch Logs or an Amazon S3 bucket

- AWS service logs from CloudWatch Logs

CloudWatch Metrics (OTel)

Selection criteria determine which OTel metrics enter a pipeline for processing. Each criterion is an expression of the form `<path> == "<value>"` that matches against a specific attribute of the incoming metric. At least one selection criterion is required.

Criteria are grouped inside a `match_all` block with AND semantics — a metric must match every expression in the group to enter the pipeline.

Supported paths

The following OTTL paths are supported in selection criteria:

Selection criteria paths

Path	Description
`resource.attributes["key"]`	Resource-level attribute
`instrumentation_scope.name`	Instrumentation scope name
`instrumentation_scope.version`	Instrumentation scope version
`instrumentation_scope.attributes["key"]`	Instrumentation scope attribute
`metric.name`	Metric name
`datapoint.attributes["key"]`	Datapoint-level attribute
`attributes["key"]`	Short form for `datapoint.attributes["key"]`

Configuration

Selection criteria are defined in the `source` section of the pipeline configuration:

```
pipeline:
```

```
  source:
    cloudwatch_metrics:
      format: otlp
      selection_criteria:
        - match_all:
            - 'resource.attributes["service.name"] == "my-service"'
            - 'metric.name == "http.server.request.duration"'
  processor:
    - add_attributes:
        attributes:
          - key: resource.attributes["team"]
            value: "platform-engineering"
  sink:
    - cloudwatch_metrics: {}
```

The following example uses all supported path types:

```
pipeline:
  source:
    cloudwatch_metrics:
      format: otlp
      selection_criteria:
        - match_all:
            - 'resource.attributes["service.name"] == "my-service"'
            - 'instrumentation_scope.name == "my-scope"'
            - 'instrumentation_scope.version == "1.0.0"'
            - 'instrumentation_scope.attributes["library"] == "otel-java"'
            - 'metric.name == "http.server.request.duration"'
            - 'datapoint.attributes["status_code"] == "200"'
            - 'attributes["environment"] == "production"'
  processor:
    - add_attributes:
        attributes:
          - key: resource.attributes["team"]
            value: "observability"
  sink:
    - cloudwatch_metrics: {}
```

Verifying with PromQL

CloudWatch maps OTLP attribute scopes to PromQL labels using the @ prefix convention. Use this mapping to verify that your pipeline is processing metrics as expected in Query Studio:

OTTL path to PromQL label mapping

Pipeline OTTL path	PromQL label prefix	Example
`resource.attributes["key"]`	`@resource.`	`@resource.service.name`
`instrumentation_scope.name`	`@instrumentation.@name`	`@instrumentation.@name`
`instrumentation_scope.attributes["key"]`	`@instrumentation.`	`@instrumentation.library`
`datapoint.attributes["key"]` / `attributes["key"]`	`@datapoint.` or bare	`status_code`

For example, if your pipeline adds `resource.attributes["team"]` with value `"platform-engineering"`, you can confirm it was applied:

```
{"CPUUtilization", "@resource.team"="platform-engineering"}
```

Requirements and limitations

Single `match_all` group

Each pipeline supports exactly one `match_all` group in `selection_criteria`. You cannot define multiple `match_all` groups in a single pipeline.

Minimum criteria

At least one expression is required in the `match_all` group.

Maximum criteria

A `match_all` group can contain at most 20 expressions.

AND semantics

All expressions in the `match_all` group must match for a metric to enter the pipeline.

Exact string matching

Values must be static strings. Wildcards, regular expressions, and partial matches are not supported. Each expression must use the == operator.

No overlapping criteria across pipelines

Each metric datapoint must match at most one pipeline. If a datapoint matches both new and existing pipeline criteria, pipeline creation fails. To prevent overlap, include at least one attribute path with distinct values in each pipeline's selection criteria.

For example, the following two selection criteria overlap because Pipeline A selects all metrics from `payment-service`, which includes the specific metric that Pipeline B targets:

```
# Pipeline A — selects ALL metrics from payment-service
selection_criteria:
  - match_all:
      - 'resource.attributes["service.name"] == "payment-service"'

# Pipeline B — FAILS: a datapoint with service.name="payment-service"
# and metric.name="http.server.request.duration" matches both pipelines
selection_criteria:
  - match_all:
      - 'metric.name == "http.server.request.duration"'
```

Third-party data sources integration

Integrating CloudWatch pipelines with your third-party data source let you connect external security tools, identity providers, and monitoring platforms to CloudWatch pipelines for centralized data analysis. This integration consolidates security events, audit logs, and telemetry data from multiple sources.

Note

Data collected from third-party sources is mutated to adhere to the required schema when it is collected by CloudWatch pipelines. The original data source is not retained by CloudWatch.

Third-party data can be collected using two methods:

1. **Direct API Integration** – Some sources offer Event Stream APIs where you only need to provide API credentials to configure the connector
2. **S3 Bucket Integration** – Data from sources can be ingested into a customer-managed S3 bucket for CloudWatch pipelines to collect

The following table identified the integrations methods used by the supported third-party data platforms:

Source	Integration Pattern	Requires S3 bucket	Requires SQS Queue	Uses Secrets Manager extension	Required IAM Policies
Akamai DataStream 2	S3 Delivery	Yes	Yes	No	Source-specific IAM policies
Check Point NGFW	S3 Delivery	Yes	Yes	No	Source-specific IAM policies
Cisco Duo	API	No	No	Yes	API caller permissions
Cisco Meraki	API	No	No	Yes	API caller permissions
Cisco Umbrella	S3 Delivery	Yes	Yes	No	Source-specific IAM policies
CrowdStrike Falcon	S3 Delivery	Yes	Yes	No	Source-specific IAM policies
Drupal Core	API	No	No	Yes	API caller permissions
Entrust IDaaS	API	No	No	Yes	API caller permissions
F5 BIG-IP	S3 Delivery	Yes	Yes	No	Source-specific IAM policies

Source	Integration Pattern	Requires S3 bucket	Requires SQS Queue	Uses Secrets Manager extension	Required IAM Policies
GitHub	API	No	No	Yes (optional)	API caller permissions
GitLab	API	No	No	Yes	API caller permissions
HashiCorp Vault	S3 Delivery	Yes	Yes	No	Source-specific IAM policies
Jamf Protect	S3 Delivery	Yes	Yes	No	Source-specific IAM policies
Microsoft Entra ID	API	No	No	Yes	API caller permissions
Microsoft Office 365	API	No	No	Yes	API caller permissions
Microsoft Windows Event Logs	API	No	No	Yes	API caller permissions
Netskope	API	No	No	Yes	API caller permissions
Okta Auth0	API	No	No	Yes	API caller permissions
Okta SSO	API	No	No	Yes	API caller permissions
OneLogin Identity	API	No	No	Yes	API caller permissions

Source	Integration Pattern	Requires S3 bucket	Requires SQS Queue	Uses Secrets Manager extension	Required IAM Policies
Palo Alto Networks NGFW	API	No	No	Yes	API caller permissions
Palo Alto Prisma Cloud	API	No	No	Yes	API caller permissions
PingIdentity PingAccess	S3 Delivery	Yes	Yes	No	Source-specific IAM policies
PingIdentity PingFederate	S3 Delivery	Yes	Yes	No	Source-specific IAM policies
PingIdentity PingOne	API	No	No	Yes	API caller permissions
Proofpoint TAP	API	No	No	Yes	API caller permissions
Slack Audit Log	API	No	No	Yes	API caller permissions
SentinelOne	S3 Delivery	Yes	Yes	No	Source-specific IAM policies
ServiceNow CMDB	API	No	No	Yes	API caller permissions
Tanium Endpoint Management	S3 Delivery	Yes	Yes	No	Source-specific IAM policies
Tenable Vulnerability Management	API	No	No	Yes	API caller permissions

Source	Integration Pattern	Requires S3 bucket	Requires SQS Queue	Uses Secrets Manager extension	Required IAM Policies
Wiz CNAPP	API	No	No	Yes	API caller permissions
Zeek	S3 Delivery	Yes	Yes	No	Source-specific IAM policies
Zscaler ZIA/ZPA	S3 Delivery	Yes	Yes	No	Source-specific IAM policies

Third-party integration sent through Security Hub CSPM is also supported. For comprehensive information about Security Hub's third-party integrations, including supported partners and integration configurations with "Sends findings" direction, refer to the Security Hub Third-Party Integration documentation.

AWS Security Hub (distinct from Security Hub CSPM) also supports third-party integrations as data sources. For the full list of supported integrations, refer to the Security Hub third-party integrations documentation.

Data transformation and standardization

Third-party integrations support data transformation to standardized formats for consistent analysis:

- **Open Cybersecurity Schema Framework (OCSF)** – Converts security events from different vendors into a common schema for unified threat detection and analysis. Because OCSF is only for certain event classes, not all raw events are mapped to OCSF.
- **Custom transformations** – Pipeline processors that normalize data formats, enrich events with additional context, and filter relevant information.
- **Field mapping** – Automatic mapping of vendor-specific fields to standardized field names for consistent querying and analysis.

> **Note**
>
> Storing telemetry data from third-party sources in OCSF is an optional feature that might not be available for all data sources.

Log group

Third-party data is ingested into a CloudWatch log group. If you are using the AWS Management Console to configure CloudWatch pipelines if the log group does not exist, it is created automatically through the wizard process.

Authentication and security

Third-party integrations use secure authentication methods to protect data in transit:

- **OAuth 2.0 and application registration** – Secure token-based authentication for cloud platforms like Microsoft and Okta.
- **API keys and certificates** – Encrypted authentication credentials for direct API access.
- **IAM roles and policies** – AWS Identity and Access Management integration for secure S3 bucket access and cross-account data sharing.

> **Note**
>
> Data collected from third-party sources is mutated to adhere to the required schema when it is collected by CloudWatch pipelines. The original data source is not retained by CloudWatch.

Each integration requires platform-specific configuration to establish secure data delivery to your AWS environment.

The following sections provide detailed setup procedures for supported third-party integrations. Each integration includes prerequisites, configuration steps, and validation procedures to ensure proper data flow.

Akamai DataStream 2 integration configuration

Akamai DataStream 2 is a near real-time log streaming service that delivers detailed performance and security metrics from the Akamai edge platform to various third-party destinations. It enables proactive monitoring, troubleshooting, and, through its support for DataStream 2.1, includes Edge DNS, Global Traffic Management (GTM), and EdgeWorkers log data.

Topics

- Source configuration for Akamai DataStream 2
- CloudWatch pipelines configuration for Akamai DataStream 2

Source configuration for Akamai DataStream 2

Integrating with Akamai DataStream 2

To integrate Akamai DataStream 2 Data Replicator with CloudWatch Logs, you must configure both the source and the pipeline. First, set up your Akamai DataStream 2 source by configuring Amazon S3 and Amazon SQS to receive data. Then, configure the CloudWatch pipeline to ingest the data from your source into CloudWatch Logs.

Log forwarding setup

Akamai DataStream 2 supports real-time log delivery via DataStream 2 to forward logs to Amazon S3.

Instructions to setup Amazon S3 and Amazon SQS

Configuring Akamai DataStream 2 to send logs to an Amazon S3 bucket involves several steps. These steps focus on setting up the Amazon S3 bucket, Amazon SQS queue, and IAM roles, and then configuring the CloudWatch pipeline.

- Create an Amazon S3 bucket that stores Akamai logs and create separate folders for each log type (for example, DNS, CDN, EdgeWorkers). Create an IAM user and grant S3 write permission, then create an access key and secret key for this account.
- Ensure the Akamai DataStream 2 log exporter is configured to send logs to Amazon S3. DataStream 2 uploads logs to Amazon S3 over TLS, so you need to enable server-side encryption for Amazon S3. Refer to the Akamai S3 streaming setup guide for detailed instructions.
- Configure the Amazon S3 bucket to create event notifications, specifically for "Object Create" events. These notifications should be sent to an Amazon SQS queue.

- Create an Amazon SQS queue in the same AWS Region as your Amazon S3 bucket. This queue will receive notifications when new log files are added to the Amazon S3 bucket.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read data from Akamai DataStream 2, choose Akamai DataStream 2 as the data source. After filling in the required information and you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and Akamai DataStream 2 events that map to DNS Activity (4003), HTTP Activity (4002), and Base Event (0). Any events that don't conform to the mentioned OCSF schema are passed through.

DNS Activity (4003) contains the following event logs:

- DNS Logs
- GTM Logs

HTTP Activity (4002) contains the following event logs:

- CDN Logs

Base Event (0) contains the following event logs:

- EdgeWorkers Logs

> **Note**
>
> DNS and Global Traffic Management (GTM) logs share the same format. No separate OCSF mappings are required.

Events that do not match any OCSF mapping transformation are automatically passed through and sent directly to the configured sink without additional processing.

CloudWatch pipelines configuration for Akamai DataStream 2

The Akamai DataStream 2 setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the Akamai DataStream 2 source using the following parameters:

```
source:
  s3:
    aws:
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      ndjson:
    data_source_name: "akamai_datastream_2"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
    on_error: "retain_messages"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name` (required)

Identifies the data source. This can be any string value that represents your data source. Example: "akamai_datastream_2".

`aws.region` (required)

The AWS Region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Supports csv, json, ndjson codecs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

`on_error` (optional)

Determines how to handle errors in Amazon SQS. Can be either retain_messages or delete_messages. Default is retain_messages.

Box integration configuration

Box is a cloud content management and file sharing platform. CloudWatch Pipelines use the Box Events API to retrieve audit logs, user activity, file operations, security events, and collaboration changes from your Box enterprise environment.

Topics

- Source configuration for Box
- CloudWatch pipelines configuration for Box

Source configuration for Box

Integrating with Box

CloudWatch Pipeline uses the Box Events API to retrieve audit logs, user activity, file operations, and security events. The Events API provides enterprise-level event data for security monitoring and compliance.

To integrate CloudWatch Pipelines with Box, complete the following high-level steps:

- Create a Box Custom App with Server Authentication (Client Credentials Grant) in the Box Developer Console.
- Note the Client ID, Client Secret, and Enterprise ID.

- Authorize the app in the Box Admin Console.
- Store the credentials in AWS Secrets Manager.
- Create a CloudWatch pipeline with Box as the data source.
- Verify that data is flowing into the pipeline.

Prerequisites

Before you begin, ensure you have the following:

- A Box Enterprise account with admin access
- A Box Custom App configured with Server Authentication (Client Credentials Grant)
- The app authorized by a Box Admin in the Admin Console
- An AWS account with permissions to create and manage CloudWatch Pipelines
- An AWS account with permissions to create, retrieve, and update secrets in AWS Secrets Manager

Authenticating with Box

Box uses OAuth 2.0 Client Credentials Grant for server-to-server authentication. The pipeline uses the Client ID and Client Secret to obtain access tokens for API requests.

Configure Authentication for Box

To configure authentication credentials for the pipeline:

1. Log in to the Box Developer Console and create a Custom App with Server Authentication (Client Credentials Grant).
2. Note the Client ID and Client Secret from the app configuration.
3. Note your Enterprise ID from the Box Admin Console under Account & Billing.
4. Authorize the app in the Box Admin Console under Apps > Custom Apps.
5. Store the `client_id` and `client_secret` in AWS Secrets Manager.

Configuring the CloudWatch Pipeline

To configure the pipeline, choose Box as the data source. Provide the `enterprise_id`, `client_id`, and `client_secret`. Once you create and activate the pipeline, log data from Box will begin flowing into the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports the following OCSF event classes:

- **Account Change [3001]** – Account and permission changes
- **Authentication [3002]** – Login and session events
- **Group Management [3006]** – Group membership changes
- **File Hosting Activity [6006]** – File uploads, downloads, and sharing
- **Entity Management [3004]** – User and collaboration management
- **Security Finding [2001]** – Security policy violations and shield events
- **User Inventory Info [5003]** – User inventory
- **Group Inventory Info [5004]** – Group and membership inventory

CloudWatch pipelines configuration for Box

Collects audit and activity log data from Box using OAuth 2.0 Client Credentials authentication through the Box Events API.

Configure the Box source with the following parameters:

```
source:
  box:
    enterprise_id: "123456789"
    authentication:
      oauth2:
        client_id: "${{aws_secrets:<secret-name>:client_id}}"
        client_secret: "${{aws_secrets:<secret-name>:client_secret}}"
```

Parameters

`enterprise_id` (required)

The Box Enterprise ID for your organization. Found in the Box Admin Console under Account & Billing.

`authentication.oauth2.client_id` (required)

The Box Custom App Client ID, stored in AWS Secrets Manager.

`authentication.oauth2.client_secret` (required)

The Box Custom App Client Secret, stored in AWS Secrets Manager.

Broadcom Carbon Black integration configuration

Broadcom Carbon Black Cloud is an endpoint detection and response (EDR) platform that provides threat detection, investigation, and containment capabilities. CloudWatch Pipelines ingest Carbon Black event data from Amazon S3 to normalize it into OCSF format for security analysis.

Topics

- Source configuration for Broadcom Carbon Black
- CloudWatch pipelines configuration for Broadcom Carbon Black

Source configuration for Broadcom Carbon Black

Integrating with Broadcom Carbon Black

CloudWatch Pipeline ingests Broadcom Carbon Black event data from Amazon S3. You configure Carbon Black Cloud to export event data to an Amazon S3 bucket, then create a pipeline that reads from that bucket using Amazon SQS notifications.

To integrate CloudWatch Pipelines with Broadcom Carbon Black, complete the following high-level steps:

- Configure Carbon Black Cloud Data Forwarder to export events to an Amazon S3 bucket.
- Set up Amazon SQS notifications on the Amazon S3 bucket for new object creation.
- Create the required IAM role for pipeline access.
- Create a CloudWatch pipeline with Broadcom Carbon Black as the data source.
- Verify that data is flowing into the pipeline.

Prerequisites

Before you begin, ensure you have the following:

- A Broadcom Carbon Black Cloud account with Data Forwarder access
- An Amazon S3 bucket configured to receive Carbon Black event exports

- An Amazon SQS queue configured with Amazon S3 event notifications
- An AWS account with permissions to create and manage CloudWatch Pipelines

Configuring the CloudWatch Pipeline

To configure the pipeline, choose Broadcom Carbon Black as the data source. Provide the Amazon SQS queue URL and IAM role ARN. Once you create and activate the pipeline, EDR event data from Carbon Black will begin flowing into the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports the following OCSF event classes:

- **Detection Finding [2004]** – Alert events (CB Analytics, Container Runtime, Device Control, Firewall, IDS, Watchlist)
- **Authentication [3002]** – Authentication/logon events
- **Process Activity [1007]** – Process start and end events
- **Module Activity [1005]** – Module and script load events
- **File System Activity [1001]** – File modification events
- **Network Activity [4001]** – Network connection events
- **API Activity [6003]** – API call events

CloudWatch pipelines configuration for Broadcom Carbon Black

Collects endpoint detection and response data from Broadcom Carbon Black via Amazon S3 bucket ingestion.

Configure the Broadcom Carbon Black source with the following parameters:

```
source:
  s3:
    notification_type: sqs
    data_source_name: broadcom_carbonblack
    codec:
      ndjson:
    sqs:
      queue_url: "https://sqs.us-east-1.amazonaws.com/123456789012/carbon-black-queue"
```

```
    aws:
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::123456789012:role/PipelineRole"
```

Parameters

`notification_type` (required)

Must be `sqs`.

`data_source_name` (required)

Must be `broadcom_carbonblack`.

`codec` (required)

Must be `ndjson` for Carbon Black event exports.

`sqs.queue_url` (required)

The Amazon SQS queue URL that receives Amazon S3 event notifications when new Carbon Black export files are created.

`aws.region` (required)

The AWS Region where the Amazon S3 bucket and Amazon SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role that the pipeline assumes to read from the Amazon S3 bucket and Amazon SQS queue.

Check Point NGFW integration configuration

Check Point Next-Generation Firewall (NGFW), also known as Check Point Quantum, is an advanced on-premises firewall that combines traditional filtering with modern threat-prevention technologies such as intrusion prevention, antivirus, and application control. CloudWatch pipelines allow ingestion of Check Point NGFW log data into CloudWatch Logs, providing scalable collection, processing, normalization, and integration with downstream AWS security and monitoring services.

Topics

- Source configuration for Check Point NGFW

- CloudWatch pipelines configuration for Check Point NGFW

Source configuration for Check Point NGFW

Integrating with Check Point NGFW

Check Point NGFW integration uses Amazon S3 and Amazon SQS to ingest log data into CloudWatch pipelines. Log data is forwarded from the Check Point appliance using the `cp_log_export` utility to a syslog receiver, then collected by Fluent Bit and delivered to an Amazon S3 bucket. Amazon SQS notifications alert the pipeline when new log objects arrive.

Prerequisites

- An AWS account with permissions to create Amazon S3 buckets, Amazon SQS queues, and IAM roles
- A Check Point NGFW appliance with access to the `cp_log_export` utility
- A Linux host with Fluent Bit installed (for log collection and delivery to Amazon S3)
- Network connectivity between the Check Point appliance, syslog receiver, and AWS

Log forwarding setup

Check Point NGFW exports logs using the `cp_log_export` utility, which forwards log data in syslog format to a designated receiver. Fluent Bit running on the syslog receiver host collects these logs and delivers them to Amazon S3 in NDJSON format.

Instructions to setup Amazon S3 and Amazon SQS

Complete the following steps to configure the Amazon S3 and Amazon SQS infrastructure for Check Point NGFW log ingestion.

Step 1: Create Amazon S3 bucket

Create an Amazon S3 bucket to store Check Point NGFW logs. The bucket must reside in the same AWS Region where you plan to create the CloudWatch pipeline.

Step 2: Create Amazon SQS queue

Create an Amazon SQS queue in the same AWS Region as your Amazon S3 bucket. This queue receives notifications when new log files are added to the bucket.

Step 3: Connect Amazon S3 to Amazon SQS

Configure the Amazon S3 bucket to send event notifications for `s3:ObjectCreated:*` events to the Amazon SQS queue.

Step 4: Configure Amazon SQS queue policy

Configure the Amazon SQS queue policy to allow the Amazon S3 bucket to send messages to the queue. Apply the following policy to your Amazon SQS queue:

```
{
  "Version": "2012-10-17",
  "Id": "AllowS3ToSQS",
  "Statement": [
    {
      "Sid": "AllowS3BucketNotification",
      "Effect": "Allow",
      "Principal": {
        "Service": "s3.amazonaws.com"
      },
      "Action": "sqs:SendMessage",
      "Resource": "arn:aws:sqs:<region>:<account-id>:<queue-name>",
      "Condition": {
        "ArnEquals": {
          "aws:SourceArn": "arn:aws:s3:::<YOUR-BUCKET>"
        },
        "StringEquals": {
          "aws:SourceAccount": "<account-id>"
        }
      }
    }
  ]
}
```

Step 5: Configure Check Point log export and Fluent Bit

On the Check Point appliance, configure `cp_log_export` to forward logs to your syslog receiver:

```
cp_log_export add name my_export target-server <syslog-host> target-port 514 protocol
 udp format syslog
```

On the syslog receiver host, install Fluent Bit and configure it to tail the Check Point NGFW log files and upload them to Amazon S3. Use the following example configuration:

```
########################################
# SERVICE SECTION
########################################
[SERVICE]
    Flush                       5
    Daemon                      Off
    Log_Level                   info
    storage.path                /etc/fluent-bit/db/storage
    storage.sync                normal
    storage.checksum            off
    storage.backlog.mem_limit   10M

########################################
# INPUT SECTION
########################################
[INPUT]
    Name                        tail
    Path                        /var/logs/<checkpoint_ip_address>/*.log
    Tag                         checkpoint.*
    Read_from_Head              True
    DB                          /etc/fluent-bit/db/checkpoint.db
    DB.Sync                     Normal
    storage.type                filesystem
    Rotate_Wait                 30
    Refresh_Interval            60

########################################
# OUTPUT SECTION
########################################
[OUTPUT]
    Name                        s3
    Match                       checkpoint.*
    Bucket                      <<Bucket name>>
    Region                      <region>
    S3_Key_Format               /checkpoint-ngfw/%Y/%m/%d/%H/%M/%S.log.gz
    compression                 gzip
    use_put_object              On
    store_dir                   /etc/fluent-bit/db/s3
    total_file_size             1M
    log_key                     log
    upload_timeout              60
```

Note

- Logs from `cp_log_export` arrive in JSON format via syslog to the receiver host.
- `log_key log` sends only the value of the `log` key to Amazon S3.
- `storage.path` and `store_dir` provide local buffering.
- The DB parameter tracks file read positions to prevent duplicate ingestion.
- Replace `<checkpoint_ip_address>` with the actual IP address.
- Replace `<<Bucket name>>` with your actual Amazon S3 bucket name.

Step 6: IAM permissions

Create an IAM policy with the following permissions for the Fluent Bit host to write objects to the Amazon S3 bucket:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "FluentBitS3Write",
      "Effect": "Allow",
      "Action": [
        "s3:PutObject",
        "s3:GetBucketLocation",
        "s3:ListBucket",
        "s3:ListMultipartUploadParts",
        "s3:AbortMultipartUpload",
        "s3:CreateMultipartUpload",
        "s3:CompleteMultipartUpload"
      ],
      "Resource": [
        "arn:aws:s3:::<YOUR-BUCKET>",
        "arn:aws:s3:::<YOUR-BUCKET>/checkpoint-ngfw/*"
      ]
    }
  ]
}
```

Step 7: Verify

Verify the setup by confirming that log files appear in the Amazon S3 bucket and that Amazon SQS notifications are being generated. Check the Amazon SQS queue for messages indicating new object creation events.

Configuring the CloudWatch pipeline

- Choose Check Point NGFW as the data source when creating the pipeline.
- Provide the Amazon SQS queue URL and IAM role ARN.
- Select the destination CloudWatch Logs log group.
- After you create the pipeline, data will be available in the selected log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0. The following table shows the mapping between Check Point NGFW event types and OCSF event classes.

Event name	OCSF event class
Firewall	Network Activity [4001]
URL Filtering	Network Activity [4001]
HTTPS Inspection	Network Activity [4001]
Application Control	Network Activity [4001]
Identity Awareness	Network Activity [4001]
Anti Virus	Detection Finding [2004]
Anti Spam	Detection Finding [2004]
IPS	Detection Finding [2004]
Anti Bot	Detection Finding [2004]
Threat Emulation	Detection Finding [2004]

Event name	OCSF event class
Audit	Entity Management [3004]
DLP	Data Security Finding [2006]

CloudWatch pipelines configuration for Check Point NGFW

The Check Point NGFW setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the S3 source with the following parameters:

```
source:
  s3:
    aws:
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      ndjson:
    data_source_name: "checkpoint_nextgenerationfirewall"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name` (required)

Identifies the data source. Must be "checkpoint_nextgenerationfirewall".

`aws.region` (required)

The AWS region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Supports csv, json, ndjson codecs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

Cisco Duo integration configuration

Cisco Duo is a cloud-based identity and access management (IAM) platform that provides secure access through multi-factor authentication (MFA), device trust, and adaptive authentication policies. CloudWatch Pipelines use the Duo Admin API to retrieve audit logs, authentication activity, administrator actions, and policy-related events from your Cisco Duo environment.

Topics

- Source configuration for Cisco Duo
- CloudWatch pipelines configuration for Cisco Duo

Source configuration for Cisco Duo

Integrating with Cisco Duo

CloudWatch Pipeline uses the Cisco Duo Admin API to retrieve audit logs, authentication activity, administrator actions, and policy-related events from your Cisco Duo environment. The Admin API exposes REST endpoints that allow fetching time-filtered event data for security monitoring and analysis.

To integrate CloudWatch Pipelines with Cisco Duo, complete the following high-level steps:

- Create an Admin API integration in the Duo Admin Panel.

- Note the Integration Key, Secret Key, and API Hostname.
- Store the credentials in AWS Secrets Manager.
- Create a CloudWatch pipeline with Cisco Duo as the data source.
- Verify that data is flowing into the pipeline.

Prerequisites

Before you begin, ensure you have the following:

- An active Cisco Duo account with Admin API access
- A Cisco Duo auth credential with Admin API access
- An AWS account with permissions to create and manage CloudWatch Pipelines
- An AWS account with permissions to create, retrieve, and update secrets in AWS Secrets Manager

Authenticating with Cisco Duo

Cisco Duo uses HMAC Authentication with an integration key and secret key, combined with request signing. The pipeline uses these credentials to authenticate each API request to the Duo Admin API.

Configure Authentication for Cisco Duo

To configure authentication credentials for the pipeline:

1. Log in to the Duo Admin Panel and navigate to Applications > Protect an Application.
2. Search for "Admin API" and create a new integration.
3. Note the Integration Key, Secret Key, and API Hostname provided by Duo.
4. Grant the "Grant read log" permission to the integration.
5. Store the `integration_key` and `secret_key` in AWS Secrets Manager.

Configuring the CloudWatch Pipeline

To configure the pipeline, choose Cisco Duo as the data source. Provide the `api_host`, `integration_key`, and `secret_key`. Once you create and activate the pipeline, log data from Cisco Duo will begin flowing into the selected CloudWatch Logs log group.

The following optional parameters are available:

- **Page sizes** – Default is 100 for all streams. Valid ranges vary by stream.
- **Polling intervals** – Default is `P1D` (one day). Valid range is `PT30M` to `P15D`.
- **Backfill durations** – Default is `P180D` (180 days). Valid range is `PT1H` to `P180D`.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports the following OCSF event classes:

- **Base Event [0]** – Telephony Logs
- **Authentication [3002]** – Authentication Logs
- **Entity Management [3004]** – Activity Logs
- **Device Inventory Info [5001]** – Registered Devices, Phones
- **User Inventory Info [5003]** – Users

CloudWatch pipelines configuration for Cisco Duo

Collects log data from Cisco Duo using HMAC authentication through the Duo Admin API.

Configure the Cisco Duo source with the following parameters:

```
source:
  cisco_duo:
    api_host: "api-XXXXXXXX.duosecurity.com"
    authentication:
      hmac:
        integration_key: "${{aws_secrets:<secret-name>:integration_key}}"
        secret_key: "${{aws_secrets:<secret-name>:secret_key}}"
    range: "P30D"
```

Parameters

`api_host` (required)

The Duo API hostname for your organization (for example, `api-XXXXXXXX.duosecurity.com`).

`authentication.hmac.integration_key` (required)

The Duo Admin API integration key, stored in AWS Secrets Manager.

`authentication.hmac.secret_key` (required)

The Duo Admin API secret key, stored in AWS Secrets Manager.

`range` (optional)

The historical time period for backfilling data. Uses ISO 8601 duration format. Minimum is `PT1H`, maximum is `P180D`. Default is `P180D`.

Cisco Meraki integration configuration

Cisco Meraki is a cloud-managed IT platform by Cisco that provides centralized management of enterprise networking infrastructure — including security appliances (MX), wireless access points (MR), switches (MS), cameras (MV), sensors (MT), and mobile device management (SM) — through a single dashboard. CloudWatch pipelines uses the Meraki Dashboard REST API v1 to retrieve security events, configuration changes, assurance alerts, and network events from your Meraki organization.

Topics

- Source configuration for Cisco Meraki
- CloudWatch pipelines configuration for Cisco Meraki

Source configuration for Cisco Meraki

Integrating with Cisco Meraki

To integrate Cisco Meraki with CloudWatch Logs, you must configure both the source and the pipeline. First, set up your Cisco Meraki source by configuring API access to the Meraki Dashboard API to retrieve data. Then, configure the CloudWatch pipeline to ingest the data from your source into CloudWatch Logs.

Authenticating with the Meraki Dashboard API

To retrieve events from Cisco Meraki, CloudWatch pipelines needs to authenticate with your Meraki organization. Cisco Meraki supports API key access.

API key

- Generate an API key from the Meraki Dashboard. Navigate to your profile and select **API access** to generate a new API key.

- In AWS Secrets Manager, create a secret and store the API key under the key `api_key`.
- API keys are permanent and can be scoped down if needed. Ensure the API key has at least read-only access to the specific organization and the APIs.

For more information on Meraki API authorization, see Meraki API Authorization.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read data from Cisco Meraki, choose Cisco Meraki as the data source. Fill in the required information including the Organization ID and the secret where your credentials are stored. You can find your organization ID in the Meraki Dashboard under **Organization > Settings**, or by calling `GET /organizations` through the Cisco Meraki API. Once you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and Cisco Meraki Dashboard API events that map to Network Activity (4001), API Activity (6003), and Detection Finding (2004).

Network Activity (4001)

Network Activity maps to Meraki Security Events — IDS/IPS alerts (Snort-based), malware detections via Advanced Malware Protection (AMP), and file scan results from MX security appliances.

API endpoint: `GET /organizations/{organizationId}/appliance/security/events`

API Activity (6003)

API Activity maps to Meraki Configuration Changes — an audit log of all administrative actions capturing who changed what configuration, when, and the before/after values. Covers changes made via the Dashboard UI and API.

API endpoint: `GET /organizations/{organizationId}/configurationChanges`

Detection Finding (2004)

Detection Finding maps to Meraki Assurance Alerts — alerts produced by Meraki's monitoring engine that analyze device telemetry and produce discrete alerts with IDs, severity, and a lifecycle status.

API endpoint: `GET /organizations/{organizationId}/assurance/alerts`

CloudWatch pipelines configuration for Cisco Meraki

Collects log data from the Cisco Meraki Dashboard REST API v1 using API key authentication.

Configure the Cisco Meraki source with the following parameters:

```
source:
  cisco_meraki:
    organization_id: "<meraki-organization-ID>"
    range: "P7D"
    authentication:
      api_key: "${{aws_secrets:<secret-name>:api_key}}"
```

Parameters

`organization_id` (required)

The Cisco Meraki organization ID. Each pipeline collects data from a single organization. You can find your organization ID in the Meraki Dashboard under **Organization > Settings**, or by calling `GET /organizations`.

`authentication.api_key` (required)

Cisco Meraki API key, stored as a key/value pair. From the preceding example, the name of the key will be `api_key`.

`range` (optional)

The time range for log collection. Uses ISO 8601 duration format (for example, `P7D` for the last 7 days, `PT21H` for 21 hours). Default is 0 hours, and the maximum is 90 days.

> **Note**
>
> Store sensitive credentials like API keys in AWS Secrets Manager and reference them using the `${{aws_secrets:secret-name:key}}` syntax in your configuration.

Cisco Umbrella

To integrate Cisco Umbrella Data Replicator with CloudWatch Logs, you must configure both the source and the pipeline. First, set up your Cisco Umbrella source by configuring Amazon S3 and

Amazon SQS to receive data. Then, configure the CloudWatch pipeline to ingest the data from your source into CloudWatch Logs.

Topics

- Source configuration for Cisco Umbrella
- Pipeline configuration for Cisco Umbrella

Source configuration for Cisco Umbrella

Integrating with Cisco Umbrella

Cisco Umbrella is a cloud-delivered security platform that provides secure internet access and threat protection across all devices, locations, and users. It uses DNS-layer security, web filtering, and cloud-delivered firewall features to block malicious domains and prevent cyberattacks before they reach your network. CloudWatch pipelines enables you to collect this data in CloudWatch Logs.

Instructions to setup Amazon S3 and Amazon SQS

Configuring Cisco Umbrella to send logs to an Amazon S3 bucket involves several steps, primarily focused on setting up the Amazon S3 bucket, Amazon SQS queue, and IAM roles, then configuring the CloudWatch pipeline.

- Ensure Cisco Umbrella logs environment exporter is configured with S3. This is typically found under Admin → Logs Management in the Cisco Umbrella console.
- Amazon S3 bucket that stores the Cisco Umbrella logs should reside in the same AWS region as your CloudWatch pipeline.
- Create an Amazon SQS queue in the same AWS region as your Amazon S3 bucket. This queue will receive notifications when new log files are added to the Amazon S3 bucket.
- Configure the Amazon S3 bucket to create event notifications, specifically for "Object Create" events. These notifications should be sent to the Amazon SQS queue you created in the previous step.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read data from Cisco Umbrella, choose Cisco Umbrella as the data source. After filling in the required information and creating the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and Cisco Umbrella events that map to DNS Activity (4003), Network Activity (4001), Data Security Finding (2006), and Entity Management (3004). Each event comes from a source as mentioned below.

DNS Activity contains the following actions:

- DNS Logs

Network Activity contains the following actions:

- Cloud Firewall Logs
- Secure Gateway logs
- IPS logs

Data Security Finding contains the following actions:

- DLP (Data Loss Prevention) logs

Entity Management contains the following actions:

- Admin Audit logs

Pipeline configuration for Cisco Umbrella

The Cisco Umbrella setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the Cisco Umbrella source using the following parameters:

```
source:
  s3:
    aws:
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      csv:
```

```
    data_source_name: "cisco_umbrella"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
    on_error: "retain_messages"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name` (required)

Identifies the data source. This can be any string value that represents your data source. Example: "cisco_umbrella".

`aws.region` (required)

The AWS region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Supports csv, json, ndjson codecs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

`on_error` (optional)

Determines how to handle errors in Amazon SQS. Can be either retain_messages or delete_messages. Default is retain_messages.

CrowdStrike integration configuration

To integrate CrowdStrike Falcon Data Replicator with CloudWatch Logs, you must configure both the source and the pipeline. First, set up your CrowdStrike source by configuring Amazon S3 and Amazon SQS to receive FDR data. Then, configure the CloudWatch pipeline to ingest the data from your source into CloudWatch Logs.

Topics

- Source configuration for CrowdStrike
- CloudWatch pipelines configuration for CrowdStrike

Source configuration for CrowdStrike

Integrating with CrowdStrike Falcon

CrowdStrike Falcon Data Replicator (FDR) delivers and enriches endpoint, cloud workload and identity data with the CrowdStrike Security Cloud and world-class artificial intelligence (AI), enabling your team to derive actionable insights to improve security operations center (SOC) performance. Amazon CloudWatch Logs enables you to collect this data in CloudWatch Logs.

Instructions to setup Amazon S3 and Amazon SQS

Configuring CrowdStrike FDR to send logs to an Amazon S3 bucket involves several steps, primarily focused on setting up the Amazon S3 bucket, Amazon SQS queue, IAM roles, and then configuring the Amazon Telemetry Pipeline.

- Ensure CrowdStrike FDR is enabled within your CrowdStrike Falcon environment. This typically requires a specific license and may involve working with CrowdStrike support.
- Amazon S3 bucket that stores the CrowdStrike logs should reside in the same AWS region where the FDR is enabled.
- Configure the Amazon S3 bucket to create event notifications, specifically for "Object Create" events. These notifications should be sent to an Amazon SQS queue.
- Create an Amazon SQS queue in the same AWS region as your Amazon S3 bucket. This queue will receive notifications when new log files are added to the Amazon S3 bucket.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read data from CrowdStrike FDR, choose CrowdStrike as the data source. After filling in the required information and you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and the CrowdStrike FDR actions that maps to Detection Findings (2004) and Process Activity (1007).

Detection Findings

Detection Findings contains the following actions:

- CloudAssociateTreeIdWithRoot
- CustomIOADomainNameDetectionInfoEvent
- TemplateDetectAnalysis

Process Activity

Process Activity contains the following actions:

- ActiveDirectoryIncomingPsExecExecution2
- AndroidIntentSentIPC
- AssociateTreeIdWithRoot
- AutoRunProcessInfo
- BamRegAppRunTime
- BlockThreadFailed
- BrowserInjectedThread
- CidMigrationConfirmation
- CodeSigningAltered
- CommandHistory

CloudWatch pipelines configuration for CrowdStrike

The CrowdStrike setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the S3 source with the following parameters:

```
source:
  s3:
    aws:
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      ndjson:
    data_source_name: "crowdstrike_falcon"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
    on_error: "retain_messages"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name` (required)

Identifies the data source. This can be any string value that represents your data source. Example: "crowdstrike_falcon".

`aws.region` (required)

The AWS region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Supports csv, json, ndjson codecs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

`on_error` (optional)

Determines how to handle errors in Amazon SQS. Can be either retain_messages or delete_messages. Default is retain_messages.

Drupal Core integration configuration

Drupal Core is the foundational open-source web application framework built on PHP that provides the base platform for building websites, applications, and digital experiences.

Topics

- Source configuration for Drupal Core
- CloudWatch pipelines configuration for Drupal Core

Source configuration for Drupal Core

Integrating with Drupal Core

Drupal Core is the foundational open-source web application framework built on PHP that provides the base platform for building websites, applications, and digital experiences. CloudWatch Pipeline uses the custom View-based REST API to retrieve audit log data — including content changes, user authentication events, and administrative actions — from your Drupal Core site. The API enables access to time-filtered log data through REST endpoints, allowing retrieval of activity records scoped to a configurable time window.

Authenticating with Drupal Core

To read the logs, the pipeline needs to authenticate with your Drupal Core site. The plugin supports Basic Authentication (HTTP Basic Auth using a username and password).

Configure Basic Authentication for Drupal Core

- Log in to your Drupal Core admin interface and navigate to Administration → Extend (`/admin/modules`).

- Enable the following modules: RESTful Web Services, Serialization, HTTP Basic Authentication, and Views. Choose Install.
- Install and enable the Admin Audit Trail module via Composer (`composer require drupal/admin_audit_trail`) and run `drush en admin_audit_trail -y && drush cr` to activate it.
- Navigate to Structure → Views and create a new View named `Audit Logs API`. Set Show to `Log entries`, enable Provide a REST export, and set the REST export path to `/api/v1/audit-logs`.
- In the View editor, add two exposed Watchdog: Timestamp filters — one with operator `is greater than or equal to` and filter identifier `starttime`, and another with operator `is less than` and filter identifier `endtime`.
- In the REST EXPORT SETTINGS section of the View, choose Authentication and enable `basic_auth`.
- Navigate to People → Permissions and grant the roles that need API access the Access admin audit trail and Administer REST resource configuration permissions. Save the View.
- In AWS Secrets Manager, create a secret and store the Drupal Core username under the key `username` and the account password under the key `password`.

Configuring the CloudWatch Pipeline

To configure the pipeline to read logs, choose Drupal Core as the data source. Fill in the required information:

- **Domain** — The base URL of your Drupal Core site (for example, `https://your-drupal-site.example.com`).
- **API Endpoint** — The path to the View REST export endpoint (for example, `/api/v1/audit-logs`). Must start with `/`.
- **Range** — Specify the lookback duration in ISO 8601 format (for example, `PT21H` for the last 21 hours, `P7D` for the last 7 days). The default is 0 hours, and the maximum is 90 days.

Once you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and transforms events that map to Authentication (3002), Entity Management (3004), HTTP Activity (4002), and Application Lifecycle

(6002). Events that are not listed are not mapped to OCSF and will be forwarded to the sink as raw logs.

Authentication contains the following event types:

- user — Login and authentication related events

Entity Management contains the following event types:

- user — User creation and deletion
- content
- comment

HTTP Activity contains the following event types:

- access denied
- page not found
- php
- new custom types

Application Lifecycle contains the following event types:

- system
- cron

CloudWatch pipelines configuration for Drupal Core

Collects audit logs from Drupal Core using basic authentication.

Configure the Drupal source with the following parameters:

```
source:
  drupal_core:
    range: "P7D"
    domain: "<drupal-site-domain>"
    api_endpoint: "<drupal-api-endpoint>"
    authentication:
```

```
      basic:
        username: "${{aws_secrets:<secret-name>:username}}"
        password: "${{aws_secrets:<secret-name>:password}}"
```

Parameters

`range` (optional)

For pulling historical logs. Uses ISO 8601 duration format (for example, `P7D` for the last 7 days, `PT21H` for the last 21 hours). The default is 0 hours, and the maximum is 90 days.

`domain` (required)

The domain name of the Drupal Core site.

`api_endpoint` (required)

The path of the Drupal Core audit logs API endpoint. Must start with `/` (for example, `/api/v1/audit-logs`).

`authentication.basic.username` (required)

The username for Basic Authentication.

`authentication.basic.password` (required)

The password for Basic Authentication.

Entrust IDaaS integration configuration

Entrust Identity as a Service (IDaaS) is a cloud-based Identity and Access Management (IAM) platform that provides multi-factor authentication (MFA), single sign-on (SSO), adaptive risk-based authentication, and comprehensive audit logging across workforce, consumer, and citizen use cases.

Topics

- Source configuration for Entrust IDaaS
- CloudWatch pipelines configuration for Entrust IDaaS

Source configuration for Entrust IDaaS

Integrating with Entrust IDaaS

Entrust Identity as a Service (IDaaS) is a cloud-based Identity and Access Management (IAM) platform that provides multi-factor authentication (MFA), single sign-on (SSO), adaptive risk-based authentication, and comprehensive audit logging across workforce, consumer, and citizen use cases. CloudWatch pipeline uses the Entrust IDaaS Administration REST API to retrieve identity and access events from your IDaaS tenant. The Administration REST API provides access to two primary log categories: Authentication Logs (capturing user authentication events across multiple event types including MFA, SSO, SAML, OIDC, and passwordless authentication methods) and Management Logs (tracking administrative actions and changes performed across various entity types such as users, groups, applications, tokens, and policies).

Authenticating with Entrust IDaaS

To read the logs, the pipeline needs to authenticate with your Entrust IDaaS tenant. The plugin supports Administration API authentication using an `applicationId` and `sharedSecret`.

Create an Administration API application

- Go to your IDaaS Admin portal and navigate to Security → Applications.
- Choose + and select Administration API from the list of available applications.
- In the General tab, enter a name and description for your application, then choose Next.
- In the Setup tab, assign the role with the permissions required by your application, then choose Submit. The Entrust IDaaS Administration API requires the Super Administrator role to access audit log endpoints.
- In the Complete tab, choose Copy to copy your `applicationId` and `sharedSecret`, or download the JSON file.
- In AWS Secrets Manager, create a secret and store the `applicationId` under the key `client_id` and the `sharedSecret` under the key `client_secret`.
- Your IDaaS API base URL is `https://<hostname>` where `hostname` is taken from the credentials (for example, `https://entrust.us.trustedauth.com`).

Configuring the CloudWatch Pipeline

To configure the pipeline to read audit logs from Entrust IDaaS, choose `entrust_idaas` as the data source. Fill in the required information such as your tenant `hostname` and the AWS Secrets

Manager secret ARN for your credentials where `client_id` and `client_secret` are stored. Once you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and events that map to Authentication (3002) and Entity Management (3004).

Authentication contains the following events:

- AuthenticationAdminApiSuccessEvent
- AuthenticationDeniedEvent
- AuthenticationExternalSecondFactorBypassEvent
- AuthenticationExternalSuccessEvent
- AuthenticationFaceSuccessEvent
- AuthenticationFidoSuccessEvent
- AuthenticationFirstFactorExternalSuccessEvent
- AuthenticationFirstFactorIdpSuccessEvent
- AuthenticationFirstFactorPasswordSuccessEvent
- AuthenticationGridSuccessEvent
- AuthenticationGridWithTempAccessCodeSuccessEvent
- AuthenticationIdpSuccessEvent
- AuthenticationKbaSuccessEvent
- AuthenticationLockedEvent
- AuthenticationMagicLinkSuccessEvent
- AuthenticationOtpCreatedEvent
- AuthenticationOtpEmailSentEvent

CloudWatch pipelines configuration for Entrust IDaaS

Collects identity and access management audit logs from Entrust IDaaS using OAuth2 authentication.

Configure the Entrust IDaaS source with the following parameters:

```
source:
  entrust_idaas:
    hostname: "<hostname>"
    range: "P7D"
    authentication:
      oauth2:
        client_id: "${{aws_secrets:<secret-name>:client_id}}"
        client_secret: "${{aws_secrets:<secret-name>:client_secret}}"
```

Parameters

`hostname` (required)

Entrust IDaaS tenant hostname (for example, `entrust.us.trustedauth.com`). Do not include the `https://` prefix.

`authentication.oauth2.client_id` (required)

OAuth2 client ID for Entrust IDaaS Administration API authentication.

`authentication.oauth2.client_secret` (required)

OAuth2 client secret for Entrust IDaaS Administration API authentication.

`range` (optional)

The time range for log collection. Uses ISO 8601 duration format (for example, `P7D` for the last 7 days, `PT21H` for 21 hours). Default is 0 hours, and the maximum is 90 days.

> **Note**
>
> The parameter information should correspond to values received in the Authenticating with Entrust IDaaS section.

F5 BIG-IP integration configuration

F5 Telemetry Streaming is a real-time log streaming solution that delivers detailed traffic and security logs from F5 BIG-IP to external destinations such as Amazon S3 and CloudWatch. It enables monitoring, troubleshooting, and analysis of logs generated by modules like AFM, LTM, APM, ASM, and Advanced WAF.

Topics

- Source configuration for F5 BIG-IP
- CloudWatch pipelines configuration for F5 BIG-IP

Source configuration for F5 BIG-IP

Integrating with F5 BIG-IP

To integrate F5 BIG-IP with CloudWatch Logs, you must configure both the source and the pipeline. First, set up your F5 BIG-IP source by configuring Amazon S3 and Amazon SQS to receive data. Then, configure the CloudWatch pipeline to ingest the data from your source into CloudWatch Logs.

Setup log forwarding

F5 BIG-IP supports real-time log delivery via Telemetry Streaming to forward logs to Amazon S3.

Instructions to setup Amazon S3 and Amazon SQS

Configuring F5 BIG-IP to send logs to an Amazon S3 bucket involves several steps. These steps focus on setting up the Amazon S3 bucket, Amazon SQS queue, and IAM credentials, and then configuring Telemetry Streaming and the CloudWatch pipeline.

- Ensure F5 BIG-IP Telemetry Streaming is installed and configured. Create an Amazon S3 bucket to store logs. It is recommended to enable server-side encryption for security.
- Amazon S3 bucket that stores the F5 BIG-IP logs should reside in the same AWS Region.

- Configure the Amazon S3 bucket to create event notifications, specifically for "Object Create" events. These notifications should be sent to an Amazon SQS queue.
- Create an Amazon SQS queue in the same AWS Region as your Amazon S3 bucket. This queue will receive notifications when new log files are added to the Amazon S3 bucket.

Configuring F5 BIG-IP log forwarding

- Install and verify the Telemetry Streaming (TS) extension.
- Create a log destination (Amazon S3, CloudWatch, or other supported destination).
- Create a log publisher and map the destination.
- Create a logging profile specific to each module (for example, ASM, Advanced WAF).
- Apply the logging profile to the virtual server.
- Configure Telemetry Streaming (JSON declaration).
- Define the destination S3 bucket and log types.

Configuring Telemetry Streaming

- Configure Telemetry Streaming using the declarative API endpoint: `/mgmt/shared/telemetry/declare`.
- Define the Telemetry configuration with class `Telemetry`.
- Define a Telemetry Listener to receive logs (for example, port 6514).
- Define a Telemetry Consumer of type Amazon S3: configure the bucket name and Region, and provide IAM access key and secret key for authentication.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read data from F5 BIG-IP, choose F5 BIG-IP as the data source. After filling in the required information and you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and F5 BIG-IP events that map to Network Activity (4001) and HTTP Activity (4002). The following lists show the source for each event.

Network Activity (4001) contains the following log formats:

- AFM
- APM

HTTP Activity (4002) contains the following log formats:

- ASM
- LTM
- Advanced WAF

Events that do not match any OCSF mapping transformation are automatically passed through and sent directly to the configured sink without additional processing.

CloudWatch pipelines configuration for F5 BIG-IP

The F5 BIG-IP setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the F5 BIG-IP source using the following parameters:

```
source:
  s3:
    aws:
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      ndjson:
    data_source_name: "f5_bigip"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
    on_error: "retain_messages"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name` (required)

Identifies the data source. This can be any string value that represents your data source. Example: "f5_bigip".

`aws.region` (required)

The AWS Region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Supports csv, json, ndjson codecs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

`on_error` (optional)

Determines how to handle errors in Amazon SQS. Can be either retain_messages or delete_messages. Default is retain_messages.

GitHub Audit Log integration configuration

Amazon Telemetry Pipelines enables you to collect audit logs from GitHub Enterprise Cloud. GitHub Enterprise is an enterprise-grade software development platform designed for the complex workflows of modern development.

Topics

- Source configuration for GitHub Audit Log

- CloudWatch pipelines configuration for GitHub Audit Log

Source configuration for GitHub Audit Log

> **Note**
>
> Important: GitHub Enterprise accounts are required to use this connector. GitHub Personal or Organization accounts are not supported.

Integrating with GitHub

Amazon Telemetry Pipelines enables you to collect audit logs from GitHub Enterprise Cloud. GitHub Enterprise is an enterprise-grade software development platform designed for the complex workflows of modern development. GitHub Enterprise Cloud is the cloud-based solution of GitHub Enterprise, hosted on GitHub's servers.

Authenticating with GitHub

To read the audit logs, pipeline needs to authenticate with your GitHub account. For Enterprise scope , you can use Personal Access Token and for Organization scope , you can either use Personal Access Token or GitHub App.

Generate the token to authenticate as Personal Access Token:

- Sign in to GitHub using credentials for the GitHub account
- The authenticated user must be an enterprise admin to use this endpoint
- Open the GitHub Personal access tokens (classic) page, locate the Generate new token (classic) and then follow the GitHub procedure to generate a token with `read:audit_log` scope and No expiration
- Store this new token in a secret in the AWS Secrets Manager under the key `personal_access_token`

Generate the private key to authenticate as GitHub App:

- Sign in to GitHub using credentials for the GitHub account
- Ensure the GitHub App has the "Administration" organization permissions (read) permission
- Follow the instructions in Managing private keys for GitHub Apps and generate the private key

- Store this private key in a secret in the AWS Secrets Manager under the key `private_key` and the GitHub App name under the key `app_id`

Configuring the CloudWatch Pipeline

When configuring the pipeline to read audit logs from GitHub Enterprise Cloud, choose GitHub Audit Logs as the data source. Select the Source Type as Enterprise or Organization based on the scope of your integration and fill in the required information like Enterprise or Organization name according to the selected scope. Once you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and the GitHub actions that maps to Account Change (3001), API Activity (6003) and Entity Management (3004).

Account Change contains the following actions:

- org.enable_two_factor_requirement
- org.disable_two_factor_requirement
- two_factor_authentication.add_factor
- two_factor_authentication.enabled
- two_factor_authentication.disabled
- two_factor_authentication.remove_factor
- org.disable_saml
- org.enable_saml
- personal_access_token.access_restriction_disabled
- personal_access_token.access_restriction_enabled
- personal_access_token.expiration_limit_set
- personal_access_token.expiration_limit_unset

API Activity contains the following actions:

- repository_secret_scanning_custom_pa....create
- repository_secret_scanning_custom_pa....update
- repository_secret_scanning_custom_pa....delete

- repository_secret_scanning_custom_pa....publish
- repository_secret_scanning_custom_p....enabled
- repository_secret_scanning_custom_p....disabled
- repository_secret_scanning_non_provi....enabled
- repository_secret_scanning_non_provi....disabled
- repository_secret_scanning_generic_s....enabled

- business_secret_scanning_push_protection.enabled_for_new_repos
- business_secret_scanning_push_protection.disabled_for_new_repos
- business_secret_scanning_push_prote....enable
- business_secret_scanning_push_prote....update
- business_secret_scanning_push_prote....disable

CloudWatch pipelines configuration for GitHub Audit Log

> **Note**
>
> Important: GitHub Enterprise accounts are required to use this connector. GitHub Personal or Organization accounts are not supported.

Collects audit log data from GitHub organizations or enterprises using personal access tokens or GitHub App authentication.

Configure the GitHub Audit Log source with the following parameters:

```
source:
  github_auditlog:
    scope: "ORGANIZATION"
    organization: "<example-org-name>"
    range: "P7D"
```

```
    authentication:
      personal_access_token: "${{aws_secrets:<secret-name>:token}}"
```

Parameters

`scope` (required)

Scope of audit logs to collect. Must be "ORGANIZATION" or "ENTERPRISE".

`organization` (required when scope is ORGANIZATION)

GitHub organization name.

`enterprise` (required when scope is ENTERPRISE)

GitHub enterprise name.

`authentication.personal_access_token` (required for PAT auth)

Personal access token for GitHub API authentication.

`range` (optional)

The time range for log collection. Uses ISO 8601 duration format (for example, `P7D` for the last 7 days, `PT21H` for 21 hours). Default is 0 hours, and the maximum is 90 days.

GitLab integration configuration

GitLab is a DevSecOps platform that provides source code management, CI/CD pipelines, project planning, and security scanning capabilities. CloudWatch Pipelines use the GitLab REST API and GraphQL API to retrieve audit events, project activity, merge request data, group membership information, and vulnerability findings from your GitLab environment.

Topics

- Source configuration for GitLab
- CloudWatch pipelines configuration for GitLab

Source configuration for GitLab

Integrating with GitLab

CloudWatch Pipeline uses the GitLab REST API and GraphQL API to retrieve audit events, project activity, merge request data, group membership information, and vulnerability findings from your

GitLab environment. The REST API exposes endpoints for fetching time-filtered event data for security monitoring and compliance analysis, while the GraphQL API is used to retrieve project vulnerability data.

To integrate CloudWatch Pipelines with GitLab, complete the following high-level steps:

- Generate a Personal Access Token (PAT) in the GitLab Console.
- Store the credentials in AWS Secrets Manager.
- Create a CloudWatch pipeline with GitLab as the data source.
- Verify that data is flowing into the pipeline.

Prerequisites

Before you begin, ensure you have the following:

- An active GitLab (SaaS) account with Owner or Admin access
- A GitLab Personal Access Token (PAT) with the `read_api` scope
- An AWS account with permissions to create and manage CloudWatch Pipelines
- An AWS account with permissions to create, retrieve, and update secrets in AWS Secrets Manager

Authenticating with GitLab

GitLab uses a Personal Access Token (PAT) for authentication. The pipeline passes the token through the `PRIVATE-TOKEN` header to authenticate each API request.

Configure Authentication for GitLab

To configure authentication credentials for the pipeline:

1. In the upper-right corner of GitLab, select your avatar.
2. Select **Edit profile**.
3. In the left sidebar, select **Access** > **Personal access tokens**.
4. From the **Generate token** dropdown, select **Legacy token**.
5. Enter a token name.
6. (Optional) Enter a token description.
7. Set an expiration date for the token.

8. Select `read_api` as the scope.
9. Select **Generate token**.
10. Save the token value.
11. Store the `pat_token` in AWS Secrets Manager.

Configuring the CloudWatch Pipeline

To configure the pipeline, choose GitLab as the data source. Provide the Personal Access Token. Once you create and activate the pipeline, audit and activity data from GitLab will begin flowing into the selected CloudWatch Logs log group.

The following optional parameters are available:

- **Polling intervals** – `members_polling_interval` (default `P1D`), `vulnerabilities_polling_interval` (default `P1D`)
- **Backfill durations** – `projects_backfill` (default `P180D`), `merge_requests_backfill` (default `P180D`), `group_audit_events_backfill` (default `P180D`), `project_audit_events_backfill` (default `P180D`)

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports the following OCSF event classes:

- **Vulnerability Finding [2002]** – Vulnerability Finding Activity
- **Group Management [3006]** – Group Audit Event Activity
- **User Inventory Info [5003]** – Member Activity
- **Software Inventory Info [5020]** – Project Activity
- **Web Resources Activity [6001]** – Merge Request Activity

CloudWatch pipelines configuration for GitLab

Collects log data from GitLab using Personal Access Token authentication through the GitLab REST API and GraphQL API.

Configure the GitLab source with the following parameters:

```
source:
```

```
  gitlab:
    authentication:
      personal_access_token: "${{aws_secrets:gitlab-account-credentials:pat_token}}"
    range: "P30D"
```

Parameters

`authentication.personal_access_token` (required)

The GitLab Personal Access Token with `read_api` scope, stored in AWS Secrets Manager.

`range` (optional)

The historical time period for backfilling data. Uses ISO 8601 duration format. Minimum is `PT1H`, maximum is `P180D`. Default is `P180D`.

HashiCorp Vault integration configuration

HashiCorp Vault is the industry-leading secrets management and encryption-as-a-service platform that enables organizations to centrally store, access, and distribute digital secrets. CloudWatch Pipelines allow ingestion of HashiCorp Vault audit log and operational log data into CloudWatch Logs.

Topics

- Source configuration for HashiCorp Vault
- CloudWatch pipelines configuration for HashiCorp Vault

Source configuration for HashiCorp Vault

Integrating with HashiCorp Vault

HashiCorp Vault integration uses Amazon S3 and Amazon SQS to ingest log data into CloudWatch pipelines. Vault produces two log types: audit logs (detailed JSON records of all API requests and responses) and operational logs (server health and performance). Fluent Bit collects both log types from the Vault host and delivers them to an Amazon S3 bucket. Amazon SQS notifications alert the pipeline when new log objects arrive.

Prerequisites

- An AWS account with permissions to create Amazon S3 buckets, Amazon SQS queues, and IAM roles

- A HashiCorp Vault server (self-managed) with administrative access
- A Linux host with Fluent Bit installed (can be the same host as Vault)
- Network connectivity between the Vault host and AWS

Log forwarding setup

HashiCorp Vault audit logs can be forwarded to Amazon S3 using the Vault file audit device combined with Fluent Bit. Vault supports three audit device types: **file**, **socket**, and **syslog**. We recommend the **file** audit device for highest reliability.

Instructions to setup Amazon S3 and Amazon SQS

Complete the following steps to configure the Amazon S3 and Amazon SQS infrastructure for HashiCorp Vault log ingestion.

Step 1: Create Amazon S3 bucket

Create an Amazon S3 bucket to store HashiCorp Vault logs. The bucket must reside in the same AWS Region where you plan to create the CloudWatch pipeline.

Step 2: Create Amazon SQS queue

Create an Amazon SQS queue in the same AWS Region as your Amazon S3 bucket. This queue receives notifications when new log files are added to the bucket.

Step 3: Connect Amazon S3 to Amazon SQS

Configure the Amazon S3 bucket to send event notifications for `s3:ObjectCreated:*` events to the Amazon SQS queue.

Step 4: Configure Amazon SQS queue policy

Configure the Amazon SQS queue policy to allow the Amazon S3 bucket to send messages to the queue. Apply the following policy to your Amazon SQS queue:

```
{
  "Version": "2012-10-17",
  "Id": "AllowS3ToSQS",
  "Statement": [
    {
      "Sid": "AllowS3BucketNotification",
      "Effect": "Allow",
```

```
      "Principal": {
        "Service": "s3.amazonaws.com"
      },
      "Action": "sqs:SendMessage",
      "Resource": "arn:aws:sqs:<region>:<account-id>:<queue-name>",
      "Condition": {
        "ArnEquals": {
          "aws:SourceArn": "arn:aws:s3:::<YOUR-BUCKET>"
        },
        "StringEquals": {
          "aws:SourceAccount": "<account-id>"
        }
      }
    }
  ]
}
```

Step 5: Configure Vault log export and Fluent Bit

Enable the Vault file audit device to write audit logs:

```
vault audit enable file file_path=/var/log/vault/audit.log
```

Configure JSON operational logs in the Vault server configuration file (`vault.hcl`):

```
log_level = "info"
log_format = "json"
```

Configure Fluent Bit to collect both audit and operational logs and deliver them to Amazon S3:

```
########################################
# SERVICE SECTION
########################################
[SERVICE]
    Flush        5
    Daemon       Off
    Log_Level    info
    storage.path /etc/fluent-bit/db/storage
    storage.sync normal
    storage.checksum off
    storage.backlog.mem_limit 10M

########################################
```

```
# INPUT SECTION
########################################
[INPUT]
    Name             tail
    Path             /var/log/vault/audit.log
    Tag              vault.audit
    Parser           json
    Read_from_Head   False
    DB               /etc/fluent-bit/db/vault-audit.db
    DB.Sync          Normal
    storage.type     filesystem
    Rotate_Wait      30
    Refresh_Interval 60

[INPUT]
    Name             tail
    Path             /var/log/vault/vault.log
    Tag              vault.operational
    Parser           json
    Read_from_Head   False
    DB               /etc/fluent-bit/db/vault-operational.db
    DB.Sync          Normal
    storage.type     filesystem
    Rotate_Wait      30
    Refresh_Interval 60

########################################
# OUTPUT SECTION
########################################
[OUTPUT]
    Name                s3
    Match               vault.*
    bucket              <YOUR-BUCKET>
    region              <region>
    s3_key_format       /hashicorp-vault/%Y/%m/%d/%H/%M/%S.log.gz
    compression         gzip
    use_put_object      On
    store_dir           /etc/fluent-bit/db/s3
    total_file_size     1M
    log_key             log
    upload_timeout      60
```

Step 6: IAM permissions

Create an IAM policy with the following permissions for the Fluent Bit host to write objects to the Amazon S3 bucket:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "FluentBitS3Write",
      "Effect": "Allow",
      "Action": [
        "s3:PutObject",
        "s3:GetBucketLocation",
        "s3:ListBucket",
        "s3:ListMultipartUploadParts",
        "s3:AbortMultipartUpload",
        "s3:CreateMultipartUpload",
        "s3:CompleteMultipartUpload"
      ],
      "Resource": [
        "arn:aws:s3:::<YOUR-BUCKET>",
        "arn:aws:s3:::<YOUR-BUCKET>/hashicorp-vault/*"
      ]
    }
  ]
}
```

Step 7: Verify

Verify the setup by confirming that log files appear in the Amazon S3 bucket and that Amazon SQS notifications are being generated. Check the Amazon SQS queue for messages indicating new object creation events.

Configuring the CloudWatch pipeline

- Choose HashiCorp Vault as the data source when creating the pipeline.
- Provide the Amazon SQS queue URL and IAM role ARN.
- Select the destination CloudWatch Logs log group.
- After you create the pipeline, data will be available in the selected log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0. The following table shows the mapping between HashiCorp Vault log types and OCSF event classes. Events that are not mapped are forwarded as raw logs.

Event name	OCSF event class
Audit	API Activity [6003]
Operational	N/A (raw pass-through)

CloudWatch pipelines configuration for HashiCorp Vault

The HashiCorp Vault setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the S3 source with the following parameters:

```
source:
  s3:
    aws:
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      ndjson:
    data_source_name: "hashicorp_vault"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name` (required)

Identifies the data source. Must be "hashicorp_vault".

`aws.region` (required)

The AWS region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Supports csv, json, ndjson codecs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

Jamf Pro integration configuration

Jamf Pro is a comprehensive device management solution for Apple devices. CloudWatch Pipelines use the Jamf Pro API to retrieve device inventory, compliance data, and management events from your Jamf Pro environment.

Topics

- Source configuration for Jamf Pro
- CloudWatch pipelines configuration for Jamf Pro

Source configuration for Jamf Pro

Integrating with Jamf Pro

CloudWatch Pipeline uses the Jamf Pro API to retrieve device inventory and management data. The API provides endpoints for querying computer, mobile device, and user information for security monitoring and compliance.

To integrate CloudWatch Pipelines with Jamf Pro, complete the following high-level steps:

- Create an API Client in the Jamf Pro console with appropriate permissions.
- Note the Client ID and Client Secret.
- Store the credentials in AWS Secrets Manager.
- Create a CloudWatch pipeline with Jamf Pro as the data source.
- Verify that data is flowing into the pipeline.

Prerequisites

Before you begin, ensure you have the following:

- An active Jamf Pro instance (cloud or on-premises)
- An API Client configured with read permissions for computers, mobile devices, and users
- An AWS account with permissions to create and manage CloudWatch Pipelines
- An AWS account with permissions to create, retrieve, and update secrets in AWS Secrets Manager

Authenticating with Jamf Pro

Jamf Pro uses OAuth 2.0 Client Credentials for API authentication. The pipeline uses the Client ID and Client Secret to obtain access tokens for API requests.

Configure Authentication for Jamf Pro

To configure authentication credentials for the pipeline:

1. Log in to Jamf Pro and navigate to Settings > System > API Roles and Clients.
2. Create a new API Client with the required permissions (Read Computers, Read Mobile Devices, Read Users).
3. Note the Client ID and Client Secret provided.
4. Store the `client_id` and `client_secret` in AWS Secrets Manager.

Configuring the CloudWatch Pipeline

To configure the pipeline, choose Jamf Pro as the data source. Provide the `hostname`, `client_id`, and `client_secret`. Once you create and activate the pipeline, device inventory data from Jamf Pro will begin flowing into the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports the following OCSF event classes:

- **Device Inventory Info [5001]** – Computer and mobile device inventory

CloudWatch pipelines configuration for Jamf Pro

Collects device inventory data from Jamf Pro using OAuth 2.0 Client Credentials authentication through the Jamf Pro API.

Configure the Jamf Pro source with the following parameters:

```
source:
  jamf_pro:
    hostname: "yourcompany.jamfcloud.com"
    authentication:
      oauth2:
        client_id: "${{aws_secrets:<secret-name>:client_id}}"
        client_secret: "${{aws_secrets:<secret-name>:client_secret}}"
```

Parameters

`hostname` (required)

The Jamf Pro instance hostname (for example, `yourcompany.jamfcloud.com`).

`authentication.oauth2.client_id` (required)

The Jamf Pro API Client ID, stored in AWS Secrets Manager.

`authentication.oauth2.client_secret` (required)

The Jamf Pro API Client Secret, stored in AWS Secrets Manager.

Jamf Protect integration configuration

Jamf Protect is an endpoint security solution purpose-built for macOS and iOS environments, providing real-time threat detection, behavioral analytics, and compliance monitoring across Apple device fleets. CloudWatch pipelines allow ingestion of Jamf Protect data into CloudWatch Logs.

Topics

- Source configuration for Jamf Protect
- CloudWatch pipelines configuration for Jamf Protect

Source configuration for Jamf Protect

Integrating with Jamf Protect

Jamf Protect integration uses Amazon S3 and Amazon SQS to ingest log data into CloudWatch pipelines. Jamf Protect supports native Amazon S3 delivery through Action Configurations (for macOS Security data) and Data Streams (for Jamf Security Cloud data), eliminating the need for an intermediate log forwarder such as Fluent Bit. Amazon SQS notifications alert the pipeline when new log objects arrive.

Prerequisites

- An AWS account with permissions to create Amazon S3 buckets, Amazon SQS queues, and IAM roles
- A Jamf Protect tenant with administrative access to configure Action Configurations or Data Streams
- IAM credentials for Jamf Protect to write to Amazon S3

Instructions to setup Amazon S3 and Amazon SQS

Complete the following steps to configure the Amazon S3 and Amazon SQS infrastructure for Jamf Protect log ingestion.

Step 1: Create Amazon S3 bucket

Create an Amazon S3 bucket to store Jamf Protect logs. The bucket must reside in the same AWS Region where you plan to create the CloudWatch pipeline.

Step 2: Create Amazon SQS queue

Create an Amazon SQS queue in the same AWS Region as your Amazon S3 bucket. This queue receives notifications when new log files are added to the bucket.

Step 3: Connect Amazon S3 to Amazon SQS

Configure the Amazon S3 bucket to send event notifications for `s3:ObjectCreated:*` events to the Amazon SQS queue.

Step 4: Configure Amazon SQS queue policy

Configure the Amazon SQS queue policy to allow the Amazon S3 bucket to send messages to the queue. Apply the following policy to your Amazon SQS queue:

```
{
  "Version": "2012-10-17",
  "Id": "AllowS3ToSQS",
  "Statement": [
    {
      "Sid": "AllowS3BucketNotification",
      "Effect": "Allow",
      "Principal": {
        "Service": "s3.amazonaws.com"
      },
      "Action": "sqs:SendMessage",
      "Resource": "arn:aws:sqs:<region>:<account-id>:<queue-name>",
      "Condition": {
        "ArnEquals": {
          "aws:SourceArn": "arn:aws:s3:::<YOUR-BUCKET>"
        },
        "StringEquals": {
          "aws:SourceAccount": "<account-id>"
        }
      }
    }
  ]
}
```

Step 5: Configure Jamf Protect to export logs to Amazon S3

Configure Jamf Protect to deliver log data directly to your Amazon S3 bucket.

macOS Security (Action Configuration)

1. In the Jamf Protect console, navigate to Action Configurations.
2. Create or edit an Action Configuration.
3. Configure the Amazon S3 destination with your bucket name, region, and IAM credentials.

Jamf Security Cloud (Data Streams)

1. In the Jamf Protect console, navigate to Integrations, then choose Data Streams.

2. Create a new Data Stream with Amazon S3 as the destination.
3. Provide the bucket name, region, and IAM credentials.

Step 6: Attach bucket policy

Apply the following bucket policy to your Amazon S3 bucket to allow the Jamf IAM user to write objects:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "s3-access",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::<<YOUR-ACCOUNT>>:user/<<JAMF-IAM-USER>>"
      },
      "Action": [
        "s3:PutObject",
        "s3:GetObject"
      ],
      "Resource": "arn:aws:s3:::<<YOUR-BUCKET>>/jamf-protect-logs/*"
    },
    {
      "Sid": "s3-list-bucket",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::<<YOUR-ACCOUNT>>:user/<<JAMF-IAM-USER>>"
      },
      "Action": "s3:ListBucket",
      "Resource": "arn:aws:s3:::<<YOUR-BUCKET>>",
      "Condition": {
        "StringLike": {
          "s3:prefix": "jamf-protect-logs/*"
        }
      }
    }
  ]
}
```

Step 7: Verify

Verify the setup by confirming that log files appear in the Amazon S3 bucket and that Amazon SQS notifications are being generated. Check the Amazon SQS queue for messages indicating new object creation events.

Configuring the CloudWatch pipeline

- Choose Jamf Protect as the data source when creating the pipeline.
- Provide the Amazon SQS queue URL and IAM role ARN.
- Select the destination CloudWatch Logs log group.
- After you create the pipeline, data will be available in the selected log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0. The following table shows the mapping between Jamf Protect data types and OCSF event classes.

Event name	OCSF event class
Alerts	Detection Finding [2004]
Telemetry	Pass-through
Unified Logs	Pass-through
Threat Events	Detection Finding [2004]
Network Traffic	Network Activity [4001] / DNS Activity [4003]
Access Events (ZTNA)	Pass-through
Device Data	Device Inventory Info [5001]
App Insights	Software Inventory Info [5020]
Vulnerability Data	Vulnerability Finding [2002]

CloudWatch pipelines configuration for Jamf Protect

The Jamf Protect setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the S3 source with the following parameters:

```
source:
  s3:
    aws:
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "automatic"
    codec:
      ndjson:
    data_source_name: "jamf_protect"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name` (required)

Identifies the data source. Must be "jamf_protect".

`aws.region` (required)

The AWS region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Supports csv, json, ndjson codecs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

Microsoft 365 integration configuration

This section describes how to configure Microsoft 365 as a data source for CloudWatch Pipeline.

Topics

- Source configuration for Microsoft 365
- CloudWatch pipelines configuration for Microsoft 365

Source configuration for Microsoft 365

Integrating with Microsoft 365

Microsoft 365 is a product family of productivity software, collaboration, and cloud-based services owned by Microsoft. CloudWatch Pipeline uses the Office 365 Management Activity API to retrieve information about user, admin, system, and policy actions and events from Office 365 and Microsoft Entra activity logs. Office 365 Management Activity API (also known as the Unified Auditing API) is a part of Office 365 security and compliance offerings. Customers and partners can use this information to create new or enhance existing operations, security, and compliance-monitoring solutions for the enterprise.

Authenticating with Office 365 Management Activity API

To retrieve the activities Office 365, pipelines needs to authenticate with your account. Follow the instructions in Office 365 Management APIs:

- Register an application in Azure with Supported account types, Accounts in this organizational directory only (Single tenant). After registration is complete, note down the Application (client) ID and Directory (tenant) ID.
- Generate a new key for your application. Key is also known as client secret, which are used when exchanging an authorization code for an access token.

- In the AWS Secrets Manager, create a secret and store the Application (client) ID under the key `client_id` and the client secret under the key `client_secret`
- Specify the permissions your application requires to access the Office 365 Management APIs. The permissions you need are:
  - ActivityFeed.Read: Required for all the audit content types you listed, including Audit.AzureActiveDirectory, Audit.Exchange, Audit.SharePoint, and Audit.General.
  - ActivityFeed.ReadDlp: Required specifically for the DLP.All content type
- Before you can access data through the Office 365 Management Activity API, you must enable unified audit logging for your Office 365 organization. You do this by turning on the Office 365 audit log. For instructions, see Turn Office 365 audit log search on or off.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read activities from Office 365, choose Microsoft 365 as the data source. Fill in the required information like Tenant Id using Directory (tenant) ID and the secret where `client_id` and `client_secret` are stored. Once you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and the actions from various workloads like Exchange, SharePoint, Teams, and Azure Active Directory are mapped to Account Change (3001), Authentication (3002), User Access Management (3005), Group Management (3006), Email Activity (4009), Web Resources Activity (6001), File Hosting Activity (6006), Application Lifecycle (6002), (2003), Detection Finding (2004), Incident Finding (2005), Vulnerability Finding (2002) and Unknown (0).

Compliance Finding

Compliance Finding contains the following actions:

- ApplyRecordLabel
- ComplianceSettingChanged
- ExclusionConfigurationDeleted
- NewComplianceTag
- NewRetentionCompliancePolicy
- NewRetentionComplianceRule

- CreateRulePackage
- CreateSuppressionRule
- ApproveDisposal
- RemoveComplianceTag
- SetComplianceTag
- SetRestrictiveRetentionUI
- SupervisionPolicyCreated
- SupervisionPolicyUpdated
- SupervisionPolicyDeleted
- HoldUpdated
- HoldCreated
- HoldRemoved
- DlpInfo

Detection Finding

Detection Finding contains the following actions:

- FileMalwareDetected
- DocumentSensitivityMismatchDetected
- TIMailData
- DeviceOffBoarding
- AddIndicator
- ChangeCustomDetectionRuleStatus
- CreateCustomDetection
- DeleteIndicator
- EditIndicator
- MonitoringAlertUpdated
- RunCustomDetection
- Trigger CMD Agent Canary check.
- DlpRuleMatch

- AlertEntityGenerated
- AlertTriggered

Incident Finding

Incident Finding contains the following actions:

- AddCommentToIncident
- AddTagsToIncident
- AssignUserToIncident
- CollectInvestigationPackage
- EditIncidentClassification
- RemediationActionAdded
- RemediationActionUpdated
- RemoveTagsFromIncident
- UnAssignUserFromIncident
- UpdateIncidentStatus
- CaseUpdated
- CaseAdded
- CaseRemoved

Account Change

Account Change contains the following actions:

- Add member to role
- Add service principal
- Add user
- Added role
- Change user license
- Change user password
- Delete user

- Deleted app permission
- Deleted role
- Edited global role assignment
- Edited role
- NetworkUserSuspended
- Remove member from role
- Remove delegation entry
- Reset user password
- Set force change user password
- AdministratorAddedToTermStore
- AdministratorDeletedFromTermStore
- AlertNotificationsRecipientDeleted
- CaseAdminUpdated
- CaseAdminAdded
- CaseAdminRemoved
- User added

Authentication

Authentication contains the following actions:

- MailboxLogin
- ClockedIn
- ClockedOut
- TeamsSessionStarted
- Logon
- SignInEvent
- SSOUserCredentialsSet
- User logged in
- UserLoggedIn
- UserLoggedOff

- UserLoginFailed

User Access Management

User Access Management contains the following actions:

- Add-MailboxPermission
- ModifyFolderPermissions
- Remove-MailboxPermission
- ApplicableAdaptiveScopeChange
- CaseMemberAdded

Group Management

Group Management contains the following actions:

- RemovedFromSecureLink
- BotAddedToTeam
- BotRemovedFromTeam
- MemberAdded
- MemberRemoved
- MemberRoleChanged
- ScheduleGroupAdded
- ScheduleGroupEdited
- ScheduleGroupDeleted
- TeamCreated
- TeamDeleted
- Add group
- Add member to group
- Created group

- Remove member from group
- RemoveSpecificResponder
- RosterMemberAdded
- RosterMemberDeleted
- CaseMemberUpdated
- CaseMemberRemoved
- Team added
- Team deleted
- UserAddedToGroup
- UserRemovedFromGroup

Email Activity

Email Activity contains the following actions:

- Send
- SendAs
- SendOnBehalf
- MessageDeletedNotification
- QuarantineDelete
- QuarantineExport
- QuarantinePreview
- QuarantineRelease

- QuarantineReleaseRequest
- QuarantineReleaseRequestDeny
- QuarantineViewHeader
- SupervisionRuleMatch
- SupervisoryReviewTag
- SupervisoryReviewOLAudit

Web Resources Activity

Web Resources Activity contains the following actions:

- UpdateCalendarDelegation
- AddFolderPermissions
- Copy
- Create
- New-InboxRule
- SoftDelete
- Move
- MailItemsAccessed
- MoveToDeletedItems
- Set-InboxRule
- HardDelete

CloudWatch pipelines configuration for Microsoft 365

Collects log data from Microsoft Office 365 Management API using OAuth2 authentication.

Configure the Microsoft Office 365 source with the following parameters:

```
source:
  microsoft_office365:
    tenant_id: "<example-tenant-ID>"
    authentication:
      oauth2:
        client_id: "${{aws_secrets:<secret-name>:client_id}}"
        client_secret: "${{aws_secrets:<secret-name>:client_secret}}"
```

Parameters

`tenant_id` (required)

The Microsoft Entra ID tenant ID for your Office 365 organization.

`authentication.oauth2.client_id` (required)

OAuth2 client ID for Microsoft Office 365 Management API authentication. Can reference AWS Secrets Manager using `${{aws_secrets:secret-name:key}}` syntax.

`authentication.oauth2.client_secret` (required)

OAuth2 client secret for Microsoft Office 365 Management API authentication. Can reference AWS Secrets Manager using `${{aws_secrets:secret-name:key}}` syntax.

> **Note**
>
> Store sensitive credentials like client IDs and secrets in AWS Secrets Manager and reference them using the `${{aws_secrets:secret-name:key}}` syntax in your configuration.

Netskope integration configuration

Netskope is a cloud-native Security Service Edge (SSE) and SASE platform that provides real-time data and threat protection for cloud services, websites, and private applications. CloudWatch pipelines use the Netskope REST API v2 endpoints to retrieve security events and alerts from your Netskope tenant, including application activity, network traffic, audit events, infrastructure logs, and threat detections across DLP, malware, and policy violations.

Topics

- Source configuration for Netskope
- CloudWatch pipelines configuration for Netskope

Source configuration for Netskope

Integrating with Netskope

Netskope is a cloud-native Security Service Edge (SSE) and SASE platform that provides real-time data and threat protection for cloud services, websites, and private applications. CloudWatch Pipeline uses the Netskope REST API v2 endpoints to retrieve security events and alerts from your Netskope tenant. The REST API v2 provides access to security event and alert logs through dedicated endpoints for each log type: application, page, network, infrastructure, audit, incident, endpoint, and alert. Alert logs cover threat detections and policy violations across alert types such as DLP, malware, malsite, policy, compromised credential, and UBA.

Authenticating with Netskope

To read Netskope event and alert logs, the pipeline needs to authenticate with your tenant using a REST API v2 token issued through a Service Account under the RBACv3 framework. Follow these steps to create a Service Account and generate an API token:

1. Log in to your Netskope Admin Console at https://<your-tenant>.goskope.com.
2. Navigate to **Settings** > **Administration** > **Administrators & Roles**.
3. Choose the **Roles** tab, then choose **Create Role**.
4. Enter a Role Name (for example, "CloudWatch-API-Role") and configure the following functional area permissions:
   - **Steering**: Application Events, Page Events, Network Events, Infrastructure Events, Incident Events, Endpoint Events, Alerts — all set to View.

- **Administration**: Audit Log — set to View.
- **Access Control**: Infrastructure — set to View.
- **DLP**: DLP Incident — set to View.

5. Choose **Save** to create the role.
6. Choose the **Administrators** tab, then choose the **Service Accounts** button.
7. Choose **New Service Account** and configure:
   - **Service Account Name**: Enter a descriptive name (for example, "CloudWatch-Collector").
   - **Role**: Select the role created in step 5 (for example, "CloudWatch-API-Role").
   - **Expire In**: Set an appropriate expiration period (for example, 365 days).
8. Choose **Create**. A dialog displays the generated REST API token. Copy this token immediately — it will not be shown again.
9. In AWS Secrets Manager, create a secret and store the API token.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read event and alert logs from Netskope, choose Netskope as the data source. Fill in the required information such as your tenant hostname and the AWS Secrets Manager secret ARN for your credentials where api_token is stored. Once you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and transforms the following events that map to Authentication (3002), Entity Management (3004), Account Change (3001), Network Activity (4001), Detection Finding (2004), Data Security Finding (2006), File Hosting Activity (6006), and Device Inventory Info (5001). Events that are not listed but pulled are not mapped to OCSF and will be forwarded to the sink as raw logs.

Authentication (3002) contains the following events from two event types:

Application Events, using the "activity" field. The supported activity values are:

- Login Attempt
- Login Failed
- Login Successful
- Logout

- Other Events which contain the keyword "login"

Audit Events, using the "audit_log_event" field. The supported audit_log_event values are:

- Login Failed
- Login Successful
- Logout Successful
- SSO Login Failed
- SSO Login Successful
- SSO Login Successful by Netskope Support
- SSO Login Failed by Netskope Support
- Admin logged out because of successive login failures

Entity Management (3004) contains the following events from Audit Events:

- Created new inline policy
- Set dedicated egress ip policy
- Created new rbi template
- Created new tunnel group
- Created new introspection policy
- Next Gen CASB API instance created
- Created a new Next Gen CASB API policy
- Next Gen CASB API retroscan created
- Edited inline policy
- Update default actions for inline policies
- Edited rbi template
- Edited tunnel group
- Edit introspection policy record
- Next Gen CASB API instance updated
- Edited Next Gen CASB API policy
- Next Gen CASB API retroscan edited

- Deleted inline policy
- Deleted rbi template
- Deleted tunnel group
- Deleted introspection policy
- Next Gen CASB API instance deleted
- Deleted Next Gen CASB API policy
- Next Gen CASB API retroscan deleted
- Pushed inline policy
- Pushed rbi template
- Pushed tunnel groups
- Applied Phoenix policy record(s)
- Pushed Introspection policies
- Pushed Next Gen CASB API policies
- Next Gen CASB API retroscan stopped
- Next Gen CASB API retroscan paused

Account Change (3001) contains the following events from Audit Events:

- Created new admin
- Added SSO Admin
- Created new support admin
- Enabled admin
- Password Change Failed Attempt
- Password Change Successful
- Reset password
- Disabled admin
- Deleted admin
- Deleted Netskope SSO admin
- Enabled Netskope Support SSO
- Disabled Netskope Support SSO

- Unlocked admin
- Edited SSO Admin Record
- Edit admin record
- Updated admin settings

Network Activity (4001) contains the following events:

Network Events are categorized using the record_type="network" and "action" fields. The supported "action" values are:

- Allow
- Block
- Bypass
- Closed
- Idle Timeout
- Proceed

All events with the value of /record_type = "connection" are also included.

Detection Finding (2004) contains the following events:

Alerts are categorized using the "alert_type" and "alert" fields, where the "alert" field value is set to "yes". The supported "alert_type" values are:

- Compromised Credential
- Malsite
- Malware
- Policy
- UBA
- C2

Data Security Finding (2006) contains the following events:

- /record_type = "alert" and /alert_type = "DLP"
- /record_type = "incident"

- /record_type = "epdlp" and /type = "endpoint"

File Hosting Activity (6006) contains the following events:

Application Events are categorized using the "activity" field, with the "alert" field value set to "no". The supported activity values are:

- Browser File Upload
- Attach
- Create
- Download
- Download All
- Download Installer
- Edit
- Quick Edit
- Insert
- Delete
- Delete All
- Copy
- Move
- Preview
- Formshare
- File Share Access
- Upload
- Share
- Post
- View
- Archive
- Bluetooth File Transfer
- Detach
- Print

- Publish

Device Inventory Info (5001) contains the following events:

All infrastructure logs with record_type="infrastructure".

CloudWatch pipelines configuration for Netskope

Collects security events and alerts from Netskope using REST API v2 token-based authentication.

Configure the Netskope source with the following parameters:

```
source:
  netskope_cloudexchange:
    tenant_url: "<<your-tenant-url>>"
    range: "P7D"
    authentication:
      api_token: "${{aws_secrets:netskope-account-credentials:apiToken}}"
```

Parameters

`tenant_url` (required)

Netskope tenant URL (for example, mycompany.goskope.com).

`authentication.api_token` (required)

REST API v2 token generated from the Netskope Service Account under RBACv3.

`range` (optional)

The time range for log collection. Uses ISO 8601 duration format (for example, `P7D` for the last 7 days, `PT21H` for 21 hours). Default is 0 hours, and the maximum is 90 days.

Microsoft Entra ID integration configuration

Microsoft Entra ID (formerly Azure Active Directory) is Microsoft's cloud-based identity and access management service that helps organizations manage user identities and secure access to resources.

Topics

- Source configuration for Microsoft Entra ID

- CloudWatch pipelines configuration for Microsoft Entra ID

Source configuration for Microsoft Entra ID

Integrating with Microsoft Entra ID

Microsoft Entra ID (formerly Azure Active Directory) is Microsoft's cloud-based identity and access management service that helps organizations manage user identities and secure access to resources. CloudWatch Pipeline uses the Microsoft Graph API to retrieve comprehensive identity and security information from Microsoft Entra ID audit logs. The Microsoft Graph API provides access to three primary log types: Directory Audit Logs (tracking directory-level changes and administrative actions), Sign-In Logs (capturing user authentication events and activities), and Provisioning Logs (monitoring user and group provisioning operations).

Authenticating with Microsoft Entra ID

To retrieve the Audit Logs EntraID, pipelines needs to authenticate with your account. The plugin supports OAuth2 Authentication. Follow the instructions in Microsoft Graph APIs and should have the Microsoft Entra ID P1 or P2 license.

- Register an application in Azure with Supported account types, Accounts in this organizational directory only (Single tenant). After registration is complete, note down the Application (client) ID and Directory (tenant) ID.
- Generate a new key for your application. Key is also known as client secret, which are used when exchanging an authorization code for an access token.
- In the AWS Secrets Manager, create a secret and store the Application (client) ID under the key `client_id` and the client secret under the key `client_secret`
- Specify the permissions your application requires to access the Microsoft Graph APIs. The permissions you need are:
  - AuditLog.Read.All: Required to read audit logs, sign-in logs, and provisioning logs
  - Directory.Read.All: Required to read directory data

Configuring the CloudWatch Pipeline

When configuring the pipeline to read Audit Logs from Microsoft EntraID, choose Microsoft EntraID as the data source. Fill in the required information like Tenant Id using Directory (tenant) ID. Once you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and Entra ID events that map to Authentication (3002), Account Change (3001), User Access Management (3005), and Entity Management (3004).

Authentication contains the following events with type in brackets:

- Invalid Username or Password (Sign-in)
- User Strong Auth ClientAuthN Required Interrupt (Sign-in)
- Pass Through User Mfa Error (Sign-in)
- Authentication Failed During Strong Auth (Sign-in)

Account Change contains the following events with type in brackets:

- Add user (Audit)
- Update user (Audit)
- Delete user (Audit)
- Hard delete user (Audit)
- Reset password (Audit)
- User changed default security info (Audit)
- Enable Strong Authentication (Audit)
- Disable Strong Authentication (Audit)

User Access Management contains the following events with type in brackets:

- Add eligible member to role (Audit)
- Remove eligible member from role (Audit)
- Add eligible member to role in PIM completed (Audit)
- Remove eligible member from role in PIM completed (Audit)
- Add member to role (Audit)
- Remove member from role (Audit)
- Remove permanent direct role assignment (Audit)
- Add permanent direct role assignment (Audit)

- Triggered PIM alert (Audit)
- Add delegated permission grant (Audit)
- Remove delegated permission grant (Audit)

Entity Management contains the following events with type in brackets:

- Create (Provisioning)
- Update (Provisioning)
- Add app role assignment to service principal (Audit)
- Remove app role assignment to service principal (Audit)
- Add service principal credentials (Audit)
- Remove service principal credentials (Audit)
- Update service principal (Audit)
- Add service principal (Audit)
- Hard delete service principal (Audit)
- Remove service principal (Audit)
- Consent to application (Audit)
- Add application (Audit)
- Add owner to application (Audit)
- Hard Delete application (Audit)
- Delete application (Audit)
- Update application (Audit)
- Update application – Certificates and secrets management (Audit)
- Add device (Audit)
- Update device (Audit)
- Delete device (Audit)
- Hard delete device (Audit)

CloudWatch pipelines configuration for Microsoft Entra ID

Collects log data from Microsoft Entra ID (formerly Azure Active Directory) using OAuth2 authentication.

Configure the Microsoft Entra ID source with the following parameters:

```
source:
  microsoft_entraid:
    tenant_id: "<example-tenant-ID>"
    authentication:
      oauth2:
        client_id: "${{aws_secrets:<secret-name>:client_id}}"
        client_secret: "${{aws_secrets:<secret-name>:client_secret}}"
```

Parameters

`tenant_id` (required)

The Microsoft Entra ID tenant ID for your organization.

`authentication.oauth2.client_id` (required)

OAuth2 client ID for Microsoft Graph API authentication.

`authentication.oauth2.client_secret` (required)

OAuth2 client secret for Microsoft Graph API authentication.

Microsoft Windows Events integration configuration

Microsoft Windows Event Logs provide a comprehensive logging system that records system, security, and application events on Windows operating systems.

Topics

- Source configuration for Microsoft Windows Events
- CloudWatch pipelines configuration for Microsoft Windows Events

Source configuration for Microsoft Windows Events

Integrating with Windows Event

Microsoft Windows Event Logs provide a comprehensive logging system that records system, security, and application events on Windows operating systems. CloudWatch Pipeline uses the Log Analytics API to retrieve information about system operations, security events, user activities,

and application behaviors from Windows servers and workstations. The Log Analytics API enables access to event data through KQL (Kusto Query Language) queries, allowing retrieval of Windows Event logs from Log Analytics workspaces.

Authenticating with Windows Event

To read Windows Event audit Logs, the pipeline needs to authenticate with your account. The plugin supports OAuth2 Authentication. Follow these instructions to get started with Microsoft Windows Event: Log Analytics APIs.

- Register an application in Azure with Supported account types, Accounts in this organizational directory only (Single tenant). After registration is complete, note down the Application (client) ID and Directory (tenant) ID.
- Generate a new client secret for your application. The client secret is used when exchanging an authorization code for an access token. Copy the secret value immediately as it won't be shown again.
- In the AWS Secrets Manager, create a secret and store the Application (client) ID under the key `client_id` and the client secret under the key `client_secret`.
- Specify the API permissions your application requires to access the Log Analytics API. The permission you need is: Data.Read: Required to execute KQL queries and read log data from Log Analytics workspaces, including Windows Event logs.
- Create and configure a Log Analytics Workspace: Create a workspace in Azure portal (Monitor → Log Analytics workspaces). Create a Data Collection Rule (DCR) to specify which Windows Event Logs to collect (System, Application, Security). Connect your Windows servers/VMs to the workspace through the DCR. Note down your Workspace ID from the workspace Overview page (required for API queries)
- Grant workspace access to your application: Navigate to your Log Analytics workspace → Access control (IAM). Assign the Log Analytics Reader role to your registered application. This RBAC role works together with the API permission to provide secure access: OAuth confirms API usage rights, while IAM confirms workspace data access rights.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read logs, choose Microsoft Windows Events as the data source. Fill in the required information like Tenant Id using Directory (tenant) ID and Workspace Id (workspace_id). Once you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and Windows audit events that map to Account Change (3001), Authentication (3002), Entity Management (3004), Event Log Activity (1008), File System Activity (1001), Group Management (3006), and Kernel Activity (1003).

Account Change contains the following events:

- 4740

Authentication contains the following events:

- 4624
- 4625
- 4634
- 4647
- 4648
- 4649
- 4672

Entity Management contains the following events:

- 4616
- 4907
- 4719
- 4902

Event Log Activity contains the following events:

- 1100
- 1102
- 1104
- 1105

File System Activity contains the following events:

- 4608
- 4660
- 4688
- 4696
- 4826
- 5024
- 5033
- 5058
- 5059
- 5061
- 5382
- 5379

Group Management contains the following events:

- 4732
- 4798
- 4799
- 4733
- 4731
- 4734
- 4735

Kernel Activity contains the following events:

- 4674

CloudWatch pipelines configuration for Microsoft Windows Events

Collects log data from Microsoft Windows Event logs using OAuth2 authentication.

Configure the Microsoft Windows Event source with the following parameters:

```
source:
```

```
  microsoft_windows:
    tenant_id: "<example-tenant-ID>"
    workspace_id: "<example-workspace-ID>"
    authentication:
      oauth2:
        client_id: "${{aws_secrets:<secret-name>:client_id}}"
        client_secret: "${{aws_secrets:<secret-name>:client_secret}}"
```

Parameters

`tenant_id` (required)

The Microsoft tenant ID for your organization.

`workspace_id` (required)

The Microsoft Log Analytics workspace ID.

`authentication.oauth2.client_id` (required)

OAuth2 client ID for Log Analytics workspace API authentication.

`authentication.oauth2.client_secret` (required)

OAuth2 client secret for Log Analytics workspace API authentication.

Okta Auth0

CloudWatch pipelines enables you to collect logs from Okta Auth0. Okta Auth0 is a flexible identity platform designed for modern application authentication and authorization.

Topics

- Source configuration for Okta Auth0
- Pipeline configuration for Okta Auth0

Source configuration for Okta Auth0

Integrating with Okta Auth0

Okta Auth0 is a flexible identity platform designed for modern application authentication and authorization. Auth0 provides developers with powerful tools to integrate secure login, user management, and access control into applications while maintaining scalability and customization.

CloudWatch Pipeline uses the Auth0 Management API to retrieve Authentication (successful and failed logins), and API Activity logs from Auth0 log events.

Authenticating with Okta Auth0

To read logs, the pipeline needs to authenticate with your Okta Auth0 tenant. Auth0 Management API access requires a Client ID and Client Secret belonging to a Machine-to-Machine (M2M) application.

Generate Client Credentials see API Settings for more details.

- Sign in to the Auth0 Dashboard using an admin account.
- Navigate to Applications → Applications.
- Select an existing Machine-to-Machine Application or create a new one.
- Ensure the application has the required scope permissions for the Management API, specifically: `read:logs`
- In the AWS Secrets Manager, create a secret and store the Client ID under the key `client_id` and the Client Secret under the key `client_secret`
- Identify your Auth0 Tenant Domain (for example: `yourtenant.us.auth0.com`) and give it in pipeline.

Once configured, the pipeline can authenticate using the Client Credentials flow and retrieve log events from Auth0.

Configuring the CloudWatch Pipeline

To configure the pipeline to read logs, choose Okta Auth0 as the data source. Select the Source Type as Tenant and provide the required details such as your Auth0 Tenant Domain and Client Credentials. Once you create the pipeline, log data from Okta Auth0 will be collected and made available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and the Auth0 events that maps to Authentication (3002) and API Activity (6003)

Authentication contains the following events:

- f

- fu
- fp
- feccft
- fepft
- feacft
- fc
- fco
- fcoa
- fd
- ferrt
- fertft
- fsa
- limit_wc
- limit_sul
- limit_mu
- pwd_leak
- reset_pwd_leak
- signup_pwd_leak
- gd_auth_fail_email_verification
- gd_auth_failed
- gd_auth_rejected
- gd_otp_rate_limit_exceed
- gd_recovery_failed
- gd_recovery_rate_limit_exceed
- gd_webauthn_challenge_failed
- passkey_challenge_failed
- scp
- sv
- ss
- s

- fi
- fv
- feoobft
- feotpft
- fercft
- ss_sso_failure
- fepotpft
- fvr
- flo

API Activity contains the following events:

- api_limit
- limit_delegation
- mgmt_api_read
- sapi
- api_limit_warning

Pipeline configuration for Okta Auth0

Collects log data from Okta Auth0 using OAuth2 authentication.

Configure the Okta Auth0 source with the following parameters:

```
source:
  okta_auth0:
    domain: "<example-domain-name>"
    authentication:
      oauth2:
        client_id: "${{aws_secrets:<secret-name>:client_id}}"
        client_secret: "${{aws_secrets:<secret-name>:client_secret}}"
```

Parameters

`domain` (required)

The Okta Auth0 domain name for your organization.

`authentication.oauth2.client_id` (required)

OAuth2 client ID for Okta Auth0 API authentication.

`authentication.oauth2.client_secret` (required)

OAuth2 client secret for Okta Auth0 API authentication.

Okta SSO integration configuration

CloudWatch pipelines enables you to collect logs from Okta SSO. Okta SSO is a leading cloud-based identity and access management solution that provides secure, centralized authentication for users and applications.

Topics

- Source configuration for Okta SSO
- CloudWatch pipelines configuration for Okta SSO

Source configuration for Okta SSO

Integrating with Okta SSO

CloudWatch Pipeline uses the Okta System Log API to retrieve Authentication, API Activity, Detection Finding and Entity Management events from your Okta SSO tenant.

Authenticating with Okta SSO

To read the logs, the pipeline needs to authenticate with your Okta SSO tenant. For Okta SSO, authentication is performed using the OAuth 2.0 Client Credentials (JWT Assertion) flow through an Okta API Services application.

Generate the private/public key pair for authentication

- Sign in to the Okta Admin Console using an administrator account.
- Navigate to Applications → Applications.
- Select an existing API Services Application or create a new one.
- Under General → Client Credentials, upload a public key or generate a new key. This key pair will be used to authenticate using a signed JWT assertion.
- Ensure the application has the required OAuth scopes assigned, specifically: `okta.logs.read`

- Admin Roles → Edit assignments → Role(Select Read-only Administrator)
- Copy the Client ID of the application.
- Store the client_id and client_secret(private key) in AWS Secrets Manager: `client_id` and `client_secret(private_key)` (the RSA private key used to sign the JWT assertion)
- Identify your Okta Organization URL and configure in the pipeline (for example: `https://yourdomain.okta.com`).

Once configured, the pipeline can authenticate using Okta's OAuth 2.0 Client Credentials (JWT Assertion) flow and begin retrieving audit log events from the Okta System Log API.

Configuring the CloudWatch Pipeline

To configure the pipeline to read logs, choose Okta SSO as the data source. Fill in the required information like Okta Domain name. Once you create and activate the pipeline, audit log data from Okta SSO will begin flowing into the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and Okta events that map to Authentication (3002), API Activity (6003), Detection Finding (2004), and Entity Management (3004).

Authentication contains the following events:

- user.authentication.auth
- user.authentication.auth_via_AD_agent
- user.authentication.auth_via_IDP
- user.authentication.auth_via_LDAP_agent
- user.authentication.auth_via_inbound_SAML
- user.authentication.auth_via_inbound_delauth
- user.authentication.auth_via_iwa
- user.authentication.auth_via_mfa
- user.authentication.auth_via_radius
- user.authentication.auth_via_richclient
- user.authentication.auth_via_social
- user.authentication.authenticate

- user.authentication.sso
- user.session.start
- user.session.impersonation.grant
- app.oauth2.signon
- user.session.impersonation.initiate
- user.authentication.universal_logout
- user.session.clear
- user.session.end
- user.authentication.slo
- user.authentication.universal_logout.scheduled
- user.session.expire
- user.session.impersonation.end
- user.authentication.verify
- policy.evaluate_sign_on
- user.mfa.attempt_bypass
- user.mfa.okta_verify
- user.mfa.okta_verify.deny_push
- user.mfa.okta_verify.deny_push_upgrade_needed
- user.mfa.factor.activate
- user.mfa.factor.deactivate
- user.mfa.factor.reset_all
- user.mfa.factor.suspend
- user.mfa.factor.unsuspend
- user.mfa.factor.update
- user.session.impersonation.extend
- user.session.impersonation.revoke
- user.session.access_admin_app
- user.session.context.change
- application.policy.sign_on.deny_access

- user.authentication.auth_unconfigured_identifier
- user.authentication.dsso_via_non_priority_source
- app.oauth2.invalid_client_credentials
- policy.auth_reevaluate.fail

API Activity contains the following events:

- oauth2.claim.created
- oauth2.scope.created
- security.trusted_origin.create
- system.api_token.create
- workflows.user.table.view
- app.oauth2.as.key.rollover
- app.saml.sensitive.attribute.update
- system.api_token.update
- oauth2.claim.updated
- oauth2.scope.updated
- security.events.provider.deactivate
- system.api_token.revoke
- oauth2.claim.deleted
- oauth2.scope.deleted

Detection Finding contains the following events:

- security.attack.start
- security.breached_credential.detected
- security.request.blocked
- security.threat.detected
- security.zone.make_blacklist
- system.rate_limit.violation
- user.account.report_suspicious_activity_by_enduser

- user.risk.change
- user.risk.detect
- zone.make_blacklist
- security.attack.end

Entity Management contains the following events:

- iam.role.create
- system.idp.lifecycle.create
- application.lifecycle.create
- group.lifecycle.create
- user.lifecycle.create
- policy.lifecycle.create
- zone.create
- oauth2.as.created
- event_hook.created
- inline_hook.created
- pam.security_policy.create
- iam.resourceset.create
- pam.secret.create
- analytics.reports.export.download
- app.audit_report.download
- system.idp.lifecycle.read_client_secret
- app.oauth2.client.read_client_secret
- pam.secret.reveal
- pam.service_account.password.reveal
- support.org.update
- system.idp.lifecycle.update
- application.lifecycle.update
- policy.lifecycle.update

- user.account.update_profile
- user.account.update_password
- user.account.reset_password
- group.profile.update
- zone.update
- group.privilege.grant
- group.privilege.revoke
- iam.resourceset.bindings.add
- user.account.privilege.grant
- user.account.privilege.revoke
- pki.cert.lifecycle.revoke
- iam.resourceset.update
- iam.role.update
- pam.security_policy.update
- oauth2.as.updated
- event_hook.updated
- inline_hook.updated
- pam.secret.update
- iam.resourceset.bindings.delete
- iam.role.delete
- pam.security_policy.delete
- policy.lifecycle.delete
- user.lifecycle.delete.initiated
- application.lifecycle.delete
- group.lifecycle.delete
- zone.delete
- oauth2.as.deleted
- event_hook.deleted
- inline_hook.deleted

- iam.resourceset.delete
- pam.secret.delete
- device.enrollment.create
- credential.register
- credential.revoke
- policy.lifecycle.activate
- system.feature.enable
- event_hook.activated
- inline_hook.activated
- system.feature.disable
- application.lifecycle.activate
- user.lifecycle.activate
- zone.activate
- oauth2.as.activated
- system.log_stream.lifecycle.activate
- policy.lifecycle.deactivate
- security.authenticator.lifecycle.deactivate
- application.lifecycle.deactivate
- user.lifecycle.deactivate
- zone.deactivate
- event_hook.deactivated
- inline_hook.deactivated
- system.log_stream.lifecycle.deactivate
- oauth2.as.deactivated
- user.account.lock
- user.account.lock.limit
- user.lifecycle.suspend
- device.lifecycle.suspend
- user.account.unlock

- user.lifecycle.unsuspend
- device.lifecycle.unsuspend
- user.lifecycle.reactivate

CloudWatch pipelines configuration for Okta SSO

Collects log data from Okta SSO using OAuth2 authentication.

Configure the Okta SSO source with the following parameters:

```
source:
  okta_sso:
    domain: "<example-domain-name>"
    range: "P7D"
    authentication:
      oauth2:
        client_id: "${{aws_secrets:<secret-name>:client_id}}"
        client_secret: "${{aws_secrets:<secret-name>:client_secret}}"
```

Parameters

`domain` (required)

The Okta domain name for your organization.

`authentication.oauth2.client_id` (required)

OAuth2 client ID for Okta SSO API authentication.

`authentication.oauth2.client_secret` (required)

OAuth2 client secret for Okta SSO API authentication.

`range` (optional)

The time range for log collection. Uses ISO 8601 duration format (for example, `P7D` for the last 7 days, `PT21H` for 21 hours). Default is 0 hours, and the maximum is 90 days.

OneLogin Identity integration configuration

OneLogin is a cloud-based identity and access management (IAM) platform that provides single sign-on (SSO), multi-factor authentication (MFA), and user provisioning capabilities.

Topics

- Source configuration for OneLogin Identity
- CloudWatch pipelines configuration for OneLogin Identity

Source configuration for OneLogin Identity

Integrating with OneLogin Identity

OneLogin is a cloud-based identity and access management (IAM) platform that provides single sign-on (SSO), multi-factor authentication (MFA), and user provisioning capabilities. CloudWatch pipelines uses the OneLogin Events API to retrieve information about authentication events, user activities, policy decisions, and administrative changes across your OneLogin environment. The Events API enables access to event data through REST endpoints, allowing retrieval of security and access logs from your OneLogin account.

Authenticating with OneLogin Identity

To read the logs, the pipeline needs to authenticate with your OneLogin account. For OneLogin, authentication is performed using OAuth2.

Configure OAuth2 authentication for OneLogin

- Log in to the OneLogin Admin Portal and navigate to Developers → API Credentials. Create a new API credential pair. Note the Client ID and Client Secret immediately.
- Assign the appropriate permissions. Select Read All or Manage All scope to ensure the credentials can access event log data.
- In AWS Secrets Manager, create a secret and store the Client ID under key `client_id` and the client secret under key `client_secret`.
- Note your Account ID (subdomain) from the OneLogin Admin Portal under Settings → Account Settings.

Configuring the CloudWatch Pipeline

To configure the pipeline to read logs, choose OneLogin as the data source. Fill in the required information like subdomain and authentication credentials. Optionally, specify the Range duration format (for example, PT21H for the last 21 hours). Once you create and activate the pipeline, event log data from OneLogin will begin flowing into the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and OneLogin events that map to Account Change (3001), Authentication (3002), and Entity Management (3004).

Account Change contains the following events:

- User requested new password
- Changed password for user
- User deactivated
- Password request approved from user
- User locked
- User suspended
- User locked out of app
- OTP device unlocked for user
- User suspended in app
- User suspended in directory
- Unlocked user in directory
- User granted permission to manage role
- User permission to manage role revoked
- User enabled desktop SSO
- User disabled desktop SSO
- Admin changed password for user
- Redirected to an external site for password reset
- API - password updated for user
- API - user locked
- User suspended via API
- User locked via API
- User enabled adaptive login for account
- User disabled adaptive login for account
- Profile change password
- Manually added user to app

- Manually removed user from app
- Failed to change password for user
- User granted permission to manage role failed
- User permission to manage role revoked failed
- Smart password updated for user
- Smart password could not be updated for user
- API - password not updated for user

Authentication contains the following events:

- User logged into OneLogin
- User logged out of OneLogin
- User logged into app
- User logged out of app
- User authenticated by RADIUS configuration
- User authenticated via API
- User successfully authenticated with VLDAP
- User signed in into OneLogin via social network
- User successfully authenticated with VLDAP (OneLogin Desktop Mac)
- API - user logged out
- API - verify factor called
- API - confirm OTP for user succeeded
- User was force logged out
- User successfully logged in on a trusted device
- User successfully logged in via OneLogin Desktop
- User denied auth via OTP push request
- User challenged for OTP
- User reauthenticated into app
- User verified OTP device
- OIDC password for app success

- API - trigger factor for user succeeded
- OIDC implicit flow for app success
- OIDC authorization code for app success
- OIDC get code for app success
- OIDC validate token for app success
- User failed authentication
- User failed to log into app
- User rejected by RADIUS configuration
- Failed to login to app via IDP
- Could not authenticate to app
- User failed authentication via API
- User failed authentication with VLDAP
- User authentication policy does not allow sign-in via social network
- User failed authentication with VLDAP (OneLogin Desktop Mac)
- API - user failed to log out
- API - verify factor failed
- API - confirm OTP for user failed
- User failed to log in on a trusted device
- User failed to login via OneLogin Desktop
- User failed to authenticate via OneLogin Desktop
- User failed OTP challenge
- OIDC implicit flow for app failed
- OIDC authorization code for app failed
- OIDC password for app failed
- OIDC validate token for app failed
- OIDC general fail
- OIDC get code for app failed

Entity Management contains the following events:

- Assigned role to user

- User was created
- User updated
- User deactivated
- User was activated
- User was deleted
- OTP device registered for user
- OTP device deregistered for user
- Updated credit card
- User provisioned in app
- User updated in app
- User suspended in app
- User reactivated in app
- User deleted in app
- Account granted permission to privilege
- Account revoked permission to privilege
- User granted permission to privilege
- User permission to privilege revoked
- Added trusted IDP
- Removed trusted IDP
- Modified trusted IDP
- User provisioned in directory
- User updated by directory
- User suspended in directory
- User reactivated in directory
- User deleted in directory
- Deleted secure note
- Updated user login information
- Attempted to update login information
- Changed the default trusted IDP

- User added to role
- User removed from role
- Created policy
- Updated policy
- Deleted policy
- Created proxy agent
- Deleted proxy agent
- Created RADIUS configuration
- Updated RADIUS configuration
- Deleted RADIUS configuration
- Enabled VPN
- Updated VPN settings
- Disabled VPN
- Enabled embedding
- Updated embedding settings
- Disabled embedding
- Created authentication factor
- Updated authentication factor
- Deleted authentication factor
- Updated security questions
- Updated desktop SSO settings
- Enabled desktop SSO
- Disabled desktop SSO
- Created certificate
- Deleted certificate
- Created API credential
- Deleted API credential
- Enabled API credential
- Disabled API credential

- Enabled virtual LDAP
- Disabled virtual LDAP
- Updated virtual LDAP settings
- Enabled branding
- Disabled branding
- Updated branding
- Deleted mapping
- Disabled mapping
- Enabled mapping
- Updated mapping
- Deleted custom user fields
- Updated company info
- Updated account settings
- Deleted directory
- Deleted connector instance from directory
- Created self registration
- Updated self registration
- Deleted self registration
- Created payment record
- Updated payment record
- Deleted payment record
- Updated terms and conditions for policy
- Manually updated user login for app
- User was created by trusted IDP
- Directory external ID was updated for user
- Directory external ID was deleted for user
- Updated broadcaster
- Deleted broadcaster
- API - roles added to user
- API - roles removed for user

- API - user updated
- API - user deleted

CloudWatch pipelines configuration for OneLogin Identity

Collects event logs from OneLogin using OAuth2 authentication.

Configure the OneLogin Identity source with the following parameters:

```
source:
  onelogin_identity:
    range: "P7D"
    subdomain: "<your-subdomain>"
    authentication:
      oauth2:
        client_id: "${{aws_secrets:<secret-name>:client_id}}"
        client_secret: "${{aws_secrets:<secret-name>:client_secret}}"
```

Parameters

`range` (optional)

For pulling historical logs. Uses ISO 8601 duration format (for example, `P7D` for the last 7 days, `PT21H` for the last 21 hours). The default is 0 hours, and the maximum is 90 days.

`subdomain` (required)

Your OneLogin account subdomain. Must be alphanumeric with hyphens only, between 1–35 characters.

`authentication.oauth2.client_id` (required)

OAuth2 client ID for OneLogin Events API authentication.

`authentication.oauth2.client_secret` (required)

OAuth2 client secret for OneLogin Events API authentication.

> **Note**
>
> The `client_id` and `client_secret` values are retrieved from AWS Secrets Manager. The above parameter information can be obtained from the API credentials generated while setting up your OneLogin application.

Palo Alto Networks Next-Generation Firewalls integration configuration

CloudWatch pipelines enables you to collect network security logs from Palo Alto Networks Next-Generation Firewalls. Palo Alto Networks provides network security solutions, including firewall, VPN, and threat detection services.

Topics

- Source configuration for Palo Alto Networks Next-Generation Firewalls
- CloudWatch pipelines configuration for Palo Alto Networks Next-Generation Firewalls

Source configuration for Palo Alto Networks Next-Generation Firewalls

Integrating with Palo Alto Networks Next-Generation Firewalls

CloudWatch Pipeline integrates with Palo Alto Networks NGFW using the PAN-OS XML API to retrieve security, authentication, network activity, process activity, detection finding and threat activity. The PAN-OS XML API enables structured access, allowing the retrieval of System Logs, GlobalProtect, Traffic Logs, Threat Logs and URL Filtering Log.

Authenticating with Palo Alto NGFW

To read network security logs, the pipeline needs to authenticate with your Palo Alto Networks NGFW login device interface. The plugin supports Basic Authentication.

- Create and Manage Users on a Palo Alto Networks NGFW Firewall via CLI
- Login firewall using with hostname using user admin and your password
- Store this username and password in a secret in AWS Secrets Manager under the keys `username` and `password`.
- Identify and note down your PAN-OS hostname.

Once configured, the pipeline can authenticate using the username and password and retrieve log activity from PAN-OS.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read logs from Palo Alto Networks NGFW, choose Palo Alto Networks Next-Generation Firewalls as the data source. Fill in the required information like

`hostname`. Once you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and events that map to Authentication (3002), Network Activity (4001), Process Activity (1007), and Detection Finding (2004).

Authentication contains the following type and subtypes:

- GlobalProtect
  - data
  - file
  - flood
  - packet
  - scan
  - spyware
  - url
  - virus
  - vulnerability
  - wildfire
  - wildfire-virus
- System Logs
  - auth

Network Activity contains the following types and subtypes:

- Traffic Logs
  - start
  - end
  - drop
  - deny
- System Logs
  - vpn

- url-filtering
- app-cloud-engine
- dhcp
- ssh
- dnsproxy
- dns-security
- wildfire
- wildfire-appliance
- ntpd
- userid

Process Activity contains the following type and subtypes:

- System Logs
  - general
  - satd
  - ras
  - sslmgr
  - hw
  - iot
  - ctd-agent
  - routing
  - port
  - device-telemetry

Detection Finding contains the following type and subtypes:

- Threat Logs
  - data
  - file
  - flood
  - packet

- scan
- spyware
- url
- ml-virus
- virus
- vulnerability
- wildfire
- wildfire-virus

- URL Filtering Log

CloudWatch pipelines configuration for Palo Alto Networks Next-Generation Firewalls

Collects log data from Palo Alto Next-Generation Firewall using basic authentication.

Configure the Palo Alto NGFW source with the following parameters:

```
source:
  paloaltonetworks_nextgenerationfirewall:
    hostname: "<example-host-name>"
    authentication:
      basic:
        username: "${{aws_secrets:<secret-name>:username}}"
        password: "${{aws_secrets:<secret-name>:password}}"
```

Parameters

`hostname` (required)

The Palo Alto NGFW hostname for your firewall.

`authentication.basic.username` (required)

Basic authentication username for Palo Alto NGFW API authentication.

`authentication.basic.password` (required)

Basic authentication password for Palo Alto NGFW API authentication.

Palo Alto Prisma Cloud integration configuration

Palo Alto Prisma Cloud is a cloud-native application protection platform (CNAPP) that secures cloud infrastructure, workloads, and applications across multi-cloud environments. CloudWatch pipelines use the Prisma Cloud CSPM and Compute (CWPP) APIs to retrieve security alerts, vulnerability findings, asset inventories, compliance posture, audit logs, and workload data from your Prisma Cloud tenant.

Topics

- Source configuration for Palo Alto Prisma Cloud
- CloudWatch pipelines configuration for Palo Alto Prisma Cloud

Source configuration for Palo Alto Prisma Cloud

Integrating with Palo Alto Prisma Cloud

CloudWatch pipelines use the Prisma Cloud CSPM and Compute (CWPP) APIs to retrieve security alerts, vulnerability findings, asset inventories, compliance posture, audit logs, and workload data from your Prisma Cloud tenant. The APIs expose REST endpoints that allow fetching security data for monitoring and analysis.

To integrate CloudWatch Pipelines with Palo Alto Prisma Cloud, complete the following high-level steps:

- Generate an Access Key and Secret Key in the Prisma Cloud Console.
- Identify the CSPM API URL, Compute Console URL, and Compute API version.
- Store the credentials in AWS Secrets Manager.
- Create a CloudWatch pipeline with Palo Alto Prisma Cloud as the data source.
- Verify that data is flowing into the pipeline.

Prerequisites

Before you begin, ensure you have the following:

- An active Palo Alto Prisma Cloud Enterprise tenant with API access
- A Prisma Cloud user with System Admin or Account Group Read Only role

- An AWS account with permissions to create and manage CloudWatch Pipelines
- An AWS account with permissions to create, retrieve, and update secrets in AWS Secrets Manager
- An AWS account with permissions to create and manage CloudWatch Logs log groups

Authenticating with Palo Alto Prisma Cloud

Palo Alto Prisma Cloud uses an Access Key and Secret Key for authentication. The pipeline sends these credentials to the CSPM login endpoint, which returns a JWT token for subsequent API access.

Configure Authentication for Palo Alto Prisma Cloud

To configure authentication credentials for the pipeline:

1. Log in to the Prisma Cloud Console and navigate to Settings > Access Control > Access Keys.
2. Choose **Add** > **Access Key**.
3. Note the Access Key ID and Secret Key.
4. Identify the CSPM API URL based on your tenant region (for example, `https://api.prismacloud.io`).
5. Identify the Compute Console URL by navigating to Compute > Manage > System > Utilities > Path to Console.
6. Identify the Compute API version (available from the bell icon in the Console).
7. Store the Access Key ID as `username` and Secret Key as `password` in AWS Secrets Manager.

Configuring the CloudWatch Pipeline

To configure the pipeline, choose Palo Alto Prisma Cloud as the data source. Provide the `cspm_base_url`, `compute_console_url`, `compute_api_version`, `access_key`, and `secret_key`. After you create and activate the pipeline, security data from Prisma Cloud will begin flowing into the selected CloudWatch Logs log group.

The following optional parameters are available:

- **Page sizes** – Configure the number of records retrieved per API request page.
- **Polling intervals** – Valid range is 10 minutes to 7 days. Uses ISO 8601 duration format.

- **Backfill durations** – Valid range is 1 hour to 90 days. Uses ISO 8601 duration format.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports the following OCSF event classes:

- **Base Event [0]** – Applications
- **Detection Finding [2004]** – Alerts
- **Vulnerability Finding [2002]** – Vulnerabilities
- **Cloud Resources Inventory Info [5023]** – Assets
- **Entity Management [3004]** – Audit Logs
- **Compliance Finding [2003]** – Compliances, Alerts
- **Device Inventory Info [5001]** – Hosts
- **Scan Activity [6007]** – Images, Containers

CloudWatch pipelines configuration for Palo Alto Prisma Cloud

Collects security data from Palo Alto Prisma Cloud using Access Key and Secret Key authentication through the CSPM and Compute APIs.

Configure the Palo Alto Prisma Cloud source with the following parameters:

```
source:
  paloaltonetworks_prismacloud:
    cspm_base_url: "https://api.prismacloud.io"
    compute_console_url: "https://us-east1.cloud.twistlock.com/us-1-123456789"
    compute_api_version: "33.01"
    authentication:
      oauth2:
        access_key: "${{aws_secrets:my-prismacloud-secret:username}}"
        secret_key: "${{aws_secrets:my-prismacloud-secret:password}}"
    range: "P30D"
```

Parameters

`cspm_base_url` (required)

The base URL for the Prisma Cloud CSPM API, determined by your tenant region (for example, `https://api.prismacloud.io`).

`compute_console_url` (required)

The URL of the Prisma Cloud Compute Console (for example, `https://us-east1.cloud.twistlock.com/us-1-123456789`).

`compute_api_version` (required)

The Compute API version for your Prisma Cloud tenant (for example, `33.01`).

`authentication.oauth2.access_key` (required)

The Prisma Cloud Access Key ID, stored in AWS Secrets Manager.

`authentication.oauth2.secret_key` (required)

The Prisma Cloud Secret Key, stored in AWS Secrets Manager.

`range` (optional)

The historical time period for backfilling data. Uses ISO 8601 duration format. Minimum is `PT1H`, maximum is `P90D`. Default is `P30D`.

Ping Identity PingAccess integration configuration

Ping Identity PingAccess is an enterprise-grade access management solution that serves as a centralized policy enforcement point for web applications and APIs. It provides fine-grained authorization, URL-level access control, and web session management across enterprise resources. CloudWatch pipelines allow ingestion of Ping Identity PingAccess audit log data into CloudWatch Logs.

Topics

- Source configuration for Ping Identity PingAccess
- CloudWatch pipelines configuration for Ping Identity PingAccess

Source configuration for Ping Identity PingAccess

Integrating with Ping Identity PingAccess

Ping Identity PingAccess integration uses Amazon S3 and Amazon SQS to ingest audit log data into CloudWatch pipelines. PingAccess is deployed on-premises and does not expose a REST API for audit log retrieval. Fluent Bit tails the JSON-formatted audit log files on the PingAccess host and delivers them to an Amazon S3 bucket. Amazon SQS notifications alert the pipeline when new log objects arrive.

Prerequisites

- An AWS account with permissions to create Amazon S3 buckets, Amazon SQS queues, and IAM roles
- A Ping Identity PingAccess server with administrative access
- A Linux host with Fluent Bit installed (can be the same host as PingAccess)
- Network connectivity between the PingAccess host and AWS

Log forwarding setup

PingAccess writes audit logs to local files using Log4j2. You configure JSON-formatted output by adding JsonTemplateLayout appenders to the `log4j2.xml` configuration file. Fluent Bit tails these JSON log files and delivers them to Amazon S3. For detailed configuration instructions, see Step 5 in the following section.

Instructions to setup Amazon S3 and Amazon SQS

Complete the following steps to configure the Amazon S3 and Amazon SQS infrastructure for Ping Identity PingAccess log ingestion.

Step 1: Create Amazon S3 bucket

Create an Amazon S3 bucket to store PingAccess audit logs. The bucket must reside in the same AWS Region where you plan to create the CloudWatch pipeline.

Step 2: Create Amazon SQS queue

Create an Amazon SQS queue in the same AWS Region as your Amazon S3 bucket. This queue receives notifications when new log files are added to the bucket.

Step 3: Connect Amazon S3 to Amazon SQS

Configure the Amazon S3 bucket to send event notifications for `s3:ObjectCreated:*` events to the Amazon SQS queue.

Step 4: Configure Amazon SQS queue policy

Configure the Amazon SQS queue policy to allow the Amazon S3 bucket to send messages to the queue. Apply the following policy to your Amazon SQS queue:

```
{
```

```
  "Version": "2012-10-17",
  "Id": "AllowS3ToSQS",
  "Statement": [
    {
      "Sid": "AllowS3BucketNotification",
      "Effect": "Allow",
      "Principal": {
        "Service": "s3.amazonaws.com"
      },
      "Action": "sqs:SendMessage",
      "Resource": "arn:aws:sqs:<region>:<account-id>:<queue-name>",
      "Condition": {
        "ArnEquals": {
          "aws:SourceArn": "arn:aws:s3:::<YOUR-BUCKET>"
        },
        "StringEquals": {
          "aws:SourceAccount": "<account-id>"
        }
      }
    }
  ]
}
```

Step 5: Configure Ping Identity PingAccess log export and Fluent Bit

Enable JSON logging on PingAccess by editing <PA_HOME>/conf/log4j2.xml. Add the following RollingFile appenders:

```
<RollingFile name="AdminAudit-JsonTemplateLayout"
             fileName="${sys:pa.log.dir}/admin_audit_json.log"
             filePattern="${sys:pa.log.dir}/admin_audit_json.%d{yyyy-MM-dd}.log"
             ignoreExceptions="false">
    <JsonTemplateLayout eventTemplateUri="${sys:pa.log4j.json.templates.uri}/admin-
audit-log.json"/>
    <Policies>
        <TimeBasedTriggeringPolicy maxRandomDelay="45"/>
    </Policies>
</RollingFile>

<RollingFile name="AccessAudit-JsonTemplateLayout"
             fileName="${sys:pa.log.dir}/audit_json.log"
             filePattern="${sys:pa.log.dir}/audit_json.%d{yyyy-MM-dd}.log"
             ignoreExceptions="false">
```

```
    <JsonTemplateLayout eventTemplateUri="${sys:pa.log4j.json.templates.uri}/access-
audit-log.json"/>
    <Policies>
        <TimeBasedTriggeringPolicy maxRandomDelay="45"/>
    </Policies>
</RollingFile>
```

Update the Loggers section to reference the new appenders:

```
<Logger name="com.pingidentity.pa.admin.audit" level="INFO" additivity="false">
    <AppenderRef ref="AdminAudit-JsonTemplateLayout"/>
</Logger>
<Logger name="com.pingidentity.pa.audit.AccessAuditLogger" level="INFO"
 additivity="false">
    <AppenderRef ref="AccessAudit-JsonTemplateLayout"/>
</Logger>
<Logger name="com.pingidentity.pa.audit.PolicyAuditLogger" level="INFO"
 additivity="false">
    <AppenderRef ref="AccessAudit-JsonTemplateLayout"/>
</Logger>
<Logger name="com.pingidentity.pa.audit.SessionAuditLogger" level="INFO"
 additivity="false">
    <AppenderRef ref="AccessAudit-JsonTemplateLayout"/>
</Logger>
```

Configure Fluent Bit to collect both audit log files and deliver them to Amazon S3:

```
########################################
# SERVICE SECTION
########################################
[SERVICE]
    Flush        5
    Daemon       Off
    Log_Level    info
    storage.path /etc/fluent-bit/db/storage
    storage.sync normal
    storage.checksum off
    storage.backlog.mem_limit 10M

########################################
# INPUT SECTION - Access Audit Log
########################################
[INPUT]
```

```
    Name              tail
    Path              /opt/pingaccess/log/audit_json.log
    Tag               pingaccess.audit
    Read_from_Head    True
    DB                /etc/fluent-bit/db/audit_checkpoint.db
    DB.Sync           Normal
    storage.type      filesystem
    Rotate_Wait       30
    Refresh_Interval 60

########################################
# INPUT SECTION - Admin Audit Log
########################################
[INPUT]
    Name              tail
    Path              /opt/pingaccess/log/admin_audit_json.log
    Tag               pingaccess.admin
    Read_from_Head    True
    DB                /etc/fluent-bit/db/admin_checkpoint.db
    DB.Sync           Normal
    storage.type      filesystem
    Rotate_Wait       30
    Refresh_Interval 60

########################################
# OUTPUT SECTION
########################################
[OUTPUT]
    Name               s3
    Match              pingaccess.*
    Bucket             <YOUR-BUCKET>
    Region             <region>
    S3_Key_Format      /pingaccess/%Y/%m/%d/%H/%M/%S.log.gz
    compression        gzip
    use_put_object     On
    store_dir          /etc/fluent-bit/db/s3
    total_file_size    1M
    log_key            log
    upload_timeout     60
```

> **Note**
>
> PingAccess writes independent log files per cluster node. Fluent Bit must be installed on each node.

The `audit_json.log` captures runtime access control events (request URL, client IP, policy decision, response code, latency). The `admin_audit_json.log` captures administrative console activity (configuration changes, admin logins, rule and application modifications).

Fluent Bit delivers gzip-compressed NDJSON files to Amazon S3. The `storage.type filesystem` setting ensures buffering to disk for reliability.

> **Important**
>
> Use only the default PingAccess-provided JSON templates.

Step 6: IAM permissions

Create an IAM policy with the following permissions for the Fluent Bit host to write objects to the Amazon S3 bucket:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "FluentBitS3Write",
      "Effect": "Allow",
      "Action": [
        "s3:PutObject",
        "s3:GetBucketLocation",
        "s3:ListBucket",
        "s3:ListMultipartUploadParts",
        "s3:AbortMultipartUpload",
        "s3:CreateMultipartUpload",
        "s3:CompleteMultipartUpload"
      ],
      "Resource": [
        "arn:aws:s3:::<YOUR-BUCKET>",
        "arn:aws:s3:::<YOUR-BUCKET>/pingaccess/*"
```

```
      ]
    }
  ]
}
```

Step 7: Verify

Verify the setup by confirming that log files appear in the Amazon S3 bucket and that Amazon SQS notifications are being generated. Check the Amazon SQS queue for messages indicating new object creation events.

Configuring the CloudWatch pipeline

- Choose Ping Identity PingAccess as the data source when creating the pipeline.
- Provide the Amazon SQS queue URL and IAM role ARN.
- Select the destination CloudWatch Logs log group.
- After you create the pipeline, data will be available in the selected log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0. The following table shows the mapping between PingAccess audit log types and OCSF event classes.

Event name	OCSF event class
Access Audit (runtime HTTP activity)	HTTP Activity [4002]
API Audit (admin API operations)	API Activity [6003]

CloudWatch pipelines configuration for Ping Identity PingAccess

The Ping Identity PingAccess setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the S3 source with the following parameters:

```
source:
  s3:
```

```
    aws:
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      ndjson:
    data_source_name: "pingidentity_pingaccess"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name` (required)

Identifies the data source. Use "pingidentity_pingaccess" for Ping Identity PingAccess.

`aws.region` (required)

The AWS region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Use `ndjson` for PingAccess JSON audit logs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

Ping Identity PingFederate integration configuration

Ping Identity PingFederate is an enterprise-grade identity federation server that serves as a central broker for Single Sign-On (SSO), token issuance, and protocol translation across SAML 2.0, OAuth 2.0, OpenID Connect, WS-Federation, and WS-Trust. CloudWatch pipelines allow ingestion of Ping Identity PingFederate audit log data into CloudWatch Logs.

Topics

- Source configuration for Ping Identity PingFederate
- CloudWatch pipelines configuration for Ping Identity PingFederate

Source configuration for Ping Identity PingFederate

Integrating with Ping Identity PingFederate

Ping Identity PingFederate integration uses Amazon S3 and Amazon SQS to ingest audit log data into CloudWatch pipelines. PingFederate is deployed on-premises and does not expose a REST API for audit log retrieval. Fluent Bit tails the JSON-formatted audit log files on the PingFederate host and delivers them to an Amazon S3 bucket. Amazon SQS notifications alert the pipeline when new log objects arrive.

Prerequisites

- An AWS account with permissions to create Amazon S3 buckets, Amazon SQS queues, and IAM roles
- A Ping Identity PingFederate server with administrative access
- A Linux host with Fluent Bit installed (can be the same host as PingFederate)
- Network connectivity between the PingFederate host and AWS

Log forwarding setup

PingFederate writes audit logs to local files using Log4j2. You configure JSON-formatted output by adding JsonTemplateLayout appenders to the `log4j2.xml` configuration file. Fluent Bit tails these JSON log files and delivers them to Amazon S3. For detailed configuration instructions, see Step 5 in the following section.

Instructions to setup Amazon S3 and Amazon SQS

Complete the following steps to configure the Amazon S3 and Amazon SQS infrastructure for Ping Identity PingFederate log ingestion.

Step 1: Create Amazon S3 bucket

Create an Amazon S3 bucket to store PingFederate audit logs. The bucket must reside in the same AWS Region where you plan to create the CloudWatch pipeline.

Step 2: Create Amazon SQS queue

Create an Amazon SQS queue in the same AWS Region as your Amazon S3 bucket. This queue receives notifications when new log files are added to the bucket.

Step 3: Connect Amazon S3 to Amazon SQS

Configure the Amazon S3 bucket to send event notifications for `s3:ObjectCreated:*` events to the Amazon SQS queue.

Step 4: Configure Amazon SQS queue policy

Configure the Amazon SQS queue policy to allow the Amazon S3 bucket to send messages to the queue. Apply the following policy to your Amazon SQS queue:

```
{
  "Version": "2012-10-17",
  "Id": "AllowS3ToSQS",
  "Statement": [
    {
      "Sid": "AllowS3BucketNotification",
      "Effect": "Allow",
      "Principal": {
        "Service": "s3.amazonaws.com"
      },
      "Action": "sqs:SendMessage",
      "Resource": "arn:aws:sqs:<region>:<account-id>:<queue-name>",
      "Condition": {
        "ArnEquals": {
          "aws:SourceArn": "arn:aws:s3:::<YOUR-BUCKET>"
        },
        "StringEquals": {
          "aws:SourceAccount": "<account-id>"
```

```
        }
      }
    }
  ]
}
```

Step 5: Configure Ping Identity PingFederate log export and Fluent Bit

Enable JSON logging on PingFederate by editing <PF_HOME>/server/default/conf/log4j2.xml. Add the following RollingFile appenders:

```
<RollingFile name="AdminAudit-JsonTemplateLayout"
             fileName="${sys:pf.log.dir}/admin_json.log"
             filePattern="${sys:pf.log.dir}/admin_json.%d{yyyy-MM-dd}.log"
             ignoreExceptions="false">
    <JsonTemplateLayout eventTemplateUri="${sys:pf.log4j.json.templates.uri}/admin-
audit-log.json"/>
    <Policies>
        <TimeBasedTriggeringPolicy maxRandomDelay="45"/>
    </Policies>
</RollingFile>

<RollingFile name="SecurityAudit-JsonTemplateLayout"
             fileName="${sys:pf.log.dir}/audit_json.log"
             filePattern="${sys:pf.log.dir}/audit_json.%d{yyyy-MM-dd}.log"
             ignoreExceptions="false">
    <JsonTemplateLayout eventTemplateUri="${sys:pf.log4j.json.templates.uri}/runtime-
audit-log.json"/>
    <Policies>
        <TimeBasedTriggeringPolicy maxRandomDelay="45"/>
    </Policies>
</RollingFile>
```

Update the Loggers section to reference the new appenders for the multiple audit loggers:

```
<Logger name="org.sourceid.websso.profiles.sp.SpAuditLogger" level="INFO"
 additivity="false">
    <AppenderRef ref="SecurityAudit-JsonTemplateLayout"/>
</Logger>
<Logger name="org.sourceid.websso.profiles.idp.IdpAuditLogger" level="INFO"
 additivity="false">
    <AppenderRef ref="SecurityAudit-JsonTemplateLayout"/>
</Logger>
```

```
<Logger name="org.sourceid.websso.profiles.idp.AsAuditLogger" level="INFO"
 additivity="false">
    <AppenderRef ref="SecurityAudit-JsonTemplateLayout"/>
</Logger>
<Logger name="org.sourceid.websso.profiles.idp.ClientRegistrationAuditLogger"
 level="INFO" additivity="false">
    <AppenderRef ref="SecurityAudit-JsonTemplateLayout"/>
</Logger>
<Logger name="org.sourceid.wstrust.log.STSAuditLogger" level="INFO" additivity="false">
    <AppenderRef ref="SecurityAudit-JsonTemplateLayout"/>
</Logger>
<Logger name="com.pingidentity.sdk.logging.LoggingUtil" level="INFO"
 additivity="false">
    <AppenderRef ref="SecurityAudit-JsonTemplateLayout"/>
</Logger>
<Logger name="AuditLogger" level="INFO" additivity="false">
    <AppenderRef ref="AdminAudit-JsonTemplateLayout"/>
</Logger>
```

Configure Fluent Bit to collect both audit log files and deliver them to Amazon S3:

```
########################################
# SERVICE SECTION
########################################
[SERVICE]
    Flush        5
    Daemon       Off
    Log_Level    info
    storage.path /etc/fluent-bit/db/storage
    storage.sync normal
    storage.checksum off
    storage.backlog.mem_limit 10M

########################################
# INPUT SECTION - Audit Log
########################################
[INPUT]
    Name             tail
    Path             /opt/pingfederate/log/audit_json.log
    Tag              pingfederate.audit
    Read_from_Head   True
    DB               /etc/fluent-bit/db/audit_checkpoint.db
    DB.Sync          Normal
```

```
    storage.type     filesystem
    Rotate_Wait      30
    Refresh_Interval 60

########################################
# INPUT SECTION - Admin Log
########################################
[INPUT]
    Name             tail
    Path             /opt/pingfederate/log/admin_json.log
    Tag              pingfederate.admin
    Read_from_Head   True
    DB               /etc/fluent-bit/db/admin_checkpoint.db
    DB.Sync          Normal
    storage.type     filesystem
    Rotate_Wait      30
    Refresh_Interval 60

########################################
# OUTPUT SECTION
########################################
[OUTPUT]
    Name              s3
    Match             pingfederate.*
    Bucket            <YOUR-BUCKET>
    Region            <region>
    S3_Key_Format     /pingfederate/%Y/%m/%d/%H/%M/%S.log.gz
    compression       gzip
    use_put_object    On
    store_dir         /etc/fluent-bit/db/s3
    total_file_size   1M
    log_key           log
    upload_timeout    60
```

Note

PingFederate writes independent log files per cluster node. You must install Fluent Bit on each node.

- The `audit_json.log` file captures runtime authentication events (SSO, credential validation, assertion issuance).

- The `admin_json.log` file captures administrative console activity (configuration changes, admin logins).
- Fluent Bit delivers gzip-compressed NDJSON files to Amazon S3.
- The `storage.type filesystem` setting ensures buffering to disk for reliability.

> **Important**
>
> Use only the default PingFederate-provided JSON templates. Modifying the `.json` template files changes the output schema and might break downstream processing.

Step 6: IAM permissions

Create an IAM policy with the following permissions for the Fluent Bit host to write objects to the Amazon S3 bucket:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "FluentBitS3Write",
      "Effect": "Allow",
      "Action": [
        "s3:PutObject",
        "s3:GetBucketLocation",
        "s3:ListBucket",
        "s3:ListMultipartUploadParts",
        "s3:AbortMultipartUpload",
        "s3:CreateMultipartUpload",
        "s3:CompleteMultipartUpload"
      ],
      "Resource": [
        "arn:aws:s3:::<YOUR-BUCKET>",
        "arn:aws:s3:::<YOUR-BUCKET>/pingfederate/*"
      ]
    }
  ]
}
```

Step 7: Verify

Verify the setup by confirming that log files appear in the Amazon S3 bucket and that Amazon SQS notifications are being generated. Check the Amazon SQS queue for messages indicating new object creation events.

Configuring the CloudWatch pipeline

- Choose Ping Identity PingFederate as the data source when creating the pipeline.
- Provide the Amazon SQS queue URL and IAM role ARN.
- Select the destination CloudWatch Logs log group.
- After you create the pipeline, data will be available in the selected log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0. The following table shows the mapping between PingFederate audit log types and OCSF event classes.

Event name	OCSF event class
Security Audit (runtime authentication lifecycle)	Authentication [3002]
Administrator Audit (admin login/logout)	Authentication [3002]
Administrator Audit (CRUD on configuration objects)	Entity Management [3004]

CloudWatch pipelines configuration for Ping Identity PingFederate

The Ping Identity PingFederate setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the S3 source with the following parameters:

```
source:
  s3:
    aws:
```

```
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      ndjson:
    data_source_name: "pingidentity_pingfederate"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name` (required)

Identifies the data source. Use "pingidentity_pingfederate" for Ping Identity PingFederate.

`aws.region` (required)

The AWS region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Use `ndjson` for PingFederate JSON audit logs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

PingIdentity PingOne integration configuration

PingOne is a cloud-based identity and access management (IAM) platform offered by Ping Identity, designed to provide secure access to applications and services across various platforms.

Topics

- Source configuration for PingIdentity PingOne
- CloudWatch pipelines configuration for PingIdentity PingOne

Source configuration for PingIdentity PingOne

Integrating with PingIdentity PingOne

PingOne is Ping Identity's cloud-based identity-as-a-service (IDaaS) platform that provides identity and access management capabilities. CloudWatch Pipeline uses the PingOne Audit Logs API to retrieve information about authentication events, user activities, policy decisions, and administrative changes across your PingOne environment. The Audit Logs API enables access to event data through REST endpoints, allowing retrieval of security and access logs from your PingOne organization.

Authenticating with PingIdentity PingOne

To read the logs, the pipeline needs to authenticate with your PingOne environment. For PingOne, authentication is performed using OAuth2.

Configure OAuth2 authentication for PingOne

- Log in to the PingOne Console and navigate to Applications → Applications. Create a new application of type Worker. Note the Client ID and Environment ID.
- Generate a new Client Secret from the Configuration tab. Copy the secret immediately.
- In AWS Secrets Manager, create a secret and store the Client ID under key `client_id` and the client secret under key `client_secret`.
- Assign Environment Admin and Application Owner roles to the application.
- Identify your PingOne Region (NA, EU, AP, AU, CA, SG).
- Note the Environment ID from Settings → Environment → Properties.

Configuring the CloudWatch Pipeline

To configure the pipeline to read logs, choose PingOne as the data source. Fill in the required information like Environment ID. Optionally, specify the Region (defaults to NA) and the Range duration format (for example, PT21H for the last 21 hours). The default range is 0 hours, and the maximum is 90 days. Once you create and activate the pipeline, audit log data from PingOne will begin flowing into the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and PingOne events that map to Account Change (3001), Authentication (3002), and Entity Management (3004).

Account Change contains the following events:

- USER.CREATED
- USER.INVITED
- USER.REINVITED
- USER.INVITE_ACCEPTED
- PASSWORD.FORCE_CHANGE
- PASSWORD.RECOVERY
- PASSWORD.RESET
- USER.INVITE_REVOKED
- USER.DELETED
- USER.LOCKED
- MFA_SETTINGS.UPDATED
- PASSWORD.UNLOCKED
- USER.UNLOCKED

Authentication contains the following events:

- AUTHENTICATION.CREATED
- RADIUS_SESSION.CREATED
- SESSION.CREATED
- SESSION.UPDATED

- SESSION.DELETED
- USER.SLO_FAILURE
- USER.SLO_PARTIAL_LOGOUT
- USER.SLO_REQUESTED
- USER.SLO_SUCCESS
- USER.KERBEROS_FAILED
- USER.KERBEROS_SUCCEEDED
- DEVICE.ACTIVATION_OTP_FAILED
- DEVICE.ACTIVATION_OTP_INVALID
- DEVICE_PAYLOAD.CHECK_INVALID
- DEVICE_PAYLOAD.CHECK_SUCCESS
- OTP.CHECK_FAILED
- OTP.CHECK_INVALID
- OTP.CHECK_SUCCESS
- PASSWORD.CHECK_FAILED
- PASSWORD.CHECK_SUCCEEDED

Entity Management contains the following events:

- ACTION.CREATED
- AGREEMENT.CREATED
- AGREEMENT_LANGUAGE.CREATED
- AGREEMENT_LANGUAGE_REVISION.CREATED
- APPLICATION.CREATED
- AUTHORIZE_POLICY.CREATED
- CERTIFICATE.CREATED
- DEVICE.CREATED
- DEVICE_AUTHENTICATION_POLICY.CREATED

CloudWatch pipelines configuration for PingIdentity PingOne

Collects audit logs from PingIdentity PingOne using OAuth2 authentication.

Configure the PingIdentity PingOne source with the following parameters:

```
source:
  pingidentity_pingone:
    range: "P7D"
    region: "NA"
    environment_id: "<your-environment-id>"
    authentication:
      oauth2:
        client_id: "${{aws_secrets:<secret-name>:client_id}}"
        client_secret: "${{aws_secrets:<secret-name>:client_secret}}"
```

Parameters

`range` (optional)

For pulling historical logs. Uses ISO 8601 duration format (for example, `P7D` for the last 7 days, `PT21H` for the last 21 hours). The default is 0 hours, and the maximum is 90 days.

`region` (optional)

PingOne region code (NA, EU, AP, AU, CA, SG). The default is "NA".

`environment_id` (required)

The PingOne environment ID.

`authentication.oauth2.client_id` (required)

OAuth2 client ID for PingIdentity PingOne API authentication.

`authentication.oauth2.client_secret` (required)

OAuth2 client secret for PingIdentity PingOne API authentication.

Proofpoint TAP integration configuration

Proofpoint TAP is an advanced email security solution that detects, analyzes, and blocks advanced threats before they reach users' inboxes. CloudWatch pipelines use the Proofpoint TAP SIEM API, Campaign API, and Forensics API to retrieve security event data including message and click events, threat campaign information, and sandbox analysis results.

Topics

- Source configuration for Proofpoint TAP
- CloudWatch pipelines configuration for Proofpoint TAP

Source configuration for Proofpoint TAP

Integrating with Proofpoint TAP

CloudWatch Pipelines use the Proofpoint TAP SIEM API, Campaign API, and Forensics API to retrieve security event data. The SIEM API returns message and click events within configurable time windows, while the Campaign and Forensics APIs provide detailed threat campaign information and sandbox analysis results. All API endpoints are available at `https://tap-api-v2.proofpoint.com`.

To integrate CloudWatch Pipelines with Proofpoint TAP, complete the following steps:

1. Configure Proofpoint TAP authentication credentials:
   - Log in to the Proofpoint TAP Threat Insight Dashboard.
   - Navigate to Settings > Connected Applications > Service Credentials.
   - Generate a new service credential.
   - Note the Service Principal and Secret values.
2. Store the `servicePrincipal` and `secret` in AWS Secrets Manager.
3. Create a CloudWatch Logs log group for the pipeline output.
4. Create an IAM role with AWS Secrets Manager access and a trust relationship for the pipeline.
5. Configure and create the CloudWatch pipeline.

Prerequisites

Before you begin, ensure you have the following:

- An active Proofpoint TAP account with Threat Insight Dashboard access
- A TAP service credential with SIEM, Campaign, and Forensics API access
- An AWS account with permissions to create and manage CloudWatch Pipelines
- An AWS account with permissions to create, retrieve, and update secrets in AWS Secrets Manager

Authenticating with Proofpoint TAP

Proofpoint TAP uses HTTP Basic authentication with a service principal and secret. The pipeline sends these credentials with each API request to authenticate access to the SIEM, Campaign, and Forensics endpoints.

Configure Authentication for Proofpoint TAP

To configure authentication credentials for the pipeline:

1. Log in to the Proofpoint TAP Threat Insight Dashboard.
2. Navigate to Settings > Connected Applications > Service Credentials.
3. Generate a new service credential.
4. Note the Service Principal and Secret values.
5. Store the `servicePrincipal` and `secret` in AWS Secrets Manager.

Configuring the CloudWatch Pipeline

To configure the pipeline, choose Proofpoint TAP as the data source. Provide the required `service_principal` and `secret` credentials. Once you create and activate the pipeline, security event data from Proofpoint TAP will begin flowing into the selected CloudWatch Logs log group.

The following optional parameters are available:

- **Polling intervals** – `siem_polling_interval` (default `PT10M`), `clicks_permitted_polling_interval` (default `PT5M`), `campaign_polling_interval` (default `P1D`)
- **Backfill durations** – `siem_backfill` (default `P1D`), `campaign_backfill` (default `P1D`). Valid range: `PT30S` to `P1D`.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports the following OCSF event classes:

- **Email Activity [4009]** – Message Delivered, Click Permitted
- **Detection Finding [2004]** – Message Blocked, Click Blocked
- **OSINT Inventory Info [5021]** – Campaign, Forensic Evidence

CloudWatch pipelines configuration for Proofpoint TAP

Collects email security event data from Proofpoint TAP using HTTP Basic authentication.

Configure the Proofpoint TAP source with the following parameters:

```
source:
  proofpoint_tap:
    authentication:
      basic:
        service_principal: "${{aws_secrets:proofpoint-tap-account-
credentials:servicePrincipal}}"
        secret: "${{aws_secrets:proofpoint-tap-account-credentials:secret}}"
    range: "P1D"
```

Parameters

`authentication.basic.service_principal` (required)

The Proofpoint TAP service principal for HTTP Basic authentication, stored in AWS Secrets Manager.

`authentication.basic.secret` (required)

The Proofpoint TAP secret for HTTP Basic authentication, stored in AWS Secrets Manager.

`range` (optional)

The historical time period for backfilling data. Uses ISO 8601 duration format. Minimum is `PT30S`, maximum is `P1D`. Default is `P1D`.

SentinelOne Singularity Endpoint integration configuration

To integrate SentinelOne Singularity Endpoint with CloudWatch Logs, you must configure both the source and the pipeline. First, set up your SentinelOne source by configuring Amazon S3 and Amazon SQS to receive endpoint logs. Then, configure the CloudWatch pipeline to ingest the data from your source into CloudWatch Logs.

Topics

- Source configuration for SentinelOne
- CloudWatch pipelines configuration for SentinelOne

Source configuration for SentinelOne

Integrating with SentinelOne Singularity Endpoint

SentinelOne Singularity Endpoint is an AI-powered endpoint security platform that provides real-time protection against malware, ransomware, and zero-day attacks. It uses behavioral analysis and machine learning to detect and stop threats autonomously. The platform supports automated response, rollback, and threat remediation. It gives centralized visibility and control across all endpoints. CloudWatch pipelines enables you to collect this data in CloudWatch Logs.

Instructions to setup Amazon S3 and Amazon SQS

Configuring SentinelOne Singularity Endpoint to send logs to an Amazon S3 bucket involves several steps, primarily focused on setting up the Amazon S3 bucket, Amazon SQS queue, IAM roles, and then configuring the Amazon Telemetry Pipeline.

- Create Amazon S3 bucket that stores SentinelOne Singularity Endpoint logs.
- Configure Singularity Cloud Funnel or intermediate Syslog server with Amazon S3 bucket details to push logs.
- Configure the Amazon S3 bucket to create event notifications, specifically for "Object Create" events. These notifications should be sent to an Amazon SQS queue.
- Create an Amazon SQS queue in the same AWS region as your Amazon S3 bucket. This queue will receive notifications when new log files are added to the Amazon S3 bucket.

Configuring the CloudWatch Pipeline

To configure the pipeline to read logs, choose SentinelOne Singularity Endpoint as the data source. After filling in the required information and you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and the SentinelOne Singularity Endpoint events that maps to File System Activity (1001), Process Activity (1007), HTTP Activity (4002) and DNS Activity (4003).

File System Activity contains the following events:

- MALICIOUSFILE

- FILECREATION
- FILEDELETION
- FILEMODIFICATION
- FILERENAME
- FILESCAN

Process Activity contains the following events:

- PROCESSCREATION
- PROCESSTERMINATION
- DUPLICATETHREAD
- REMOTETHREAD
- PROCESSMODIFICATION
- DUPLICATEPROCESS
- OPENPROCESS
- PROCESSINJECTION
- PROCESSMODIFIER
- PROCESSEXIT
- OPENPRIVILEGEDPROCESSFROMKERNEL

HTTP Activity contains the following events:

- HTTP

DNS Activity contains the following events:

- DNS

CloudWatch pipelines configuration for SentinelOne

The SentinelOne setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the SentinelOne source using the following parameters:

```
source:
  s3:
    aws:
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      ndjson:
    data_source_name: "sentinelone_endpointsecurity"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
    on_error: "retain_messages"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name` (required)

Identifies the data source. This can be any string value that represents your data source. Example: "sentinelone_endpointsecurity".

`aws.region` (required)

The AWS region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Supports csv, json, ndjson codecs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

`on_error` (optional)

Determines how to handle errors in Amazon SQS. Can be either retain_messages or delete_messages. Default is retain_messages.

ServiceNow CMDB Audit Log

ServiceNow is an enterprise platform that provides IT service management (ITSM) and configuration management database (CMDB) capabilities for tracking and managing IT assets, configurations, and changes across organizations.

Topics

- Source configuration for ServiceNow CMDB Audit Log
- CloudWatch pipelines configuration for ServiceNow CMDB Audit Log

Source configuration for ServiceNow CMDB Audit Log

Integrating with ServiceNow CMDB

ServiceNow is an enterprise platform that provides IT service management (ITSM) and configuration management database (CMDB) capabilities for tracking and managing IT assets, configurations, and changes across organizations. CloudWatch Pipeline uses the ServiceNow Table API to retrieve information about sys_audit, syslog, sysevent, and syslog_transactions from your ServiceNow instance.

Authenticating with ServiceNow CMDB

To read the logs, the pipeline needs to authenticate with your ServiceNow instance. The ServiceNow Table API supports OAuth 2.0.

- Ensure the REST API is enabled on your ServiceNow instance.
- Enable OAuth 2.0 Client Credentials grant type in your ServiceNow instance
- Create an OAuth Application Registry for external client authentication

- In the AWS Secrets Manager, create a secret and store the Application (client) ID under the key `client_id` and the client secret under the key `client_secret`.
- Configure OAuth Application User and assign required roles

Configuring the CloudWatch Pipeline

When configuring the pipeline to read audit logs from ServiceNow choose ServiceNow CMDB as the data source. Fill in the required information like `instance_url` and the secret where `client_id` and `client_secret` are stored. Once you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and events that map to Entity Management (3004), API Activity (6003), and Datastore Activity (6005). These events are from specific tables and filtered for CMDB reference.

Entity Management contains events from following tables:

- sys_audit

API Activity contains events from following tables:

- sysevent
- syslog

Datastore Activity contains events from following tables:

- syslog_transactions

CloudWatch pipelines configuration for ServiceNow CMDB Audit Log

Collects configuration management database (CMDB) data from ServiceNow using OAuth2 authentication.

Configure the ServiceNow CMDB source with the following parameters:

```
source:
```

```
  servicenow_cmdb:
    instance_url: "<example-instance-url>"
    range: "P7D"
    authentication:
      oauth2:
        client_id: "${{aws_secrets:<secret-name>:client_id}}"
        client_secret: "${{aws_secrets:<secret-name>:client_secret}}"
```

Parameters

`instance_url` (required)

ServiceNow instance URL.

`authentication.oauth2.client_id` (required)

OAuth2 client ID for ServiceNow API authentication.

`authentication.oauth2.client_secret` (required)

OAuth2 client secret for ServiceNow API authentication.

`range` (optional)

The time range for log collection. Uses ISO 8601 duration format (for example, `P7D` for the last 7 days, `PT21H` for 21 hours). Default is 0 hours, and the maximum is 90 days.

Slack Audit Log integration configuration

Slack is a cloud-based collaboration and messaging platform that enables team communication through channels, direct messages, file sharing, and integrations with external applications. CloudWatch pipelines use the Slack APIs (such as Events API and Audit Logs API) to retrieve information about user activities, messages, channel events, app interactions, and administrative actions across your Slack workspace.

Topics

- Source configuration for Slack Audit Log
- CloudWatch pipelines configuration for Slack Audit Log

Source configuration for Slack Audit Log

Integrating with Slack Audit Log

Slack is a cloud-based collaboration and messaging platform that enables team communication through channels, direct messages, file sharing, and integrations with external applications. CloudWatch pipelines use the Slack APIs (such as Events API and Audit Logs API) to retrieve information about user activities, messages, channel events, app interactions, and administrative actions across your Slack workspace. These APIs provide REST endpoints that allow access to event data, enabling the collection of communication and audit logs from your Slack environment for monitoring and analysis.

Authenticating with Slack

To read Slack audit logs, the pipeline needs to authenticate with your Slack workspace. The plugin supports OAuth API token authentication. Follow these instructions to get started with Slack APIs:

1. Before creating an app, register for the Slack Developer Program by visiting: `https://api.slack.com/developer-program`.
2. Log in to the Slack API portal and navigate to "Your Apps" then "Create New App." Choose "From scratch" and provide an app name and workspace. After creation, note down the Client ID and Client Secret from the "Basic Information" section.
3. Configure OAuth scopes under "OAuth & Permissions." Add required scopes such as `auditlogs:read`, `channels:read`, `groups:read`, `users:read`, and `channels:history` depending on your use case. Install the app to your workspace by choosing the install button in the Slack API portal. After installation, copy the User OAuth Token (starts with `xoxp-`). The `auditlogs:read` scope requires a user OAuth token.
4. In AWS Secrets Manager, create a secret that will hold the Slack token obtained in step 3. The secret's value must be a JSON object with a key that stores the token. Pick any secret name and any key name you prefer, but remember both — the pipeline configuration references them together using the syntax `${{aws_secrets:<secret-name>:<key-name>}}`.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read logs, choose Slack as the data source. Specify the range duration format (for example, PT21H for the last 21 hours) to control the time window of logs retrieved. Once you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and events that map to Web Resources Activity (6001), Authentication (3002), Entity Management (3004), Account Change (3001), User Access Management (3005), File Hosting Activity (6006), and Detection Finding (2004), and these events are sourced from the Slack AuditLogs API. Events that are not listed are not mapped to OCSF and will be forwarded to the sink as raw logs.

Web Resources Activity (6001) contains the following event types:

- private_channel_created
- private_channel_archive
- private_channel_converted_to_public
- private_channel_deleted
- private_channel_unarchive
- public_channel_archive
- public_channel_converted_to_private
- public_channel_created
- public_channel_deleted
- public_channel_preview
- public_channel_unarchive
- file_public_link_created
- file_public_link_revoked
- huddle_screenshare_on
- huddle_ended
- huddle_knock_accepted
- huddle_participant_dropped
- huddle_participant_joined
- huddle_participant_left
- huddle_started
- huddle_screenshare_off
- huddle_transcription_cancelled

- huddle_transcription_paused
- huddle_transcription_resumed
- huddle_transcription_started
- huddle_transcription_start_notification
- slack_ai_huddle_notes_generated
- list_linksharing_enabled
- canvas_linksharing_enabled
- list_linksharing_disabled
- canvas_linksharing_disabled

Entity Management (3004) contains the following event types:

- external_shared_channel_invite_accepted
- external_shared_channel_invite_approved
- external_shared_channel_invite_auto_revoked
- external_shared_channel_invite_created
- external_shared_channel_access_upgraded
- external_shared_channel_disconnect_and_archived
- external_shared_channel_disconnected
- external_shared_channel_invite_declined
- external_shared_channel_invite_expired
- external_shared_channel_invite_revoked
- channels_export_completed
- channels_export_deleted
- channels_export_downloaded
- channels_export_started
- scheduled_export_completed
- scheduled_export_deleted
- scheduled_export_downloaded
- scheduled_export_started

- manual_export_completed
- manual_export_deleted
- manual_export_downloaded
- manual_export_started
- manual_user_export_downloaded
- manual_user_export_completed
- manual_user_export_deleted
- manual_user_export_started
- external_shared_channel_connected

Account Change (3001) contains the following event types:

- role_change_to_owner
- role_change_to_admin
- role_change_to_guest
- role_change_to_user
- role_removed
- role_assigned
- guest_created
- guest_deactivated
- guest_reactivated
- user_created
- user_deactivated
- user_reactivated
- user_email_updated
- user_profile_updated
- user_profile_deleted
- guest_expiration_cleared
- guest_expiration_set
- guest_expired

- user_force_upgrade_non_compliant_mobile_app_version
- owner_transferred
- service_owner_transferred
- user_password_reset_requested
- user_password_reset_slack_security
- custom_tos_accepted
- user_session_settings_changed
- role_added_to_usergroup
- role_removed_from_usergroup

Authentication (3002) contains the following event types:

- bulk_session_reset_by_admin
- user_session_reset_by_admin
- user_logout_non_compliant_mobile_app_version
- user_logout
- user_logout_compromised
- user_login
- user_login_failed
- cli_login
- user_sessions_reset_by_anomaly_event_response
- user_session_invalidated

User Access Management (3005) contains the following event types:

- permissions_assigned
- user_channel_join
- guest_channel_join
- user_added_to_usergroup
- workflow_trigger_permission_added
- workflow_trigger_permission_set

- app_resources_granted
- app_resources_added
- app_scopes_expanded
- permissions_removed
- user_channel_leave
- guest_channel_leave
- user_removed_from_usergroup
- workflow_trigger_permission_removed
- role_modified_on_usergroup

File Hosting Activity (6006) contains the following event types:

- file_deleted
- file_download_blocked
- file_downloaded
- file_shared
- file_uploaded

Detection Finding (2004) contains the following event types:

- file_malicious_content_detected
- Anomaly

CloudWatch pipelines configuration for Slack Audit Log

Collects event logs from Slack using API token authentication.

Configure the Slack source with the following parameters:

```
source:
  slack_auditlogs:
    authentication:
        api_token: "${{aws_secrets:slack-account-credentials:apiToken}}"
    # Provide the time range (e.g., P7D for the last 7 days)
    range: "P7D"
```

Parameters

`authentication` (required)

Block containing Slack authentication settings. Contains the nested parameters listed in the following entry.

`api_token` (required)

Slack API token (`xoxp-...`) with the `auditlogs:read` scope. Typically sourced from AWS Secrets Manager using the `${{aws_secrets:<secret-name>:<key>}}` reference syntax.

`range` (optional)

The time range for log collection. Uses ISO 8601 duration format (for example, `P7D` for the last 7 days, `PT21H` for 21 hours). Default is 0 hours, and the maximum is 90 days.

> **Note**
>
> The `api_token` value is retrieved from AWS Secrets Manager. The preceding parameter information can be obtained from the API credentials generated while setting up your Slack application.

Tanium integration configuration

Tanium is an endpoint management and security platform that provides real-time visibility and control across enterprise endpoints. CloudWatch pipelines collect detailed telemetry from Tanium including endpoint inventory, compliance posture, vulnerability findings, threat response alerts, and audit logs covering authentication, account changes, and group management activities.

Topics

- Source configuration for Tanium
- CloudWatch pipelines configuration for Tanium

Source configuration for Tanium

Integrating with Tanium

Tanium is an endpoint management and security platform that provides real-time visibility and control across enterprise endpoints. It collects detailed telemetry such as endpoint activity, security

events, authentication events, and network activity. This data can be exported and integrated with AWS services for centralized monitoring and analytics. CloudWatch pipelines enable the ingestion of this data into CloudWatch Logs for further analysis and alerting.

Instructions to setup Tanium Connect, Amazon S3 and Amazon SQS

Prerequisites

- Access to the AWS Management Console with IAM administrative privileges.
- Access to the Tanium Console with permissions to configure Tanium Connect.

To set up Tanium Connect, Amazon S3, and Amazon SQS

1. In the AWS Console, create an Amazon S3 bucket in your desired region. Create separate prefixes (sub-folders) within the bucket for each log type to ensure clear log segregation and easier downstream processing.
2. Create an Amazon SQS Queue for Event Notifications. Create an Amazon SQS queue in the same AWS region as your Amazon S3 bucket. Configure Amazon S3 Event Notifications on the bucket to send `s3:ObjectCreated:*` events to the Amazon SQS queue. This enables downstream consumers to be notified when new log files are delivered.
3. Create an IAM User with Programmatic Access. In IAM, create a new user with programmatic (CLI) access only. Attach a policy granting the minimum required permissions like `s3:PutObject`. Scope the policy to the target Amazon S3 bucket and prefixes. Generate an Access Key ID and Secret Access Key for the user. Store these credentials securely (for example, in a secrets manager). These will be needed in the following step.
4. Configure the Tanium Connect Destination. Log in to the Tanium Console. Navigate to Tanium Connect and create a new connection, select the type of log data and other general information. Select Amazon S3 as the destination. Enter the following details:
   a. AWS Access Key ID
   b. AWS Secret Access Key
   c. S3 Bucket Name
   d. AWS Region
   e. Object key prefix (matching the sub-folder for the relevant log type)
5. Validate the Configuration. Save the connection and execute a test run. Verify that log data is successfully delivered to the expected Amazon S3 bucket and prefix. Confirm that the Amazon SQS queue is receiving event notifications for newly created objects.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read data from Tanium, choose Tanium as the data source. Using Tanium Connect, data from Tanium custom and default reports is exported to Amazon S3, with event notifications delivered through Amazon SQS. Once you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and transforms the following report data and maps them to one of the 8 OCSF Classes: Device Inventory Info (5001), Vulnerability Finding (2002), Compliance Finding (2003), Detection Finding (2004), Authentication (3002), Account Change (3001), Entity Management (3004), and Group Management (3006). Out of all the custom reports pushed to S3 by the end user, the reports from the following listed datasources are transformed to the respective OCSF Classes. The rest of the data is ingested in raw format.

There is no specific event type in Tanium (except for audit logs). The following custom reports are generated by choosing the relevant modules in Tanium Connect:

- Tanium Platform
- Compliance Data – Comply Module
- Vulnerability Data – Comply Module
- Discovery Data – Discover Module
- Threat Response Alerts – Threat Response Module

The following sections describe the audit log mappings to OCSF event classes.

Authentication (3002)

From audit logs where `object_type_name` = "authentication":

- New Session Created
- New System User Session Created
- Authentication Failed
- User Logged Out
- User Failed to Log Out

Account Change (3001)

From audit logs where `object_type_name` = "api_token" or "user":

- `type_name` = CreateObject and `object_type_name` = api_token
- `type_name` = DeleteObject and `object_type_name` = api_token
- `type_name` = CreateObject and `object_type_name` = user
- `type_name` = DeleteObject and `object_type_name` = user
- `type_name` = UpdateObject and `object_type_name` = user

Entity Management (3004)

From audit logs where `reportName` = "TaniumThreatAuditLog":

- action = create
- action = update
- action = deleteBulk

Group Management (3006)

From audit logs where `object_type_name` = "user_group":

- action = UpdateObject and details containing "Assigned role" / "updated with role ids"
- action = UpdateObject and details containing "removed role"
- action = UpdateObject and details containing "user ids added"
- action = UpdateObject and details containing "user ids removed"
- action = UpdateObject and details containing "persona updated with user groups"
- action = DeleteObject
- action = CreateObject

CloudWatch pipelines configuration for Tanium

The Tanium setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the S3 source with the following parameters:

```
source:
  s3:
    acknowledgments: true
    sqs:
      queue_url: "https://sqs.us-east-1.amazonaws.com/1234567890/tanium-sqs"
      maximum_messages: '10'
      visibility_duplication_protection: true
      visibility_timeout: 180s
    aws:
      region: "us-east-1"
    notification_type: sqs
    notification_source: s3
    bucket_owners:
      tanium-test-logs-test: '1234567890'
    default_bucket_owner: '1234567890'
    codec:
      ndjson: {}
    compression: none
```

Parameters

`acknowledgments` (required)

Prevents data loss by only considering logs successfully processed after they are received by the sink. Set to `true` to enable.

`sqs.queue_url` (required)

The Amazon SQS queue URL that receives Amazon S3 event notifications when new objects land.

`sqs.maximum_messages` (optional)

Max number of Amazon SQS messages to pull per poll (batch size, up to Amazon SQS max of 10).

`sqs.visibility_duplication_protection` (optional)

Uses Amazon SQS visibility timeout to prevent duplicate processing of the same message by multiple workers.

`sqs.visibility_timeout` (optional)

How long (in seconds) a message stays invisible to other consumers after being picked up, giving the worker time to process it.

`aws.region` (required)

AWS region where the Amazon SQS queue and Amazon S3 bucket live.

`notification_type` (required)

`sqs` – Tells the plugin to expect notifications through Amazon SQS.

`notification_source` (optional)

`s3` – Indicates the Amazon SQS notifications originate from Amazon S3 event notifications.

`bucket_owners` (required)

Maps specific bucket names to their owning AWS account IDs, needed for cross-account access.

`default_bucket_owner` (required)

Fallback AWS account ID used for any bucket not explicitly listed in `bucket_owners`.

`codec` (required)

`ndjson` – Parses each Amazon S3 object as newline-delimited JSON (one JSON record per line).

`compression` (required)

none – Indicates the Amazon S3 objects are not compressed, so no decompression is applied before parsing.

Tenable Vulnerability Management integration configuration

Tenable Vulnerability Management is a cloud-based vulnerability management platform that provides continuous visibility into assets, vulnerabilities, compliance posture, and security findings. CloudWatch pipelines use the Tenable REST API to retrieve asset inventories, vulnerability findings, compliance data, scan results, audit logs, and plugin metadata from your Tenable environment.

Topics

- Source configuration for Tenable Vulnerability Management
- CloudWatch pipelines configuration for Tenable Vulnerability Management

Source configuration for Tenable Vulnerability Management

Integrating with Tenable Vulnerability Management

CloudWatch pipelines use the Tenable REST API to retrieve asset inventories, vulnerability findings, compliance data, scan results, audit logs, and plugin metadata from your Tenable environment. The API exposes REST and bulk export endpoints that allow fetching security data for monitoring and analysis.

To integrate CloudWatch Pipelines with Tenable Vulnerability Management, complete the following high-level steps:

- Generate an Access Key and Secret Key from the Tenable UI.
- Store the credentials in AWS Secrets Manager.
- Create a CloudWatch pipeline with Tenable as the data source.
- Verify that data is flowing into the pipeline.

Prerequisites

Before you begin, ensure you have the following:

- An active Tenable account with the Administrator role
- An AWS account with permissions to create and manage CloudWatch Pipelines
- An AWS account with permissions to create, retrieve, and update secrets in AWS Secrets Manager
- An AWS account with permissions to create and manage CloudWatch Logs log groups

Authenticating with Tenable Vulnerability Management

Tenable uses API key authentication with an access key and secret key. The pipeline passes these credentials through the `X-ApiKeys` header to authenticate each API request.

Configure Authentication for Tenable Vulnerability Management

To configure authentication credentials for the pipeline:

1. Log in to the Tenable Vulnerability Management UI.
2. Navigate to Settings > My Account > API Keys.
3. Generate a new API key pair. Note the Access Key and Secret Key values.

4. Ensure your account has the Administrator role.
5. Store the `access_key` and `secret_key` in AWS Secrets Manager.

Configuring the CloudWatch Pipeline

To configure the pipeline, choose Tenable as the data source. Provide the `access_key` and `secret_key`. After you create and activate the pipeline, vulnerability management data from Tenable will begin flowing into the selected CloudWatch Logs log group.

The following optional parameters are available:

- **Export settings** – `chunk_size` (default 1000, range 100–10,000), `export_backfill` (default `P30D`, range 30 minutes–90 days), `export_polling_interval` (default `P1D`, range 30 minutes–7 days)
- **Backfill durations** – Configure historical backfill for audit logs, plugins, and scans independently.
- **Polling intervals** – Configure independent polling intervals for audit, scan, and plugin streams.
- **Page sizes** – Configure the number of records retrieved per API request page.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports the following OCSF event classes:

- **Device Inventory Info [5001]** – Assets
- **Compliance Finding [2003]** – Compliance
- **Vulnerability Finding [2002]** – Vulnerability
- **Scan Activity [6007]** – Scans
- **Authentication [3002]** – Audit Logs (authentication-related actions)
- **API Activity [6003]** – Audit Logs (API-related actions)
- **Account Change [3001]** – Audit Logs (account modification actions)

Plugins are passed as raw data and are not mapped to OCSF event classes.

CloudWatch pipelines configuration for Tenable Vulnerability Management

Collects vulnerability management data from Tenable using API key authentication.

Configure the Tenable Vulnerability Management source with the following parameters:

```
source:
  tenable_vulnerabilitymanagement:
    authentication:
      access_key: "${{aws_secrets:<secret-name>:access_key}}"
      secret_key: "${{aws_secrets:<secret-name>:secret_key}}"
    range: "P30D"
```

Parameters

`authentication.access_key` (required)

The Tenable API access key, stored in AWS Secrets Manager.

`authentication.secret_key` (required)

The Tenable API secret key, stored in AWS Secrets Manager.

`range` (optional)

The historical time period for backfilling data. Uses ISO 8601 duration format. Minimum is `P1D`, maximum is `P90D`. Default is `P30D`.

Wazuh Platform integration configuration

Wazuh is an open-source security platform that provides threat detection, integrity monitoring, incident response, and compliance. CloudWatch Pipelines use the Wazuh Indexer API (OpenSearch-based) to retrieve security alerts, agent monitoring data, and inventory information from your Wazuh environment.

Topics

- Source configuration for Wazuh Platform
- CloudWatch pipelines configuration for Wazuh Platform

Source configuration for Wazuh Platform

Integrating with Wazuh Platform

CloudWatch Pipeline uses the Wazuh Indexer API to retrieve security alerts, agent monitoring data, and inventory information. The Indexer API (OpenSearch-based, port 9200) exposes REST endpoints for querying time-filtered security event data.

To integrate CloudWatch Pipelines with Wazuh Platform, complete the following high-level steps:

- Obtain the Wazuh Indexer host URL and credentials.
- Store the username and password in AWS Secrets Manager.
- Create a CloudWatch pipeline with Wazuh Platform as the data source.
- Verify that data is flowing into the pipeline.

Prerequisites

Before you begin, ensure you have the following:

- An active Wazuh deployment with Indexer API access (port 9200)
- Wazuh Indexer credentials with read access to security indices
- An AWS account with permissions to create and manage CloudWatch Pipelines
- An AWS account with permissions to create, retrieve, and update secrets in AWS Secrets Manager

Authenticating with Wazuh Platform

Wazuh Platform uses Basic Authentication with a username and password. The pipeline uses these credentials to authenticate each API request to the Wazuh Indexer.

Configure Authentication for Wazuh Platform

To configure authentication credentials for the pipeline:

1. Obtain the Wazuh Indexer admin username and password from your Wazuh deployment.
2. Store the `username` and `password` in AWS Secrets Manager.

Configuring the CloudWatch Pipeline

To configure the pipeline, choose Wazuh Platform as the data source. Provide the `host`, `username`, and `password`. Once you create and activate the pipeline, log data from Wazuh will begin flowing into the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports the following OCSF event classes:

- **API Activity [6003]** – Wazuh API activity events
- **Application Lifecycle [6002]** – Application lifecycle events
- **Authentication [3002]** – Authentication events
- **Compliance Finding [2003]** – Compliance findings
- **Detection Finding [2004]** – Threat detection findings
- **Device Inventory Info [5001]** – Agent inventory information
- **File System Activity [1001]** – File integrity monitoring events
- **Remediation Activity [1007]** – Remediation actions
- **Vulnerability Finding [2002]** – Vulnerability assessment findings

CloudWatch pipelines configuration for Wazuh Platform

Collects security event data from Wazuh Platform using Basic authentication through the Wazuh Indexer API.

Configure the Wazuh Platform source with the following parameters:

```
source:
  wazuh_platform:
    host: "https://wazuh-indexer.example.com:9200"
    authentication:
      basic:
        username: "${{aws_secrets:<secret-name>:username}}"
        password: "${{aws_secrets:<secret-name>:password}}"
```

Parameters

`host` (required)

The Wazuh Indexer base URL including scheme and port (for example, `https://wazuh-indexer.example.com:9200`).

`authentication.basic.username` (required)

The Wazuh Indexer username, stored in AWS Secrets Manager.

`authentication.basic.password` (required)

The Wazuh Indexer password, stored in AWS Secrets Manager.

WIZ CNAPP integration configuration

To integrate WIZ CNAPP with CloudWatch Logs, you must configure both the source and the pipeline. First, set up your WIZ source by authenticating with OAuth2 and configuring API access. Then, configure the CloudWatch pipeline to ingest the data from your source into CloudWatch Logs.

Topics

- Source configuration for WIZ CNAPP
- CloudWatch pipelines configuration for WIZ

Source configuration for WIZ CNAPP

Integrating with Wiz CNAPP

Wiz is a cloud-native application protection platform (CNAPP) that provides comprehensive visibility and security across multi-cloud environments. CloudWatch Pipeline uses the Wiz GraphQL API to retrieve information about security posture, vulnerabilities, misconfigurations, threats, and audit activities from your cloud infrastructure. The Wiz GraphQL API enables access to security data through flexible GraphQL queries, allowing retrieval of audit logs, issues, vulnerability findings, configuration findings, and detections from the Wiz platform.

Authenticating with Wiz CNAPP

To read Wiz Cnapp audit Logs, the pipeline needs to authenticate with your account. The plugin supports OAuth2 Authentication. Follow these instructions to get started.

- Create a Service Account in Wiz with appropriate permissions. You must be logged in as a Wiz user with Write (W) permission on service accounts.
- Configure the Service Account and get newly created Client ID and Client Secret.
- In the AWS Secrets Manager, create a secret and store the Application (client) ID under the key `client_id` and the client secret under the key `client_secret`.
- Configure API permissions (scopes) for your Service Account.

  Required scope: `read:issues`, `read:detections`, `read:cloud_events_cloud`, `read:cloud_events_sensor`, `read:security_scans`, `read:vulnerabilities`, `read:cloud_configuration`, `admin:audit`

- Identify your GraphQL API endpoint: To find your specific endpoint check Tenant Info in the Wiz portal. The Wiz GraphQL API endpoint is `https://api.<region>.app.wiz.io/graphql`, where `<region>` corresponds to your Wiz tenant's datacenter (e.g., us1, us2, eu1, eu2).

Configuring the CloudWatch Pipeline

When configuring the pipeline to read audit logs from Wiz, choose Wiz CNAPP as the data source. Fill in the required information like Region. Once you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and events that map to Detection Finding (2004), Vulnerability Finding (2002), Compliance Finding (2003), Authentication (3002), and API Activity (6003).

Detection Finding contains all events from following sources:

- Issues
- Detections

Vulnerability Finding contains all events from following sources:

- Vulnerability Findings

Compliance Finding contains all events from following sources:

- Cloud Configuration Findings

Authentication contains events from following sources and given actions:

- Audit logs
- DeviceLogin
- Login

API Activity contains events from following sources and given actions:

- Audit logs

CloudWatch pipelines configuration for WIZ

Collects cloud-native application protection platform (CNAPP) data from Wiz using OAuth2 authentication.

Configure the Wiz CNAPP source with the following parameters:

```
source:
  wiz_cnapp:
    region: "<example-region>"
    range: "P7D"
    authentication:
      oauth2:
        client_id: "${{aws_secrets:<secret-name>:client_id}}"
        client_secret: "${{aws_secrets:<secret-name>:client_secret}}"
```

Parameters

`region` (required)

Wiz region for your organization.

`authentication.oauth2.client_id` (required)

OAuth2 client ID for Wiz API authentication.

`authentication.oauth2.client_secret` (required)

OAuth2 client secret for Wiz API authentication.

`range` (optional)

The time range for log collection. Uses ISO 8601 duration format (for example, `P7D` for the last 7 days, `PT21H` for 21 hours). Default is 0 hours, and the maximum is 90 days.

Zscaler Internet Access

CloudWatch pipelines enables you to collect logs from Zscaler Internet Access (ZIA). ZIA is a cloud-based secure web gateway that protects users connecting to the internet.

Topics

- Source configuration for Zscaler Internet Access

- Pipeline configuration for Zscaler Internet Access

Source configuration for Zscaler Internet Access

Integrating with Zscaler Internet Access

Zscaler Internet Access (ZIA) is a cloud-based secure web gateway that protects users connecting to the internet. It inspects all internet traffic to block malware, phishing, and data leaks using advanced threat detection and SSL inspection. ZIA enforces security policies in real time without requiring on-premises hardware. It ensures safe and compliant internet access for users anywhere. CloudWatch pipelines enables you to collect this data in CloudWatch Logs.

Instructions to setup Amazon S3 and Amazon SQS

Configuring ZIA to send logs to an Amazon S3 bucket involves several steps, primarily focused on setting up the Amazon S3 bucket, Amazon SQS queue, IAM roles, and then configuring the Amazon Telemetry Pipeline.

- Create Amazon S3 bucket that stores ZIA logs and create separate folders for each log type. Create IAM user and grant s3 write permission, console access not needed only CLI and create Access key and Secret key for this account.
- Configure NSS feeds with Amazon S3 bucket details to push logs.
- Configure the Amazon S3 bucket to create event notifications, specifically for "Object Create" events. These notifications should be sent to an Amazon SQS queue.
- Create an Amazon SQS queue in the same AWS region as your Amazon S3 bucket. This queue will receive notifications when new log files are added to the Amazon S3 bucket.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read data from Zscaler Internet Access, choose Zscaler Internet Access (ZIA) as the data source. After filling in the required information and you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and events that map to DNS Activity (4003), HTTP Activity (4002), Network Activity (4001), and Authentication (3002). Each event comes from a source as mentioned below.

DNS Activity covers all events from source:

- DNS Logs

HTTP Activity covers all events from source:

- Web Logs

Network Activity covers all events from source:

- Firewall Logs

Authentication covers events from source:

- Admin Audit Logs - Event actions: SIGN_IN, SIGN_OUT

Pipeline configuration for Zscaler Internet Access

The Zscaler setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the Zscalar source using the following parameters:

```
source:
  s3:
    aws:
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      ndjson:
    data_source_name: "zscaler_internetaccess"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
    on_error: "retain_messages"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name` (required)

Identifies the data source. This can be any string value that represents your data source. Example: "zscaler_internetaccess".

`aws.region` (required)

The AWS region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Supports csv, json, ndjson codecs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

`on_error` (optional)

Determines how to handle errors in Amazon SQS. Can be either retain_messages or delete_messages. Default is retain_messages.

Zeek integration configuration

Zeek is an open-source network security monitoring platform widely used for analyzing network traffic and generating detailed logs about network activities across an organization's infrastructure. It passively monitors network traffic and provides deep visibility into communications by producing structured logs for multiple network protocols and security-relevant events. CloudWatch pipelines allow ingestion of Zeek log data into CloudWatch Logs, providing scalable collection, processing, normalization, and integration with downstream AWS security and monitoring services.

Topics

- Source configuration for Zeek
- CloudWatch pipelines configuration for Zeek

Source configuration for Zeek

Integrating with Zeek

To integrate Zeek with CloudWatch Logs, you must configure both the source and the pipeline. First, set up your Zeek source by configuring Amazon S3 and Amazon SQS to receive data. Then, configure the CloudWatch pipeline to ingest the data from your source into CloudWatch Logs.

Instructions to setup Amazon S3 and Amazon SQS

Configuring Zeek with Fluent Bit to send logs to an Amazon S3 bucket involves several steps, primarily focused on setting up the Amazon S3 bucket, Amazon SQS queue, IAM roles, and then configuring the CloudWatch Pipeline.

Configuring Zeek logs using Fluent Bit

- Install Fluent Bit (a lightweight log collector that reads log files and forwards them to destinations such as Amazon S3) on the Zeek host and configure it to tail Zeek log files (for example, `/opt/zeek/logs/current/*.log`).
- Configure AWS credentials (IAM role or `aws configure`) so Fluent Bit has permission to upload objects to the Amazon S3 bucket.
- Update the Fluent Bit configuration to use the S3 output plugin, specifying the bucket name, Region, and S3 key path for Zeek logs.
- Start and enable the Fluent Bit service to continuously collect Zeek logs and upload them to Amazon S3 for downstream ingestion.

Amazon S3 and Amazon SQS configuration

- Amazon S3 bucket that stores the Zeek logs should reside in the same AWS Region.
- Configure the Amazon S3 bucket to create event notifications, specifically for "Object Create" events. These notifications should be sent to an Amazon SQS queue.
- Create an Amazon SQS queue in the same AWS Region as your Amazon S3 bucket. This queue will receive notifications when new log files are added to the Amazon S3 bucket.

Configuring the CloudWatch Pipeline

When configuring the pipeline to read data from Zeek, choose Zeek as the data source. After filling in the required information and you create the pipeline, data will be available in the selected CloudWatch Logs log group.

Supported Open Cybersecurity Schema Framework Event Classes

This integration supports OCSF schema version v1.5.0 and events that map to multiple OCSF classes. The following table lists the supported event mappings.

Zeek OCSF event mappings

Event name	OCSF class
conn	Network Activity (4001)
dns	DNS Activity (4003)
http	HTTP Activity (4002)
ssl	Network Activity (4001)
ssh	SSH Activity (4007)
kerberos	Authentication (3002)
rdp	RDP Activity (4005)
files	Network Activity (4001)
notice	Detection Finding (2004)
known_hosts	Base Event (0)
x509	Network Activity (4001)
ftp	FTP Activity (4008)
smtp	Email Activity (4009)
dhcp	DHCP Activity (4004)

Event name	OCSF class
ntlm	Authentication (3002)
smb_files	SMB Activity (4006)
smb	SMB Activity (4006)
dce_rpc	SMB Activity (4006)
ldap	Authentication (3002)
ldap_search	Network Activity (4001)
quic	Network Activity (4001)
tunnel	Tunnel Activity (4014)
pe	Base Event (0)
weird	Base Event (0)
known_services	Base Event (0)
software	Software Inventory Info (5020)
reporter	Base Event (0)

Events that do not match any OCSF mapping transformation are automatically passed through and sent directly to the configured sink without additional processing.

CloudWatch pipelines configuration for Zeek

The Zeek setup on AWS reads log data from Amazon S3 buckets using Amazon SQS notifications for new object events.

Configure the Zeek source using the following parameters:

```
source:
  s3:
    aws:
```

```
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      ndjson:
    data_source_name: "zeek"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
    on_error: "retain_messages"
```

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name` (required)

Identifies the data source. This can be any string value that represents your data source. Example: "zeek".

`aws.region` (required)

The AWS Region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Supports csv, json, ndjson codecs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

on_error (optional)

Determines how to handle errors in Amazon SQS. Can be either retain_messages or delete_messages. Default is retain_messages.

Custom log data from CloudWatch Logs or an Amazon S3 bucket

You can create pipelines for custom data sources using the following approaches:

1. **CloudWatch Custom Logs** – Define pipelines on your existing CloudWatch custom log groups by providing:
   - A data source name
   - A data source type

   For more information on data source name and type, see the CloudWatch Logs User Guide.
2. **S3 Custom Sources** – Process arbitrary logs stored in S3 buckets by configuring source for the pipeline:

```
source:
  s3:
    aws:
      region: "us-east-1"
      sts_role_arn: "arn:aws:iam::<account>:role/<role-name>"
    compression: "gzip"
    codec:
      ndjson:
    data_source_name: "my_custom_logs"
    default_bucket_owner: "123456789012"
    bucket_owners:
      my-bucket: "123456789012"
    disable_bucket_ownership_validation: false
    notification_type: "sqs"
    sqs:
      queue_url: "https://sqs.region.amazonaws.com/<account>/<queue-name>"
    on_error: "retain_messages"
```

> **Note**
>
> The CSV processor can't be used with S3 custom sources. Instead, use the CSV codec in the S3 source.

Parameters

`notification_type` (required)

Specifies the notification mechanism. Must be "sqs" to use SQS for S3 event notifications.

`data_source_name`

Identifies the data source. This can be any string value that represents your data source. Example: "my_custom_logs".

`aws.region` (required)

The AWS region where the S3 bucket and SQS queue are located.

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing S3 and SQS resources.

`codec` (required)

Codec configuration for parsing S3 objects. Supports `csv`, `json`, `ndjson` codecs.

`compression` (optional)

Compression type of the S3 objects. Valid values are "none", "gzip", "automatic". Defaults to "none".

`sqs.queue_url` (required for SQS)

The complete SQS queue URL that receives S3 bucket notifications when new objects are created.

`on_error` (optional)

Determines how to handle errors in Amazon SQS. Can be either `retain_messages` or `delete_messages`. Default is `retain_messages`.

Custom source configuration

When creating a pipeline for custom sources:

- A parser must be the first processor in the pipeline if the data source is CloudWatch Logs
- You can specify any supported processor for custom log pipelines

Topics

- Configuring Custom S3 Bucket Sources

Configuring Custom S3 Bucket Sources

With CloudWatch pipelines, you can process arbitrary logs stored in S3 buckets.

Prerequisites

To use Amazon S3 as the source for a pipeline, first create an S3 bucket. For instructions, see Creating a general purpose bucketin the *Amazon S3 User Guide*.

> **Note**
>
> If the S3 bucket used as a source in the pipeline is in a different AWS account, you also need to enable cross-account read permissions on the bucket. This allows the pipeline to read and process the data. To enable cross-account permissions, see Bucket owner granting cross-account bucket permissions in the *Amazon S3 User Guide*.
> If your S3 buckets are in multiple accounts, use a `bucket_owners` map. For an example, see Cross-account S3 access in the *OpenSearch* documentation.

To set up S3-SQS processing, you also need to perform the following steps:

- Create an Amazon SQS queue.
- Enable event notifications on the S3 bucket with the SQS queue as a destination.

Configure the pipeline role

Unlike other source plugins that push data to a pipeline, the S3 source plugin has a read-based architecture in which the pipeline pulls data from the source. Therefore, in order for a pipeline to

read from S3, you must specify a role within the pipeline's S3 source configuration that has access to both the S3 bucket and the Amazon SQS queue. The pipeline will assume this role in order to read data from the queue.

You can find example role permissions in Source-specific IAM policies. Note that this role must have a trust relationship with the CloudWatch pipelines service principle. You can find an example trust policy configuration for your pipeline role in Trust relationships.

Create the pipeline

After you've set up your permissions, you can configure a pipeline depending on your Amazon S3 use case.

Select **Create pipeline** in the **Pipelines** tab under **Ingestion** in the CloudWatch Console. Follow the pipeline wizard steps and provide the SQS queue ARN and required pipeline IAM role when prompted. Optionally provide a data source name and type to attach to the log group destination in CloudWatch Logs.

Be sure to configure a CloudWatch Logs resource policy if one isn't already configured to the destination log group and then select **Create pipeline** in the **Review and create** step. The pipeline will be created and data will begin to flow within 5 minutes if successful.

Amazon S3 cross account as a source

You can grant access across accounts with Amazon S3 so that CloudWatch pipelines can access S3 buckets in another account as a source. To enable cross-account access, see Bucket owner granting cross-account bucket permissions in the *Amazon S3 User Guide*. After you have granted access, ensure that your pipeline role has the required permissions.

Then, you can create a pipeline using `bucket_owners` to enable cross-account access to an Amazon S3 bucket as a source.

Custom source configuration

When creating a pipeline for custom sources:

- A parser must be the first processor in the pipeline
- You can specify any supported processor for custom log pipelines

AWS service logs from CloudWatch Logs

Intercepts log events from CloudWatch Logs that match the log event metadata configuration.

> **Important**
>
> Pipelines with processors mutate the log events in the original CloudWatch log group they are intercepted from for logs from AWS services. To preserve unmodified copies of your log data, enable the `include_original` option in the `cloudwatch_logs` sink configuration, or use the **Keep original log** toggle in the console. For more information, see the section called “Sinks”.

Configuration

Configure the CloudWatch Logs source with the following parameters:

```
source:
  cloudwatch_logs:
    aws:
      sts_role_arn: "arn:aws:iam::123456789012:role/MyCloudWatchLogsRole"
    log_event_metadata:
      data_source_name: "<data_source_name>"
      data_source_type: "<data_source_type>"
```

Parameters

`aws.sts_role_arn` (required)

The ARN of the IAM role to assume for CloudWatch Logs interception.

`log_event_metadata.data_source_name` (required)

Identifies the specific AWS service that generated the log events or a custom log source name. For custom logs, this can be any string up to 15 characters when `data_source_type` is "default".

`log_event_metadata.data_source_type` (required)

Specifies the category or type of logs within the AWS service, or "default" for custom logs. Set to "default" to enable custom log source names.

For more information on data source name and type, see the CloudWatch Logs User Guide.

Restrictions

The following restrictions apply to CloudWatch Logs sources:

- No two pipelines can use the `cloudwatch_logs` source with identical `data_source_name` and `data_source_type` metadata criteria.
- When `data_source_name` is `aws_cloudtrail`, only empty processors (`[]`) or the `ocsf` processor are allowed.

CloudWatch pipelines processors

CloudWatch pipelines processors transform, parse, and enrich log data as it flows through the pipeline. Log pipelines support up to 20 processors that are applied sequentially in the order they are defined. Metrics pipelines support up to 20 processors, applied sequentially in the order you define them. For metrics pipeline processors, see the section called "Metrics processors".

Transformation metadata

When a pipeline processes log events, CloudWatch pipelines automatically adds transformation metadata to each processed log entry. This metadata indicates that the log has been transformed, making it easy to distinguish between original and processed data. If you enable the **Keep original log** option during pipeline creation, you can compare the original log with the transformed version at any time.

Processor categories

Category	Description
Parsers	Convert raw log data into structured formats, such as Open Cybersecurity Schema Framework (OCSF), CSV, JSON, and so on
Transformers	Modify log data structure; add, copy, move, or delete fields
String Processors	Manipulate string values; case conversion, trimming, substitution

Category	Description
Metrics processors	Add, delete, rename attributes and metrics on OTel metric datapoints

Topics

- Parser processors
- Transformation processors
- String manipulation processors
- Filter processors
- Common processor use cases
- Processor compatibility and restrictions
- Metrics pipeline processors

Parser processors

Parser processors convert raw or semi-structured log data into structured formats. Each pipeline can have at most one primary parser processor, which must be the first processor in the pipeline. The XML parser is an exception: it operates on fields produced by a primary parser and you can add at most 5 instances to a single pipeline.

> **Conditional processing not supported**
>
> Parser processors (except Grok and XML) do not support conditional processing with the `when` parameter. This includes OCSF, CSV, JSON, KeyValue, VPC, Route53, RDS, WAF, Postgres, and Amazon CloudFront parsers. For more information, see the section called "Expression syntax for conditional processing".

OCSF processor

Parses and transforms log data according to Open Cybersecurity Schema Framework (OCSF) standards.

Configuration

Configure the OCSF processor with the following parameters:

```
processor:
  - ocsf:
      version: "1.5"
      mapping_version: 1.5.0
      schema:
          microsoft_office365_management_activity:
```

Parameters

`version` (required)

The OCSF schema version to use for transformation. Must be 1.5

`mapping_version` (required)

The OCSF mapping version for transformation. Must be 1.5.0.

`schema` (required)

Schema object specifying the data source type. The supported schemas depend on the pipeline source type - each source type has its own set of compatible OCSF schemas. You must use a schema that matches your pipeline's source type.

This table lists the supported schema combinations.

Pipeline Source Type	Supported Schemas	Version	Mapping Version
`cloudwatch_logs`	`cloud_trail:`	`1.5`	Not required
`cloudwatch_logs`	`route53_resolver:`	`1.5`	Not required
`cloudwatch_logs`	`vpc_flow:`	`1.5`	Not required
`cloudwatch_logs`	`eks_audit:`	`1.5`	Not required
`cloudwatch_logs`	`aws_waf:`	`1.5`	Not required
`cloudwatch_logs`	`aws_nlb:`	`1.5`	Not required

Pipeline Source Type	Supported Schemas	Version	Mapping Version
s3	Any OCSF schema	Any	Any
microsoft_office365	microsoft_office365:	1.5	1.5.0
microsoft_entraid	microsoft_entraid:	1.5	1.5.0
microsoft_windows_event	microsoft_windows_event:	1.5	1.5.0
paloaltonetworks_nextgenerationfirewall	paloaltonetworks_nextgenerationfirewall:	1.5	1.5.0
okta_auth0	okta_auth0:	1.5	1.5.0
okta_sso	okta_sso:	1.5	1.5.0
crowdstrike_falcon	crowdstrike_falcon:	1.5	1.5.0
github_auditlogs	github_auditlogs:	1.5	1.5.0
sentinelone_endpointsecurity	sentinelone_endpointsecurity:	1.5	1.5.0
servicenow_cmdb	servicenow_cmdb:	1.5	1.5.0
wiz_cnapp	wiz_cnapp:	1.5	1.5.0
zscaler_internetaccess	zscaler_internetaccess:	1.5	1.5.0

CSV processor

Parses CSV formatted data into structured fields.

Configuration

Configure the CSV processor with the following parameters:

```
processor:
  - csv:
      column_names: ["col1", "col2", "col3"]
      delimiter: ","
      quote_character: '"'
```

Parameters

`column_names` (optional)

Array of column names for parsed fields. Maximum 100 columns, each name up to 128 characters. If not provided, defaults to column_1, column_2, and so on.

`delimiter` (optional)

Character used to separate CSV fields. Must be a single character. Defaults to comma (,).

`quote_character` (optional)

Character used to quote CSV fields containing delimiters. Must be a single character. Defaults to double quote (").

To use the processor without specifying additional parameters, use the following command:

```
processor:
  - csv: {}
```

Grok processor

Parses unstructured data using Grok patterns. At most 1 Grok is supported per pipeline. For details on the Grok transformer in CloudWatch Logs see Processors that you can use in the *CloudWatch Logs User Guide*.

Configuration

Configure the Grok processor with the following parameters:

When the data source is a dictionary, you can use this configuration:

```
processor:
  - grok:
      match:
       source_key: ["%{WORD:level} %{GREEDYDATA:msg}"]
```

When the data source is CloudWatch Logs, you can use this configuration:

```
processor:
  - grok:
      match:
       source_key: ["%{WORD:level} %{GREEDYDATA:msg}"]
```

Parameters

`match` (required)

Field mapping with Grok patterns. Only one field mapping allowed.

`match.<field>` (required)

Array with single Grok pattern. Maximum 512 characters per pattern.

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

> **Important**
>
> If the Grok processor is used as the parser (first processor) in a pipeline and its `when` condition evaluates to false, the entire pipeline does not execute for that log event. Parsers must run for downstream processors to receive structured data.

VPC processor

Parses VPC Flow Log data into structured fields.

Configuration

Configure the VPC processor with the following parameters:

```
processor:
  - parse_vpc: {}
```

JSON processor

Parses JSON data into structured fields.

Configuration

Configure the JSON processor with the following parameters:

```
processor:
  - parse_json:
      source: "message"
      destination: "parsed_json"
```

Parameters

`source` (optional)

The field containing the JSON data to parse. If omitted, the entire log message is processed

`destination` (optional)

The field where the parsed JSON will be stored. If omitted, parsed fields are added to the root level

Route 53 processor

Parses Route 53 resolver log data into structured fields.

Configuration

Configure the Route 53 processor with the following parameters:

```
processor:
  - parse_route53: {}
```

Amazon RDS processor

Parses Amazon RDS Aurora log data into structured fields. The `parse_rds` processor is supported only when the pipeline's `data_source_name` is `amazon_rds`. It applies the parsing logic that matches the pipeline's `data_source_type`.

Configuration

Configure the Amazon RDS processor with the following parameters:

```
processor:
  - parse_rds: {}
```

Key-value processor

Parses key-value pair formatted data into structured fields.

Configuration

Configure the key-value processor with the following parameters:

```
processor:
  - key_value:
      source: "message"
      destination: "parsed_kv"
      field_delimiter: "&"
      key_value_delimiter: "="
```

Parameters

`source` (optional)

Field containing key-value data. Maximum 128 characters.

`destination` (optional)

Target field for parsed key-value pairs. Maximum 128 characters.

`field_delimiter` (optional)

Pattern to split key-value pairs. Maximum 10 characters.

`key_value_delimiter` (optional)

Pattern to split keys from values. Maximum 10 characters.

`overwrite_if_destination_exists` (optional)

Whether to overwrite existing destination field.

`prefix` (optional)

Prefix to add to extracted keys. Maximum 128 characters.

non_match_value (optional)

Value for keys without matches. Maximum 128 characters.

To use the processor without specifying additional parameters, use the following command:

```
processor:
  - key_value: {}
```

XML parser

Use the XML parser to convert a specified field that contains an XML string to JSON format. Use the XML parser when your log events contain embedded XML fields that you want to query as structured data. The XML parser operates on a named field that already contains an XML string. Place this parser after a primary parser in the pipeline. You can add at most 5 `parse_xml` parsers to a single pipeline.

Configuration

Configure the XML parser with the following parameters:

```
processor:
  - parse_json:
      source: "@message"
  - parse_xml:
      source: "body"
      destination: "parsed_xml"
```

Parameters

`source` (Required)

Specifies the field that contains the XML string to parse. Use dot notation to access nested fields. For example, `event.body`. Maximum 128 characters.

`destination` (Optional)

Specifies the field where the parsed XML structure is stored. If you omit this parameter, the parsed fields are added to the root level. Maximum 128 characters.

`when` (Optional)

A conditional expression that determines whether this parser runs. Maximum length is 256 characters. For more information, see the section called “Expression syntax for conditional processing”.

Example – XML parser output

Given the following JSON log event with an embedded XML field:

```
{
  "body": "<Person id=\"123\" active=\"true\"><name>John</name><age>30</age></Person>"
}
```

With the following configuration:

```
processor:
  - parse_json:
      source: "@message"
  - parse_xml:
      source: "body"
      destination: "parsed_xml"
```

The XML parser produces the following output:

```
{
  "body": "<Person id=\"123\" active=\"true\"><name>John</name><age>30</age></Person>",
  "parsed_xml": {
    "id": "123",
    "active": "true",
    "name": "John",
    "age": "30"
  }
}
```

Behavior notes

Nesting depth

The XML parser supports a maximum nesting depth of 25 levels. Elements nested beyond this limit produce an error.

Error handling

Malformed XML does not fail the pipeline. The parser preserves the original `@message` and sets `@pipeline.processing.status = "error"` on the event.

Transformation processors

Transformation processors modify the structure of log events by adding, copying, moving, or removing fields.

add_entries processor

Adds static key-value pairs to log events. At most 1 `add_entries` processor can be added to a pipeline.

Configuration

Configure the add_entries processor with the following parameters:

```
processor:
  - add_entries:
      entries:
        - key: "environment"
          value: "production"
          overwrite_if_key_exists: false
```

Parameters

`entries` (required)

Array of key-value pairs to add to each log event.

`entries[].key` (required)

The field name to add to the log event. Supports nested fields using dot notation.

`entries[].value` (required)

The static value to assign to the key.

`entries[].overwrite_if_key_exists` (optional)

Boolean flag that determines behavior when the key already exists. Defaults to false.

`when` (optional)

Processor-level conditional expression. When specified, the entire processor is skipped if the expression evaluates to false. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

`entries[].when` (optional)

Entry-level conditional expression. When specified, only this entry is skipped if the expression evaluates to false. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

`entries[].when_else` (optional)

Fallback entry that executes only when none of the other `when` conditions in the same processor matched. The expression value identifies which `when` conditions to consider. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

copy_values processor

Copies values from one field to another. At most 1 `copy_values` processor can be added to a pipeline.

Configuration

Configure the copy_values processor with the following parameters:

```
processor:
  - copy_values:
      entries:
        - from_key: "user_id"
          to_key: "backup_user"
          overwrite_if_to_key_exists: false
```

Parameters

`entries` (required)

Array of copy operations to perform on each log event.

`entries[].from_key` (required)

The field name to copy the value from. Uses dot notation for nested fields.

`entries[].to_key` (required)

The field name to copy the value to. Will create nested structures if using dot notation.

`entries[].overwrite_if_to_key_exists` (optional)

Boolean flag controlling behavior when target field already exists. Defaults to false.

`when` (optional)

Processor-level conditional expression. When specified, the entire processor is skipped if the expression evaluates to false. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

`entries[].when` (optional)

Entry-level conditional expression. When specified, only this entry is skipped if the expression evaluates to false. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

`entries[].when_else` (optional)

Fallback entry that executes only when none of the other `when` conditions in the same processor matched. The expression value identifies which `when` conditions to consider. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

delete_entries processor

Removes specified fields from log events.

Configuration

Configure the delete_entries processor with the following parameters:

```
processor:
```

```
  - delete_entries:
      with_keys: ["temp_field", "debug_info"]
```

Parameters

`with_keys` (required)

Array of field names to remove from each log event. Supports nested field deletion using dot notation.

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

move_keys processor

Moves fields from one location to another.

Configuration

Configure the move_keys processor with the following parameters:

```
processor:
  - move_keys:
      entries:
        - from_key: "old_field"
          to_key: "new_field"
          overwrite_if_to_key_exists: true
```

Parameters

`entries` (required)

Array of move operations. Maximum 5 entries.

`entries[].from_key` (required)

Source field name. Maximum 128 characters.

`entries[].to_key` (required)

Target field name. Maximum 128 characters.

`entries[].overwrite_if_to_key_exists` (optional)

Whether to overwrite existing target field.

`when` (optional)

Processor-level conditional expression. When specified, the entire processor is skipped if the expression evaluates to false. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

`entries[].when` (optional)

Entry-level conditional expression. When specified, only this entry is skipped if the expression evaluates to false. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

`entries[].when_else` (optional)

Fallback entry that executes only when none of the other `when` conditions in the same processor matched. The expression value identifies which `when` conditions to consider. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

flatten processor

Flattens nested object structures.

Configuration

Configure the flatten processor with the following parameters:

```
processor:
  - flatten:
      source: "metadata"
      target: "flattened"
      remove_processed_fields: true
      exclude_keys: ["sensitive_data"]
```

Parameters

`source` (required)

Field containing nested object to flatten.

`target` (required)

Target field prefix for flattened keys.

`remove_processed_fields` (optional)

Whether to remove the original nested field after flattening.

`exclude_keys` (optional)

Array of keys to exclude from flattening. Maximum 20 keys, each up to 128 characters.

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

lookup processor

Enriches log events with data from a CloudWatch Logs lookup table. The processor matches fields in your log events against fields in the lookup table and appends specified fields to your log events. Use this processor for data enrichment scenarios such as mapping user IDs to user details, product codes to product information, or error codes to error descriptions. At most 1 `lookup` processor can be added to a pipeline.

> **Note**
>
> If a lookup table is used in a pipeline, you must provide an execution role with `logs:GetLookupTable` permissions on the table. For more information, see the section called “CloudWatch pipelines IAM policies and permissions”.

Configuration

Configure the lookup processor with the following parameters:

```
processor:
  - lookup:
      lookup_table: "arn:aws:logs:us-east-1:123456789012:lookup-table:my_lookup_table"
      match_keys:
        - log_key: "src_ip"
          lookup_key: "ip_address"
      entries:
```

```
        - source: "hostname"
          target: "src_hostname"
          overwrite_if_exists: true
```

Parameters

`lookup_table` (required)

The ARN of the CloudWatch Logs lookup table to use for enrichment. Maximum length is 2048 characters.

`match_keys` (required)

Array of key pairs that define how to match log event fields to lookup table fields. Minimum 1, maximum 5 match keys. When multiple match keys are specified, a lookup table row must match all keys to produce a result (AND logic).

`match_keys[].log_key` (required)

The field name in the log event to match against. Maximum 128 characters.

`match_keys[].lookup_key` (required)

The column name in the lookup table to match against. Maximum 128 characters.

`entries` (required)

Array of fields to add to the log event from the matching lookup table row. Minimum 1, maximum 10 entries.

`entries[].source` (required)

The column name in the lookup table to retrieve the value from. Maximum 128 characters.

`entries[].target` (optional)

The field name to add to the log event. If not specified, the `source` column name is used as the field name. Maximum 128 characters.

`entries[].overwrite_if_exists` (optional)

Boolean flag that determines behavior when the target field already exists in the log event. Defaults to false.

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

Example

Consider a lookup table named `network_assets` with the following rows:

network_assets lookup table

ip_address	hostname	owner	location
10.0.1.12	web-server-01	team-alpha	us-east-1
10.0.2.45	db-server-03	team-beta	us-west-2
10.0.3.78	cache-node-07	team-alpha	eu-west-1

Given the following log event:

```
{
  "timestamp": "2026-05-04T12:00:00Z",
  "src_ip": "10.0.2.45",
  "action": "connection_opened",
  "bytes": 2048
}
```

And the following processor configuration:

```
processor:
  - lookup:
      lookup_table: "arn:aws:logs:us-east-1:123456789012:lookup-table:network_assets"
      match_keys:
        - log_key: "src_ip"
          lookup_key: "ip_address"
      entries:
        - source: "hostname"
          target: "src_hostname"
        - source: "owner"
        - source: "location"
          target: "src_region"
          overwrite_if_exists: false
```

The processor produces the following enriched log event:

```
{
```

```
  "timestamp": "2026-05-04T12:00:00Z",
  "src_ip": "10.0.2.45",
  "action": "connection_opened",
  "bytes": 2048,
  "src_hostname": "db-server-03",
  "owner": "team-beta",
  "src_region": "us-west-2"
}
```

IAM permissions

When a pipeline uses the lookup processor, the pipeline's execution role must include `logs:GetLookupTable` permission for the referenced table. The following example policy statement grants this permission:

```
{
  "Effect": "Allow",
  "Action": "logs:GetLookupTable",
  "Resource": "arn:aws:logs:<region>:<account-id>:lookup-table:<table-name>"
}
```

geoip processor

The geoip processor enriches log events with geographic location data based on IP addresses. The processor uses MaxMind databases to resolve IP addresses to geographic information such as city, country, continent, coordinates, and autonomous system number (ASN) details. Use this processor for network traffic analysis, user location enrichment, and security investigation scenarios.

Configuration

Configure the geoip processor with the following parameters:

```
processor:
  - geoip:
      entries:
        - source: "client_ip"
          target: "client_geo"
          include_fields:
            - "city_name"
            - "country_name"
            - "country_iso_code"
```

```
            - "continent_name"
            - "latitude"
            - "longitude"
          when: '.client_ip != "127.0.0.1"'
```

Parameters

`entries` (required)

Array of entry objects that define which IP fields to enrich with geographic data. Minimum 1, maximum 10 entries.

`entries[].source` (required)

The field name in the log event that contains the IP address to look up. Must reference a valid IPv4 or IPv6 address. Maximum 128 characters.

`entries[].target` (required)

The field name where the processor writes geographic enrichment data in the log event. Maximum 128 characters.

`entries[].include_fields` (required)

Array of geographic fields to include in the enrichment result. Minimum 1, maximum 12 fields. The following fields are available:

- `continent_code` – Two-letter continent code (for example, "NA").
- `continent_name` – Name of the continent (for example, "North America").
- `country_name` – Name of the country (for example, "United States").
- `country_iso_code` – ISO 3166-1 alpha-2 country code (for example, "US").
- `city_name` – Name of the city (for example, "Seattle").
- `postal_code` – Postal code associated with the IP address location.
- `time_zone` – IANA time zone name (for example, "America/Los_Angeles").
- `latitude` – Latitude coordinate of the IP address location.
- `longitude` – Longitude coordinate of the IP address location.
- `network` – CIDR notation of the network associated with the IP address.
- `asn` – Autonomous system number associated with the IP address.
- `asn_organization` – Organization name associated with the autonomous system number.

`entries[].when` (optional)

Conditional expression that determines whether this entry executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

`when` (optional)

Top-level conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

Example

The following example shows a sample log event with IP address fields:

```
{
  "timestamp": "2026-05-04T12:00:00Z",
  "src_ip": "203.0.113.50",
  "dst_ip": "198.51.100.25",
  "action": "ALLOW",
  "bytes": 4096
}
```

The following processor configuration maps both source and destination IP fields to geographic enrichment targets:

```
processor:
  - geoip:
      entries:
        - source: "src_ip"
          target: "src_geo"
          include_fields:
            - "city_name"
            - "country_name"
            - "country_iso_code"
            - "latitude"
            - "longitude"
            - "asn"
            - "asn_organization"
        - source: "dst_ip"
          target: "dst_geo"
          include_fields:
            - "country_name"
```

```
            - "country_iso_code"
```

The processor produces the following enriched log event:

```
{

String manipulation processors

String processors modify text values within log events through operations like case conversion, trimming, and pattern matching.

lowercase_string processor

Converts specified fields to lowercase.

Configuration

Configure the lowercase_string processor with the following parameters:

```
processor:
  - lowercase_string:
      with_keys: ["status", "method"]
```

Parameters

`with_keys` (required)

Array of field names to convert to lowercase. Only processes string values.

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

uppercase_string processor

Converts specified fields to uppercase.

Configuration

Configure the uppercase_string processor with the following parameters:

```
processor:
  - uppercase_string:
      with_keys: ["status_code", "method"]
```

Parameters

`with_keys` (required)

Array of field names to convert to uppercase. Only processes string values.

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

trim_string processor

Removes leading and trailing whitespace from specified fields.

Configuration

Configure the trim_string processor with the following parameters:

```
processor:
  - trim_string:
```

```
      with_keys: ["message", "user_input"]
```

Parameters

`with_keys` (required)

Array of field names to trim whitespace from. Only processes string values.

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

substitute_string processor

Performs string substitution using regular expressions.

Configuration

Configure the substitute_string processor with the following parameters:

```
processor:
  - substitute_string:
      entries:
        - source: "message"
          from: "ERROR"
          to: "WARN"
```

Parameters

`entries` (required)

Array of substitution operations to perform on each log event.

`entries[].source` (required)

The field to perform string substitution on.

`entries[].from` (required)

The regular expression pattern to match and replace.

`entries[].to` (required)

The replacement string for matched patterns.

`when` (optional)

Processor-level conditional expression. When specified, the entire processor is skipped if the expression evaluates to false. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

`entries[].when` (optional)

Entry-level conditional expression. When specified, only this entry is skipped if the expression evaluates to false. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

`entries[].when_else` (optional)

Fallback entry that executes only when none of the other `when` conditions in the same processor matched. The expression value identifies which `when` conditions to consider. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

truncate processor

Truncates field values to specified length.

Configuration

Configure the truncate processor with the following parameters:

```
processor:
  - truncate:
      source_keys: ["message", "description"]
      length: 100
      start_at: 0
```

Parameters

`source_keys` (required)

Array of field names to truncate. Each field name maximum 128 characters.

`length` (optional)

Maximum length after truncation. Range: 1-8192.

`start_at` (optional)

Starting position for truncation. Range: 0-8192. Defaults to 0.

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

extract_value processor

Extracts values using regular expressions.

Configuration

Configure the extract_value processor with the following parameters:

```
processor:
  - extract_value:
      entries:
        - source: "message"
          target: "extracted_data"
          from: "user=(?<user>\\w+)"
          to: "${user}"
          target_type: "string"
```

Parameters

`entries` (required)

Array of extraction operations. Maximum 20 entries.

`entries[].source` (required)

Field to extract from. Maximum 128 characters.

`entries[].target` (required)

Target field for extracted value. Maximum 128 characters.

`entries[].from` (required)

Regular expression pattern. Maximum 128 characters.

`entries[].to` (required)

Replacement pattern with capture groups. Maximum 128 characters.

`entries[].target_type` (optional)

Target data type ("integer", "double", "string", "boolean").

`when` (optional)

Processor-level conditional expression. When specified, the entire processor is skipped if the expression evaluates to false. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

`entries[].when` (optional)

Entry-level conditional expression. When specified, only this entry is skipped if the expression evaluates to false. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

`entries[].when_else` (optional)

Fallback entry that executes only when none of the other `when` conditions in the same processor matched. The expression value identifies which `when` conditions to consider. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

convert_entry_type processor

Converts field values between different data types.

Configuration

Configure the convert_entry_type processor with the following parameters:

```
processor:
  - convert_entry_type:
      key: "count"
      type: "integer"
```

Parameters

`key` (required)

Single field name to convert.

`type` (required)

Target data type. Options: "integer", "double", "string", "boolean".

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

date processor

Parses and formats date/time fields.

Configuration

Configure the date processor with the following parameters:

```
processor:
  - date:
      match:
        - key: "timestamp"
          patterns: ["yyyy-MM-dd'T'HH:mm:ss.SSSSSS'Z'"]
      destination: "@timestamp"
      source_timezone: "UTC"
      destination_timezone: "America/New_York"
```

Parameters

`match` (required)

Array of date matching configurations. Maximum 10 entries.

`match[].key` (required)

Field containing the date string. Maximum 128 characters.

`match[].patterns` (required)

Array of date format patterns to try. Maximum 5 patterns, each up to 256 characters.

`destination` (optional)

Single target field for all parsed dates. Maximum 128 characters.

`source_timezone` (optional)

Source timezone for parsing.

`destination_timezone` (optional)

Target timezone for output.

`output_format` (optional)

Output date format. Maximum 64 characters.

`destination_type` (optional)

Output type - "timestampz", "long", or "string".

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

dissect processor

Extracts structured data using pattern matching.

Configuration

Configure the dissect processor with the following parameters:

```
processor:
  - dissect:
      map:
        message: "%{timestamp} %{level}"
```

Parameters

`map` (required)

Field mapping with dissect patterns.

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

list_to_map processor

Converts array fields to map structures.

Configuration

Configure the list_to_map processor with the following parameters:

```
processor:
  - list_to_map:
      source: "tags"
      key: "name"
      value_key: "value"
      target: "tag_map"
```

Parameters

`source` (required)

Field containing array data. Maximum 128 characters.

`key` (required)

Field name to use as map key. Maximum 128 characters.

`value_key` (optional)

Field name to use as map value. Maximum 128 characters.

`target` (optional)

Target field for map structure. Maximum 128 characters.

`flatten` (optional)

Whether to flatten the resulting map.

`flattened_element` (optional)

Which element to use when flattening ("first" or "last").

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

rename_keys processor

Renames fields in log events.

Configuration

Configure the rename_keys processor with the following parameters:

```
processor:
  - rename_keys:
      entries:
        - from_key: "old_name"
          to_key: "new_name"
          overwrite_if_to_key_exists: true
```

Parameters

`entries` (required)

Array of rename operations. Maximum 5 entries.

`entries[].from_key` (required)

Current field name. Maximum 128 characters.

`entries[].to_key` (required)

New field name. Maximum 128 characters.

`entries[].overwrite_if_to_key_exists` (optional)

Whether to overwrite existing target field.

`when` (optional)

Processor-level conditional expression. When specified, the entire processor is skipped if the expression evaluates to false. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

`entries[].when` (optional)

Entry-level conditional expression. When specified, only this entry is skipped if the expression evaluates to false. Maximum length is 256 characters. See the section called "Expression syntax for conditional processing".

`entries[].when_else` (optional)

Fallback entry that executes only when none of the other `when` conditions in the same processor matched. The expression value identifies which `when` conditions to consider. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

select_entries processor

Selects only specified fields from events.

Configuration

Configure the select_entries processor with the following parameters:

```
processor:
  - select_entries:
      include_keys: ["timestamp", "level", "message"]
```

Parameters

`include_keys` (required)

Array of field names to keep. Maximum 50 keys, each up to 128 characters.

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

translate processor

Translates field values using lookup tables.

Configuration

Configure the translate processor with the following parameters:

```
processor:
  - translate:
      mappings:
        - source: "status_code"
          targets:
```

```
            - target: "status_text"
              map:
                "200": "OK"
                "404": "Not Found"
```

Parameters

`mappings` (required)

Array of translation configurations. Maximum 10 mappings.

`mappings[].source` (required)

Field to translate. Maximum 128 characters.

`mappings[].targets` (required)

Array of target configurations. Maximum 10 targets.

`mappings[].targets[].target` (required)

Target field name. Maximum 128 characters.

`mappings[].targets[].map` (required)

Translation mapping. Maximum 100 entries, each value up to 512 characters.

`when` (optional)

Conditional expression that determines whether this processor executes. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing”.

Filter processors

Filter processors let you selectively remove log entries from the pipeline based on conditions you define.

drop_events processor

Filters out unwanted log entries based on conditional expressions. Use this processor to reduce noise from third-party pipeline connectors and lower storage costs by removing log events that match specified conditions.

Configuration

Configure the drop_events processor with the following parameters:

```
processor:
  - drop_events:
      when: "log.level == 'DEBUG' or log.level == 'TRACE'"
```

Parameters

when (required)

Conditional expression that determines which log entries to drop. Log entries matching this expression are removed from the pipeline. Maximum length is 256 characters. See the section called “Expression syntax for conditional processing” for expression syntax.

handle_expression_failure (optional)

Behavior when the when expression evaluation fails. Allowed values: "skip" (default) keeps the event, or "apply" drops the event regardless of the failure.

Example Drop low-severity log entries

The following configuration drops all DEBUG and TRACE log entries, keeping only higher-severity events:

```
processor:
  - drop_events:
      when: "log.level in {'DEBUG', 'TRACE'}"
      handle_expression_failure: "skip"
```

Common processor use cases

Here are common scenarios and example configurations for combining processors.

Logs pipeline examples

Example Standardize log formats and add metadata

Parse JSON logs, standardize field names, and add environment information:

```
processor:
  - parse_json: {}
  - rename_keys:
      entries:
        - from_key: "timestamp"
```

```
          to_key: "@timestamp"
        - from_key: "log_level"
          to_key: "level"
  - add_entries:
      entries:
        - key: "environment"
          value: "production"
        - key: "application"
          value: "payment-service"
```

Example Clean and normalize field values

Standardize status codes and remove sensitive data:

```
processor:
  - uppercase_string:
      with_keys: ["status", "method"]
  - delete_entries:
      with_keys: ["credit_card", "password"]
  - substitute_string:
      entries:
        - source: "status"
          from: "SUCCESS"
          to: "OK"
```

Example Extract and transform specific fields

Extract user information and format for analysis:

```
processor:
  - extract_value:
      entries:
        - source: "user_agent"
          target: "browser"
          from: "(?<browser>Chrome|Firefox|Safari)"
          to: "${browser}"
  - lowercase_string:
      with_keys: ["browser"]
  - move_keys:
      entries:
        - from_key: "browser"
          to_key: "user_data.browser"
```

Example Conditional processing with entry-level conditions

Add different metadata based on log severity using entry-level when conditions:

```
processor:
  - add_entries:
      entries:
        - key: "alert_level"
          value: "critical"
          when: "log.level == 'ERROR'"
        - key: "alert_level"
          value: "info"
          when_else: "log.level == 'ERROR'"
```

Example Drop unwanted log entries

Filter out debug and trace log entries from a third-party source to reduce noise and storage costs:

```
processor:
  - drop_events:
      when: "log.level in {'DEBUG', 'TRACE'}"
      handle_expression_failure: "skip"
```

Example Processor-level conditional with delete_entries

Remove sensitive fields only when the environment is production:

```
processor:
  - delete_entries:
      with_keys: ["password", "api_key", "ssn"]
      when: "environment in {'prod', 'staging'}"
```

Metrics pipeline examples

The following examples show processor configurations for metrics pipelines. Metrics processors use OTTL path expressions to target attributes at different scopes.

Example Add business context to metrics

Add team ownership and environment tags to metric datapoints:

```
processor:
```

```
  - add_attributes:
      attributes:
        - key: resource.attributes["team"]
          value: "platform-engineering"
        - key: resource.attributes["cost_center"]
          value: "CC-1234"
```

Example Remove high-cardinality attributes

Strip attributes that drive up storage costs. Does not apply to cumulative metrics or vended metrics — if any metrics in the selection criteria have unsupported temporality, the pipeline emits an `UnsupportedTemporality` warning metric that you can monitor in the `AWS/Observability Admin` namespace:

```
processor:
  - delete_attributes:
      with_keys:
        - resource.attributes["host.id"]
        - datapoint.attributes["http.request.id"]
```

Example Standardize naming conventions

Rename metrics and attributes to align with OpenTelemetry semantic conventions. Does not apply to cumulative metrics or vended metrics:

```
processor:
  - rename_metrics:
      metrics:
        - from: "cpu_usage_percent"
          to: "system.cpu.utilization"
  - rename_attributes:
      attributes:
        - from_key: resource.attributes["hostname"]
          to_key: resource.attributes["host.name"]
```

Processor compatibility and restrictions

General processor rules

Maximum count

A pipeline can have at most 20 processors.

Parser placement

Parser processors (OCSF, CSV, Grok, etc.), if used, must be the first processor in a pipeline.

Unique processors

The following processors can appear only once per pipeline:

- `add_entries`
- `copy_values`

Processor Type	CloudWatch Logs Source	S3 Source	API-based Sources
OCSF	Must be first processor	Must be first processor	Must be first processor
parse_vpc	Must be first processor	Not applicable	Not applicable
parse_route53	Must be first processor	Not applicable	Not applicable
parse_rds	Must be first processor	Not applicable	Not applicable
parse_json	Must be first processor	Must be first processor	Must be first processor
grok	Must be first processor	Must be first processor	Must be first processor
csv	Must be first processor	Not compatible	Not compatible
key_value	Must be first processor	Must be first processor	Must be first processor
add_entries	Must be first processor	Must be first processor	Must be first processor

Processor Type	CloudWatch Logs Source	S3 Source	API-based Sources
copy_values	Must be first processor	Must be first processor	Must be first processor
String processors (lowercase, uppercase, trim)	Must be first processor	Must be first processor	Must be first processor
Field processors (move_keys, rename_keys)	Must be first processor	Must be first processor	Must be first processor
Data transformation (date, flatten)	Must be first processor	Must be first processor	Must be first processor

Compatibility definitions

Must be first processor

When used, must be the first processor in the pipeline configuration

Not compatible

Cannot be used with this source type

Not applicable

Processor is not relevant for this source type

Processor-specific restrictions

Processor restrictions by source type

Processor	Source Type	Restrictions
OCSF	CloudWatch Logs with CloudTrail	• Only allowed when `data_source_name` is `aws_cloudtrail`

Processor	Source Type	Restrictions
		• Must use CloudTrail-specific schema version • Cannot be combined with other processors
OCSF	API-based Sources	• Must use source-specific schema (e.g., microsoft_office365_management_activity for Office 365) • Requires specific mapping version for each source type • Must be first processor in pipeline
parse_vpc	CloudWatch Logs	• Only valid for VPC Flow Logs • Must be first processor • Input must contain raw VPC Flow Log format
parse_route53	CloudWatch Logs	• Only valid for Route 53 Resolver Query Logs • Must be first processor • Input must contain Route 53 Resolver query log format
parse_rds	CloudWatch Logs	• Only valid when `data_source_name` is `amazon_rds` • Must be first processor • Takes no parameters; the log type is inferred from the pipeline's `data_source_type`
add_entries	All Sources	• Maximum one instance per pipeline • Key names must be valid according to field naming rules
copy_values	All Sources	• Maximum one instance per pipeline • Source fields must exist in the event

Important

When using processors with restrictions:

- Always validate your pipeline configuration using the `ValidateTelemetryPipelineConfiguration` API before deployment
- Test the pipeline with sample data using the `TestTelemetryPipeline` API to ensure proper processing
- Monitor pipeline metrics after deployment to ensure events are being processed as expected

Metrics pipeline processors

Metrics pipeline processors transform OTel metric datapoints during ingestion. A metrics pipeline can have up to 20 processors, applied sequentially in the order they are defined.

Processors use OTTL path expressions to target attributes at different scopes:

OTTL path scopes

Path	Scope	Example
`resource.attributes["key"]`	Resource-level	`resource.attributes["service.name"]`
`instrumentation_scope.attributes["key"]`	Scope attribute	`instrumentation_scope.attributes["library"]`
`datapoint.attributes["key"]`	Datapoint-level	`datapoint.attributes["status_code"]`
`attributes["key"]`	Short form for datapoint	`attributes["environment"]`

add_attributes processor

Adds or overwrites attributes on metric datapoints. Works with all temporality types.

OTTL equivalent: `set(attributes["key"], "value")`

Configuration

Configure the add_attributes processor with the following parameters:

```
processor:
  - add_attributes:
      attributes:
        - key: resource.attributes["team"]
          value: "payments"
        - key: attributes["environment"]
          value: "production"
        - key: instrumentation_scope.attributes["version"]
          value: "1.0"
          overwrite_if_key_exists: true
```

Parameters

`attributes` (required)

Array of attribute objects to add.

`attributes[].key` (required)

OTTL attribute path specifying where to add the attribute.

`attributes[].value` (required)

String value to assign.

`attributes[].overwrite_if_key_exists` (optional)

Boolean. When `true`, overwrites existing values. Defaults to `false`. When set to `true`, this operation is considered destructive and does not apply to cumulative metrics or vended metrics.

delete_attributes processor

Removes specific attributes from metric datapoints. **Does not apply to cumulative metrics or vended metrics.**

OTTL equivalent: `delete_key(attributes, "key")`

Configuration

Configure the delete_attributes processor with the following parameters:

```
processor:
  - delete_attributes:
      with_keys:
        - resource.attributes["obsolete"]
        - attributes["temp"]
        - datapoint.attributes["debug"]
```

Parameters

`with_keys` (required)

Array of OTTL attribute paths to remove.

rename_attributes processor

Renames attribute keys on metric datapoints. **Does not apply to cumulative metrics or vended metrics.**

OTTL equivalent: `set() + delete_key()`

Configuration

Configure the rename_attributes processor with the following parameters:

```
processor:
  - rename_attributes:
      attributes:
        - from_key: resource.attributes["old_key"]
          to_key: resource.attributes["new_key"]
          overwrite_if_to_key_exists: true
```

Parameters

`attributes` (required)

Array of rename operations.

`attributes[].from_key` (required)

Source OTTL attribute path.

`attributes[].to_key` (required)

Target OTTL attribute path.

`attributes[].overwrite_if_to_key_exists` (optional)

Boolean. When `true`, overwrites if target key exists. Defaults to `false`.

rename_metrics processor

Renames metric names. **Does not apply to cumulative metrics or vended metrics.**

OTTL equivalent: `set(name, "new.metric.name") where name == "old.metric.name"`

Configuration

Configure the rename_metrics processor with the following parameters:

```
processor:
  - rename_metrics:
      metrics:
        - from: "old.metric.name"
          to: "new.metric.name"
```

Parameters

`metrics` (required)

Array of rename operations.

`metrics[].from` (required)

Current metric name.

`metrics[].to` (required)

New metric name.

substitute_attribute_values processor

Maps attribute values via a lookup table. **Does not apply to cumulative metrics or vended metrics.**

OTTL equivalent: `replace_match()`

Configuration

Configure the substitute_attribute_values processor with the following parameters:

```
processor:
  - substitute_attribute_values:
      attributes:
        - key: resource.attributes["region"]
          from: "us-east-1a"
          to: "us-east-1"
```

Parameters

`attributes` (required)

Array of substitution operations.

`attributes[].key` (required)

OTTL attribute path to match against.

`attributes[].from` (required)

Value to match.

`attributes[].to` (required)

Replacement value.

Full example

The following example uses all five processors in a single pipeline:

```
pipeline:
  source:
    cloudwatch_metrics:
      format: otlp
      selection_criteria:
        - match_all:
            - 'resource.attributes["service.name"] == "my-service"'
            - 'metric.name == "CPUUtilization"'
  processor:
    - add_attributes:
        attributes:
          - key: resource.attributes["env"]
```

```
            value: "prod"
            overwrite_if_key_exists: true
    - delete_attributes:
        with_keys:
          - resource.attributes["internal.trace"]
    - rename_attributes:
        attributes:
          - from_key: resource.attributes["old_key"]
            to_key: resource.attributes["new_key"]
    - rename_metrics:
        metrics:
          - from: "CPUUtilization"
            to: "system.cpu.utilization"
    - substitute_attribute_values:
        attributes:
          - key: resource.attributes["environment"]
            from: "dev"
            to: "development"
  sink:
    - cloudwatch_metrics: {}
```

Processor compatibility and restrictions

Maximum processors

A metrics pipeline can have at most 20 processors.

Destructive processors and temporality

Destructive processors (`delete_attributes`, `rename_attributes`, `rename_metrics`, `substitute_attribute_values`, and `add_attributes` with `overwrite_if_key_exists: true`) do not apply to cumulative metrics or vended metrics. These metrics are passed through unchanged.

Vended metrics protection

Destructive processors cannot modify metrics where `instrumentation_scope.name` starts with `cloudwatch.aws/`. These metrics are passed through unchanged.

Expression syntax for conditional processing

CloudWatch pipelines processors that support conditional processing accept a `when` parameter containing an expression. When the expression evaluates to true, the processor or entry executes.

Expressions use dot notation (`.`) for nested field access. For example, `user.role` accesses the `role` field inside the `user` object. For more details on processors that support conditional processing and their specific parameters, see the section called "Processors". For configuration examples, see the section called "Common processor use cases".

> **Note**
>
> Conditional processing applies to log pipelines only. Metrics pipelines do not support the `when` parameter.

Processor-level and entry-level conditions

There are two levels at which you can apply a `when` condition, depending on the processor.

Processor-level `when` (outer level)

A `when` placed at the top level of the processor configuration. If the expression evaluates to false, the entire processor is skipped and no operations within it execute. All processors that support conditional processing support this level.

Example Processor-level condition — skip entire processor

The following `delete_entries` processor only runs when the environment is production or staging. If the condition is false, none of the keys are deleted.

```
processor:
  - delete_entries:
      with_keys: ["password", "api_key", "ssn"]
      when: "environment in {'prod', 'staging'}"
```

Entry-level `when` (within each entry)

A `when` placed inside an individual entry in the `entries` array. Each entry is evaluated independently — if the expression is false, only that specific entry is skipped while other entries in the same processor still execute. Only processors with an `entries` array support this level (such as `add_entries`, `copy_values`, `rename_keys`, `move_keys`, `extract_value`, and `substitute_string`).

Example Entry-level condition — skip individual entries

The following `add_entries` processor adds different keys depending on each entry's condition. The first entry only adds `severity` when the log level is ERROR. The second entry always adds `processed` because it has no condition.

```
processor:
  - add_entries:
      entries:
        - key: "severity"
          value: "high"
          when: "log.level == 'ERROR'"
        - key: "processed"
          value: "true"
```

Processors that support both levels can use them together. When both are specified, the processor-level condition is evaluated first. If it is false, the entire processor is skipped and no entry-level conditions are evaluated.

Example Both levels combined

The processor-level `when` ensures the entire processor only runs for production traffic. Within that, each entry has its own condition to control which key is added.

```
processor:
  - add_entries:
      when: "environment == 'prod'"
      entries:
        - key: "alert_level"
          value: "critical"
          when: "log.level == 'ERROR'"
        - key: "alert_level"
          value: "warning"
          when: "log.level == 'WARN'"
```

For a table showing which processors support which level, see the the section called “Conditional processing support” section below.

Fallback with `when_else`

Processors that support entry-level conditions also support `when_else`. An entry with `when_else` acts as a fallback — it executes only when none of the other `when` conditions in the same processor matched. The expression value provided to `when_else` identifies which set of `when` conditions to consider, but the entry itself runs based solely on whether those conditions all evaluated to false. There is no explicit negation check — the entry simply runs when no other `when` matched.

Example Fallback entry with when_else

The first entry runs when the log level is ERROR. The second entry uses `when_else` and runs only when the first entry's `when` condition did not match (i.e., the log level is anything other than ERROR).

```
processor:
  - add_entries:
      entries:
        - key: "alert_level"
          value: "critical"
          when: "log.level == 'ERROR'"
        - key: "alert_level"
          value: "info"
          when_else: "log.level == 'ERROR'"
```

Conditional processing support

The following table shows which processors support conditional processing and at what level.

Processor conditional support

Processor	Conditional support	Level
add_entries	Yes	Processor and entry
copy_values	Yes	Processor and entry
delete_entries	Yes	Processor
move_keys	Yes	Processor and entry
flatten	Yes	Processor
lowercase_string	Yes	Processor

Processor	Conditional support	Level
uppercase_string	Yes	Processor
trim_string	Yes	Processor
substitute_string	Yes	Processor and entry
truncate	Yes	Processor
extract_value	Yes	Processor and entry
convert_entry_type	Yes	Processor
date	Yes	Processor
dissect	Yes	Processor
list_to_map	Yes	Processor
rename_keys	Yes	Processor and entry
select_entries	Yes	Processor
translate	Yes	Processor
grok	Yes	Processor
drop_events	Yes	Processor (required)
OCSF, CSV, JSON, KeyValue, WAF, Postgres, CloudFront, VPC, Route53	No	—

Operators

Supported operators

Category	Operators	Example
Relational	<, <=, >, >=	`status_code >= 200 and status_code < 300`
Equality	==, !=	`log.level == "ERROR"`
Conditional	and, or, not	`log.level == "ERROR" or log.level == "FATAL"`
Arithmetic	+, -, *, /	`response_time * 1000 > 5000`
Set membership	in, not in	`environment in {"prod", "staging", "preprod"}`
Regex matching	=~, !~	`message =~ "^ERROR.*timeout"`

Functions

`length(value)`

Returns the length of a string or array. Example: `length(message) > 100`

`contains(value, search)`

Checks whether a string contains a substring or an array contains an element. Example: `contains(message, "error")`

`startsWith(field, prefix)`

Checks whether a string starts with a specified prefix. Example: `startsWith(message, "ERROR")`

Expression examples

```
log.level == "ERROR"
```

```
status_code >= 200 and status_code < 300
environment in {"prod", "staging", "preprod"}
message =~ "^ERROR.*timeout"
user.role == "admin" and user.permissions.write == true
length(message) > 100 and contains(message, "error")
(log.level == "ERROR" or log.level == "FATAL") and environment == "prod"
```

Limitations

- Expression maximum length is 256 characters.
- Parser processors (except Grok) do not support conditional processing. This includes JSON, CSV, KeyValue, WAF, Postgres, CloudFront, VPC, Route53, and OCSF parsers.
- If the Grok processor is used as the parser (first processor) in a pipeline and its `when` condition evaluates to false, the entire pipeline does not execute for that log event.

Sinks

Sinks define the destination where processed data is sent. Each pipeline must have exactly one sink. Logs pipelines use the `cloudwatch_logs` sink and metrics pipelines use the `cloudwatch_metrics` sink.

CloudWatch Logs sink (`cloudwatch_logs`)

For logs pipelines, the `cloudwatch_logs` sink sends processed log events to a CloudWatch Logs log group.

Sink behavior by source type

Source Type	Log Group Configuration	Behavior
CloudWatch Logs	Must use `@original`	Events are sent back to their original log group
S3	Custom log group path	Events are sent to the specified log group
Third-party APIs	Custom log group path	Events are sent to the specified log group

Configuration

Configure the sink with the following parameters:

Example Non-CloudWatch Logs source configuration

```
sink:
  cloudwatch_logs:
    log_group: "/aws/my-application/logs"
```

Example CloudWatch Logs source configuration

```
sink:
  cloudwatch_logs:
    log_group: "@original"
```

Parameters

`log_group` (required)

The name of the CloudWatch Logs log group where processed events will be sent. For pipelines with non-`cloudwatch_logs` sources, this must be an existing log group name. For pipelines using the `cloudwatch_logs` source, the ONLY allowed value is `@original`.

`include_original` (optional)

When present, stores a copy of each raw log event before any transformation takes place in the `@original_message` system field of the event. This preserves the original data for audit or compliance purposes. Specify as an empty object (`{}`). Available only for pipelines with `cloudwatch_logs` sources. At least one processor must be configured when this option is enabled.

Example CloudWatch Logs sink with original log preservation

```
sink:
  - cloudwatch_logs:
      log_group: "@original"
      include_original: {}
```

Requirements and limitations

Log group existence

If created using the AWS Management Console, CloudWatch will attempt to create the specified log group and appropriate resource policy if it does not exist when using a non-CloudWatch logs source. Otherwise, the specified log group must exist before creating the pipeline.

Event size

Each log event cannot exceed 256 KB in size after processing.

Log group retention

The pipeline uses the retention settings configured on the destination log group.

Log group resource policy

CloudWatch Logs resource policies are required for pipelines that write to log groups, except for pipelines using the `cloudwatch_logs` source. When you use the AWS Management Console to configure the pipeline, CloudWatch will attempt to add the resource policy if needed. If you are creating the pipeline using the AWS CLI or an API, you must create the policy manually and add it using the `logs:PutResourcePolicy` request. For more information, see Resource policies.

Cross-Region support

The destination log group must be in the same Region as the pipeline.

Important

For pipelines using the `cloudwatch_logs` source type:

- You must use `@original` as the log group value.
- Events are always sent back to their original log group.
- The original log group must exist throughout the pipeline's lifecycle.
- Pipelines with processors mutate the log events in the original CloudWatch log group they are intercepted from for logs from AWS services. To preserve the original data, enable `include_original` in the sink configuration. The original log copy is stored in the `@original_message` system field of the event.

> **Note**
>
> Log events are subject to CloudWatch Logs quotas and limitations.

CloudWatch Metrics sink (`cloudwatch_metrics`)

For metrics pipelines, the `cloudwatch_metrics` sink stores processed metrics in CloudWatch. Processed metrics are queryable via PromQL in Query Studio and fully compatible with CloudWatch Alarms, Anomaly Detection, and Dashboards.

Configuration

The `cloudwatch_metrics` sink has no parameters:

```
sink:
  - cloudwatch_metrics: {}
```

CloudWatch pipelines IAM policies and permissions

This section provides IAM requirements for CloudWatch pipelines. Permissions vary based on your data source and integration method.

The following table helps you identify which IAM sections apply to your use case.

Use case	Integration method	Source type in pipeline configuration	IAM sections you need
Third-party integrations (API Pull)	Pipeline pulls from vendor API using stored credentials	`microsoft_office365`, `okta_sso`, `palo_alto_ngfw`, etc.	the section called “API caller permissions” + the section called “Third-party sources (API Pull)” + the section called “Resource policies”
Third-party integrations (S3 delivery)	Vendor delivers files to your S3 bucket	`s3`	the section called “API caller permissions” + the section called “Third-party sources

Use case	Integration method	Source type in pipeline configuration	IAM sections you need
			(S3 delivery)" + the section called "Resource policies"
Custom data from S3	Your applications write to S3, pipeline reads from bucket	`s3`	the section called "API caller permissions" + the section called "Custom data from S3" + the section called "Resource policies"
Custom data from CloudWatch Logs	Your applications log to a CloudWatch Logs log group	`cloudwatch_logs`	the section called "API caller permissions" + the section called "Custom data from CloudWatch Logs"
Vended AWS service logs	AWS services deliver logs to CloudWatch Logs (VPC Flow Logs, Route 53)	`cloudwatch_logs`	the section called "API caller permissions" + the section called "Vended AWS service logs"
CloudWatch Metrics (OTel)	AWS services emit metrics via OTLP	`cloudwatch_metrics`	the section called "Pipeline rule permissions for CloudWatch Metrics sources"

Note

S3-based sources (`s3`) require a resource policy after pipeline creation. CloudWatch Logs sources (`cloudwatch_logs`) do not.

API caller permissions

The IAM principal that calls `CreateTelemetryPipeline` needs `iam:PassRole` permission for any roles referenced in the pipeline configuration.

Example PassRole policy template

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "PassRoleForPipelineSource",
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "arn:aws:iam::your-account-id:role/your-source-role",
            "Condition": {
                "StringEquals": {
                    "iam:PassedToService": [
                        "service-principal"
                    ],
                    "iam:AssociatedResourceARN": [
                        "arn:aws:observabilityadmin:your-region:your-account-
id:telemetry-pipeline/*"
                    ]
                }
            }
        }
    ]
}
```

Replace *service-principal* with the value from the following table based on your use case.

Use case	Service principal value
Third-party (API Pull)	telemetry-pipelines.observabilityadmin.amazonaws.com
Third-party (S3 delivery)	telemetry-pipelines.observabilityadmin.amazonaws.com
Custom data from S3	telemetry-pipelines.observabilityadmin.amazonaws.com
Custom data from CloudWatch Logs	logs.amazonaws.com
Vended AWS service logs	logs.amazonaws.com

> **Note**
>
> The `Condition` block is recommended but optional. Without it, the role can be passed to any service.

Pipeline rule permissions (CloudWatch Logs sources only)

When using `cloudwatch_logs` as a source, the API caller also needs permissions for pipeline rule operations. The `logs:PutPipelineRule` permission is required for `CreateTelemetryPipeline` and `UpdateTelemetryPipeline` operations. The `logs:DeletePipelineRule` permission is required for `DeleteTelemetryPipeline` operations.

Example IAM policy for CloudWatch Logs pipeline rules

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "PipelineRuleForCloudWatchLogs",
            "Effect": "Allow",
            "Action": [
                "logs:PutPipelineRule",
                "logs:DeletePipelineRule"
            ],
            "Resource": "*"
        }
    ]
}
```

Pipeline rule permissions for CloudWatch Metrics sources

When you use `cloudwatch_metrics` as a source, you need permissions for pipeline rule operations. To create or update a pipeline, grant the `cloudwatch:PutPipelineRule` permission. To delete a pipeline, grant the `cloudwatch:DeletePipelineRule` permission. Metrics pipelines do not require `iam:PassRole` or CloudWatch Logs resource policies. You can scope these actions down to the `dataset/default` resource.

Example IAM policy for CloudWatch metrics pipeline rules

```
{
```

```
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "PipelineRuleForCloudWatchMetrics",
            "Effect": "Allow",
            "Action": [
                "cloudwatch:PutPipelineRule",
                "cloudwatch:DeletePipelineRule"
            ],
            "Resource": "arn:aws:cloudwatch:your-region:your-account-id:dataset/
default"
        }
    ]
}
```

Reducing scope with condition keys

Source role policies

Each pipeline requires a dedicated IAM role that the service assumes to read your data. The following subsections provide the complete policies (permission and trust) for each use case.

Third-party sources (API Pull)

This section applies to Microsoft Office 365, Microsoft Entra ID, Okta SSO, Palo Alto NGFW, and other vendor API integrations that store credentials in AWS Secrets Manager.

Permission policy

The following policy allows the role to retrieve your stored API credentials.

Example IAM policy for Secrets Manager sources

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "secrets-manager-access",
            "Effect": "Allow",
            "Action": [
                "secretsmanager:GetSecretValue"
            ],
            "Resource": "arn:aws:secretsmanager:your-region:your-account-
id:secret:your-secret-name*"
```

```
        },
        {
            "Sid": "kms-access",
            "Effect": "Allow",
            "Action": "kms:Decrypt",
            "Resource": "arn:aws:kms:your-region:your-account-id:key/your-key-id"
        }
    ]
}
```

> **Note**
>
> The `kms:Decrypt` statement is only required if your secret in Secrets Manager is encrypted with a customer-managed KMS key.

Trust policy

Example Trust policy for API Pull sources

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "telemetry-pipelines.observabilityadmin.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

Complete IAM setup for API Pull pipelines

The following example shows all the IAM policies needed to create a third-party API Pull pipeline end to end.

Caller identity policy — attach to the principal calling `CreateTelemetryPipeline`:

```
{
    "Version": "2012-10-17",
```

```
    "Statement": [
        {
            "Sid": "CreateApiPullPipeline",
            "Effect": "Allow",
            "Action": [
                "observabilityadmin:CreateTelemetryPipeline",
                "iam:PassRole"
            ],
            "Resource": "*"
        }
    ]
}
```

Source role permission policy — attach to the role the pipeline assumes:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "SecretsManagerAccess",
            "Effect": "Allow",
            "Action": [
                "secretsmanager:GetSecretValue"
            ],
            "Resource": "arn:aws:secretsmanager:your-region:your-account-
id:secret:your-secret-name*"
        }
    ]
}
```

Source role trust policy:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "telemetry-pipelines.observabilityadmin.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
```

```
}
```

> **Note**
>
> After creating the pipeline, you must also create a resource policy within 5 minutes. See the section called “Resource policies”.

> **Note**
>
> For production use, scope down `iam:PassRole` by using the condition keys shown in the section called “API caller permissions”. If your secret uses a customer-managed KMS key, add `kms:Decrypt` to the source role permission policy.

Third-party sources (S3 delivery)

This section applies to any third-party vendor that delivers log files to your S3 bucket (for example, CrowdStrike Falcon, Wiz, or Cisco Umbrella).

Permission policy

The following policy allows the role to read objects from S3 and consume SQS notifications.

Example IAM policy for S3 sources

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "s3-access",
            "Effect": "Allow",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": "arn:aws:s3:::your-bucket-name/*"
        },
        {
            "Sid": "sqs-access",
            "Effect": "Allow",
            "Action": [
```

```
                "sqs:ReceiveMessage",
                "sqs:DeleteMessage",
                "sqs:ChangeMessageVisibility"
            ],
            "Resource": "arn:aws:sqs:your-region:your-account-id:your-queue-name"
        },
        {
            "Sid": "kms-access",
            "Effect": "Allow",
            "Action": "kms:Decrypt",
            "Resource": "arn:aws:kms:your-region:your-account-id:key/your-key-id"
        }
    ]
}
```

> **Note**
>
> The `kms:Decrypt` statement is only required if your S3 bucket or SQS queue uses a customer-managed KMS key for encryption.

Trust policy

Example Trust policy for S3 delivery sources

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "telemetry-pipelines.observabilityadmin.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

Complete IAM setup for S3 delivery pipelines

The following example shows all the IAM policies needed to create an S3 delivery pipeline end to end.

Caller identity policy — attach to the principal calling `CreateTelemetryPipeline`:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "CreateS3Pipeline",
            "Effect": "Allow",
            "Action": [
                "observabilityadmin:CreateTelemetryPipeline",
                "iam:PassRole"
            ],
            "Resource": "*"
        }
    ]
}
```

Source role permission policy — attach to the role the pipeline assumes:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "S3Access",
            "Effect": "Allow",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": "arn:aws:s3:::your-bucket-name/*"
        },
        {
            "Sid": "SqsAccess",
            "Effect": "Allow",
            "Action": [
                "sqs:ReceiveMessage",
                "sqs:DeleteMessage",
                "sqs:ChangeMessageVisibility"
            ],
            "Resource": "arn:aws:sqs:your-region:your-account-id:your-queue-name"
        }
    ]
}
```

Source role trust policy:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "telemetry-pipelines.observabilityadmin.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

Note

After creating the pipeline, you must also create a resource policy within 5 minutes. See the section called “Resource policies”.

Note

For production use, scope down `iam:PassRole` by using the condition keys shown in the section called “API caller permissions”. If your S3 bucket or SQS queue uses a customer-managed KMS key, add `kms:Decrypt` to the source role permission policy.

Custom data from S3

This section applies to your own applications or infrastructure writing log files to an S3 bucket.

The IAM setup is identical to the section called “Third-party sources (S3 delivery)”. Use the same permission policy and trust policy. The pipeline reads from your bucket through SQS event notifications regardless of who wrote the data.

Custom data from CloudWatch Logs

This section applies to your own applications logging to a CloudWatch Logs log group (for example, Lambda functions, ECS containers, or custom EC2 applications).

Permission policy

The following policy allows the role to process logs from your specified log groups.

Example IAM policy for CloudWatch Logs sources

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "logs-processing-access",
            "Effect": "Allow",
            "Action": [
                "logs:processWithPipeline"
            ],
            "Resource": [
                "arn:aws:logs:your-region:your-account-id:log-group:your-log-group-01",
                "arn:aws:logs:your-region:your-account-id:log-group:your-log-group-02"
            ]
        }
    ]
}
```

You can scope down this permission by using the `logs:data_source_name` and `logs:data_source_type` condition keys to restrict which pipeline sources can invoke transformations. The `logs:data_source_name` value corresponds to the `data_source_name` in your pipeline configuration, and `logs:data_source_type` corresponds to the `data_source_type` in your pipeline configuration.

Example Permission policy for CloudWatch Logs sources (scoped down with condition keys)

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowProcessWithPipelineScopedDown",
            "Effect": "Allow",
            "Action": "logs:ProcessWithPipeline",
            "Resource": "arn:aws:logs:your-region:your-account-id:log-group:your-log-
group-name",
            "Condition": {
                "StringEquals": {
```

```
                    "aws:ResourceAccount": "your-account-id",
                    "logs:data_source_name": "your-source-name",
                    "logs:data_source_type": "your-source-type"
                }
            }
        }
    ]
}
```

> **Note**
>
> The IAM role for CloudWatch Logs sources requires both the trust policy (to allow `logs.amazonaws.com` to assume the role) and the permission policy (to grant `logs:ProcessWithPipeline`). Without both policies, CloudWatch pipelines cannot transform log events during ingestion.

Trust policy

Example Trust policy for CloudWatch Logs sources

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "logs.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

> **Note**
>
> No resource policy is needed for CloudWatch Logs source pipelines.

Complete IAM setup for CloudWatch Logs pipelines

The following example shows all the IAM policies needed to create a CloudWatch Logs pipeline end to end.

Caller identity policy — attach to the principal calling `CreateTelemetryPipeline`:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "CreateLogsPipeline",
            "Effect": "Allow",
            "Action": [
                "observabilityadmin:CreateTelemetryPipeline",
                "logs:PutPipelineRule",
                "logs:DeletePipelineRule",
                "iam:PassRole"
            ],
            "Resource": "*"
        }
    ]
}
```

Source role permission policy — attach to the role the pipeline assumes:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "LogsProcessing",
            "Effect": "Allow",
            "Action": [
                "logs:processWithPipeline"
            ],
            "Resource": [
                "arn:aws:logs:your-region:your-account-id:log-group:your-log-group"
            ]
        }
    ]
}
```

Source role trust policy:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "logs.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

Note

For production use, scope down `iam:PassRole` by using the condition keys shown in the section called "API caller permissions".

Vended AWS service logs

This section applies to AWS service logs delivered to CloudWatch Logs, such as VPC Flow Logs, Route 53 query logs, and other AWS vended log types.

The IAM setup is identical to the section called "Custom data from CloudWatch Logs". Use the same permission policy (`logs:processWithPipeline` scoped to the log group) and the same trust policy (`logs.amazonaws.com`).

Because this uses the `cloudwatch_logs` source type, the caller also needs `logs:PutPipelineRule` and `logs:DeletePipelineRule` permissions. See the section called "Pipeline rule permissions (CloudWatch Logs sources only)".

Resource policies

CloudWatch Logs resource policies are required for S3-based sources and Secrets Manager-based sources (third-party integrations). Resource policies are **not** required for CloudWatch Logs sources (custom data or vended logs).

After calling `CreateTelemetryPipeline`, you receive a pipeline ARN. You must then call `logs:PutResourcePolicy` to allow the CloudWatch pipelines service principal to write to the configured log group.

Timing constraint

You have less than 5 minutes after receiving the pipeline ARN to create this resource policy. If the pipeline becomes active before the policy is in place, data will be dropped.

Example logs:PutResourcePolicy request

```
{
    "policyName": "resourceArn=arn:aws:logs:your-region:your-account-id:log-group:your-log-group-name:*",
    "policyDocument": {
        "Version": "2012-10-17",
        "Statement": [
            {
                "Effect": "Allow",
                "Principal": {
                    "Service": "telemetry-pipelines.observabilityadmin.amazonaws.com"
                },
                "Action": [
                    "logs:CreateLogStream",
                    "logs:PutLogEvents"
                ],
                "Condition": {
                    "StringEquals": {
                        "aws:SourceArn": "arn:aws:observabilityadmin:your-region:your-account-id:telemetry-pipeline/your-pipeline-id"
                    }
                }
            }
        ]
    }
}
```

Managing resource policies

Use the AWS CLI to create or update CloudWatch Logs resource policies for CloudWatch pipelines.

To check for existing policies

```
aws logs describe-resource-policies \
```

```
    --resource-arn arn:aws:logs:your-region:your-account-id:log-group:your-log-group-name:*
```

To create a new policy

```
aws logs put-resource-policy \
    --region your-region \
    --policy-name "resourceArn=arn:aws:logs:your-region:your-account-id:log-group:your-log-group-name:*" \
    --policy-document file://policy.json
```

To merge with an existing policy

If a resource policy already exists, add the new statement to the existing `Statement` array in the policy document, then call `put-resource-policy` again with the merged file.

1. Retrieve the existing policy:

```
aws logs describe-resource-policies \
    --resource-arn arn:aws:logs:your-region:your-account-id:log-group:your-log-group-name:*
```

2. Add the new statement to the existing `Statement` array:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "existing-service.amazonaws.com"
            },
            "Action": [
                "logs:SomeAction"
            ]
        },
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "telemetry-pipelines.observabilityadmin.amazonaws.com"
            },
            "Action": [
```

```
                "logs:CreateLogStream",
                "logs:PutLogEvents"
            ],
            "Condition": {
                "StringEquals": {
                    "aws:SourceArn": "arn:aws:observabilityadmin:your-region:your-
account-id:telemetry-pipeline/your-pipeline-id"
                }
            }
        }
    ]
}
```

3. Update the policy:

```
aws logs put-resource-policy \
    --region your-region \
    --policy-name "resourceArn=arn:aws:logs:your-region:your-account-id:log-
group:your-log-group-name:*" \
    --policy-document file://existing-policy.json
```

Confirm the policy was created or updated successfully:

```
aws logs describe-resource-policies \
    --resource-arn arn:aws:logs:your-region:your-account-id:log-group:your-log-group-
name:*
```

Replace the following placeholders:

- *your-region* – Your AWS Region (for example, us-east-1)
- *your-account-id* – Your 12-digit AWS account ID
- *your-log-group-name* – Your CloudWatch Logs log group name
- *your-pipeline-id* – Your telemetry pipeline ID (returned by `CreateTelemetryPipeline`)

Pipeline condition keys

CloudWatch pipelines supports IAM condition keys that let you restrict who can create pipelines based on the source name and type. Use these condition keys to enforce governance policies across your organization.

Available condition keys

`observabilityadmin:SourceName`

Restricts pipeline creation to specific source names. Applies to logs pipelines only.

`observabilityadmin:SourceType`

Restricts pipeline creation to specific source types.

Use these condition keys in identity policies to control which pipelines a principal can create.

`observabilityadmin:SourceType`

Restricts pipeline creation to specific source types. Supported values include `cloudwatch_logs`, `s3`, `microsoft_office365`, `okta_sso`, and `palo_alto_ngfw`.

Example Restrict pipeline creation by source type

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowPipelineCreationForSpecificSourceType",
            "Effect": "Allow",
            "Action": "observabilityadmin:CreateTelemetryPipeline",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "observabilityadmin:SourceType": "cloudwatch_logs"
                }
            }
        }
    ]
}
```

Source role trust policy conditions

Use these condition keys in the trust policy of your source role to restrict which account can assume the role. This prevents confused deputy attacks where the service might act on behalf of a different account.

`aws:SourceAccount`

Restricts role assumption to requests originating from a specific AWS account.

`aws:SourceArn`

Restricts role assumption to requests originating from a specific resource ARN (for example, a log group).

Example Trust policy with SourceAccount condition (CloudWatch Logs sources)

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "logs.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "your-account-id"
                },
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:logs:your-region:your-account-id:log-
group:*"
                }
            }
        }
    ]
}
```

AI-assisted processor configuration permissions

To use AI-assisted processor configuration in the CloudWatch pipelines console, the IAM principal must have the `logs:GeneratePipeline` permission. This permission authorizes the generation of processor configurations from natural language descriptions.

Example IAM policy for AI-assisted processor configuration

```
{
```

```
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowGeneratePipeline",
            "Effect": "Allow",
            "Action": "logs:GeneratePipeline",
            "Resource": "*"
        }
    ]
}
```

CloudWatch pipelines extensions

CloudWatch pipelines extensions provide additional functionality to the pipeline. You can use the AWS Secrets Manager integration for credential management.

AWS Secrets Manager extension

Configures access to AWS Secrets Manager for retrieving credentials and sensitive configuration values. This extension is only supported for third-party sources that require authentication credentials.

Configuration

Configure the AWS Secrets Manager extension with the following parameters:

```
extension:
  aws:
    secrets:
      <secret-name>:
        secret_id: "<secret arn>"
        region: "<secret region>"
        sts_role_arn: "arn:aws:iam::123456789012:role/Example-Role"
        refresh_interval: PT1H
        disable_refresh: false
```

Parameters

`aws.secrets.<secret-name>.secret_id` (required)

The ARN of the AWS Secrets Manager secret containing the credentials.

`aws.secrets.<secret-name>.region` (required)

The AWS region where the secret is stored.

`aws.secrets.<secret-name>.sts_role_arn` (required)

The ARN of the IAM role to assume for accessing the AWS Secrets Manager secret.

`aws.secrets.<secret-name>.refresh_interval` (optional)

How often to refresh the secret from AWS Secrets Manager. Uses ISO 8601 duration format. Defaults to PT1H (1 hour).

`aws.secrets.<secret-name>.disable_refresh` (optional)

Whether to disable automatic secret refresh. Defaults to false.

Secret reference syntax

Reference secrets in your pipeline configuration using the following syntax:

```
${{aws_secrets:<secret-name>:<key>}}
```

For example, to reference a client ID and secret:

```
source:
  microsoft_office365:
    authentication:
      oauth2:
        client_id: "${{aws_secrets:office365-creds:client_id}}"
        client_secret: "${{aws_secrets:office365-creds:client_secret}}"
```

Requirements and limitations

Secret format

Secrets must be stored as JSON key-value pairs in AWS Secrets Manager.

Cross-Region access

Secrets can be accessed from any Region where AWS Secrets Manager is available.

Refresh interval limits

Minimum refresh interval is 5 minutes (PT5M). Maximum is 24 hours (PT24H).

Maximum secrets

A pipeline can reference up to 10 different secrets.

Important

Consider the following when using secrets:

- Ensure the IAM role has appropriate permissions to access the secrets
- Monitor secret access using AWS CloudTrail
- Use separate secrets for different environments (development, production)

Monitoring pipelines

CloudWatch pipelines publishes metrics to Amazon CloudWatch in the `AWS/Observability Admin` namespace. You can use these metrics to monitor your pipelines' health, performance, and data flow.

Available metrics

The following tables list the available metrics for CloudWatch pipelines.

Note

Pipelines metrics are only emitted when the value is non-zero.

Pipeline health metrics

The following metrics are emitted for all pipeline types (logs and metrics):

Metric	Description	Dimension	Unit
`PipelineErrors`	Aggregate count of errors in pipeline	PipelineName	Count

Metric	Description	Dimension	Unit
PipelineErrorsByErrorType	Detailed error counts by type	PipelineName, ErrorType	Count
PipelineWarnings	Number of warnings encountered	PipelineName	Count
PipelineWarningsByWarningType	Detailed warnings by type	PipelineName, WarningType	Count

> **Note**
>
> For logs pipelines, PipelineErrorsByErrorType includes additional dimensions (ErrorSource, ErrorComponent) and PipelineWarningsByWarningType includes additional dimensions (WarningSource, WarningComponent).

Logs pipeline metrics

The following metrics are emitted for logs pipelines:

Metric	Description	Dimension	Unit
PipelineBytesIn	Volume of log records going into pipeline in uncompressed bytes	PipelineName	Bytes
PipelineBytesInByDataSource	Volume of incoming data with source/type breakdown	PipelineName, DataSource, DataType	Bytes

Metric	Description	Dimension	Unit
PipelineBytesOut	Volume of data routed to destination	PipelineName	Bytes
PipelineBytesOutByDataSource	Volume of outgoing data with source/type breakdown	PipelineName, DataSource, DataType	Bytes
PipelineRecordsIn	Number of records entering the pipeline	PipelineName	Count
PipelineRecordsInByDataSource	Number of incoming records with source/type breakdown	PipelineName, DataSource, DataType	Count
PipelineRecordsOut	Number of records exiting the pipeline	PipelineName	Count
PipelineRecordsOutByDataSource	Number of outgoing records with source/type breakdown	PipelineName, DataSource, DataType	Count
PipelineRecordsUnprocessed	Number of records that couldn't be processed	PipelineName	Count
PipelineRecordsUnprocessedByDataSource	Number of unprocessed records with source/type breakdown	PipelineName, DataSource, DataType	Count

Metrics pipeline metrics

The following metrics are emitted for metrics pipelines:

Metric	Description	Dimension	Unit
`PipelineDataPointsIn`	Number of metric datapoints entering the pipeline (matched selection criteria)	PipelineName, dataset	Count
`PipelineDataPointsOut`	Number of metric datapoints exiting the pipeline after processing	PipelineName, dataset	Count
`PipelineDataPointsUnprocessed`	Number of metric datapoints that matched selection criteria but passed through unchanged because all processors were skipped. For example, this occurs when `UnsupportedTemporality` or `DestructiveOnVended` restrictions apply. You can create an alarm on this metric to detect metrics in your selection criteria that cannot be processed.	PipelineName, dataset	Count

Dimensions

CloudWatch pipelines metrics use the following dimensions:

PipelineName

Name of the pipeline.

ErrorType

Type of error encountered.

WarningType

Type of warning encountered.

DataSource (logs pipelines)

Source of the data (AWS service name or third-party source).

DataType (logs pipelines)

Type of data being processed.

ErrorSource (logs pipelines)

Origin of the error (s3, aws.secrets, cloudwatch_logs).

ErrorComponent (logs pipelines)

Component where error occurred (source, sink, extension).

dataset (metrics pipelines)

The OTel metric dataset identifier. Currently always `default`.

Error types

The following error types are tracked in `PipelineErrorsByErrorType`:

`ALL`

The total count of all errors on the pipeline.

`PARSE_FAILURE`

Data parsing errors.

`PROCESSOR_ERRORS`

Processing operation failures.

`ACCESS_DENIED` (logs pipelines)

Permission-related failures.

`RESOURCE_NOT_FOUND` (logs pipelines)

Specified resource doesn't exist.

`SOURCE_READ_FAILURE` (logs pipelines)

Failures reading from source.

`PAYLOAD_SIZE_EXCEEDED` (logs pipelines)

Data size limit exceeded.

Warning types

The following warning types can occur on a pipeline:

`THROTTLED`

Indicates that the volume of data being sent has exceeded existing rate limits, causing some data points or events to be dropped or delayed to protect the system and ensure stability.

`DestructiveOnVended` (metrics pipelines)

A destructive processor attempted to modify a vended metric (`instrumentation_scope.name` starting with `cloudwatch.aws/`). The pipeline skipped the operation and counted the affected datapoints in `PipelineDataPointsUnprocessed`.

`UnsupportedTemporality` (metrics pipelines)

A destructive processor attempted to modify a metric with cumulative aggregation temporality. The pipeline skipped the operation and passed the metric through unchanged. Cumulative temporality means the metric reports values accumulated since a fixed start time (as defined by the OpenTelemetry metrics data model). The pipeline counts the affected datapoints in `PipelineDataPointsUnprocessed`. Monitor this warning to identify metrics in your selection criteria that cannot be processed by destructive operations.

`UnknownOttlPath` (metrics pipelines)

Processor configuration references an unrecognized OTTL path — attribute operation skipped.

Viewing metrics

You can view CloudWatch pipelines metrics using the following methods:

Using the CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/
2. In the navigation pane, choose **Metrics**
3. Choose the **AWS/Observability Admin** namespace
4. Select the metric dimension to view

Using the AWS CLI

```
aws cloudwatch get-metric-statistics \
  --namespace "AWS/Observability Admin" \
  --metric-name "PipelineBytesIn" \
  --dimensions Name=PipelineName,Value=my-pipeline \
  --start-time "2025-10-29T00:00:00" \
  --end-time "2025-10-29T23:59:59" \
  --period 300 \
  --statistics Sum
```

Creating alarms

You can create CloudWatch alarms based on any of these metrics. Here's an example of creating an alarm for pipeline errors:

```
aws cloudwatch put-metric-alarm \
  --alarm-name "HighPipelineErrors" \
  --alarm-description "Alert on high error rate" \
  --metric-name "PipelineErrors" \
  --namespace "AWS/Observability Admin" \
  --dimensions Name=PipelineName,Value=my-pipeline \
  --period 300 \
  --evaluation-periods 2 \
  --threshold 10 \
  --comparison-operator GreaterThanThreshold \
  --statistic Sum \
  --alarm-actions arn:aws:sns:region:account-id:topic-name
```

Best practices for CloudWatch pipelines metrics

Monitor data flow

- Use `PipelineBytesIn` and `PipelineBytesOut` to track data volume
- Monitor `PipelineRecordsIn` and `PipelineRecordsOut` to track record counts
- Watch for unexpected changes in throughput patterns
- To monitor dropped records, compute `PipelineRecordsIn` - `PipelineRecordsOut` over a given period; a sustained positive difference indicates records that did not reach the destination.

Track errors and warnings

- Create alarms for `PipelineErrors` to detect issues quickly
- Use `PipelineErrorsByErrorType` to diagnose specific problems
- Monitor `PipelineWarnings` to identify potential issues early

Configure appropriate thresholds

- Base thresholds on your expected data patterns
- Account for normal variations in data volume
- Consider peak usage periods when setting alarm thresholds

Troubleshooting

This section covers common issues you might encounter when working with CloudWatch pipelines and their solutions.

Pipeline creation failures

- **Issue:** Pipeline creation fails with permission errors

  Solution: Verify that your IAM role has the required PassRole permissions for any roles specified in the pipeline configuration
- **Issue:** Configuration validation errors

  Solution: Use the ValidateTelemetryPipeline API to check your configuration syntax before creating the pipeline

- **Issue:** Log source not available to select

  Possible reason: There is already a log source with the same data source name and type. Duplicate combinations are greyed out since you can only create one of each.

Data processing issues

- **Issue:** No data flowing through pipeline

  Solution: Check that your data source is properly configured and generating data, and verify that CloudWatch Logs resource policies are correctly set
- **Issue:** Processor errors in pipeline

  Solution: Review processor configuration and ensure input data format matches processor expectations

Amazon CloudWatch managed Prometheus collectors

Amazon CloudWatch managed Prometheus collectors provides a fully managed, agentless scraper, or collector, that automatically discovers and pulls Prometheus-compatible metrics. With Amazon CloudWatch managed Prometheus collectors, you eliminate the operational overhead of running and scaling your own metric collection infrastructure. The collectors automatically discover targets in your VPC, scrape Prometheus-compatible metrics, and deliver them to CloudWatch. You don't have to manage, install, patch, or maintain agents, collectors or scrapers for Prometheus metrics. Managed collectors automatically scale to provide highly available, reliable metric collection for your AWS infrastructure.

A managed collector creates an Elastic Network Interface (ENI) for each subnet that you specify when you create the scraper. The collector scrapes metrics through these ENIs using OpenTelemetry Protocol (OTLP). It delivers the metrics to your CloudWatch dataset through a VPC endpoint. The scraped data never travels on the public internet. You can query metrics in CloudWatch with PromQL (Prometheus Query Language) for flexible and scalable analytics.

> **Note**
>
> Scraping metrics might incur VPC data transfer charges between the collector and your targets. To reduce this network transfer cost, configure your Prometheus `/metrics` endpoint to compress responses (for example, with gzip). Compression lowers the volume

of data that the collector transfers across the network. It does not change the number of metrics that CloudWatch ingests.

We charge for Prometheus collectors by the hour, and CloudWatch OpenTelemetry metric ingestion pricing applies. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

Topics

- Integrate Amazon MSK
- Integrate Amazon EKS
- VPC-connected managed collector
- Scraper configuration
- Monitor collectors

Integrate Amazon MSK

With an Amazon CloudWatch managed Prometheus collector, you can automatically discover and collect Prometheus metrics from your Amazon MSK clusters. When you enable Open Monitoring on your Amazon MSK cluster, it exposes Prometheus metrics through the Java Management Extensions (JMX) Exporter and Node Exporter. The managed collector connects to your VPC and scrapes these metrics from all brokers using DNS-based service discovery and delivers these metrics directly to CloudWatch. With this integration, you can monitor host-level metrics, JVM-level metrics, and Kafka broker metrics in CloudWatch without deploying any agents.

Note

When a Amazon CloudWatch managed Prometheus collector delivers your Amazon MSK metrics to CloudWatch, it automatically enriches each metric with attributes that identify its origin. Every metric carries the collector's instrumentation scope, cloud attributes that record the AWS account and Region, and a unit that the collector infers from the metric name. You can filter and group on these attributes when you query your metrics with PromQL.

Prerequisites

This procedure assumes familiarity with Amazon MSK cluster administration and Amazon VPC networking concepts.

- Amazon MSK cluster in provisioned mode (managed collectors do not support Amazon MSK Serverless or Amazon MSK Express)
- Open Monitoring enabled on the cluster. For more information, see Open Monitoring with Prometheus in the *Amazon MSK Developer Guide*.
- At least two subnets in different Availability Zones
- Security group allowing the collector to reach broker ports 11001 and 11002

Step 1: Enable Open Monitoring

Enable Open Monitoring on your Amazon MSK cluster to expose Prometheus metrics. For instructions on enabling Open Monitoring, see Open Monitoring with Prometheus in the *Amazon MSK Developer Guide*.

```
aws kafka update-monitoring \
  --cluster-arn "arn:aws:kafka:us-west-2:123456789012:cluster/my-cluster/abc123-def456"
 \
  --current-version "K1A2B3C4D5" \
  --open-monitoring '{
    "Prometheus": {
      "JmxExporter": {"EnabledInBroker": true},
      "NodeExporter": {"EnabledInBroker": true}
    }
  }'
```

Note

The `--open-monitoring` parameter alone exposes the Prometheus endpoints on ports 11001 and 11002. Enhanced monitoring tiers such as `PER_TOPIC_PER_PARTITION` are separate from Open Monitoring and can incur additional charges, so set them only if you need that level of Amazon MSK metrics.

Step 2: Get your cluster's DNS name

Amazon MSK provides a cluster-level DNS name that resolves to all broker IPs. Using this for service discovery makes your monitoring resilient to broker replacements and cluster scaling.

Get your cluster DNS name (remove the broker-specific prefix like `b-1.` or `b-2.`):

```
aws kafka get-bootstrap-brokers --cluster-arn "arn:aws:kafka:us-
west-2:123456789012:cluster/my-cluster/abc123-def456"
```

For example, if the bootstrap broker returns `b-1.my-cluster.abc123.c4.kafka.us-west-2.amazonaws.com`, use `my-cluster.abc123.c4.kafka.us-west-2.amazonaws.com` as your cluster DNS name.

Step 3: Configure scrape config

The following is an example scrape configuration for Amazon MSK. You reference this configuration when you create the scraper in the next step. For more information about configuration options, see Scraper configuration.

```
global:
  scrape_interval: 60s
  external_labels:
    cluster_name: my-msk-cluster

scrape_configs:
  - job_name: 'msk-jmx'
    dns_sd_configs:
      - names:
          - my-cluster.abc123.c4.kafka.us-west-2.amazonaws.com
        type: A
        port: 11001
    relabel_configs:
      - source_labels: [__meta_dns_name]
        target_label: broker_dns
      - source_labels: [__address__]
        target_label: instance
      - target_label: compute_platform
        replacement: 'msk'

  - job_name: 'msk-node'
```

```
    dns_sd_configs:
      - names:
          - my-cluster.abc123.c4.kafka.us-west-2.amazonaws.com
        type: A
        port: 11002
    relabel_configs:
      - source_labels: [__meta_dns_name]
        target_label: broker_dns
      - source_labels: [__address__]
        target_label: instance
      - target_label: compute_platform
        replacement: 'msk'
```

Step 4: Create the scraper

Create the scraper with a CloudWatch destination, using the scrape configuration for your Amazon MSK brokers from the previous step.

AWS API

Use the `CreateScraper` API operation to create a scraper with a CloudWatch destination. Replace the subnet, security group, and dataset information with your own values.

```
POST /scrapers HTTP/1.1

{
  "alias": "msk-metrics-scraper",
  "source": {
    "vpcConfiguration": {
      "subnetIds": ["subnet-subnet-id-1", "subnet-subnet-id-2"],
      "securityGroupIds": ["sg-security-group-id"]
    }
  },
  "destination": {
    "cloudWatchConfiguration": {
      "datasetArn": "arn:aws:cloudwatch:us-west-2:123456789012:dataset/default"
    }
  },
  "scrapeConfiguration": {
    "configurationBlob": "base64-encoded-blob"
  }
}
```

AWS CLI

Use the `create-scraper` command to create a scraper with a CloudWatch destination. Replace the subnet, security group, and dataset information with your own values.

```
aws amp create-scraper \
  --alias "msk-metrics-scraper" \
  --source '{
    "vpcConfiguration": {
      "subnetIds": ["subnet-subnet-id-1", "subnet-subnet-id-2"],
      "securityGroupIds": ["sg-security-group-id"]
    }
  }' \
  --scrape-configuration configurationBlob=$(cat msk-config.yaml | base64 -w 0) \
  --destination '{
    "cloudWatchConfiguration": {
      "datasetArn": "arn:aws:cloudwatch:us-west-2:123456789012:dataset/default"
    }
  }'
```

Available metrics

- **JMX Exporter (port 11001)** — Kafka broker internals including topic metrics, partition metrics, request rates, consumer lag, and under-replicated partitions.
- **Node Exporter (port 11002)** — Host-level metrics including CPU, memory, disk I/O, and network throughput.

For a complete list of available metrics, see MSK metrics collected by managed collectors in the *Amazon Managed Service for Prometheus User Guide*.

Validate metrics collection

To confirm that the collector is delivering both JMX and Node Exporter metrics, run the following queries in CloudWatch with Query Studio. If each query returns data points, the collector is scraping the corresponding exporter successfully.

The following query returns a broker-level Kafka metric from the JMX Exporter (port 11001). It reports the mean rate of broker topic activity, such as messages and bytes flowing through the brokers. Data points confirm that the collector is scraping Kafka broker metrics.

```
kafka_server_BrokerTopicMetrics_MeanRate
```

The following query returns host-level CPU utilization from the Node Exporter (port 11002). It subtracts the average idle CPU rate over a five-minute window from 100 to give the percentage of CPU that the brokers are using. Data points confirm that the collector is scraping host-level metrics.

```
100 - (avg by (instance) (rate(node_cpu_seconds_total{mode="idle"}[5m])) * 100)
```

View the automatic dashboard

After the collector begins delivering your Amazon MSK metrics to CloudWatch, the CloudWatch console provides an automatic dashboard named **MSK OTel**. To open it, sign in to the AWS Management Console, open the CloudWatch console, choose **Dashboards** in the navigation pane, choose **Automatic dashboards**, and then choose **MSK OTel**. You can start monitoring your clusters without building any widgets or dashboards yourself.

If the automatic dashboard meets your needs, you can use it as is. To build a tailored monitoring experience, you can add any of its widgets to a custom dashboard. For more information about custom dashboards, see Using CloudWatch dashboards.

Cross-account observability

For cross-account Amazon MSK monitoring, we recommend using Amazon CloudWatch metric centralization. For more information, see CloudWatch metrics centralization.

For alternative cross-account scraper configurations using role chaining, see Cross-account Amazon MSK integration in the *Amazon Managed Service for Prometheus User Guide*.

Current limitations

- Managed collectors do not support Amazon MSK Serverless or Amazon MSK Express clusters.
- Managed collectors do not support public access combined with KRaft metadata mode.
- Each Amazon MSK cluster and CloudWatch dataset combination requires one collector.

Integrate Amazon EKS

An Amazon CloudWatch managed Prometheus collector scrapes metrics that are Prometheus-compatible. For more information about Prometheus-compatible metrics, see What are Prometheus-compatible metrics?. Amazon EKS clusters expose metrics for the API server. Amazon EKS clusters that are Kubernetes version 1.28 or above also expose metrics for the kube-scheduler and kube-controller-manager. For more information, see Fetch control plane raw metrics in Prometheus format in the *Amazon EKS User Guide*.

The *Amazon Managed Service for Prometheus User Guide* provides detailed setup instructions. For instructions on configuring Amazon EKS clusters, access entries, and ConfigMap setup, see Set up managed collectors for Amazon EKS.

> **Note**
>
> The collector enriches each Amazon EKS metric with attributes that identify its origin — the instrumentation scope, the AWS account and Region, an inferred unit, and the cluster name and cluster ARN. You can filter and group on these attributes when you query your metrics with PromQL.

Create a scraper with CloudWatch destination

You can use GetDefaultScraperConfiguration to retrieve a general-purpose scraper configuration, or provide your own.

AWS API

Use the `CreateScraper` API operation to create a scraper with a CloudWatch destination. Replace the AWS account, security group, subnet, Amazon EKS cluster, and dataset information with your own values.

```
POST /scrapers HTTP/1.1

{
  "alias": "eks-metrics-scraper",
  "source": {
    "eksConfiguration": {
      "clusterArn": "arn:aws:eks:us-west-2:123456789012:cluster/my-cluster",
```

```
      "securityGroupIds": ["sg-security-group-id"],
      "subnetIds": ["subnet-subnet-id-1", "subnet-subnet-id-2"]
    }
  },
  "destination": {
    "cloudWatchConfiguration": {
      "datasetArn": "arn:aws:cloudwatch:us-west-2:123456789012:dataset/default"
    }
  },
  "scrapeConfiguration": {
    "configurationBlob": "base64-encoded-blob"
  }
}
```

AWS CLI

Use the `create-scraper` command to create a scraper with a CloudWatch destination. Replace the AWS account, security group, subnet, Amazon EKS cluster, and dataset information with your own values.

```
aws amp create-scraper \
  --alias "eks-metrics-scraper" \
  --source eksConfiguration="{clusterArn='arn:aws:eks:us-
west-2:123456789012:cluster/my-cluster', \
    securityGroupIds=['sg-security-group-id'], \
    subnetIds=['subnet-subnet-id-1','subnet-subnet-id-2']}" \
  --scrape-configuration configurationBlob=$(cat eks-config.yaml | base64 -w 0) \
  --destination cloudWatchConfiguration="{datasetArn='arn:aws:cloudwatch:us-
west-2:123456789012:dataset/default'}"
```

View the automatic dashboard

After the collector begins delivering your Amazon EKS metrics to CloudWatch, the CloudWatch console provides an automatic dashboard named **EKS OTel**. To open it, sign in to the AWS Management Console, open the CloudWatch console, choose **Dashboards** in the navigation pane, choose **Automatic dashboards**, and then choose **EKS OTel**. You can start monitoring your clusters without building any widgets or dashboards yourself.

If the automatic dashboard meets your needs, you can use it as is. To build a tailored monitoring experience, you can add any of its widgets to a custom dashboard. For more information about custom dashboards, see Using CloudWatch dashboards.

Cross-account observability

For cross-account Amazon EKS monitoring, we recommend using Amazon CloudWatch metric centralization. For more information, see CloudWatch metrics centralization.

For alternative cross-account scraper configurations, see Cross-account scrapers in the *Amazon Managed Service for Prometheus User Guide*.

VPC-connected managed collector

The VPC-connected Amazon CloudWatch managed Prometheus collector scrapes Prometheus-compatible metrics from any resource reachable within your VPC — Amazon EC2 instances and Amazon ECS tasks. You provide subnets and a security group; the collector creates ENIs and scrapes Prometheus `/metrics` endpoints according to your configuration.

For detailed, workload-specific walkthroughs, see the CloudWatch observability solutions for Prometheus metric collection: Amazon CloudWatch solution: Prometheus metric collection on Amazon Amazon EC2 and Amazon CloudWatch solution: Prometheus metric collection on Amazon ECS.

Prerequisites

This procedure assumes familiarity with Amazon VPC subnets, security groups, and Prometheus exporter endpoints.

- Amazon VPC with DNS enabled
- At least two subnets in different Availability Zones
- Security group allowing the collector to reach your target exporter ports
- Targets that expose a Prometheus-compatible `/metrics` endpoint
- An interface VPC endpoint for CloudWatch if you deploy the collector in private subnets that have no internet access. The collector delivers metrics to CloudWatch through this endpoint. For more information, see Configure VPC endpoints for private subnets.

Configure VPC endpoints for private subnets

A managed collector delivers the metrics it scrapes to your CloudWatch dataset over the AWS network, without traversing the public internet. When you deploy the collector in private subnets

that have no route to the internet, you must create an interface VPC endpoint so that the collector can reach the CloudWatch API. Without this endpoint, the collector can scrape your targets but cannot deliver the metrics to CloudWatch.

Create an interface VPC endpoint for the CloudWatch service (`com.amazonaws.region.monitoring`) in the same VPC and subnets that you assign to the collector. Associate a security group that allows inbound HTTPS (port 443) from the collector's security group. For step-by-step instructions, see Using CloudWatch and interface VPC endpoints.

> **Note**
>
> If your subnets reach the internet through a NAT gateway, the collector can deliver metrics to CloudWatch without a VPC endpoint. However, we recommend an interface VPC endpoint so that traffic to CloudWatch stays within the AWS network.

Create a scraper

You can use GetDefaultScraperConfiguration to retrieve a general-purpose scraper configuration, or provide your own.

AWS API

Use the `CreateScraper` API operation to create a scraper with a CloudWatch destination. Replace the subnet, security group, and dataset information with your own values.

```
POST /scrapers HTTP/1.1

{
  "alias": "vpc-metrics-scraper",
  "source": {
    "vpcConfiguration": {
      "subnetIds": ["subnet-subnet-id-1", "subnet-subnet-id-2"],
      "securityGroupIds": ["sg-security-group-id"]
    }
  },
  "destination": {
    "cloudWatchConfiguration": {
      "datasetArn": "arn:aws:cloudwatch:us-west-2:123456789012:dataset/default"
    }
  },
```

```
  "scrapeConfiguration": {
    "configurationBlob": "base64-encoded-blob"
  }
}
```

AWS CLI

Use the `create-scraper` command to create a scraper with a CloudWatch destination. Replace the subnet, security group, and dataset information with your own values.

```
aws amp create-scraper \
  --alias "vpc-metrics-scraper" \
  --source '{
    "vpcConfiguration": {
      "subnetIds": ["subnet-subnet-id-1", "subnet-subnet-id-2"],
      "securityGroupIds": ["sg-security-group-id"]
    }
  }' \
  --scrape-configuration configurationBlob=$(cat scrape-config.yaml | base64 -w 0) \
  --destination '{
    "cloudWatchConfiguration": {
      "datasetArn": "arn:aws:cloudwatch:us-west-2:123456789012:dataset/default"
    }
  }'
```

Collecting metrics from Amazon EC2

To scrape metrics from Amazon EC2 instances running Prometheus exporters such as DCGM Exporter or Node Exporter, use `static_configs` with the instance private IP addresses:

```
global:
  scrape_interval: 60s

scrape_configs:
  - job_name: 'ec2-node-exporter'
    static_configs:
      - targets:
          - '10.0.1.10:9100'
          - '10.0.1.11:9100'
    relabel_configs:
      - source_labels: [__address__]
```

```
        target_label: instance
      - target_label: compute_platform
        replacement: 'ec2'

  - job_name: 'ec2-dcgm-exporter'
    static_configs:
      - targets:
          - '10.0.1.10:9400'
          - '10.0.1.11:9400'
    relabel_configs:
      - source_labels: [__address__]
        target_label: instance
      - target_label: compute_platform
        replacement: 'ec2'
```

Collecting metrics from Amazon ECS

For Amazon ECS tasks that you register with AWS Cloud Map, use DNS service discovery to automatically find and scrape your containers:

```
global:
  scrape_interval: 60s

scrape_configs:
  - job_name: 'ecs-services'
    dns_sd_configs:
      - names:
          - 'my-service.my-namespace.local'
        type: A
        port: 9090
    relabel_configs:
      - source_labels: [__meta_dns_name]
        target_label: service_name
      - source_labels: [__address__]
        target_label: instance
      - target_label: compute_platform
        replacement: 'ecs'
```

Cross-account observability

For cross-account VPC monitoring, we recommend using Amazon CloudWatch metric centralization. For more information, see CloudWatch metrics centralization.

For alternative cross-account scraper configurations, see Cross-account scrapers in the *Amazon Managed Service for Prometheus User Guide*.

Security best practices

- Deploy scrapers in private subnets without direct internet access.
- Use an interface VPC endpoint for CloudWatch connectivity so that metric delivery stays within the AWS network. For private subnets without internet access, this endpoint is required. For more information, see Configure VPC endpoints for private subnets.
- Restrict security group ingress to the scraper security group on specific exporter ports only.
- Enable TLS encryption in transit for all exporter endpoints where possible.

Scraper configuration

Amazon CloudWatch managed Prometheus collectors use a Prometheus-compatible YAML configuration to define how the collector scrapes metrics. You provide this configuration as a base64-encoded blob when creating or updating a scraper. The configuration uses standard Prometheus scrape configuration format, with some limitations specific to managed collectors.

You can use GetDefaultScraperConfiguration to retrieve a general-purpose scraper configuration, or provide your own.

Supported configuration sections

The following top-level sections of the Prometheus scrape configuration are supported:

- `global` — Global settings including `scrape_interval`, `scrape_timeout`, and `external_labels`.
- `scrape_configs` — A list of scrape jobs, each defining targets and how to scrape them.

Within each `scrape_configs` entry, the following fields are supported:

- `job_name` — A unique name for the scrape job.
- `metrics_path` — The HTTP path to scrape (defaults to `/metrics`).
- `scheme` — The protocol scheme (`http` or `https`).
- `scrape_interval` — Per-job override of the global scrape interval.

- `scrape_timeout` — Per-job override of the global scrape timeout.
- `static_configs` — Static list of targets.
- `dns_sd_configs` — DNS-based service discovery.
- `relabel_configs` — Relabeling rules applied before scraping.
- `metric_relabel_configs` — Relabeling rules applied after scraping.
- `tls_config` — TLS configuration for HTTPS targets.

Example configuration

The following example demonstrates a basic scrape configuration:

```
global:
  scrape_interval: 60s
  scrape_timeout: 10s
  external_labels:
    environment: production

scrape_configs:
  - job_name: 'my-service'
    metrics_path: /metrics
    scheme: http
    static_configs:
      - targets:
          - '10.0.1.10:9090'
          - '10.0.1.11:9090'
        labels:
          team: platform
    relabel_configs:
      - source_labels: [__address__]
        target_label: instance
    metric_relabel_configs:
      - source_labels: [__name__]
        regex: 'go_.*'
        action: drop
```

Limitations

- The minimum `scrape_interval` is 30 seconds.
- Managed collectors do not support file-based service discovery (`file_sd_configs`).

- Managed collectors do not support Consul, Eureka, or other external service discovery mechanisms.
- Remote write and remote read configurations do not apply, because the collector handles delivery to CloudWatch.
- The maximum configuration size is 256 KB.

Troubleshooting

If your scraper is not collecting metrics as expected, check the following:

- Verify that the security group attached to the scraper allows outbound traffic to your target ports.
- Confirm that your targets are reachable from the subnets that you specified in the scraper configuration.
- Check that DNS names used in `dns_sd_configs` resolve correctly within the VPC.
- Ensure your targets respond on the configured `metrics_path` with valid Prometheus exposition format.

For additional troubleshooting guidance, see Troubleshooting managed collectors in the *Amazon Managed Service for Prometheus User Guide*.

Monitor collectors

Amazon CloudWatch managed Prometheus collectors automatically vend logs to CloudWatch Logs so you can monitor scraper health, diagnose connectivity issues, and track scraping activity. These logs include information about target discovery, scrape successes and failures, and configuration errors. For more information about collector logging, see Logging for managed collectors in the *Amazon Managed Service for Prometheus User Guide*.

List scrapers

Use the following command to list all scrapers in your account and Region:

```
aws amp list-scrapers
```

To filter scrapers by alias:

```
aws amp list-scrapers --filters alias=my-scraper-alias
```

Describe a scraper

To view the details and current status of a specific scraper:

```
aws amp describe-scraper --scraper-id scraper-id
```

Delete a scraper

To delete a scraper that is no longer needed:

```
aws amp delete-scraper --scraper-id scraper-id
```

> **Note**
>
> Deleting a scraper removes the ENIs that the collector created in your VPC. Allow a few minutes for the deletion to complete and for CloudWatch to clean up all associated resources.

AWS usage metrics

CloudWatch collects metrics that track the usage of some AWS resources and APIs. These metrics are published in the `AWS/Usage` namespace. Usage metrics in CloudWatch allow you to proactively manage usage by visualizing metrics in the CloudWatch console, creating custom dashboards, detecting changes in activity with CloudWatch anomaly detection, and configuring alarms that alert you when usage approaches a threshold.

Some AWS services integrate these usage metrics with Service Quotas. For these services, you can use CloudWatch to manage your account's use of your service quotas. For more information, see Visualizing your service quotas and setting alarms.

Topics

- Visualizing your service quotas and setting alarms
- AWS API usage metrics
- CloudWatch usage metrics

Visualizing your service quotas and setting alarms

For some AWS services, you can use the usage metrics to visualize your current service usage on CloudWatch graphs and dashboards. You can use a CloudWatch metric math function to display the service quotas for those resources on your graphs. You can also configure alarms that alert you when your usage approaches a service quota. For more information about service quotas, see What Is Service Quotas in the *Service Quotas User Guide*.

If you are signed in to an account that is set up as a monitoring account in CloudWatch cross-account observability, you can use that monitoring account to visualize service quotas and set alarms for metrics in the source accounts that are linked to that monitoring account. For more information, see CloudWatch cross-account observability.

The following services integrate their usage metrics with Service Quotas:

- AWS CloudHSM
- Amazon Chime SDK
- Amazon CloudWatch

- Amazon CloudWatch Logs
- Amazon DynamoDB
- Amazon EC2
- Amazon Elastic Container Registry
- Elastic Load Balancing
- AWS Fargate
- AWS Fault Injection Service
- AWS Interactive Video Service
- AWS Key Management Service
- Amazon Data Firehose
- Amazon Location Service
- Amazon Managed Blockchain (AMB) Query
- Amazon SageMaker AI
- Multi-party approval

To visualize a service quota and optionally set an alarm

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. On the **Browse** tab, choose **Usage**, and then choose **By AWS Resource**.

   The list of service quota usage metrics appears.
4. Select the check box next to one of the metrics.

   The graph displays your current usage of that AWS resource.
5. To add your service quota to the graph, do the following:

   a. Choose the **Graphed metrics** tab.

   b. Choose **Math expression**, **Start with an empty expression**. In the new row, under **Details**, enter **`SERVICE_QUOTA(m1)`**.

      A new line is added to the graph, displaying the service quota for the resource represented in the metric.

6. To see your current usage as a percentage of the quota, add a new expression or change the current **SERVICE_QUOTA** expression. The new expression to use is **`m1/SERVICE_QUOTA(m1)*100`**.
7. (Optional) To set an alarm that notifies you if you approach the service quota, do the following:

   a. On the row with **`m1/SERVICE_QUOTA(m1)*100`**, under **Actions**, choose the alarm icon. It looks like a bell.

      The alarm creation page appears.

   b. Under **Conditions**, ensure that **Threshold type** is **Static** and **Whenever Expression1 is** is set to **Greater**. Under **than**, enter **`80`**. This creates an alarm that goes into ALARM state when your usage exceeds 80 percent of the quota.

   c. Choose **Next**.

   d. On the next page, select an Amazon SNS topic or create a new one, and then choose **Next**. The topic you select is notified when the alarm goes to ALARM state.

   e. On the next page, enter a name and description for the alarm, and then choose **Next**.

   f. Choose **Create alarm**.

AWS API usage metrics

Most APIs that support AWS CloudTrail logging also report usage metrics to CloudWatch. API usage metrics in CloudWatch allow you to proactively manage API usage by visualizing metrics in the CloudWatch console, creating custom dashboards, detecting changes in activity with CloudWatch anomaly detection, and configuring alarms that alert when usage approaches a threshold.

You can use the he following table to learn about services that report API usage metrics to CloudWatch. The table lists the values to use for the `Service` dimension, so you can see the usage metrics from that service. You can use the procedure in this section to view the list of a service's APIs that report usage metrics to CloudWatch.

Service	Value for the `Service` dimension
AWS Identity and Access Management Access Analyzer	`Access Analyzer`

Service	Value for the Service dimension
AWS Account Management	Account Management
Alexa for Business	A4B
Amazon API Gateway	API Gateway
AWS App Mesh	App Mesh
AWS AppConfig	AWS AppConfig
Amazon AppFlow	AppFlow
Application Auto Scaling	Application Auto Scaling
Application Discovery Service	Application Discovery Service
Amazon AppStream	AppStream
WorkSpaces Applications Image Builder	Image Builder
Amazon Athena	Athena
AWS Audit Manager	Audit Manager
AWS Backup	Backup
AWS Batch	Batch
Amazon Braket	Braket
AWS Budgets	Budgets
AWS Certificate Manager	Certificate Manager
Amazon Chime SDK	ChimeSDK
Amazon Cloud Directory	Cloud Directory
AWS Cloud Map	Cloud Map

Service	Value for the `Service` dimension
AWS CloudFormation	`CloudFormation`
AWS CloudHSM	`CloudHSM`
Amazon CloudSearch	`CloudSearch`
AWS CloudShell	`CloudShell`
AWS CloudTrail	`CloudTrail`
Amazon CloudWatch	`CloudWatch`
Amazon CloudWatch Application Signals	`CloudWatch Application Signals`
Amazon CloudWatch Logs	`Logs`
Amazon CloudWatch Application Insights	`CloudWatch Application Insights`
AWS CodeBuild	`CodeBuild`
AWS CodeCommit	`CodeCommit`
Amazon CodeGuru Profiler	`CodeGuru Profiler`
AWS CodePipeline	`CodePipeline`
AWS CodeStar	`CodeStar`
AWS CodeStar Notifications	`CodeStar Notifications`
AWS CodeStar Connections	`CodeStar Connections`
Amazon Cognito Identity pools	`Cognito Identity Pools`
Amazon Cognito Sync	`Cognito Sync`
Amazon Comprehend	`Comprehend`
Amazon Comprehend Medical	`Comprehend Medical`

Service	Value for the Service dimension
AWS Compute Optimizer	ComputeOptimzier
Amazon Connect Customer	Connect
Amazon Connect Customer Customer Profiles	Customer Profiles
AWS Cost and Usage Reports	Cost and Usage Report
AWS Cost Explorer	Cost Explorer
AWS Data Exchange	Data Exchange
AWS Data Lifecycle Manager	Data Lifecycle Manager
AWS Database Migration Service	Database Migration Service
AWS DataSync	DataSync
AWS DeepLens	AWS DeepLens
Amazon Detective	Detective
Device Advisor	Device Advisor
Direct Connect	Direct Connect
AWS Directory Service	Directory Service
DynamoDB Accelerator	DynamoDBAccelerator
Amazon EC2	EC2
EC2 Auto Scaling	EC2 Auto Scaling
Amazon Elastic Container Registry	ECR Public
Amazon Elastic Container Service	ECS
Amazon Elastic File System	EFS

Service	Value for the `Service` dimension
Amazon Elastic Kubernetes Service	`EKS`
AWS Elastic Beanstalk	`Elastic Beanstalk`
Amazon Elastic Inference	`Elastic Inference`
Elastic Load Balancing	`Elastic Load Balancing`
Amazon EMR	`EMR Containers`
AWS Firewall Manager	`Firewall Manager`
Amazon FSx	`FSx`
Amazon GameLift Servers	`GameLift`
AWS Glue DataBrew	`DataBrew`
Amazon Managed Grafana	`Grafana`
AWS IoT Greengrass	`Greengrass`
AWS Ground Station	`Ground Station`
AWS Health APIs And Notifications	`AWS Health APIs And Notifications`
Amazon Interactive Video Service	`IVS`
AWS IoT Core	`IoT`
AWS IoT Events	`IoT Events`
AWS IoT RoboRunner	`IoT RoboRunner`
AWS IoT SiteWise	`IoT Sitewise`
AWS IoT Wireless	`IoT Wireless`
Amazon Kendra	`Kendra`

Service	Value for the Service dimension
Amazon Keyspaces (for Apache Cassandra)	Keyspaces
Amazon Managed Service for Apache Flink	Kinesis Analytics
Amazon Data Firehose	Firehose
Kinesis Video Streams	Kinesis Video Streams
AWS Key Management Service	KMS
AWS Lambda	Lambda
AWS Launch Wizard	Launch Wizard
Amazon Lex	Amazon Lex
Amazon Lightsail	Lightsail
Amazon Location Service	Location
Amazon Lookout for Vision	Lookout for Vision
Amazon Machine Learning	Amazon Machine Learning
Amazon Macie	Macie
Amazon Managed Blockchain (AMB) Query	Amazon Managed Blockchain Query
AWS Managed Services	AWS Managed Services
AWS Marketplace Commerce Analytics	Marketplace Analytics Service
AWS Elemental MediaConnect	MediaConnect
AWS Elemental MediaConvert	MediaConvert
AWS Elemental MediaLive	MediaLive
AWS Elemental MediaStore	Mediastore

Service	Value for the Service dimension
AWS Elemental MediaTailor	MediaTailor
AWS Mobile Hub	Mobile Hub
AWS Network Firewall	Network Firewall
OpsWorks	OpsWorks
OpsWorks for Configuration Management	OPsWorks CM
AWS Outposts	Outposts
AWS Organizations	Organizations
Amazon RDS Performance Insights	Performance Insights
Amazon Pinpoint	Pinpoint
AWS Private Certificate Authority	Private Certificate Authority
Amazon Managed Service for Prometheus	Prometheus
AWS Proton	Proton
Amazon Quantum Ledger Database (Amazon QLDB)	QLDB

AWS X-Ray	X-Ray

Some services report usage metrics for additional APIs as well. To see whether an API reports usage metrics to CloudWatch, use the CloudWatch console to see the metrics reported by that service in the AWS/Usage namespace.

To see the list of a service's APIs that report usage metrics to CloudWatch

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. On the **Browse** tab, choose **Usage**, and then choose **By AWS Resource**.
4. In the search box near the list of metrics, enter the name of the service. The metrics are filtered by the service you entered.

CloudWatch usage metrics

CloudWatch collects metrics that track the usage of some AWS resources. These metrics correspond to AWS service quotas. Tracking these metrics can help you proactively manage your quotas. For more information, see Visualizing your service quotas and setting alarms. Service quota usage metrics are in the `AWS/Usage` namespace and are collected every minute.

The metrics that can be published in this namespace include `CallCount`, `ResourceCount`, and `ThrottleCount`. These metrics are published with the dimensions `Resource`, `Service`, and `Type`. The `Resource` dimension specifies the name of the API operation being tracked. For example, the `CallCount` metric with the dimensions `"Service": "CloudWatch"`, `"Type": "API"` and `"Resource": "PutMetricData"` indicates the number of times the CloudWatch `PutMetricData` API operation has been called in your account.

The `CallCount` metric does not have a specified unit. The most useful statistic for the metric is `SUM`, which represents the total operation count for the 1-minute period.

Metrics

Metric	Description
`CallCount`	The number of specified operations performed in your account.

Dimensions

Dimension	Description
`Service`	The name of the AWS service containing the resource. For CloudWatch usage metrics, the value for this dimension is `CloudWatch` .
`Class`	The class of resource being tracked. CloudWatch API usage metrics use this dimension with a value of `None`.
`Type`	The type of resource being tracked. When the `Service` dimension is `CloudWatch` , the only valid value for `Type` is `API`.
`Resource`	The name of the API operation. Valid values include the following:

Dimension	Description
	DeleteAlarms ,DeleteDashboards ,DescribeAlarmHistory ,DescribeAlarms ,GetDashboard ,GetMetricData , GetMetricStatistics ,ListMetrics ,PutDashboard ,and PutMetricData

Amazon CloudWatch tutorials

The following scenarios illustrate how you can use Amazon CloudWatch. In the first scenario, you use the CloudWatch console to create a billing alarm that tracks your AWS usage and lets you know when you have exceeded a certain spending threshold. In the second scenario, you use the AWS Command Line Interface (AWS CLI) to publish a single metric for a hypothetical application named *GetStarted*.

Scenarios

- Monitor your estimated charges
- Publish metrics

Scenario: Monitor your estimated charges using CloudWatch

In this scenario, you create an Amazon CloudWatch alarm to monitor your estimated charges. When you enable the monitoring of estimated charges for your AWS account, the estimated charges are calculated and sent several times daily to CloudWatch as metric data.

Billing metric data is stored in the US East (N. Virginia) Region and reflects worldwide charges. This data includes the estimated charges for every service in AWS that you use, as well as the estimated overall total of your AWS charges.

You can choose to receive alerts by email when charges have exceeded a certain threshold. These alerts are triggered by CloudWatch and messages are sent using Amazon Simple Notification Service (Amazon SNS).

> **Note**
>
> For information about analyzing CloudWatch charges that you have already been billed for, see Analyzing, optimizing, and reducing CloudWatch costs.

Tasks

- Step 1: Enable billing alerts
- Step 2: Create a billing alarm

- Step 3: Check the alarm status
- Step 4: Edit a billing alarm
- Step 5: Delete a billing alarm

Step 1: Enable billing alerts

Before you can create an alarm for your estimated charges, you must enable billing alerts, so that you can monitor your estimated AWS charges and create an alarm using billing metric data. After you enable billing alerts, you cannot disable data collection, but you can delete any billing alarms that you created.

After you enable billing alerts for the first time, it takes about 15 minutes before you can view billing data and set billing alarms.

Requirements

- You must be signed in using root user credentials or as a user who has been given permission to view billing information.
- For consolidated billing accounts, billing data for each linked account can be found by logging in as the paying account. You can view billing data for total estimated charges and estimated charges by service for each linked account, in addition to the consolidated account.
- In a consolidated billing account, member linked account metrics are captured only if the payer account enables the **Receive Billing Alerts** preference. If you change which account is your management/payer account, you must enable the billing alerts in the new management/payer account.
- The account must not be part of the Amazon Partner Network (APN) because billing metrics are not published to CloudWatch for APN accounts. For more information, see AWS Partner Network.

To enable the monitoring of estimated charges

1. Open the AWS Billing and Cost Management console at https://console.aws.amazon.com/costmanagement/.
2. In the navigation pane, choose **Billing Preferences**.
3. By **Alert preferences** choose **Edit**.
4. Choose **Receive CloudWatch Billing Alerts**.
5. Choose **Save preferences**.

Step 2: Create a billing alarm

> **Important**
>
> Before you create a billing alarm, you must set your Region to US East (N. Virginia). Billing metric data is stored in this Region and represents worldwide charges. You also must enable billing alerts for your account or in the management/payer account (if you are using consolidated billing). For more information, see Step 1: Enable billing alerts.

In this procedure, you create an alarm that sends a notification when your estimated charges for AWS exceed a defined threshold.

To create a billing alarm using the CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, and then choose **All alarms**.
3. Choose **Create alarm**.
4. Choose **Select metric**. In the **Browse** tab, choose **Billing**, and then choose **Total Estimated Charge**.

   > **Note**
   >
   > If you don't see the **Billing/Total Estimated Charge** metric, enable billing alerts, and change your Region to US East (N. Virginia). For more information, see Enabling billing alerts.

5. Select the checkbox for the **EstimatedCharges** metric, and then choose **Select metric**.
6. For **Statistic**, choose **Maximum**.
7. For **Period**, choose **6 hours**.
8. For **Threshold type**, choose **Static**.
9. For **Whenever EstimatedCharges is . . .**, choose **Greater**.
10. For **than . . .**, define the value that you want to cause your alarm to trigger. For example, **200** USD.

    The **EstimatedCharges** metric values are only in US dollars (USD), and the currency conversion is provided by Amazon Services LLC. For more information, see What is AWS Billing?.

11. Choose **Additional Configuration** and do the following:

    - For **Datapoints to alarm**, specify **1 out of 1**.
    - For **Missing data treatment**, choose **Treat missing data as missing**.

12. Choose **Next**.
13. Under **Notification**, ensure that **In alarm** is selected. Then specify an Amazon SNS topic to be notified when your alarm is in the ALARM state. The Amazon SNS topic can include your email address so that you recieve email when the billing amount crosses the threshold that you specified.

    You can select an existing Amazon SNS topic, create a new Amazon SNS topic, or use a topic ARN to notify other account. If you want your alarm to send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

14. Choose **Next**.
15. Under **Name and description**, enter a name for your alarm.

    - (Optional) Enter a description of your alarm.

16. Choose **Next**.
17. Under **Preview and create**, make sure that your configuration is correct, and then choose **Create alarm**.

Step 3: Check the alarm status

Now, check the status of the billing alarm that you just created.

To check the alarm status

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. If necessary, change the Region to US East (N. Virginia). Billing metric data is stored in this Region and reflects worldwide charges.
3. In the navigation pane, choose **Alarms**, **All alarms**.
4. Find the row in the table for your new alarm. Until the subscription is confirmed, it is shown as "Pending confirmation". After the subscription is confirmed, refresh the console to show the updated status.

Step 4: Edit a billing alarm

For example, you may want to increase the amount of money you spend with AWS each month from $200 to $400. You can edit your existing billing alarm and increase the monetary amount that must be exceeded before the alarm is triggered.

To edit a billing alarm

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. If necessary, change the Region to US East (N. Virginia). Billing metric data is stored in this Region and reflects worldwide charges.
3. In the navigation pane, choose **Alarms**, **All alarms**.
4. Select the checkbox next to the alarm and choose **Actions**, **Edit**.
5. For **than...**, specify the new amount that must be exceeded to trigger the alarm and send an email notification.
6. Choose **Save Changes**.

Step 5: Delete a billing alarm

If you no longer need your billing alarm, you can delete it.

To delete a billing alarm

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. If necessary, change the Region to US East (N. Virginia). Billing metric data is stored in this Region and reflects worldwide charges.
3. In the navigation pane, choose **Alarms**, **All alarms**.
4. Select the checkbox next to the alarm and choose **Actions**, **Delete**.
5. When prompted for confirmation, choose **Yes, Delete**.

Scenario: Publish metrics to CloudWatch

In this scenario, you use the AWS Command Line Interface (AWS CLI) to publish a single metric for a hypothetical application named *GetStarted*. If you haven't already installed and configured the AWS CLI, see Getting Set Up with the AWS Command Line Interface in the *AWS Command Line Interface User Guide*.

Tasks

- Step 1: Define the data configuration
- Step 2: Add metrics to CloudWatch
- Step 3: Get statistics from CloudWatch
- Step 4: View graphs with the console

Step 1: Define the data configuration

In this scenario, you publish data points that track the request latency for the application. Choose names for your metric and namespace that make sense to you. For this example, name the metric *RequestLatency* and place all of the data points into the *GetStarted* namespace.

You publish several data points that collectively represent three hours of latency data. The raw data comprises 15 request latency readings distributed over three hours. Each reading is in milliseconds:

- Hour one: 87, 51, 125, 235
- Hour two: 121, 113, 189, 65, 89
- Hour three: 100, 47, 133, 98, 100, 328

You can publish data to CloudWatch as single data points or as an aggregated set of data points called a *statistic set*. You can aggregate metrics to a granularity as low as one minute. You can publish the aggregated data points to CloudWatch as a set of statistics with four predefined keys: `Sum`, `Minimum`, `Maximum`, and `SampleCount`.

You publish the data points from hour one as single data points. For the data from hours two and three, you aggregate the data points and publish a statistic set for each hour. The key values are shown in the following table.

Hour	Raw data	Sum	Minimum	Maximum	SampleCount
1	87				
1	51				

Hour	Raw data	Sum	Minimum	Maximum	SampleCount
1	125				
1	235				
2	121, 113, 189, 65, 89	577	65	189	5
3	100, 47, 133, 98, 100, 328	806	47	328	6

Step 2: Add metrics to CloudWatch

After you have defined your data configuration, you are ready to add data.

To publish data points to CloudWatch

1. At a command prompt, run the following put-metric-data commands to add data for the first hour. Replace the example timestamp with a timestamp that is two hours in the past, in Universal Coordinated Time (UTC).

```
aws cloudwatch put-metric-data --metric-name RequestLatency --namespace GetStarted
 \
--timestamp 2016-10-14T20:30:00Z --value 87 --unit Milliseconds
aws cloudwatch put-metric-data --metric-name RequestLatency --namespace GetStarted
 \
--timestamp 2016-10-14T20:30:00Z --value 51 --unit Milliseconds
aws cloudwatch put-metric-data --metric-name RequestLatency --namespace GetStarted
 \
--timestamp 2016-10-14T20:30:00Z --value 125 --unit Milliseconds
aws cloudwatch put-metric-data --metric-name RequestLatency --namespace GetStarted
 \
--timestamp 2016-10-14T20:30:00Z --value 235 --unit Milliseconds
```

2. Add data for the second hour, using a timestamp that is one hour later than the first hour.

```
aws cloudwatch put-metric-data --metric-name RequestLatency --namespace GetStarted
 \
```

```
--timestamp 2016-10-14T21:30:00Z --statistic-values
 Sum=577,Minimum=65,Maximum=189,SampleCount=5 --unit Milliseconds
```

3. Add data for the third hour, omitting the timestamp to default to the current time.

```
aws cloudwatch put-metric-data --metric-name RequestLatency --namespace GetStarted
 \
--statistic-values Sum=806,Minimum=47,Maximum=328,SampleCount=6 --unit Milliseconds
```

Step 3: Get statistics from CloudWatch

Now that you have published metrics to CloudWatch, you can retrieve statistics based on those metrics using the get-metric-statistics command as follows. Be sure to specify `--start-time` and `--end-time` far enough in the past to cover the earliest timestamp that you published.

```
aws cloudwatch get-metric-statistics --namespace GetStarted --metric-name
 RequestLatency --statistics Average \
--start-time 2016-10-14T00:00:00Z --end-time 2016-10-15T00:00:00Z --period 60
```

The following is example output:

```
{
 "Datapoints": [],
 "Label": "Request:Latency"
}
```

Step 4: View graphs with the console

After you have published metrics to CloudWatch, you can use the CloudWatch console to view statistical graphs.

To view graphs of your statistics on the console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the **Navigation** pane, choose **Metrics**.
3. On the **Browse** tab, in the search box, type **RequestLatency** and press Enter.
4. Select the check box for the **RequestLatency** metric. A graph of the metric data is displayed in the upper pane.

For more information, see Graphing metrics.

SDK and API reference

This section provides reference material for developers who interact with CloudWatch programmatically. Use AWS SDKs to integrate CloudWatch into your applications, review code examples for common operations, and learn about the protocols and security model that CloudWatch supports.

Topics

- FAQs on CloudWatch supported protocols
- Using CloudWatch with an AWS SDK
- Security in Amazon CloudWatch

FAQs on CloudWatch supported protocols

CloudWatch SDKs started using two additional protocols: AWS JSON 1.0 and Smithy RPC v2 CBOR. These protocols are more performant than AWS Query that was previously utilized by the CloudWatch SDKs and CLIs. AWS SDKs will prioritize the protocol that is the most performant for each language.

What is the AWS JSON protocol, and how does it differ from existing CloudWatch API requests and responses?

JSON is one of the most widely used and accepted data formats for communication between heterogeneous systems. CloudWatch uses JSON as a medium to communicate between an AWS SDK client (for example, Java, Python, Golang, JavaScript) and CloudWatch server. An HTTP request of an CloudWatch API operation accepts input in the form of JSON. The CloudWatch operation is executed and the response of execution is shared back to the SDK client in the form of JSON. Compared to AWS Query, JSON is more efficient at transporting data between client and server.

- CloudWatch AWS JSON protocol acts as a mediator between CloudWatch client and server.
- The CloudWatch AWS SDK handles the serialization (convert object to JSON format) and de-serialization (convert JSON format to object) between the CloudWatch client and server.

What is the Smithy RPC v2 CBOR protocol, and how does it differ from existing CloudWatch API requests and responses?

Smithy RPC v2 CBOR (Concise Binary Object Representation) is a protocol developed by Amazon for more efficient data transmission. It's a data format designed to keep message sizes compact, and allow the format to evolve without requiring version negotiation between systems. The key difference from JSON encoding is that JSON uses human-readable text (like "name": "John"), while CBOR uses a binary format (sequences of 1s and 0s). This binary approach creates smaller data packages that travel faster over the network and reduces serialization time since computers process binary data directly.

- CloudWatch RPC v2 CBOR protocol acts as a mediator between CloudWatch client and server.
- The CloudWatch SDK handles the serialization (convert object to CBOR format) and deserialization (convert CBOR format to object) between the CloudWatch client and server.

How do I get started with the newer protocols for CloudWatch?

To get started, use the latest AWS SDK/CLI version to use the latest supported protocol for CloudWatch. Upgrade your AWS SDK to the specified version or any subsequent version.

SDK Client Protocol Support

Language	Protocol	SDK versions
C++	RPC v2 CBOR	1.11.708
Golang 2.x	RPC v2 CBOR	1.53.0
Java 1.x	RPC v2 CBOR	1.12.795
Java 2.x	RPC v2 CBOR	2.40.6
JavaScript v3.x	AWS JSON 1.0	3.949.0
.NET v3	AWS JSON 1.0	3.7.1182.0
.NET v4	RPC v2 CBOR	4.0.150.0
PHP	AWS JSON 1.0	3.367.0

Language	Protocol	SDK versions
Python-boto3	AWS JSON 1.0	1.42.7
Python-botocore	AWS JSON 1.0	1.42.7
AWS CLI v1	AWS JSON 1.0	1.43.13
AWS CLI v2	AWS JSON 1.0	2.32.14
Ruby	AWS JSON 1.0	1.126.0
Powershell	AWS JSON 1.0	5.0.114
Rust	RPC v2 CBOR	1.100.0
Swift	RPC v2 CBOR	1.6.14
Kotlin	RPC v2 CBOR	1.5.100

What are the risks of enabling these new protocols for my CloudWatch workloads?

The migration into these new SDK versions is expected to be fully transparent and effortless for customers. There is one known behavioral change in between protocols related with how `null` values are treated within lists: CloudWatch API calls with list inputs that may contain `null` values will be handled differently in the AWS JSON and Smithy RPC v2 CBOR protocols as compared to the previous AWS Query protocol: In AWS Query protocol, null values within lists are removed, while in JSON/CBOR protocols will be propagated through the API calls.

Additionally, if you are using a custom implementation of AWS SDK or a combination of custom clients and AWS SDK to interact with CloudWatch that generates AWS Query based (aka XML-based) responses, it may be incompatible with AWS JSON or CBOR protocol. If you encounter any issues, contact AWS Support.

What if I am already on the latest AWS SDK version, but my open sourced solution does not support JSON or CBOR?

You must change your SDK version to a previous version. See the How do I get started with the newer protocols for CloudWatch? section and select a version lower than listed. If you change your AWS SDK to the previous version, your CloudWatch APIs will use the AWS Query protocol.

What regions are supported for AWS JSON and CBOR protocols used in CloudWatch APIs

CloudWatch supports AWS JSON and CBOR protocol in all AWS regions where CloudWatch is available.

What latency improvements can I expect when upgrading to the specified AWS SDK versions for CloudWatch using the newer protocols?

Both JSON and CBOR provide up to 80% lower latency and CPU usage when compared to the AWS Query. Both protocols are up to 20% more efficient in network bandwidth usage.

Will the AWS Query protocol be deprecated?

AWS Query protocol will continue to be supported. You can continue using the AWS Query protocol as long as your AWS SDK version is set any version before what is listed in How do I get started with the newer protocols for CloudWatch?.

Where can I find more information about AWS JSON and Smithy RPC v2 CBOR protocols?

You can find more information about JSON protocol at AWS JSON 1.0 protocol in the Smithy documentation, and about CBOR at AWS RPC v2 CBOR protocol in the Smithy documentation.

For more about CloudWatch API requests, see Making API Requests in the CloudWatch API Reference Guide.

Using CloudWatch with an AWS SDK

AWS software development kits (SDKs) are available for many popular programming languages. Each SDK provides an API, code examples, and documentation that make it easier for developers to build applications in their preferred language.

SDK documentation	Code examples
AWS SDK for C++	AWS SDK for C++ code examples
AWS CLI	AWS CLI code examples
AWS SDK for Go	AWS SDK for Go code examples
AWS SDK for Java	AWS SDK for Java code examples
AWS SDK for JavaScript	AWS SDK for JavaScript code examples
AWS SDK for Kotlin	AWS SDK for Kotlin code examples
AWS SDK for .NET	AWS SDK for .NET code examples
AWS SDK for PHP	AWS SDK for PHP code examples
AWS Tools for PowerShell	AWS Tools for PowerShell code examples
AWS SDK for Python (Boto3)	AWS SDK for Python (Boto3) code examples
AWS SDK for Ruby	AWS SDK for Ruby code examples
AWS SDK for Rust	AWS SDK for Rust code examples
AWS SDK for SAP ABAP	AWS SDK for SAP ABAP code examples
AWS SDK for Swift	AWS SDK for Swift code examples

For examples specific to CloudWatch, see Code examples for CloudWatch using AWS SDKs.

Example availability

Security in Amazon CloudWatch

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS Compliance Programs. To learn about the compliance programs that apply to CloudWatch, see AWS Services in Scope by Compliance Program.
- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your company's requirements, and applicable laws and regulations

This documentation helps you understand how to apply the shared responsibility model when using Amazon CloudWatch. It shows you how to configure Amazon CloudWatch to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your CloudWatch resources.

Contents

- Data protection in Amazon CloudWatch
- Encryption at rest for OpenTelemetry metrics
- Identity and access management for Amazon CloudWatch
- Compliance validation for Amazon CloudWatch

- Security considerations for Synthetics canaries

Data protection in Amazon CloudWatch

The AWS shared responsibility model applies to data protection in Amazon CloudWatch. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see Data Privacy FAQ. For information about data protection in Europe, see the General Data Protection Regulation (GDPR) Center.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual users with AWS IAM Identity Center or AWS Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with AWS CloudTrail. For information about using CloudTrail trails to capture AWS activities, see Working with CloudTrail trails in the *AWS CloudTrail User Guide*.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-3 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-3.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a **Name** field. This includes when you work with CloudWatch or other AWS services using the console, API, AWS CLI, or AWS

SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Encryption at rest

CloudWatch always encrypts data at rest. By default, CloudWatch uses AWS owned keys to encrypt your data. You don't need to take any action to use AWS owned keys.

For CloudWatch Dataset resources, you can optionally use a customer managed key in AWS Key Management Service to encrypt your data. For more information, see Encryption at rest for OpenTelemetry metrics.

Encryption in transit

CloudWatch uses end-to-end encryption of data in transit. For more information, see Encryption of data in transit.

Encryption at rest for OpenTelemetry metrics

What is a CloudWatch Dataset

OpenTelemetry (OTel) metrics that you send to Amazon CloudWatch are stored in a resource called a Dataset. Every AWS account has a `default` dataset in each Region where all OTel metrics reside. The `default` dataset is the only supported dataset — you cannot create additional datasets.

Datasets can be encrypted and tagged like other AWS resources. The dataset ARN has the following format:

`arn:`*`{partition}`*`:cloudwatch:`*`{region}`*`:`*`{account-id}`*`:dataset/default`

To view the current encryption configuration of your dataset, use the `GetDataset` API:

```
aws cloudwatch get-dataset \
    --dataset-identifier default
```

If a customer managed key is associated with the dataset, the response includes the key ARN. If no customer managed key is associated, the dataset is encrypted with an AWS owned key.

Options for encryption at rest

CloudWatch always encrypts Dataset data at rest. By default, CloudWatch encrypts all data at rest using AWS owned keys. You don't need to take any action to protect your data using AWS owned keys. For more information, see AWS owned keys in the AWS Key Management Service Developer Guide.

If you want to manage the keys that are used to encrypt your Dataset data, you can use a customer managed key in AWS Key Management Service (AWS KMS). For more information, see Customer managed keys in the AWS Key Management Service Developer Guide.

When you use a customer managed key, AWS KMS charges apply. For more information about pricing, see AWS Key Management Service pricing.

How CloudWatch uses a customer managed key for Dataset encryption

> **Important**
>
> Customer managed key encryption applies to the `default` dataset. The `default` dataset is the only supported dataset — you cannot create additional datasets.

When you associate a customer managed key with the `default` dataset, CloudWatch uses the key to encrypt all OTel metric data stored in that dataset.

CloudWatch uses the service principal (`cloudwatch.amazonaws.com`) directly with key policy permissions. CloudWatch does not use grants or IAM roles to access your AWS KMS key.

CloudWatch does not cache data keys. However, CloudWatch caches `kms:Decrypt` responses for up to 15 minutes. Changes to a key policy might take up to 15 minutes to take effect.

CloudWatch uses the following encryption context for all AWS KMS cryptographic operations:

- Key: `aws:cloudwatch:arn`
- Value: `arn:`*`{partition}`*`:cloudwatch:`*`{region}`*`:`*`{account-id}`*`:dataset/default`

Configuring a customer managed key for Dataset

The AWS KMS key that you use with CloudWatch Dataset must meet the following requirements:

- The key must be a symmetric encryption key (SYMMETRIC_DEFAULT) with key usage ENCRYPT_DECRYPT. Asymmetric keys are not supported.
- Multi-Region keys are not supported.
- The key must be in the same AWS Region as the Dataset.
- You must specify the key as a fully qualified key ARN. Key aliases and key IDs are not supported.

Configuring key policy permissions

To use a customer managed key with CloudWatch Dataset, the key policy must grant CloudWatch permission to use the key. The following example key policy grants CloudWatch the necessary permissions and includes confused deputy protection.

The caller who associates or uses the Dataset must have `kms:Decrypt` permission, scoped to the CloudWatch `ViaService` and encryption context as shown in the `AllowCallerDecrypt` statement below. Replace *`YourApplicationRole`* with the IAM role used to call CloudWatch Dataset APIs.

Example Key policy for CloudWatch Dataset encryption

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowCloudWatchDatasetDescribeKey",
            "Effect": "Allow",
            "Principal": {
                "Service": "cloudwatch.amazonaws.com"
            },
            "Action": "kms:DescribeKey",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "account-id"
                },
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:cloudwatch:region:account-id:dataset/
default"
                }
            }
        },
```

```
        {
            "Sid": "AllowCloudWatchDatasetEncryption",
            "Effect": "Allow",
            "Principal": {
                "Service": "cloudwatch.amazonaws.com"
            },
            "Action": [
                "kms:GenerateDataKey",
                "kms:Encrypt",
                "kms:Decrypt",
                "kms:ReEncrypt*"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "account-id",
                    "kms:EncryptionContext:aws:cloudwatch:arn":
 "arn:aws:cloudwatch:region:account-id:dataset/default"
                },
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:cloudwatch:region:account-id:dataset/
default"
                }
            }
        },
        {
            "Sid": "AllowCallerDecrypt",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::account-id:role/YourApplicationRole"
            },
            "Action": "kms:Decrypt",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "kms:ViaService": "cloudwatch.region.amazonaws.com",
                    "kms:EncryptionContext:aws:cloudwatch:arn":
 "arn:aws:cloudwatch:region:account-id:dataset/default"
                }
            }
        }
    ]
}
```

Replace *account-id* and *region* with your own values.

For more information about key policies, see Key policies in AWS KMS in the AWS Key Management Service Developer Guide.

To associate a customer managed key with a Dataset

Use the `AssociateDatasetKmsKey` API to associate a customer managed key with a Dataset. You must specify `default` as the dataset identifier.

To associate a customer managed key by using the AWS CLI, run the following command:

```
aws cloudwatch associate-dataset-kms-key \
    --dataset-name default \
    --kms-key-arn arn:aws:kms:region:account-id:key/key-id
```

Changing or removing encryption configuration

You can change or remove the customer managed key that encrypts your Dataset data.

To change the customer managed key

To replace the customer managed key, call `AssociateDatasetKmsKey` again with a new key ARN. The caller must have `kms:Decrypt` permission on both the current key and the new key. CloudWatch begins using the new key for subsequent encryption operations.

To remove the customer managed key

To remove the customer managed key and revert to AWS owned key encryption, call `DisassociateDatasetKmsKey`. The caller must have `kms:Decrypt` permission on the currently associated key.

```
aws cloudwatch disassociate-dataset-kms-key \
    --dataset-name default
```

> **Important**
>
> After you disassociate a customer managed key, there is a 3-hour enforcement window during which CloudWatch still requires `kms:Decrypt` permission on the previously associated key. Don't disable or delete the key during this window.

If your key is in a disabled state, you must re-enable the key before you can disassociate it from the Dataset.

Scoping down key policy access

You can use conditions in the key policy to limit access to your AWS KMS key.

Encryption context condition

Use the `kms:EncryptionContext:aws:cloudwatch:arn` condition key to restrict key usage to your `default` Dataset.

```
"Condition": {
    "StringEquals": {
        "kms:EncryptionContext:aws:cloudwatch:arn":
 "arn:aws:cloudwatch:region:account-id:dataset/default"
    }
}
```

Confused deputy protection

Use the `aws:SourceArn` and `aws:SourceAccount` conditions to prevent cross-account confused deputy attacks.

```
"Condition": {
    "StringEquals": {
        "aws:SourceAccount": "account-id"
    },
    "ArnLike": {
        "aws:SourceArn": "arn:aws:cloudwatch:region:account-id:dataset/default"
    }
}
```

kms:ViaService condition

Use the `kms:ViaService` condition key to restrict key usage to requests that come from CloudWatch.

```
"Condition": {
    "StringEquals": {
        "kms:ViaService": "cloudwatch.region.amazonaws.com"
```

```
    }
}
```

Monitoring CloudWatch interaction with AWS KMS

You can use AWS CloudTrail to track the requests that CloudWatch sends to AWS KMS on your behalf. The AWS CloudTrail log entries use the service principal `cloudwatch.amazonaws.com` and a `ViaService` value of `cloudwatch.{region}.amazonaws.com`.

The following CloudTrail event names appear in log entries for CloudWatch Dataset encryption operations:

- `GenerateDataKey`
- `Encrypt`
- `Decrypt`
- `DescribeKey`
- `ReEncrypt`

Each log entry includes the encryption context, which you can use to identify the specific Dataset that the operation applies to.

For more information about monitoring AWS KMS key usage, see Monitoring AWS Key Management Service in the AWS Key Management Service Developer Guide.

Identity and access management for Amazon CloudWatch

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use CloudWatch resources. IAM is an AWS service that you can use with no additional charge.

Topics

- Audience
- Authenticating with identities
- Managing access using policies

- How Amazon CloudWatch works with IAM
- Identity-based policy examples for Amazon CloudWatch
- Troubleshooting Amazon CloudWatch identity and access
- CloudWatch dashboard permissions update
- AWS managed (predefined) policies for CloudWatch
- Customer managed policy examples
- Using condition keys to limit access to CloudWatch
- Using service-linked roles for CloudWatch
- Using service-linked roles for CloudWatch RUM
- Using service-linked roles for CloudWatch Application Insights
- AWS managed policies for Amazon CloudWatch Application Insights
- Amazon CloudWatch permissions reference

Audience

How you use AWS Identity and Access Management (IAM) differs based on your role:

- **Service user** - request permissions from your administrator if you cannot access features (see Troubleshooting Amazon CloudWatch identity and access)
- **Service administrator** - determine user access and submit permission requests (see How Amazon CloudWatch works with IAM)
- **IAM administrator** - write policies to manage access (see Identity-based policy examples for Amazon CloudWatch)

Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. You must be authenticated as the AWS account root user, an IAM user, or by assuming an IAM role.

You can sign in as a federated identity using credentials from an identity source like AWS IAM Identity Center (IAM Identity Center), single sign-on authentication, or Google/Facebook credentials. For more information about signing in, see How to sign in to your AWS account in the *AWS Sign-In User Guide*.

For programmatic access, AWS provides an SDK and CLI to cryptographically sign requests. For more information, see AWS Signature Version 4 for API requests in the *IAM User Guide*.

AWS account root user

When you create an AWS account, you begin with one sign-in identity called the AWS account *root user* that has complete access to all AWS services and resources. We strongly recommend that you don't use the root user for everyday tasks. For tasks that require root user credentials, see Tasks that require root user credentials in the *IAM User Guide*.

Federated identity

As a best practice, require human users to use federation with an identity provider to access AWS services using temporary credentials.

A *federated identity* is a user from your enterprise directory, web identity provider, or Directory Service that accesses AWS services using credentials from an identity source. Federated identities assume roles that provide temporary credentials.

For centralized access management, we recommend AWS IAM Identity Center. For more information, see What is IAM Identity Center? in the *AWS IAM Identity Center User Guide*.

IAM users and groups

An *IAM user* is an identity with specific permissions for a single person or application. We recommend using temporary credentials instead of IAM users with long-term credentials. For more information, see Require human users to use federation with an identity provider to access AWS using temporary credentials in the *IAM User Guide*.

An *IAM group* specifies a collection of IAM users and makes permissions easier to manage for large sets of users. For more information, see Use cases for IAM users in the *IAM User Guide*.

IAM roles

An *IAM role* is an identity with specific permissions that provides temporary credentials. You can assume a role by switching from a user to an IAM role (console) or by calling an AWS CLI or AWS API operation. For more information, see Methods to assume a role in the *IAM User Guide*.

IAM roles are useful for federated user access, temporary IAM user permissions, cross-account access, cross-service access, and applications running on Amazon EC2. For more information, see Cross account resource access in IAM in the *IAM User Guide*.

Managing access using policies

You control access in AWS by creating policies and attaching them to AWS identities or resources. A policy defines permissions when associated with an identity or resource. AWS evaluates these policies when a principal makes a request. Most policies are stored in AWS as JSON documents. For more information about JSON policy documents, see Overview of JSON policies in the *IAM User Guide*.

Using policies, administrators specify who has access to what by defining which **principal** can perform **actions** on what **resources**, and under what **conditions**.

By default, users and roles have no permissions. An IAM administrator creates IAM policies and adds them to roles, which users can then assume. IAM policies define permissions regardless of the method used to perform the operation.

Identity-based policies

Identity-based policies are JSON permissions policy documents that you attach to an identity (user, group, or role). These policies control what actions identities can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Define custom IAM permissions with customer managed policies in the *IAM User Guide*.

Identity-based policies can be *inline policies* (embedded directly into a single identity) or *managed policies* (standalone policies attached to multiple identities). To learn how to choose between managed and inline policies, see Choose between managed policies and inline policies in the *IAM User Guide*.

Resource-based policies

Resource-based policies are JSON policy documents that you attach to a resource. Examples include IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. You must specify a principal in a resource-based policy.

Resource-based policies are inline policies that are located in that service. You can't use AWS managed policies from IAM in a resource-based policy.

Other policy types

AWS supports additional policy types that can set the maximum permissions granted by more common policy types:

- **Permissions boundaries** – Set the maximum permissions that an identity-based policy can grant to an IAM entity. For more information, see Permissions boundaries for IAM entities in the *IAM User Guide*.
- **Service control policies (SCPs)** – Specify the maximum permissions for an organization or organizational unit in AWS Organizations. For more information, see Service control policies in the *AWS Organizations User Guide*.
- **Resource control policies (RCPs)** – Set the maximum available permissions for resources in your accounts. For more information, see Resource control policies (RCPs) in the *AWS Organizations User Guide*.
- **Session policies** – Advanced policies passed as a parameter when creating a temporary session for a role or federated user. For more information, see Session policies in the *IAM User Guide*.

Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the *IAM User Guide*.

How Amazon CloudWatch works with IAM

Before you use IAM to manage access to CloudWatch, learn what IAM features are available to use with CloudWatch.

The following tables list the IAM features that you can use with Amazon CloudWatch.

IAM feature	CloudWatch support
Identity-based policies	Yes
Resource-based policies	No
Policy actions	Yes
Policy resources	Yes
Policy condition keys (service-specific)	Yes
ACLs	No

IAM feature	CloudWatch support
ABAC (tags in policies)	Partial
Temporary credentials	Yes
Principal permissions	Yes
Service roles	Yes
Service-linked roles	No

To get a high-level view of how CloudWatch and other AWS services work with most IAM features, see AWS services that work with IAM in the *IAM User Guide*.

Identity-based policies for CloudWatch

Supports identity-based policies: Yes

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Define custom IAM permissions with customer managed policies in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. To learn about all of the elements that you can use in a JSON policy, see IAM JSON policy elements reference in the *IAM User Guide*.

Identity-based policy examples for CloudWatch

To view examples of CloudWatch identity-based policies, see Identity-based policy examples for Amazon CloudWatch.

Resource-based policies within CloudWatch

Supports resource-based policies: No

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific

resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. For more information, see Cross account resource access in IAM in the *IAM User Guide*.

Policy actions for CloudWatch

Supports policy actions: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Action` element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Include actions in a policy to grant permissions to perform the associated operation.

To see a list of CloudWatch actions, see Actions defined by Amazon CloudWatch in the *Service Authorization Reference*.

Policy actions in CloudWatch use the following prefix before the action:

```
cloudwatch
```

To specify multiple actions in a single statement, separate them with commas.

```
"Action": [
      "cloudwatch:action1",
      "cloudwatch:action2"
         ]
```

To view examples of CloudWatch identity-based policies, see Identity-based policy examples for Amazon CloudWatch.

Policy resources for CloudWatch

Supports policy resources: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Resource` JSON policy element specifies the object or objects to which the action applies. As a best practice, specify a resource using its Amazon Resource Name (ARN). For actions that don't support resource-level permissions, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

To see a list of CloudWatch resource types and their ARNs, see Resources defined by Amazon CloudWatch in the *Service Authorization Reference*. To learn with which actions you can specify the ARN of each resource, see Actions defined by Amazon CloudWatch.

To view examples of CloudWatch identity-based policies, see Identity-based policy examples for Amazon CloudWatch.

Policy condition keys for CloudWatch

Supports service-specific policy condition keys: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Condition` element specifies when statements execute based on defined criteria. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request. To see all AWS global condition keys, see AWS global condition context keys in the *IAM User Guide*.

To see a list of CloudWatch condition keys, see Condition keys for Amazon CloudWatch in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see Actions defined by Amazon CloudWatch.

To view examples of CloudWatch identity-based policies, see Identity-based policy examples for Amazon CloudWatch.

ACLs in CloudWatch

Supports ACLs: No

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

ABAC with CloudWatch

Supports ABAC (tags in policies): Partial

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes called tags. You can attach tags to IAM entities and AWS resources, then design ABAC policies to allow operations when the principal's tag matches the tag on the resource.

To control access based on tags, you provide tag information in the condition element of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see Define permissions with ABAC authorization in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see Use attribute-based access control (ABAC) in the *IAM User Guide*.

Using temporary credentials with CloudWatch

Supports temporary credentials: Yes

Temporary credentials provide short-term access to AWS resources and are automatically created when you use federation or switch roles. AWS recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see Temporary security credentials in IAM and AWS services that work with IAM in the *IAM User Guide*.

Cross-service principal permissions for CloudWatch

Supports forward access sessions (FAS): Yes

Forward access sessions (FAS) use the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. For policy details when making FAS requests, see Forward access sessions.

Service roles for CloudWatch

Supports service roles: Yes

A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Create a role to delegate permissions to an AWS service in the *IAM User Guide*.

> **Warning**
>
> Changing the permissions for a service role might break CloudWatch functionality. Edit service roles only when CloudWatch provides guidance to do so.

Identity-based policy examples for Amazon CloudWatch

By default, users and roles don't have permission to create or modify CloudWatch resources. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies.

To learn how to create an IAM identity-based policy by using these example JSON policy documents, see Create IAM policies (console) in the *IAM User Guide*.

For details about actions and resource types defined by CloudWatch, including the format of the ARNs for each of the resource types, see Actions, resources, and condition keys for Amazon CloudWatch in the *Service Authorization Reference*.

Topics

- Policy best practices
- Using the CloudWatch console

Policy best practices

Identity-based policies determine whether someone can create, access, or delete CloudWatch resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with AWS managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *AWS managed policies* that grant permissions for many common use cases. They are available in your AWS account. We

recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see AWS managed policies or AWS managed policies for job functions in the *IAM User Guide*.

- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see Policies and permissions in IAM in the *IAM User Guide*.
- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as CloudFormation. For more information, see IAM JSON policy elements: Condition in the *IAM User Guide*.
- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see Validate policies with IAM Access Analyzer in the *IAM User Guide*.
- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your AWS account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see Secure API access with MFA in the *IAM User Guide*.

For more information about best practices in IAM, see Security best practices in IAM in the *IAM User Guide*.

Using the CloudWatch console

To access the Amazon CloudWatch console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the CloudWatch resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for entities (users or roles) with that policy.

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that they're trying to perform.

To ensure that users and roles can still use the CloudWatch console, also attach the CloudWatch *ConsoleAccess* or *ReadOnly* AWS managed policy to the entities. For more information, see Adding permissions to a user in the *IAM User Guide*.

Permissions needed for CloudWatch console

The full set of permissions required to work with the CloudWatch console are listed below. These permissions provide full write and read access to the CloudWatch console.

- application-autoscaling:DescribeScalingPolicies
- autoscaling:DescribeAutoScalingGroups
- autoscaling:DescribePolicies
- cloudtrail:DescribeTrails
- cloudwatch:DeleteAlarms

Troubleshooting Amazon CloudWatch identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with CloudWatch and IAM.

Topics

- I am not authorized to perform an action in CloudWatch
- I am not authorized to perform iam:PassRole
- I want to allow people outside of my AWS account to access my CloudWatch resources

I am not authorized to perform an action in CloudWatch

If you receive an error that you're not authorized to perform an action, your policies must be updated to allow you to perform the action.

The following example error occurs when the `mateojackson` IAM user tries to use the console to view details about a fictional *`my-example-widget`* resource but doesn't have the fictional `cloudwatch:`*`GetWidget`* permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:
 cloudwatch:GetWidget on resource: my-example-widget
```

In this case, the policy for the `mateojackson` user must be updated to allow access to the *`my-example-widget`* resource by using the `cloudwatch:`*`GetWidget`* action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I am not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, your policies must be updated to allow you to pass a role to CloudWatch.

Some AWS services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named `marymajor` tries to use the console to perform an action in CloudWatch. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform:
 iam:PassRole
```

In this case, Mary's policies must be updated to allow her to perform the `iam:PassRole` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I want to allow people outside of my AWS account to access my CloudWatch resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether CloudWatch supports these features, see How Amazon CloudWatch works with IAM.
- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the *IAM User Guide*.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see Cross account resource access in IAM in the *IAM User Guide*.

CloudWatch dashboard permissions update

On May 1, 2018, AWS changed the permissions required to access CloudWatch dashboards. Dashboard access in the CloudWatch console now requires permissions that were introduced in 2017 to support dashboard API operations:

- **cloudwatch:GetDashboard**

- **cloudwatch:ListDashboards**
- **cloudwatch:PutDashboard**
- **cloudwatch:DeleteDashboards**

To access CloudWatch dashboards, you need one of the following:

- The **AdministratorAccess** policy.
- The **CloudWatchFullAccess** policy.
- A custom policy that includes one or more of these specific permissions:
  - `cloudwatch:GetDashboard` and `cloudwatch:ListDashboards` to be able to view dashboards
  - `cloudwatch:PutDashboard` to be able to create or modify dashboards
  - `cloudwatch:DeleteDashboards` to be able to delete dashboards

For more information about using policies to change permissions for an IAM user, see Changing Permissions for an IAM user.

For more information about CloudWatch permissions, see Amazon CloudWatch permissions reference.

For more information about dashboard API operations, see PutDashboard in the Amazon CloudWatch API Reference.

AWS managed (predefined) policies for CloudWatch

AWS addresses many common use cases by providing standalone IAM policies that are created and administered by AWS. These AWS managed policies grant necessary permissions for common use cases so that you can avoid having to investigate what permissions are needed. For more information, see AWS managed policies in the *IAM User Guide*.

The following AWS managed policies, which you can attach to users in your account, are specific to CloudWatch.

Topics

- CloudWatch updates to AWS managed policies
- CloudWatchFullAccessV2
- CloudWatchFullAccess

CloudWatch updates to AWS managed policies

View details about updates to AWS managed policies for CloudWatch since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the CloudWatch Document history page.

Change	Description	Date
CloudWatchFullAccessV2 – Updated policy	CloudWatch added permissions to **CloudWatchFullAccessV2**. Two `iam:PassRole` permissions were added to support the `PutLogAlarm` API: passing a Scheduled Query Execution Role to `logs.amazonaws.com` (scoped to scheduled-query	June 15, 2026

Change	Description	Date
	resources), and passing a Log Lines Role to `cloudwatch.amazonaws.com` (scoped to alarm resources).	
CloudWatchSyntheticsFullAccess – Updated policy	CloudWatch updated the **CloudWatchSyntheticsFullAccess** policy. The `cloudwatch:ListMetrics` permission was added so that CloudWatch Synthetics can list available metrics. Additionally, the `apigateway:GET` permission has been changed from allowing all resources to specific API Gateway resources: REST APIs, REST API stages, REST API stage Swagger exports, and HTTP APIs.	March 31, 2026

Change	Description	Date
AIOpsAssistantPolicy – Updated policy	CloudWatch updated the **AIOpsAssistantPolicy** IAM policy. It added permissions to enable CloudWatch investigations to assist in queries, troubleshooting, and topology mapping. The following permissions were added: `appsync:GetGraphqlApiEnvironmentVariables`, `cloudtrail:GetEventConfiguration`, `kms:GetKeyPolicy`, and `s3:GetBucketAbac`	February 06, 2026
AIOpsAssistantPolicy – Updated policy	CloudWatch updated the **AIOpsAssistantPolicy** IAM policy. It added permissions to enable CloudWatch investigations to assist in queries, troubleshooting, and topology mapping. The following permissions were added: `kms:GetKeyRotationStatus`, `kms:ListAliases`, and `kms:ListKeyRotations`	December 17, 2025

Change	Description	Date
CloudWatchNetworkMonitorServiceRolePolicy – Updated policy	CloudWatch added the `ec2:DescribeRouteTables` , `ec2:DescribeTransitGatewayAttachments` , `ec2:DescribeTransitGatewayRouteTables` , `ec2:SearchTransitGatewayRoutes` permissions to the **CloudWatchNetworkMonitorServiceRolePolicy** managed policy to grant permissions for Network Synthetic Monitor to generate the Network Health Indicator values for customers using Transit Gateways.	December 12, 2025
CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy – Updated policy	CloudWatch added the `ec2:DescribeVpcEndpoints` and `ec2:DescribeVpcEndpointServiceConfigurations` permissions to the **CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy** managed policy to grant permissions for Network Flow Monitor to generate topology snapshots of VPC endpoints and vpce service config.	December 10, 2025

Change	Description	Date
CloudWatchFullAccessV2 – Updated policy	CloudWatch added permissions to **CloudWatchFullAccessV2**. Permissions for observability administration actions were added to allow full access to telemetry pipelines and S3 table integrations.	December 02, 2025
CloudWatchReadOnlyAccess – Updated policy	CloudWatch added permissions to **CloudWatchReadOnlyAccess**. Permissions for observability administration actions were added to allow read-only access to telemetry pipelines and S3 table integrations.	December 02, 2025
CloudWatchFullAccessV2 – Updated policy	CloudWatch updated the **CloudWatchFullAccessV2** policy to include permissions to support viewing change events for a given entity and time range, and querying uninstrumented services and resources from Application Signals by enabling resource explorer.	November 20th, 2025

Change	Description	Date
CloudWatchApplicationSignalsFullAccess – Updated policy	CloudWatch updated the **CloudWatchApplicationSignalsFullAccess** policy to include permissions to support viewing change events for a given entity and time range, and querying uninstrumented services and resources from Application Signals by enabling resource explorer.	November 20th, 2025
CloudWatchReadOnlyAccess – Updated policy	CloudWatch updated the **CloudWatchReadOnlyAccess** policy to include permissions to support viewing change events for a given entity and time range, and querying uninstrumented services and resources from Application Signals.	November 20th, 2025
CloudWatchApplicationSignalsReadOnlyAccess – Updated policy	CloudWatch updated the **CloudWatchApplicationSignalsReadOnlyAccess** policy to include permissions to support viewing change events for a given entity and time range, and querying uninstrumented services and resources from Application Signals.	November 20th, 2025

Change	Description	Date
CloudWatchApplicationSignalsServiceRolePolicy – Update to an existing policy	CloudWatch updated the policy named **CloudWatchApplicationSignalsServiceRolePolicy**. Updated the policy to include `resource-explorer-2:Search` and `cloudtrail:CreateServiceLinkedChannel` to enable new Application Signals features.	November 20, 2025
AIOpsConsoleAdminPolicy – Updated policy	CloudWatch updated the **AIOpsConsoleAdminPolicy** policy to include Amazon Q integration permissions, enabling users to interact with CloudWatch investigations incident reports through Amazon Q's conversational interface.	November 17, 2025
AIOpsOperatorAccess – Updated policy	CloudWatch updated the **AIOpsOperatorAccess** policy to include Amazon Q integration permissions, enabling users to interact with CloudWatch investigations incident reports through Amazon Q's conversational interface.	November 7, 2025

Change	Description	Date
CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy – Updated policy	CloudWatch added the `ec2:DescribeManagedPrefixLists` and `ec2:GetManagedPrefixListEntries` permissions to the **CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy** managed policy to grant permissions for Network Flow Monitor to generate topology snapshots of managed prefix lists.	November 06, 2025
AIOpsAssistantIncidentReportPolicy – New policy	CloudWatch added the **AIOpsAssistantIncidentReportPolicy** policy to enable CloudWatch investigations to generate incident reports from investigation data, including permissions to access investigations, create reports, and manage AI-derived facts.	October 10, 2025
AIOpsOperatorAccess – Updated policy	CloudWatch updated the **AIOpsOperatorAccess** policy to include incident report generation permissions, allowing users to create and manage incident reports and work with AI-derived facts in CloudWatch investigations.	October 10, 2025

Change	Description	Date
CloudWatchReadOnlyAccess – Update to an existing policy.	CloudWatch added permissions to **CloudWatchReadOnlyAccess**. Permissions for observability administration actions were added to allow read-only access to telemetry rules, centralization configurations, and resource telemetry data across AWS Organizations.	October 10, 2025
CloudWatchFullAccessV2 – Updates to existing policies	CloudWatch updated **CloudWatchFullAccessV2** to include CloudTrail and Service Quotas permissions to support top observations and change indicators functionality within Application Signals.	October 8, 2025
CloudWatchReadOnlyAccess – Updates to existing policies	CloudWatch updated **CloudWatchReadOnlyAccess** to include CloudTrail and Service Quotas permissions to support top observations and change indicators functionality within Application Signals.	October 8, 2025

Change	Description	Date
CloudWatchApplicationSignalsReadOnlyAccess – Updated policy	CloudWatch updated the **CloudWatchApplicationSignalsReadOnlyAccess** policy to view how resources and services change in your account and view top observations for service anomalies in your account.	September 29, 2025
CloudWatchApplicationSignalsFullAccess – Updated policy	CloudWatch updated the **CloudWatchApplicationSignalsFullAccess** policy to view how resources and services change in your account and view top observations for service anomalies in your account.	September 29, 2025
AIOpsAssistantPolicy – Updated policy	CloudWatch updated the **AIOpsAssistantPolicy** to allow CloudWatch investigations access to additional resources to assist in queries, troubleshooting, and topology mapping. This policy grants CloudWatch investigations the necessary permissions for conducting investigations.	September 24, 2025

Change	Description	Date
AIOpsConsoleAdminPolicy – Updated policy	CloudWatch updated the **AIOpsConsoleAdminPolicy** policy to permit validation of investigation groups across accounts. This policy grants users access to CloudWatch investigations actions, and to additional AWS actions that are necessary for accessing investigation events.	June 13, 2025
AIOpsOperatorAccess – Updated policy	CloudWatch updated the **AIOpsOperatorAccess** policy to permit validation of investigation groups across accounts. This policy grants users access to CloudWatch investigations actions, and to additional AWS actions that are necessary for accessing investigation events.	June 13, 2025

Change	Description	Date
AIOpsAssistantPolicy – Updates to existing policy	CloudWatch updated the **AIOpsAssistantPolicy** IAM policy. It added permissio ns to enable CloudWatch Application Insights operation al investigations to find information in your resources during investigations. The following permissions were added: `appsync:G etGraphqlApi` , `appsync:GetDataSou rce` , `iam:ListA ttachedRolePolicie s` , `iam:ListRolePolici es` ,and `iam:ListRoles` Additionally, the `elastic-i nference:Describe*` permission was removed from the policy.	June 13, 2025

Change	Description	Date
AmazonCloudWatchRUMReadOnlyAccess – Updated policy	CloudWatch added permissions to the **AmazonCloudWatchRUMReadOnlyAccess** policy. The `synthetics:describeCanaries` and `synthetics:describeCanariesLastRun` was added so that CloudWatch RUM can display associated Synthetics Canaries to the RUM app monitor. The `cloudwatch:GetMetricData` was added so that CloudWatch RUM can display associated CloudWatch metrics to the RUM app monitor. The `cloudwatch:DescribeAlarms` was added so that CloudWatch RUM can display associated CloudWatch alarms to the RUM app monitor. The `logs:DescribeLogGroups` was added so that CloudWatch RUM can display associated CloudWatch logs to the RUM app monitor.	June 28, 2025

Change	Description	Date
	The `xray:GetTraceSummaries` was added so that CloudWatch RUM can display associated X-Ray Trace segments to the RUM app monitor. The `rum:ListTagsForResources` was added so that CloudWatch RUM can display associated tags to the RUM app monitor.	
AIOpsReadOnlyAccess – Updated policy	CloudWatch updated the **AIOpsReadOnlyAccess** policy to permit validation of investigation groups across accounts. This policy grants a user read-only permissions for Amazon AI Operations and other related services.	June 5, 2025
AmazonCloudWatchRUMReadOnlyAccess – Updated policy	CloudWatch added a permission to the **AmazonCloudWatchRUMReadOnlyAccess** policy. The `rum:GetResourcePolicy` permission was added so that CloudWatch RUM can view the resource policy attached to the RUM application monitor.	April 28, 2025

Change	Description	Date
AIOpsConsoleAdminPolicy – New policy	CloudWatch created a new policy named **AIOpsConsoleAdminPolicy**. This policy grants users full administrative access for managing CloudWatch investigations, including the management of trusted identity propagation, and the management of IAM Identity Center and organizational access.	December 3, 2024
AIOpsOperatorAccess – New policy	CloudWatch created a new policy named **AIOpsOperatorAccess**. This policy grants users access to CloudWatch investigations actions, and to additional AWS actions that are necessary for accessing investigation events.	December 3, 2024
AIOpsReadOnlyAccess – New policy	CloudWatch created a new policy named **AIOpsReadOnlyAccess**. This policy grants a user read-only permissions for Amazon AI Operations and other related services.	December 3, 2024

Change	Description	Date
AIOpsAssistantPolicy – New policy	CloudWatch created a new policy named **AIOpsAssistantPolicy**. You don't assign this policy to a user. You assign this policy to the Amazon AI Operations assistant to enable CloudWatch investigations to analyze your AWS resources during the investigation of operational events.	December 3, 2024
CloudWatchFullAccessV2 – Updates to existing policies	CloudWatch updated both **CloudWatchFullAccessV2** and **CloudWatchFullAccess**. Permissions for Amazon OpenSearch Service were added to to enable CloudWatch Logs integration with OpenSearch Service for some features.	December 1, 2024

Change	Description	Date
CloudWatchNetworkFlowMonitorServiceRolePolicy – New policy	CloudWatch added a new policy **CloudWatchNetworkFlowMonitorServiceRolePolicy**. The **CloudWatchNetworkFlowMonitorServiceRolePolicy** grants permissions for Network Flow Monitor to publish metrics to CloudWatch. It also allows the service to use AWS Organizations to get information for multi-account scenarios.	December 1, 2024
CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy – New policy	CloudWatch added a new policy **CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy**. The **CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy** grants permissions for Network Flow Monitor to generate topology snapshots of resources used in your account.	December 1, 2024

Change	Description	Date
CloudWatchNetworkFlowMonitorAgentPublishPolicy – New policy	CloudWatch added a new policy **CloudWatchNetworkFlowMonitorAgentPublishPolicy**. The **CloudWatchNetworkFlowMonitorAgentPublishPolicy** grants permissions for resources, such as Amazon EC2 and Amazon EKS instances, to send telemetry reports (metrics) to a Network Flow Monitor endpoint.	December 1, 2024

Change	Description	Date
CloudWatchSyntheticsFullAccess – Update to an existing policy	CloudWatch updated the policy named **CloudWatchSyntheticsFullAccess**. The following CloudWatch Logs actions have been added to allow CloudWatch Synthetics to get and use canary log data in Lambda log groups. The `lambda:GetFunction` permission has also been added to allow Synthetics to get information about a specific function. • `logs:GetLogRecord` – Required to expand a log entry in CloudWatch Logs Insights. (Required to view logs in the Synthetics console.) • `logs:DescribeLogStreams` – Required to list all log streams on a log group. • `logs:StartQuery` – Required to start a Logs Insights query (required in the Synthetics console to view logs). • `logs:GetLogEvents` –	November 20, 2024

Change	Description	Date
	Required to list log events from the specified log stream. Used for querying a specific log stream on a log group. • `logs:FilterLogEvents` – Required to view logs in a canary's log group. • `logs:GetLogGroupFields` – Required for running a Logs Insights query in the console. (The Synthetics console links to the Logs Insights query. Without this permission, Logs Insights queries on a log group fail.) Additionally, Lambda layer version actions now apply to all CloudWatch Synthetics layer ARNs.	

Change	Description	Date
CloudWatchInternetMonitorReadOnlyAccess – New **CloudWatchInternetMonitorReadOnlyAccess**. This policy grants read only access to resources and actions available in the CloudWatch console for Internet Monitor. The scope of this policy includes `internetmonitor:` so that users can use read-only Internet Monitor actions and resources. It includes some `cloudwatch:` policies to retrieve information on CloudWatch metrics. It includes some `logs:` policies to manage log queries.	November 14, 2024	

Change	Description	Date
CloudWatchInternetMonitorFullAccess – New policy	CloudWatch created a new policy named **CloudWatchInternetMonitorFullAccess**. This policy grants full access to resources and actions available in the CloudWatch console for Internet Monitor. The scope of this policy includes `internetmonitor:` so that users can use Internet Monitor actions and resources. It includes some `cloudwatch:` policies to retrieve information on CloudWatch alarms and metrics. It includes some `logs:` policies to manage log queries. It includes some `ec2:`, `cloudfront:`, `elasticloadbalancing:`, and `workspaces:` policies to work with resources that you add to monitors so that Internet Monitor can create a traffic profile for your application. It contains some `iam:` policies to manage IAM roles.	October 23, 2024

Change	Description	Date
CloudWatchLambdaApplicationSignalsExecutionRolePolicy – New **CloudWatchLambdaApplicationSignalsExecutionRolePolicy**. This policy is used when CloudWatch Application Signals is enabled for Lambda workloads. It enables write access to X-Ray and the log group used by CloudWatch Application Signals.	October 16, 2024	
CloudWatchSyntheticsFullAccess – Update to an existing policy	CloudWatch updated the policy named **CloudWatchSyntheticsFullAccess**. The `lambda:ListTags` , `lambda:TagResource` , and `lambda:UntagResource` permissions were added so that when you apply or change tags on a canary, you can choose to have Synthetics also apply those same tags or changes to the Lambda function that the canary uses.	October 11, 2024

Change	Description	Date
CloudWatchApplicationSignalsReadOnlyAccess – New policy	CloudWatch created a new policy named **CloudWatchApplicationSignalsReadOnlyAccess**. This policy grants read only access to resources and actions available in the CloudWatch console for Application Signals. The scope of this policy includes `application-signals:` policies so that users can use read only actions and resources available in the CloudWatch console under Application Signals. It contains an `iam:` policy to manage IAM roles. It includes some `logs:` policies to manage log queries and filters. It includes `cloudwatch:` policies to retrieve information on CloudWatch alarms and metrics. It includes some `synthetics:` policies to retrive information about synthetics canaries. It includes `rum:` policies to manage RUM clients and jobs. It contains an `xray:` policy to obtain trace summaries.	June 7, 2024

Change	Description	Date
CloudWatchApplicationSignalsFullAccess – New policy	CloudWatch created a new policy named **CloudWatchApplicationSignalsFullAccess**. This policy grants full access to resources and actions available in the CloudWatch console for Application Signals. The scope of this policy includes `application-signals:` so that users can use Application Signals actions and resources. It includes some `cloudwatch:` policies to retrieve information on CloudWatch alarms and metrics. It includes some `logs:` policies to manage log queries. It includes some `synthetics:` policies to write and retrieve information about synthetics canaries. It includes `rum:` policies to manage RUM clients and jobs. It contains an `xray:` policy to obtain trace summaries. It includes some `cloudwatch:` policies to manage CloudWatch alarms. It contains some `iam:` policies to manage IAM roles. It includes some `sns:`	June 7, 2024

Change	Description	Date
	policies to manage Amazon Simple Notification Service notifications.	
CloudWatchFullAccessV2 – Update to an existing policy	CloudWatch updated the policy named **CloudWatchFullAccessV2**. The scope of the `CloudWatchFullAccessPermissions` policy was updated to add `application-signals:*` so that users can use CloudWatch Application Signals to view, investigate, and diagnose issues with the health of their services.	May 20, 2024

Change	Description	Date
CloudWatchReadOnlyAccess – Update to an existing policy	CloudWatch updated the policy named **CloudWatchReadOnlyAccess**. The scope of the `CloudWatchReadOnlyAccessPermissions` policy was updated to add `application-signals:BatchGet*`, `application-signals:List*`, and `application-signals:Get*` so that users can use CloudWatch Application Signals to view, investigate, and diagnose issues with the health of their services. The scope of `CloudWatchReadOnlyGetRolePermissions` was updated to add the `iam:GetRole` action so that users can check if CloudWatch Application Signals is set up.	May 20, 2024

Change	Description	Date
CloudWatchApplicationSignalsServiceRolePolicy – Update to an existing policy	CloudWatch updated the policy named **CloudWatchApplicationSignalsServiceRolePolicy**. The scoping of the `logs:StartQuery` and `logs:GetQueryResults` permissions was changed to add the `arn:aws:logs:*:*:log-group:/aws/appsignals/*:*` and `arn:aws:logs:*:*:log-group:/aws/application-signals/data:*` ARNs to enable Application Signals on more architectures.	April 18, 2024
CloudWatchApplicationSignalsServiceRolePolicy – Update to an existing policy	CloudWatch changed the scope of a permission in **CloudWatchApplicationSignalsServiceRolePolicy**. The scope of the `cloudwatch:GetMetricData` permission was changed to * so that Application Signals can retrieve metrics from sources in linked accounts.	April 08, 2024

Change	Description	Date
CloudWatchAgentServerPolicy – Update to an existing policy	CloudWatch added permissions to **CloudWatchAgentServerPolicy**. The `xray:PutTraceSegments` , `xray:PutTelemetryRecords` , `xray:GetSamplingRules` , `xray:GetSamplingTargets` , `xray:GetSamplingStatisticSummaries` and `logs:PutRetentionPolicy` permissions were added so that the CloudWatch agent can publish X-Ray traces and modify log group retention periods.	February 12, 2024

Change	Description	Date
CloudWatchAgentAdminPolicy – Update to an existing policy	CloudWatch added permissions to **CloudWatchAgentAdminPolicy**. The `xray:PutTraceSegments`, `xray:PutTelemetryRecords`, `xray:GetSamplingRules`, `xray:GetSamplingTargets`, `xray:GetSamplingStatisticSummaries` and `logs:PutRetentionPolicy` permissions were added so that the CloudWatch agent can publish X-Ray traces and modify log group retention periods.	February 12, 2024

Change	Description	Date
CloudWatchFullAccessV2 – Update to an existing policy	CloudWatch added permissions to **CloudWatchFullAccessV2**. Existing permissions for CloudWatch Synthetics, X-Ray, and CloudWatch RUM actions and new permissions for CloudWatch Application Signals were added so that users with this policy can manage CloudWatch Application Signals. The permission to create the CloudWatch Application Signals service-linked role was added to allow CloudWatch Application Signals to discover telemetry data in logs, metrics, traces, and tags.	December 5, 2023

Change	Description	Date
CloudWatchReadOnlyAccess – Update to an existing policy	CloudWatch added permissions to **CloudWatchReadOnlyAccess**. Existing read-only permissions for CloudWatch Synthetics, X-Ray, and CloudWatch RUM actions and new read-only permissions for CloudWatch Application Signals were added so that users with this policy can triage and dignose their service health issues as reported by CloudWatch Application Signals. The `cloudwatch:GenerateQuery` permission was added so that users with this policy can generate a CloudWatch Metrics Insights query string from a natural language prompt.	December 5, 2023

Change	Description	Date
CloudWatchReadOnlyAccess – Update to an existing policy.	CloudWatch added a permission to **CloudWatchReadOnlyAccess**. The `cloudwatch:GenerateQuery` permission was added, so that users with this policy can generate a CloudWatch Metrics Insights query string from a natural language prompt.	December 01, 2023
CloudWatchApplicationSignalsServiceRolePolicy – New policy	CloudWatch added a new policy **CloudWatchApplicationSignalsServiceRolePolicy**. The **CloudWatchApplicationSignalsServiceRolePolicy** grants an upcoming feature permissions to collect CloudWatch Logs data, X-Ray trace data, CloudWatch metrics data, and tagging data.	November 9, 2023

Change	Description	Date
AWSServiceRoleForCloudWatchMetrics_DbPerfInsightsServiceRolePolicy – New policy	CloudWatch added a new policy **AWSServiceRoleForCloudWatchMetrics_DbPerfInsightsServiceRolePolicy**. The **AWSServiceRoleForCloudWatchMetrics_DbPerfInsightsServiceRolePolicy** grants permission to CloudWatch to fetch Performance Insights metrics from databases on your behalf.	September 20, 2023
CloudWatchReadOnlyAccess – Update to an existing policy	CloudWatch added a permission to **CloudWatchReadOnlyAccess**. The `application-autoscaling:DescribeScalingPolicies` permission was added so that users with this policy can access information about Application Auto Scaling policies.	September 14, 2023

Change	Description	Date
CloudWatchFullAccessV2 – New policy	CloudWatch added a new policy **CloudWatchFullAccessV2**. The **CloudWatchFullAccessV2** grants full access to CloudWatch actions and resources while better scoping the permissions granted to other services such as Amazon SNS and Amazon EC2 Auto Scaling. For more information, see CloudWatchFullAccessV2.	August 1, 2023
AWSServiceRoleForInternetMonitor – Update to an existing policy	Amazon CloudWatch Internet Monitor added new permissions to monitor Network Load Balancer resources. The `elasticloadbalancing:DescribeLoadBalancers` and `ec2:DescribeNetworkInterfaces` permissions are required so that Internet Monitor can monitor customers' Network Load Balancer traffic by analyzing flow logs for NLB resources. For more information, see Using Internet Monitor.	July 15, 2023

Change	Description	Date
CloudWatchReadOnlyAccess – Update to an existing policy	CloudWatch added permissions to **CloudWatchReadOnlyAccess**. The `logs:StartLiveTail` and `logs:StopLiveTail` permissions were added so that users with this policy can use the console to start and stop CloudWatch Logs live tail sessions. For more information, see Use live tail to view logs in near real time.	June 6, 2023
CloudWatchCrossAccountSharingConfiguration – New policy	CloudWatch added a new policy to enable you to manage CloudWatch cross-account observability links that share CloudWatch metrics. For more information, see CloudWatch cross-account observability.	November 27, 2022
OAMFullAccess – New policy	CloudWatch added a new policy to enable you to fully manage CloudWatch cross-account observability links and sinks. For more information, see CloudWatch cross-account observability.	November 27, 2022

Change	Description	Date
OAMReadOnlyAccess – New policy	CloudWatch added a new policy to enable you to view information about CloudWatch cross-account observability links and sinks. For more information, see CloudWatch cross-account observability.	November 27, 2022
CloudWatchFullAccess – Update to an existing policy	CloudWatch added permissions to **CloudWatchFullAccess**. The `oam:ListSinks` and `oam:ListAttachedLinks` permissions were added so that users with this policy can use the console to view data shared from source accounts in CloudWatch cross-account observability.	November 27, 2022
CloudWatchReadOnlyAccess – Update to an existing policy	CloudWatch added permissions to **CloudWatchReadOnlyAccess**. The `oam:ListSinks` and `oam:ListAttachedLinks` permissions were added so that users with this policy can use the console to view data shared from source accounts in CloudWatch cross-account observability.	November 27, 2022

Change	Description	Date
AmazonCloudWatchRUMServiceRolePolicy – Update to an existing policy	CloudWatch RUM updated a condition key in **AmazonCloudWatchRUMServiceRolePolicy**. The `"Condition": { "StringEquals": { "cloudwatch:namespace": "AWS/RUM" } }` condition key was changed to the following so that CloudWatch RUM can send custom metrics to custom metric namespaces. `"Condition": { "StringLike": { "cloudwatch:namespace": [ "RUM/CustomMetrics/*", "AWS/RUM" ] } }`	February 2, 2023

Change	Description	Date
AmazonCloudWatchRUMReadOnlyAccess – Updated policy	CloudWatch added permissions the **AmazonCloudWatchRUMReadOnlyAccess** policy. The `rum:ListRumMetricsDestinations` and `rum:BatchGetRumMetricsDefinitions` permissions were added so that CloudWatch RUM can send extended metrics to CloudWatch.	October 27, 2022
AmazonCloudWatchRUMServiceRolePolicy – Update to an existing policy	CloudWatch RUM added permissions to **AmazonCloudWatchRUMServiceRolePolicy**. The `cloudwatch:PutMetricData` permission was added so that CloudWatch RUM can send extended metrics to CloudWatch.	October 26, 2022

Change	Description	Date
CloudWatchSyntheticsFullAccess – Update to an existing policy	CloudWatch Synthetics added permissions to **CloudWatchSyntheticsFullAccess**. The `lambda:DeleteFunction` and `lambda:DeleteLayerVersion` permissions were added so that CloudWatch Synthetics can delete related resources when a canary is deleted. The `iam:ListAttachedRolePolicies` was added so that customers can view the policies that are attached to a canary's IAM role.	May 6, 2022
AmazonCloudWatchRUMFullAccess – New policy	CloudWatch added a new policy to enable full management of CloudWatch RUM. CloudWatch RUM allows you to perform real user monitoring of your web application. For more information, see CloudWatch RUM.	November 29, 2021

Change	Description	Date
AmazonCloudWatchRUMReadOnlyAccess – New policy	CloudWatch added a new policy to enable read-only access to CloudWatch RUM. CloudWatch RUM allows you to perform real user monitoring of your web application. For more information, see CloudWatch RUM.	November 29, 2021
AWSServiceRoleForCloudWatchRUM – New managed policy	CloudWatch added a policy for a new service-linked role to allow CloudWatch RUM to pubish monitoring data to other relevant AWS services.	November 29, 2021

Change	Description	Date
CloudWatchSyntheticsFullAccess – Update to an existing policy	CloudWatch Synthetics added permissions to **CloudWatchSyntheticsFullAccess**, and also changed the scope of one permission. The `kms:ListAliases` permission was added so that users can list available AWS KMS keys that can be used to encrypt canary artifacts. The `kms:DescribeKey` permission was added so that users can see the details of keys that will be used to encrypt for canary artifacts. And the `kms:Decrypt` permission was added to enable users to decrypt canary artifacts. This decryption ability is limited to use on resources within Amazon S3 buckets. The `Resource` scope of the `s3:GetBucketLocation` permission was changed from * to `arn:aws:s3:::*` .	September 29, 2021

Change	Description	Date
CloudWatchSyntheticsFullAccess – Update to an existing policy	CloudWatch Synthetics added a permission to **CloudWatchSyntheticsFullAccess**. The `lambda:UpdateFunctionCode` permission was added so that users with this policy can change the runtime version of canaries.	July 20, 2021
AWSCloudWatchAlarms_ActionSSMIncidentsServiceRolePolicy – New managed policy	CloudWatch added a new managed IAM policy to allow CloudWatch to create incidents in AWS Systems Manager Incident Manager.	May 10, 2021
CloudWatchAutomaticDashboardsAccess – Update to an existing policy	CloudWatch added a permission to the **CloudWatchAutomaticDashboardsAccess** managed policy. The `synthetics:DescribeCanariesLastRun` permission was added to this policy to enable cross-account dashboard users to see details about CloudWatch Synthetics canary runs.	April 20, 2021
CloudWatch started tracking changes	CloudWatch started tracking changes for its AWS managed policies.	April 14, 2021

CloudWatchFullAccessV2

AWS recently added the **CloudWatchFullAccessV2** managed IAM policy. This policy grants full access to CloudWatch actions and resources and also more properly scopes the permissions granted for other services such as Amazon SNS and Amazon EC2 Auto Scaling. We recommend that you begin using this policy instead of using **CloudWatchFullAccess**. AWS plans to deprecate **CloudWatchFullAccess** in the near future.

It includes `application-signals:` permissions so that users can access all the functionality from the CloudWatch console under Application Signals. It includes some `autoscaling:Describe` permissions so that users with this policy can see the Auto Scaling actions that are associated with CloudWatch alarms. It includes some `sns` permissions so that users with this policy can retrieve create Amazon SNS topics and associate them with CloudWatch alarms. It includes IAM permissions so that users with this policy can view information about service-linked roles associated with CloudWatch. It includes the `oam:ListSinks` and `oam:ListAttachedLinks` permissions so that users with this policy can use the console to view data shared from source accounts in CloudWatch cross-account observability. It also includes CloudTrail and Service Quotas permissions to support top observations and change indicators functionality within Application Signals.

It includes Amazon OpenSearch Service permissions to support vended logs dashboards in CloudWatch Logs, which are created with Amazon OpenSearch Service analytics. It includes `resource-explorer-2:` policies so that users can use the console to view unstrumented services in their account.

It includes `rum`, `synthetics`, and `xray` permissions so that users can have full access to CloudWatch Synthetics, AWS X-Ray, and CloudWatch RUM, all of which are under the CloudWatch service.

To see the full contents of the policy, see CloudWatchFullAccessV2 in the *AWS Managed Policy Reference Guide*.

CloudWatchFullAccess

The **CloudWatchFullAccess** policy is on the path to deprecation. We recommend that you stop using it, and use CloudWatchFullAccessV2 instead.

CloudWatchReadOnlyAccess

The **CloudWatchReadOnlyAccess** policy grants read-only access to CloudWatch and related observability features.

The policy includes some `logs:` permissions, so that users with this policy can use the console to view CloudWatch Logs information and CloudWatch Logs Insights queries. It includes `autoscaling:Describe*`, so that users with this policy can see the Auto Scaling actions that are associated with CloudWatch alarms. It includes the `application-signals:` permissions so that users can use Application Signals to monitor the health of their services. It includes `application-autoscaling:DescribeScalingPolicies`, so that users with this policy can access information about Application Auto Scaling policies. It includes `sns:Get*` and `sns:List*`, so that users with this policy can retrieve information about the Amazon SNS topics that receive notifications about CloudWatch alarms. It includes the `oam:ListSinks` and `oam:ListAttachedLinks` permissions, so that users with this policy can use the console to view data shared from source accounts in CloudWatch cross-account observability. It includes the `iam:GetRole` permissions so that users can check if CloudWatch Application Signals have been set up. It also includes CloudTrail and Service Quotas permissions to support top observations and change indicators functionality within Application Signals. It includes observability administration permissions for viewing telemetry rules, centralization configurations, and resource telemetry data across AWS Organizations. It includes the `cloudwatch:GenerateQuery` permission, so that users with this policy can generate a CloudWatch Metrics Insights query string from a natural language prompt. It includes `resource-explorer-2:` policies so that users can use the console to view unstrumented services in their account.

It includes `rum`, `synthetics`, and `xray` permissions so that users can have read-only access to CloudWatch Synthetics, AWS X-Ray, and CloudWatch RUM, all of which are under the CloudWatch service.

To see the full contents of the policy, see CloudWatchReadOnlyAccess in the *AWS Managed Policy Reference Guide*.

CloudWatchActionsEC2Access

The **CloudWatchActionsEC2Access** policy grants read-only access to CloudWatch alarms and metrics in addition to Amazon EC2 metadata. It also grants access to the Stop, Terminate, and Reboot API actions for EC2 instances.

To see the full contents of the policy, see CloudWatchActionsEC2Access in the *AWS Managed Policy Reference Guide*.

CloudWatch-CrossAccountAccess

The **CloudWatch-CrossAccountAccess** managed policy is used by the **CloudWatch-CrossAccountSharingRole** IAM role. This role and policy enable users of cross-account dashboards to view automatic dashboards in each account that is sharing dashboards.

To see the full contents of the policy, see CloudWatch-CrossAccountAccess in the *AWS Managed Policy Reference Guide*.

CloudWatchAutomaticDashboardsAccess

The **CloudWatchAutomaticDashboardsAccess** managed policy grants access to CloudWatch for non-CloudWatch APIs, so that resources such as Lambda functions can be displayed on CloudWatch automatic dashboards.

To see the full contents of the policy, see CloudWatchAutomaticDashboardsAccess in the *AWS Managed Policy Reference Guide*.

CloudWatchAgentServerPolicy

The **CloudWatchAgentServerPolicy** policy can be used in IAM roles that are attached to Amazon EC2 instances to allow the CloudWatch agent to read information from the instance and write it to CloudWatch.

To see the full contents of the policy, see CloudWatchAgentServerPolicy in the *AWS Managed Policy Reference Guide*.

CloudWatchAgentAdminPolicy

The **CloudWatchAgentAdminPolicy** policy can be used in IAM roles that are attached to Amazon EC2 instances. This policy allows the CloudWatch agent to read information from the instance and write it to CloudWatch, and also to write information to Parameter Store.

To see the full contents of the policy, see CloudWatchAgentAdminPolicy in the *AWS Managed Policy Reference Guide*.

CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy

You can't attach `CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy` to your IAM entities. This policy is attached to a service-linked role named **AWSServiceRoleForNetworkFlowMonitor_Topology**. Using these permissions, as well as internal meta data information gathering (for performance efficiencies), this service-linked role gathers

meta data about resource network configurations, such as describing route tables and gateways, for resources that this service monitors network traffic for. This meta data enables Network Flow Monitor to generate topology snapshots of the resources. When there is network degradation, Network Flow Monitor uses the topologies to provide insights into the location of issues in the network and to help determine attribution for issues.

To view the permissions for this policy, see CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy in the *AWS Managed Policy Reference*.

For more information, see Service-linked roles for Network Flow Monitor.

> **Note**
>
> You can review these permissions policies by signing in to the IAM console and searching for specific policies there.

You can also create your own custom IAM policies to allow permissions for CloudWatch actions and resources. You can attach these custom policies to the IAM users or groups that require those permissions.

AWS managed (predefined) policies for CloudWatch cross-account observability

The policies in this section grant permissions related to CloudWatch cross-account observability. For more information, see CloudWatch cross-account observability.

CloudWatchCrossAccountSharingConfiguration

The **CloudWatchCrossAccountSharingConfiguration** policy grants access to create, manage, and view Observability Access Manager links for sharing CloudWatch resources between accounts. For more information, see CloudWatch cross-account observability.

To see the full contents of the policy, see CloudWatchCrossAccountSharingConfiguration in the *AWS Managed Policy Reference Guide*.

OAMFullAccess

The **OAMFullAccess** policy grants access to create, manage, and view Observability Access Manager sinks and links, which are used for CloudWatch cross-account observability.

The **OAMFullAccess** policy by itself does not permit you to share observability data across links. To create a link to share CloudWatch metrics, you also need either

CloudWatchFullAccess or **CloudWatchCrossAccountSharingConfiguration**. To create a link to share CloudWatch Logs log groups, you also need either **CloudWatchLogsFullAccess** or **CloudWatchLogsCrossAccountSharingConfiguration**. To create a link to share X-Ray traces, you also need either **AWSXRayFullAccess** or **AWSXRayCrossAccountSharingConfiguration**.

For more information, see CloudWatch cross-account observability.

To see the full contents of the policy, see OAMFullAccess in the *AWS Managed Policy Reference Guide*.

OAMReadOnlyAccess

The **OAMReadOnlyAccess** policy grants read-only access to Observability Access Manager resources, which are used for CloudWatch cross-account observability. For more information, see CloudWatch cross-account observability.

To see the full contents of the policy, see OAMReadOnlyAccess in the *AWS Managed Policy Reference Guide*.

AWS managed (predefined) policies for CloudWatch investigations

The policies in this section grant permissions related to CloudWatch investigations. For more information, see CloudWatch investigations.

AIOpsConsoleAdminPolicy

The **AIOpsConsoleAdminPolicy** policy grants full access to all CloudWatch investigations actions and their required permissions via the AWS console. This policy also grants limited access to other service's APIs required for CloudWatch investigations functionality.

- The `aiops` permissions grant access to all CloudWatch investigations actions.
- The `organizations`, `sso`, `identitystore`, and `sts` permissions allow actions needed for IAM Identity Center management which help identity-aware sessions.
- The `ssm` permissions are required for SSM Ops Item integration with third-party issue management.
- The `iam` permissions are needed so that administrators can pass IAM roles to the `aiops` and `ssm.integrations` services, and the role is later used by the assistant to analyze AWS resources

> **Important**
>
> These permissions allow users with this policy to pass any IAM role to the `aiops` and `ssm.integrations` services.

- It allows APIs from services outside CloudWatch investigations, which are required for investigation feature functionality. These include actions to configure Amazon Q Developer in chat applications, AWS KMS, CloudTrail trails, and SSM third-party issue management.
- The `q` permissions enable integration with Amazon Q, allowing users to interact with and update CloudWatch investigations reports through Amazon Q's conversational interface.

To see the full contents of the policy, see AIOpsConsoleAdminPolicy in the *AWS Managed Policy Reference Guide*.

AIOpsOperatorAccess

The **AIOpsOperatorAccess** policy grants access to a limited set of CloudWatch investigations APIs which include creating, updating, and deleting investigations, investigation events, and investigation resources.

This policy only provides access to investigations. You should be sure that IAM principals with this policy also have permissions to read CloudWatch observability data such as metrics, SLOs, and CloudWatch Logs query results.

- The `aiops` permissions allow access to CloudWatch investigations APIs to create, update, and delete investigations.
- The `sso-directory`, `sso`, `identitystore`, and `sts` permissions allow actions needed for IAM Identity Center management which help identity-aware sessions.
- The `ssm` permissions are required for SSM Ops Item integration with third-party issue management.
- The `q` permissions enable integration with Amazon Q, allowing users to interact with and update CloudWatch investigations reports through Amazon Q's conversational interface.

To see the full contents of the policy, see AIOpsOperatorAccess in the *AWS Managed Policy Reference Guide*.

AIOpsReadOnlyAccess

The **AIOpsReadOnlyAccess** policy grants read-only permissions for CloudWatch investigations and other related services.

- The `aiops` permissions allow access to CloudWatch investigations APIs to get, list, and validate investigation groups.
- The `sso` permissions allow actions needed for IAM Identity Center management which help identity-aware sessions.
- The `ssm` permissions are required for SSM Ops Item integration with third-party issue management.

To see the full contents of the policy, see AIOpsReadOnlyAccess in the *AWS Managed Policy Reference Guide*.

AIOpsAssistantPolicy

The **AIOpsAssistantPolicy** policy is the default policy recommended by AWS to assign to the Amazon AI Operations (AIOps) role used by your investigation group to enable it to analyze your AWS resources during investigations of operational events. This policy is not intended for use by human users.

You can choose to have the policy assigned automatically when you create an investigation, or you can assign the policy manually to the role being used by the investigation. This policy is scoped based on the resources that CloudWatch investigations analyzes when performing investigations, and will be updated as more resources are supported. For a complete list of services that work with CloudWatch investigations see, AWS services where investigations are supported.

You can also choose to assign the general AWS **ReadOnlyAccess** to the assistant in addition to assigning it **AIOpsAssistantPolicy**. The reason to do this is that **ReadOnlyAccess** will be updated more frequently by AWS with permissions for new AWS services and actions that are released. The **AIOpsAssistantPolicy** will also be updated for new actions, but not as frequently.

To see the full contents of the policy, see AIOpsAssistantPolicy in the *AWS Managed Policy Reference Guide*.

AIOpsAssistantIncidentReportPolicy

The **AIOpsAssistantIncidentReportPolicy** policy grants permissions required by CloudWatch investigations to generate incident reports from investigation data.

This policy is intended for use by CloudWatch investigations to enable automated incident report generation from investigation findings.

- The `aiops` permissions allow access to CloudWatch investigations APIs to read investigation data and events, create and update incident reports, and manage AI-derived facts that form the foundation of report generation.

To see the full contents of the policy, see AIOpsAssistantIncidentReportPolicy in the *AWS Managed Policy Reference Guide*.

AWS managed (predefined) policies for CloudWatch Application Signals

The policies in this section grant permissions related to CloudWatch Application Signals. For more information, see Application Signals.

CloudWatchApplicationSignalsReadOnlyAccess

AWS has added the **CloudWatchApplicationSignalsReadOnlyAccess** managed IAM policy. This policy grants read only access to actions and resources available to users in the CloudWatch console under Application Signals. It includes `application-signals:` policies so that users can use CloudWatch Application signals to view, investigate and monitor the health of their services. It includes an `iam:GetRole` policy to allow users to retrieve information about an IAM role. It includes `logs:` policies to start and stop queries, retrieve the configuration for a metruc filter, and obtain query results. It includes `cloudwatch:` policies so that users can obtain information about a CloudWatch alarm or metrics. It includes `synthetics:` policies so that users can retrieve information about synthetics canary runs. It includes `rum:` policies to run batch operations, retrieve data, and update metrics definitions for RUM clients. It includes an `xray:` policy to retrieve trace summaries. It includes `oam:` policies so that users can use the console to view data shared from source accounts in CloudWatch cross-account observability. It includes `resource-explorer-2:` policies so that users can use the console to view unstrumented services in their account.

To see the full contents of the policy, see CloudWatchApplicationSignalsReadOnlyAccess in the *AWS Managed Policy Reference Guide*.

CloudWatchApplicationSignalsFullAccess

AWS has added the **CloudWatchApplicationSignalsFullAccess** managed IAM policy. This policy grants access to all actions and resources available to users in the CloudWatch console.

It includes `application-signals:` policies so that users can use CloudWatch Application signals to view, investigate and monitor the health of their services. It uses `cloudwatch:` policies to retrieve data from metrics and alarms. It uses `logs:` policies to manage queries and filters. It uses `synthetics:` policies so that users can retrieve information about synthetics canary runs. It includes `rum:` policies to run batch operations, retrieve data and update metrics definitions for RUM clients. It includes an `xray:` policy to retrieve trace summaries. It includes `arn:aws:cloudwatch:*:*:alarm:` policies so that users can retrieve information about a service level objective (SLO) alarm. It includes `iam:` policies to manage IAM roles. It uses `sns:` policies to create, list, and subscribe to an Amazon SNS topic. It includes `oam:` policies so that users can use the console to view data shared from source accounts in CloudWatch cross-account observability. It includes `resource-explorer-2:` policies so that users can use the console to view unstrumented services in their account

To see the full contents of the policy, see CloudWatchApplicationSignalsFullAccess in the *AWS Managed Policy Reference Guide*.

CloudWatchLambdaApplicationSignalsExecutionRolePolicy

This policy is used when CloudWatch Application Signals is enabled for Lambda workloads. It enables write access to X-Ray and the log group used by CloudWatch Application Signals.

To see the full contents of the policy, see CloudWatchLambdaApplicationSignalsExecutionRolePolicy in the *AWS Managed Policy Reference Guide*.

AWS managed (predefined) policies for CloudWatch Synthetics

The **CloudWatchSyntheticsFullAccess** and **CloudWatchSyntheticsReadOnlyAccess** AWS managed policies are available for you to assign to users who will manage or use CloudWatch Synthetics. The following additional policies are also relevant:

- **AmazonS3ReadOnlyAccess** and **CloudWatchReadOnlyAccess** – These are necessary to read all Synthetics data in the CloudWatch console.
- **AWSLambdaReadOnlyAccess** – Required to view the source code used by canaries.
- **CloudWatchSyntheticsFullAccess** – Allows you to create canaries. Additionally, to create and delete canaries that have a new IAM role created for them, you need specific inline policy permissions.

> **Important**
>
> Granting a user the `iam:CreateRole`, `iam:DeleteRole`, `iam:CreatePolicy`, `iam:DeletePolicy`, `iam:AttachRolePolicy`, and `iam:DetachRolePolicy` permissions gives that user full administrative access to create, attach, and delete roles and policies that have ARNs that match `arn:aws:iam::*:role/service-role/CloudWatchSyntheticsRole*` and `arn:aws:iam::*:policy/service-role/CloudWatchSyntheticsPolicy*`. For example, a user with these permissions can create a policy that has full permissions for all resources, and attach that policy to any role that matches that ARN pattern. Be careful to whom you grant these permissions.

For information about attaching policies and granting permissions to users, see Changing Permissions for an IAM User and To embed an inline policy for a user or role.

CloudWatchSyntheticsFullAccess

To see the full contents of the policy, see CloudWatchSyntheticsFullAccess in the *AWS Managed Policy Reference Guide*.

CloudWatchSyntheticsReadOnlyAccess

To see the full contents of the policy, see CloudWatchSyntheticsReadOnlyAccess in the *AWS Managed Policy Reference Guide*.

AWS managed (predefined) policies for Amazon CloudWatch RUM

The **AmazonCloudWatchRUMFullAccess** and **AmazonCloudWatchRUMReadOnlyAccess** AWS managed policies are available for you to assign to users who will manage or use CloudWatch RUM.

AmazonCloudWatchRUMFullAccess

To see the full contents of the policy, see AmazonCloudWatchRUMFullAccess in the *AWS Managed Policy Reference Guide*.

AmazonCloudWatchRUMReadOnlyAccess

The **AmazonCloudWatchRUMReadOnlyAccess** allows read-only administrative access to CloudWatch RUM.

- The `synthetics` permission allows displaying associated Synthetics Canaries to the RUM app monitor
- The `cloudwatch` permission allows displaying associated CloudWatch metrics to the RUM app monitor
- The `cloudwatch alarms` permission allows displaying associated CloudWatch alarms to the RUM app monitor
- The `cloudwatch logs` permission allows displaying associated CloudWatch logs to the RUM app monitor
- The `x-ray` permission allows displaying associated X-Ray Trace segments to the RUM app monitor
- The `rum` permission allows displaying associated tags to the RUM app monitor

To see the full contents of the policy, see AmazonCloudWatchRUMReadOnlyAccess in the *AWS Managed Policy Reference Guide*.

AmazonCloudWatchRUMServiceRolePolicy

You can't attach **AmazonCloudWatchRUMServiceRolePolicy** to your IAM entities. This policy is attached to a service-linked role that allows CloudWatch RUM to publish monitoring data to other relevant AWS services. For more information about this service linked role, see Using service-linked roles for CloudWatch RUM.

To see the full contents of the policy, see AmazonCloudWatchRUMServiceRolePolicy in the *AWS Managed Policy Reference Guide*.

AWS managed policy for AWS Systems Manager Incident Manager

The **AWSCloudWatchAlarms_ActionSSMIncidentsServiceRolePolicy** policy is attached to a service-linked role that allows CloudWatch to start incidents in AWS Systems Manager Incident Manager on your behalf. For more information, see Service-linked role permissions for CloudWatch alarms Systems Manager Incident Manager actions.

The policy has the following permission:

- ssm-incidents:StartIncident

Customer managed policy examples

In this section, you can find example user policies that grant permissions for various CloudWatch actions. These policies work when you are using the CloudWatch API, AWS SDKs, or the AWS CLI.

Examples

- Example 1: Allow user full access to CloudWatch
- Example 2: Allow read-only access to CloudWatch
- Example 3: Stop or terminate an Amazon EC2 instance

Example 1: Allow user full access to CloudWatch

To grant a user full access to CloudWatch, you can use grant them the **CloudWatchFullAccess** managed policy instead of creating a customer-managed policy. The contents of the **CloudWatchFullAccess** are listed in CloudWatchFullAccess.

Example 2: Allow read-only access to CloudWatch

The following policy allows a user read-only access to CloudWatch and view Amazon EC2 Auto Scaling actions, CloudWatch metrics, CloudWatch Logs data, and alarm-related Amazon SNS data.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Action": [
        "autoscaling:Describe*",
        "cloudwatch:Describe*",
        "cloudwatch:Get*",
        "cloudwatch:List*",
        "logs:Get*",
        "logs:Describe*",
        "logs:StartQuery",
        "logs:StopQuery",
        "logs:TestMetricFilter",
        "logs:FilterLogEvents",
        "logs:StartLiveTail",
        "logs:StopLiveTail",
```

```
        "sns:Get*",
        "sns:List*"
      ],
      "Effect": "Allow",
      "Resource": "*"
    }
  ]
}
```

Example 3: Stop or terminate an Amazon EC2 instance

The following policy allows an CloudWatch alarm action to stop or terminate an EC2 instance. In the sample below, the GetMetricData, ListMetrics, and DescribeAlarms actions are optional. It is recommended that you include these actions to ensure that you have correctly stopped or terminated the instance.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Action": [
        "cloudwatch:PutMetricAlarm",
        "cloudwatch:GetMetricData",
        "cloudwatch:ListMetrics",
        "cloudwatch:DescribeAlarms"
      ],
      "Resource": [
        "*"
      ],
      "Effect": "Allow"
    },
    {
      "Action": [
        "ec2:DescribeInstanceStatus",
        "ec2:DescribeInstances",
        "ec2:StopInstances",
        "ec2:TerminateInstances"
      ],
      "Resource": [
```

```
        "*"
      ],
      "Effect": "Allow"
    }
  ]
}
```

Using condition keys to limit access to CloudWatch

See the following topics to learn about the service-specific condition keys that can be used in the `Condition` element of an IAM policy. You can use these keys to further refine the conditions under which the policy statement applies.

- Using condition keys to limit access to CloudWatch namespaces
- Condition keys for Contributor Insights log group access
- Using condition keys to limit alarm actions
- Condition keys for CloudWatch Observability Admin

To see the global condition keys that are available to all services, see Available global condition keys.

Using condition keys to limit access to CloudWatch namespaces

Use IAM condition keys to limit users to publishing metrics only in the CloudWatch namespaces that you specify. This section provides examples that describe how to allow and exclude users from publishing metrics in a namespace.

Allowing publishing in one namespace only

The following policy limits the user to publishing metrics only in the namespace named `MyCustomNamespace`.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Resource": "*",
```

```
        "Action": "cloudwatch:PutMetricData",
        "Condition": {
            "StringEquals": {
                "cloudwatch:namespace": "MyCustomNamespace"
            }
        }
    }
}
```

Excluding publishing from a namespace

The following policy allows the user to publish metrics in any namespace except for `CustomNamespace2`.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Resource": "*",
            "Action": "cloudwatch:PutMetricData"
        },
        {
            "Effect": "Deny",
            "Resource": "*",
            "Action": "cloudwatch:PutMetricData",
            "Condition": {
                "StringEquals": {
                    "cloudwatch:namespace": "CustomNamespace2"
                }
            }
        }
    ]
}
```

Controlling OTLP ingest

The following policy allows the user to publish metrics using the OTLP API:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Resource": "*",
            "Action": "cloudwatch:PutMetricData"
        }
    ]
}
```

For disabling dual ingest, that is, only using PutMetricData and deny any OTLP ingest, you can use the following policy. It limits the user to publishing metrics using PutMetricData in the namespace `MyCustomNamespace` and at the same time implicitly denies any OTLP ingest due to the `StringEquals` condition:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "cloudwatch:PutMetricData",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                     "cloudwatch:namespace": "MyCustomNamespace"
                }
            }
         }
    ]
}
```

For enabling dual ingest, that is, to allow both PutMetricData and OTLP ingest, you can use the following policy. It limits the user to publishing metrics using PutMetricData in the namespace named `MyCustomNamespace` and at the same time allows OTLP ingest due to the `StringEqualsIfExists` condition:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "cloudwatch:PutMetricData",
            "Resource": "*",
            "Condition": {
                "StringEqualsIfExists": {
                     "cloudwatch:namespace": "MyCustomNamespace"
                }
            }
         }
    ]
}
```

Condition keys for Contributor Insights log group access

To create a rule in Contributor Insights and see its results, a user must have the `cloudwatch:PutInsightRule` permission. By default, a user with this permission can create a rule that evaluates any log group in CloudWatch Logs and then view the results. Results can include contributor data from those log groups, which might contain sensitive information.

You can create IAM policies with condition keys to grant users permission to write Contributor Insights rules for specific log groups, while preventing access to data from other log groups.

For more information about the `Condition` element in IAM policies, see IAM JSON policy elements: Condition.

Understanding the Contributor Insights permissions model

Contributor Insights operations use the `cloudwatch:` IAM namespace. Log group operations use the `logs:` namespace. Contributor Insights does not require or evaluate `logs:` permissions when it processes log group data.

A principal with `cloudwatch:PutInsightRule` and `cloudwatch:GetInsightRuleReport` permissions can create rules that evaluate any log group and retrieve the results – even without any `logs:` permissions on those log groups.

Important

Aggregated results can contain sensitive information, such as log fields used as contributor keys. Grant `cloudwatch:PutInsightRule` and `cloudwatch:GetInsightRuleReport` permissions only to principals who need access to data across all referenced log groups.

For cross-account access, if a source account configured an AWS Organizations link that shares log group access, a principal in the monitoring account needs only `cloudwatch:PutInsightRule` to create rules that target source account log groups.

Restricting Contributor Insights access to specific log groups

Use the following condition keys to restrict which log groups a principal can specify when creating Contributor Insights rules:

- `cloudwatch:requestInsightRuleLogGroups` – Matches log group names specified in a rule
- `cloudwatch:requestInsightRuleLogGroupARNs` – Matches log group ARNs specified in a rule

Important

After a rule is created, any principal with `cloudwatch:GetInsightRuleReport` permission can retrieve its results, regardless of log group restrictions.

The following policy grants permission to create Contributor Insights rules for the log group named `AllowedLogGroup` and log groups with names that start with `AllowedWildCard`. It does not grant permission to create rules for any other log groups.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowCertainLogGroups",
            "Effect": "Allow",
```

```
            "Action": "cloudwatch:PutInsightRule",
            "Resource": "arn:aws:cloudwatch:*:*:insight-rule/*",
            "Condition": {
                "ForAllValues:StringLike": {
                    "cloudwatch:requestInsightRuleLogGroups": [
                        "AllowedLogGroup",
                        "AllowedWildcard*"
                    ]
                }
            }
        }
    ]
}
```

The following policy allows creating rules for any log group by default, but explicitly denies creating rules for the log group named `ExplicitlyDeniedLogGroup`.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AllowInsightRulesOnLogGroupsByDefault",
            "Effect": "Allow",
            "Action": "cloudwatch:PutInsightRule",
            "Resource": "arn:aws:cloudwatch:*:*:insight-rule/*"

        },
        {
            "Sid": "ExplicitDenySomeLogGroups",
            "Effect": "Deny",
            "Action": "cloudwatch:PutInsightRule",
            "Resource": "arn:aws:cloudwatch:*:*:insight-rule/*",
            "Condition": {
                "ForAllValues:StringEqualsIgnoreCase": {
                    "cloudwatch:requestInsightRuleLogGroups": [
                        "/test/alpine/ExplicitlyDeniedLogGroup"
                    ]
                }
            }
```

```
        }
    ]
}
```

The following policy denies creation of rules that target log groups with `/production/` in the ARN path.

```
{
    "Version": "       ",
    "Statement": [
        {
            "Sid": "DenyProductionLogGroupsByARN",
            "Effect": "Deny",
            "Action": "cloudwatch:PutInsightRule",
            "Resource": "*",
            "Condition": {
                "ForAnyValue:StringLike": {
                    "cloudwatch:requestInsightRuleLogGroupARNs": [
                        "arn:aws:logs:*:*:log-group:*/production/*"
                    ]
                }
            }
        }
    ]
}
```

Note

- Condition keys match against the pattern strings as written in the rule definition, not against the resolved log groups.
- If rules specify log groups as full ARNs, a condition value such as `/production/*` does not match because the full ARN string does not start with that prefix. Use `*/production/*` as the wildcard prefix to match ARN-based log group references.

Security best practices for Contributor Insights

Follow these best practices to secure your Contributor Insights configuration.

- **Apply least privilege** – Grant `cloudwatch:PutInsightRule` and `cloudwatch:GetInsightRuleReport` only to principals who must analyze log group data
- **Use condition keys to restrict log groups** – Limit which log groups a principal can reference in Contributor Insights rules
- **Protect sensitive fields** – Use CloudWatch Logs data protection to mask sensitive log data before Contributor Insights processes it. For more information, see Protect sensitive log data with masking.
- **Consider contributor key sensitivity** – Contributor keys might expose values such as IP addresses or user identifiers in rule results
- **Review cross-account access** – Audit AWS Organizations link configurations to confirm that only intended monitoring accounts can create rules against source account log groups

Using condition keys to limit alarm actions

When CloudWatch alarms change state, they can perform different actions such as stopping and terminating EC2 instances and performing Systems Manager actions. These actions can be initiated when the alarm changes to any state, including ALARM, OK, or INSUFFICIENT_DATA.

Use the `cloudwatch:AlarmActions` condition key to allow a user to create alarms that can only perform the actions you specify when the alarm state changes. For example, you can allow a user to create alarms that can only perform actions which are not EC2 actions.

Allow a user to create alarms that can only send Amazon SNS notifications or perform Systems Manager actions

The following policy limits the user to creating alarms that can only send Amazon SNS notifications and perform Systems Manager actions. The user can't create alarms that perform EC2 actions.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "CreateAlarmsThatCanPerformOnlySNSandSSMActions",
            "Effect": "Allow",
            "Action": "cloudwatch:PutMetricAlarm",
```

```
            "Resource": "*",
            "Condition": {
                "ForAllValues:StringLike": {
                    "cloudwatch:AlarmActions": [
                        "arn:aws:sns:*",
                        "arn:aws:ssm:*"
                    ]
                }
            }
        }
    ]
}
```

Condition keys for CloudWatch Observability Admin

You can use IAM policies to control access to Amazon CloudWatch Observability Admin resources and actions by using condition keys.

Observability Admin has the following condition keys:

Condition Key	Description	Type
CentralizationSourceRegions	ArrayOfString	Filters access by the source Regions that are passed in the request
CentralizationDestinationRegion	String	Filters access by the destination Region that is passed in the request
CentralizationBackupRegion	String	Filters access by the backup Region that is passed in the request

CentralizationSourceRegions

Filters access by the backup region specified for centralization rules.

- *Availability* – This key is available for the following resource types: organization-centralization-rule
- *Value type* – String

Example JSON policy with observabilityadmin:CentralizationBackupRegion

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "cloudwatch:PutMetricData",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
        "aws:RequestedRegion": "us-east-1"
        }
      }
    }
  ]
}
```

CentralizationDestinationRegion

Filters access by the destination region specified for centralization rules.

- *Availability* – This key is available for the following resource types: organization-centralization-rule
- *Value type* – String

Example JSON policy with observabilityadmin:CentralizationDestinationRegion

JSON

```
{
  "Version":"2012-10-17",
```

```
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "cloudwatch:PutMetricData",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
        "aws:RequestedRegion": "us-east-1"
        }
      }
    }
  ]
}
```

CentralizationBackupRegion

Filters access by the source regions specified for centralization rules.

- *Availability* – This key is available for the following resource types: organization-centralization-rule
- *Value type* – List of strings

Example JSON policy with observabilityadmin:CentralizationSourceRegions

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "cloudwatch:PutMetricData",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
        "aws:RequestedRegion": ["us-east-1", "us-east-1"]
        }
      }
    }
  ]
```

```
}
```

Using service-linked roles for CloudWatch

Amazon CloudWatch uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to CloudWatch. Service-linked roles are predefined by CloudWatch and include all the permissions that the service requires to call other AWS services on your behalf.

One service-linked role in CloudWatch makes setting up CloudWatch alarms that can terminate, stop, or reboot an Amazon EC2 instance without requiring you to manually add the necessary permissions. Another service-linked role enables a monitoring account to access CloudWatch data from other accounts that you specify, to build cross-account cross-Region dashboards.

CloudWatch defines the permissions of these service-linked roles, and unless defined otherwise, only CloudWatch can assume the role. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete the roles only after first deleting their related resources. This restriction protects your CloudWatch resources because you can't inadvertently remove permissions to access the resources.

For information about other services that support service-linked roles, see AWS Services That Work with IAM and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for CloudWatch alarms EC2 actions

CloudWatch uses the service-linked role named **AWSServiceRoleForCloudWatchEvents** – CloudWatch uses this service-linked role to perform Amazon EC2 alarm actions.

The AWSServiceRoleForCloudWatchEvents service-linked role trusts the CloudWatch Events service to assume the role. CloudWatch Events invokes the terminate, stop, or reboot instance actions when called upon by the alarm.

The AWSServiceRoleForCloudWatchEvents service-linked role permissions policy allows CloudWatch Events to complete the following actions on Amazon EC2 instances:

- `ec2:StopInstances`
- `ec2:TerminateInstances`

- ec2:RecoverInstances
- ec2:DescribeInstanceRecoveryAttribute
- ec2:DescribeInstances
- ec2:DescribeInstanceStatus

The **ServiceRoleForCloudWatchCrossAccountV2** service role permissions policy allows CloudWatch to complete the following actions:

- sts:AssumeRole

Service-linked role permissions for CloudWatch telemetry config

CloudWatch observability admin creates and uses a service-linked role named **AWSServiceRoleForObservabilityAdmin** – CloudWatch uses this service-linked role to support resource and telemetry config discovery for AWS Organizations. When a management account creates an organization-level rule, the service-linked role is automatically created in all member accounts and the delegated administrator account in the organization. However, when a delegated administrator account creates an organization-level rule, the service-linked role is automatically created in all member accounts but is *not* automatically created in the management account. If a delegated administrator account creates the organization-level rule, you must manually create the service-linked role in the management account.

The **AWSServiceRoleForObservabilityAdmin** service-linked role trusts Observability Admin to assume the role. Observability Admin manages AWS Config Service Linked Configuration Recorders and Service Linked Configuration Aggregator in your Organizations accounts.

The **AWSServiceRoleForObservabilityAdmin** service-linked role has a policy, called AWSObservabilityAdminServiceRolePolicy, attached and this policy grants permission to CloudWatch Observability Admin to complete the following actions:

- organizations:ListAccounts
- organizations:ListAccountsForParent
- organizations:ListChildren
- organizations:ListParents
- organizations:DescribeOrganization
- organizations:DescribeOrganizationalUnit

- organizations:EnableAWSServiceAccess
- organizations:ListDelegatedAdministrators
- config:PutServiceLinkedConfigurationRecorder
- config:DeleteServiceLinkedConfigurationRecorder
- config:PutConfigurationAggregator
- config:DeleteConfigurationAggregator
- config:SelectAggregateResourceConfig
- iam:CreateServiceLinkedRole
- iam:PassRole

The complete contents of the AWSObservabilityAdminServiceRolePolicy policy are as follows:

JSON

```
{
 "Version":"2012-10-17",
 "Statement": [
  {
   "Effect": "Allow",
   "Action": [
    "organizations:ListAccounts",
    "organizations:ListAccountsForParent",
    "organizations:ListChildren",
    "organizations:ListParents",
    "organizations:DescribeOrganization",
    "organizations:DescribeOrganizationalUnit"
   ],
   "Resource": "*"
  },
  {
   "Effect": "Allow",
   "Action": [
    "config:PutServiceLinkedConfigurationRecorder",
    "config:DeleteServiceLinkedConfigurationRecorder"
   ],
   "Resource": [
    "arn:aws:config:*:*:configuration-recorder/
AWSConfigurationRecorderForObservabilityAdmin/*"
```

```
    ]
   },
   {
    "Effect": "Allow",
    "Action": [
     "config:PutConfigurationAggregator",
     "config:DeleteConfigurationAggregator",
     "config:SelectAggregateResourceConfig"
    ],
    "Resource": [
     "arn:aws:config:*:*:config-aggregator/aws-service-config-aggregator/
observabilityadmin.amazonaws.com/*"
    ]
   },
   {
    "Effect": "Allow",
    "Action": [
     "iam:CreateServiceLinkedRole"
    ],
    "Resource": [
     "arn:aws:iam::*:role/aws-service-role/config.amazonaws.com/
AWSServiceRoleForConfig"
    ],
    "Condition": {
     "StringEquals": {
      "iam:AWSServiceName": [
       "config.amazonaws.com"
      ]
     }
    }
   },
   {
    "Effect": "Allow",
    "Action": [
     "iam:PassRole"
    ],
    "Resource": [
     "arn:aws:iam::*:role/aws-service-role/config.amazonaws.com/
AWSServiceRoleForConfig"
    ],
    "Condition": {
     "StringEquals": {
      "iam:PassedToService": [
       "config.amazonaws.com"
```

```
      ]
     }
    }
   },
   {
    "Effect": "Allow",
    "Action": [
     "organizations:EnableAWSServiceAccess"
    ],
    "Resource": "*",
    "Condition": {
     "StringEquals": {
      "organizations:ServicePrincipal": [
       "config.amazonaws.com"
      ]
     }
    }
   },
   {
    "Effect": "Allow",
    "Action": [
     "organizations:ListDelegatedAdministrators"
    ],
    "Resource": "*",
    "Condition": {
     "StringEquals": {
      "organizations:ServicePrincipal": [
       "observabilityadmin.amazonaws.com",
       "config.amazonaws.com"
      ]
     }
    }
   }
  ]
}
```

Service-linked role permissions for CloudWatch telemetry enablement

The `AWSObservabilityAdminTelemetryEnablementServiceRolePolicy` grants permissions necessary to enable and manage telemetry configurations for AWS resources based on telemetry rules.

This policy grants permissions for:

- Basic telemetry operations including describing VPCs, flow logs, log groups. It also includes permissions to enable logging configuration for EKS cluster logging, WAF put logging configuration, enabling NLB logs, Route53 Resolver query logging, Amazon EC2 detailed monitoring, AWS Security Hub, Amazon Bedrock Agentcore Gateway, Amazon Bedrock Agentcore Memory, Amazon CloudFront distribution, S3 bucket server access logs, MSK Cluster, OpenTelemetry Enrichment, and Amazon Bedrock Agentcore Workload Identity.
- Resource tagging operations with the `CloudWatchTelemetryRuleManaged` tag for tracking managed resources
- Log delivery configuration for services like AWS Bedrock and VPC Flow Logs
- Configuration recorder management for telemetry enablement tracking

The policy enforces security boundaries through conditions that:

- Restrict operations to resources within the same account using `aws:ResourceAccount`
- Require the `CloudWatchTelemetryRuleManaged` tag for resource modifications
- Limit configuration recorder access to those associated with telemetry enablement

The complete contents of the AWSObservabilityAdminTelemetryEnablementServiceRolePolicy policy can be found here: AWSObservabilityAdminTelemetryEnablementServiceRolePolicy.

Service-linked role permissions for CloudWatch Application Signals

CloudWatch Application Signals uses the service-linked role named **AWSServiceRoleForCloudWatchApplicationSignals** – CloudWatch uses this service-linked role to collect CloudWatch Logs data, X-Ray trace data, CloudWatch metrics data, and tagging data from applications that you have enabled for CloudWatch Application Signals.

The **AWSServiceRoleForCloudWatchApplicationSignals** service-linked role trusts CloudWatch Application Signals to assume the role. Application Signals collects the logs, traces, metrics, and tags data from your account.

The **AWSServiceRoleForCloudWatchApplicationSignals** has an IAM policy attached, and this policy is named **CloudWatchApplicationSignalsServiceRolePolicy**. This policy grants permission to CloudWatch Application Signals to collect monitoring and tagging data from other relevant AWS services. It includes permissions for Application Signals to complete the following actions:

- `xray` – Retrieve X-Ray traces.
- `logs` – Retrieve the current CloudWatch logs information.
- `cloudwatch` – Retrieve the current CloudWatch metric information.
- `tags` – Retrieve the current tags.
- `application-signals` – Retrieve information on SLOs and their associated time exclusion windows.
- `autoscaling` – Retrieve application tags from Amazon EC2 Autoscaling group.
- `resource-explorer-2` – Retrieve current AWS resources information from AWS Resource Explorer.
- `cloudtrail` – Enable creation of service-linked channels for retrieving CloudTrail events.

The complete contents of **CloudWatchApplicationSignalsServiceRolePolicy** are as follows:

JSON

```
{
 "Version":"2012-10-17",
 "Statement": [
  {
   "Sid": "XRayPermission",
   "Effect": "Allow",
   "Action": [
    "xray:GetServiceGraph"
   ],
   "Resource": [
    "*"
   ],
   "Condition": {
    "StringEquals": {
     "aws:ResourceAccount": "${aws:PrincipalAccount}"
    }
   }
  },
  {

     ],
     "Resource": [
      "*"
     ],
     "Condition": {
      "StringEquals": {
       "aws:ResourceAccount": "${aws:PrincipalAccount}"
      }
     }
    }
   ]
}
```

Service-linked role permissions for CloudWatch alarms Systems Manager OpsCenter actions

CloudWatch uses the service-linked role named **AWSServiceRoleForCloudWatchAlarms_ActionSSM** – CloudWatch uses this service-linked role to perform Systems Manager OpsCenter actions when a CloudWatch alarm goes into ALARM state.

The AWSServiceRoleForCloudWatchAlarms_ActionSSM service-linked role trusts the CloudWatch service to assume the role. CloudWatch alarms invoke the Systems Manager OpsCenter actions when called upon by the alarm.

The **AWSServiceRoleForCloudWatchAlarms_ActionSSM** service-linked role permissions policy allows Systems Manager to complete the following actions:

- `ssm:CreateOpsItem`

Service-linked role permissions for CloudWatch alarms Systems Manager Incident Manager actions

CloudWatch uses the service-linked role named **AWSServiceRoleForCloudWatchAlarms_ActionSSMIncidents** – CloudWatch uses this service-linked role to start Incident Manager incidents when a CloudWatch alarm goes into ALARM state.

The **AWSServiceRoleForCloudWatchAlarms_ActionSSMIncidents** service-linked role trusts the CloudWatch service to assume the role. CloudWatch alarms invoke the Systems Manager Incident Manager action when called upon by the alarm.

The **AWSServiceRoleForCloudWatchAlarms_ActionSSMIncidents** service-linked role permissions policy allows Systems Manager to complete the following actions:

- `ssm-incidents:StartIncident`

Service role permissions for CloudWatch cross-account cross-Region

CloudWatch uses the service role named **ServiceRoleForCloudWatchCrossAccountV2** – CloudWatch uses this role to access CloudWatch data in other AWS accounts that you specify. The SLR only provides the assume role permission to allow the CloudWatch service to assume the role in the sharing account. It is the sharing role that provides access to data.

The **ServiceRoleForCloudWatchCrossAccountV2** service role permissions policy allows CloudWatch to complete the following actions:

- `sts:AssumeRole`

The **ServiceRoleForCloudWatchCrossAccountV2** service role trusts the CloudWatch service to assume the role.

Service-linked role permissions for CloudWatch database Performance Insights

CloudWatch uses the service-linked role named **AWSServiceRoleForCloudWatchMetrics_DbPerfInsights** – CloudWatch uses this role to retrieve Performance Insights metrics for creating alarms and snapshotting.

The **AWSServiceRoleForCloudWatchMetrics_DbPerfInsights** service-linked role has the `AWSServiceRoleForCloudWatchMetrics_DbPerfInsightsServiceRolePolicy` IAM policy attached. The contents of that policy are as follows:

JSON

```
{
 "Version":"2012-10-17",
 "Statement": [
  {
   "Effect": "Allow",
   "Action": [
    "pi:GetResourceMetrics"
   ],
   "Resource": "*",
   "Condition": {
    "StringEquals": {
     "aws:ResourceAccount": "${aws:PrincipalAccount}"
    }
   }
  }
 ]
}
```

The **AWSServiceRoleForCloudWatchMetrics_DbPerfInsights** service-linked role trusts the CloudWatch service to assume the role.

Service-linked role permissions for CloudWatch Logs centralization

The **AWSObservabilityAdminLogsCentralizationServiceRolePolicy** attaches to appropriate IAM entity in your central management account, such as the CloudWatch service role –, to grant necessary permissions for setting up and managing centralized log collection. CloudWatch uses this role to access telemetry data from other AWS accounts that you specify to create CloudWatch log groups, log streams, and log events in your organization's monitoring account. The SLR only provides the assume role permission to allow the CloudWatch service to assume the role in the monitoring account. This policy is attached automatically if you set up centralized log collection using the AWS Management Console. If you use the AWS CLI or API to configure log centralization you must attach this policy manually to the IAM role that will be used for observability administration tasks.

The **AWSObservabilityAdminLogsCentralizationServiceRolePolicy** service-linked role permissions policy allows CloudWatch to complete the following actions:

- `sts:AssumeRole`
- `logs:CreateLogGroup`
- `logs:CreateLogStream`
- `logs:PutLogEvents`
- `kms:Encrypt`
- `kms:Decrypt`
- `kms:GenerateDataKey`

The **AWSObservabilityAdminLogsCentralizationServiceRolePolicy** service-linked role trusts the `logs-centralization.observabilityadmin.amazonaws.com` service to assume the role.

Creating a service-linked role for CloudWatch

You do not need to manually create any of these service-linked roles. The first time you create an alarm in the AWS Management Console, the IAM CLI, or the IAM API, CloudWatch creates AWSServiceRoleForCloudWatchEvents and **AWSServiceRoleForCloudWatchAlarms_ActionSSM** for you.

The first time that you enable service and topology discovery, Application Signals creates **AWSServiceRoleForCloudWatchApplicationSignals** for you.

When you first enable an account to be a monitoring account for cross-account cross-Region functionality, CloudWatch creates **ServiceRoleForCloudWatchCrossAccountV2** for you.

When you first create an alarm that uses the `DB_PERF_INSIGHTS` metric math function, CloudWatch creates **AWSServiceRoleForCloudWatchMetrics_DbPerfInsights** for you.

For more information, see Creating a Service-Linked Role in the *IAM User Guide*.

Editing a service-linked role for CloudWatch

CloudWatch does not allow you to edit the **AWSServiceRoleForCloudWatchEvents**, **AWSServiceRoleForCloudWatchAlarms_ActionSSM**, **ServiceRoleForCloudWatchCrossAccountV2**, or **AWSServiceRoleForCloudWatchMetrics_DbPerfInsights** roles. After you create these roles, you cannot change their names because various entities might reference these roles. However, you can edit the description of these roles using IAM.

Editing a service-linked role description (IAM console)

You can use the IAM console to edit the description of a service-linked role.

To edit the description of a service-linked role (console)

1. In the navigation pane of the IAM console, choose **Roles**.
2. Choose the name of the role to modify.
3. To the far right of **Role description**, choose **Edit**.
4. Type a new description in the box, and choose **Save**.

Editing a service-linked role description (AWS CLI)

You can use IAM commands from the AWS Command Line Interface to edit the description of a service-linked role.

To change the description of a service-linked role (AWS CLI)

1. (Optional) To view the current description for a role, use the following commands:

```
$ aws iam get-role --role-name role-name
```

Use the role name, not the ARN, to refer to roles with the AWS CLI commands. For example, if a role has the following ARN: `arn:aws:iam::123456789012:role/myrole`, you refer to the role as **`myrole`**.

2. To update a service-linked role's description, use the following command:

```
$ aws iam update-role-description --role-name role-name --description description
```

Editing a service-linked role description (IAM API)

You can use the IAM API to edit the description of a service-linked role.

To change the description of a service-linked role (API)

1. (Optional) To view the current description for a role, use the following command:

   GetRole

2. To update a role's description, use the following command:

   UpdateRoleDescription

Deleting a service-linked role for CloudWatch

If you no longer have alarms that automatically stop, terminate, or reboot EC2 instances, we recommend that you delete the AWSServiceRoleForCloudWatchEvents role.

If you not longer have alarms that perform Systems Manager OpsCenter actions, we recommend that you delete the AWSServiceRoleForCloudWatchAlarms_ActionSSM role.

If you delete all alarms that use the `DB_PERF_INSIGHTS` metric math function, we recommend that you delete the **AWSServiceRoleForCloudWatchMetrics_DbPerfInsights** service-linked role.

That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up your service-linked role before you can delete it.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

To check whether the service-linked role has an active session in the IAM console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**. Choose the name (not the check box) of the AWSServiceRoleForCloudWatchEvents role.
3. On the **Summary** page for the selected role, choose **Access Advisor** and review the recent activity for the service-linked role.

> **Note**
>
> If you are unsure whether CloudWatch is using the AWSServiceRoleForCloudWatchEvents role, try to delete the role. If the service is using the role, then the deletion fails and you can view the Regions where the role is being used. If the role is being used, then you must wait for the session to end before you can delete the role. You cannot revoke the session for a service-linked role.

Deleting a service-linked role (IAM console)

You can use the IAM console to delete a service-linked role.

To delete a service-linked role (console)

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**. Select the check box next to the name of the role you want to delete, not the name or row itself.
3. For **Role actions**, choose **Delete role**.
4. In the confirmation dialog box, review the service last accessed data, which shows when each of the selected roles last accessed an AWS service. This helps you to confirm whether the role is currently active. To proceed, choose **Yes, Delete**.
5. Watch the IAM console notifications to monitor the progress of the service-linked role deletion. Because the IAM service-linked role deletion is asynchronous, the deletion task can succeed or fail after you submit the role for deletion. If the task fails, choose **View details** or **View Resources** from the notifications to learn why the deletion failed. If the deletion fails because there are resources in the service that are being used by the role, then the reason for the failure includes a list of resources.

Deleting a service-linked role (AWS CLI)

You can use IAM commands from the AWS Command Line Interface to delete a service-linked role.

To delete a service-linked role (AWS CLI)

1. Because a service-linked role cannot be deleted if it is being used or has associated resources, you must submit a deletion request. That request can be denied if these conditions are not met. You must capture the `deletion-task-id` from the response to check the status of the deletion task. Type the following command to submit a service-linked role deletion request:

   ```
   $ aws iam delete-service-linked-role --role-name service-linked-role-name
   ```

2. Type the following command to check the status of the deletion task:

   ```
   $ aws iam get-service-linked-role-deletion-status --deletion-task-id deletion-task-id
   ```

   The status of the deletion task can be `NOT_STARTED`, `IN_PROGRESS`, `SUCCEEDED`, or `FAILED`. If the deletion fails, the call returns the reason that it failed so that you can troubleshoot.

Deleting a service-linked role (IAM API)

You can use the IAM API to delete a service-linked role.

To delete a service-linked role (API)

1. To submit a deletion request for a service-linked role, call DeleteServiceLinkedRole. In the request, specify the role name that you want to delete.

   Because a service-linked role cannot be deleted if it is being used or has associated resources, you must submit a deletion request. That request can be denied if these conditions are not met. You must capture the `DeletionTaskId` from the response to check the status of the deletion task.

2. To check the status of the deletion, call GetServiceLinkedRoleDeletionStatus. In the request, specify the `DeletionTaskId`.

   The status of the deletion task can be `NOT_STARTED`, `IN_PROGRESS`, `SUCCEEDED`, or `FAILED`. If the deletion fails, the call returns the reason that it failed so that you can troubleshoot.

CloudWatch updates to AWS service-linked roles

View details about updates to AWS managed policies for CloudWatch since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the CloudWatch Document history page.

Change	Description	Date
AWSObservabilityAdminTelemetryEnablementServiceRolePolicy – Update to service-linked role policy.	Updated information about the AWSObservabilityAdminTelemetryEnablementServiceRolePolicy that grants CloudWatch the permissions necessary to enable and manage telemetry configurations for the additional AWS resources based on telemetry rules.	April 30, 2026
AWSObservabilityAdminTelemetryEnablementServiceRolePolicy – Update to service-linked role policy.	Updated information about the AWSObservabilityAdminTelemetryEnablementServiceRolePolicy that grants CloudWatch the permissions necessary to enable and manage telemetry configurations for the additional AWS resources based on telemetry rules.	March 31, 2026
AWSObservabilityAdminTelemetryEnablementServiceRolePolicy – Update to service-linked role policy.	Updated information about the AWSObservabilityAdminTelemetryEnablementServiceRolePolicy that grants CloudWatch the permissions necessary to enable and manage	March 10, 2026

Change	Description	Date
	telemetry configurations for the additional AWS resources based on telemetry rules.	
AWSObservabilityAdminTelemetryEnablementServiceRolePolicy – Update to service-linked role policy.	Updated information about the AWSObservabilityAdminTelemetryEnablementServiceRolePolicy that grants CloudWatch the permissions necessary to enable and manage telemetry configurations for the additional AWS resources based on telemetry rules.	December 2, 2025
AWSServiceRoleForCloudWatchApplicationSignals – Update to permissions of service-linked role policy	Updated the CloudWatchApplicationSignalsServiceRolePolicy to include `resource-explorer-2:Search` and `cloudtrail:CreateServiceLinkedChannel` to enable new Application Signals features.	November 12, 2025
AWSObservabilityAdminLogsCentralizationServiceRolePolicy – New service-linked role policy.	Added information about the AWSObservabilityAdminLogsCentralizationServiceRolePolicy that grants CloudWatch the permissions necessary to enable and manage telemetry configurations for AWS resources based on telemetry rules.	September 5, 2025

Change	Description	Date
AWSObservabilityAdminTelemetryEnablementServiceRolePolicy – New service-linked role policy.	Added information about the AWSObservabilityAdminTelemetryEnablementServiceRolePolicy that grants CloudWatch the permissions necessary to enable and manage telemetry configurations for AWS resources based on telemetry rules.	July 17, 2025
AWSServiceRoleForCloudWatchApplicationSignals – Update to permissions of service-linked role policy	Updated the CloudWatchApplicationSignalsServiceRolePolicy to exclude time windows from impacting the SLO attainment rate, error budget, and burn rate metrics. CloudWatch can retrieve exclusion windows on behalf of you.	March 13, 2025
AWSServiceRoleForObservabilityAdmin – New service-linked role	CloudWatch added this new service-linked role and corresponding managed policy, AWSObservabilityAdminServiceRolePolicy, to support resource and telemetry config discovery for AWS Organizations.	November 26, 2024

Change	Description	Date
AWSServiceRoleForCloudWatchApplicationSignals – Update to permissions of service-linked role policy	CloudWatch add more log groups to the scope of the `logs:StartQuery` and `logs:GetQueryResults` permissions granted by this role.	April 24, 2024
AWSServiceRoleForCloudWatchApplicationSignals – New service-linked role	CloudWatch added this new service-linked role to allow CloudWatch Application Signals to collect CloudWatch Logs data, X-Ray trace data, CloudWatch metrics data, and tagging data from applications that you have enabled for CloudWatch Application Signals.	November 9, 2023
AWSServiceRoleForCloudWatchMetrics_DbPerfInsights – New service-linked role	CloudWatch added this new service-linked role to allow CloudWatch to fetch Performance Insights metrics for alarming and snapshotting. An IAM policy is attached to this role, and the policy grants permission to CloudWatch to fetch Performance Insights metrics on your behalf.	September 13, 2023

Change	Description	Date
AWSServiceRoleFo rCloudWatchAlarms_ ActionSSMIncidents – New service-linked role	CloudWatch added a new service-linked role to allow CloudWatch to create in cidents in AWS Systems Manager Incident Manager.	April 26, 2021
CloudWatch started tracking changes	CloudWatch started tracking changes for its service-linked roles.	April 26, 2021

Using service-linked roles for CloudWatch RUM

CloudWatch RUM uses a AWS Identity and Access Management (IAM) service-linked role. A service-linked role is a unique type of IAM role that is linked directly to RUM. The service-linked role is predefined by RUM and includes all the permissions that the service requires to call other AWS services on your behalf.

RUM defines the permissions of the service-linked role, and unless defined otherwise, only RUM can assume the role. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete the role only after first deleting its related resources. This restriction protects your RUM resources because you can't inadvertently remove permissions to access the resources.

For information about other services that support service-linked roles, see AWS services that work with IAM and look for the services that have **Yes** in the **Service-linked roles** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for RUM

RUM uses the service-linked role named **AWSServiceRoleForCloudWatchRUM** – this role allows RUM to send AWS X-Ray trace data into your account, for app monitors that you enable X-Ray tracing for.

The **AWSServiceRoleForCloudWatchRUM** service-linked role trusts the X-Ray service to assume the role. X-Ray sends the trace data to your account.

The **AWSServiceRoleForCloudWatchRUM** service-linked role has an IAM policy attached named **AmazonCloudWatchRUMServiceRolePolicy**. This policy grants permission to CloudWatch RUM to publish monitoring data to other relevant AWS services. It includes permissions that allow RUM to complete the following actions:

- `xray:PutTraceSegments`
- `cloudwatch:PutMetricData`

The complete contents of **AmazonCloudWatchRUMServiceRolePolicy** are as follows.

JSON

```
{
 "Version":"2012-10-17",
 "Statement": [
  {
   "Effect": "Allow",
   "Action": [
    "xray:PutTraceSegments"
   ],
   "Resource": [
    "*"
   ]
  },
  {
   "Effect": "Allow",
   "Action": "cloudwatch:PutMetricData",
   "Resource": "*",
   "Condition": {
    "StringLike": {
     "cloudwatch:namespace": [
      "RUM/CustomMetrics/*",
      "AWS/RUM"
     ]
    }
   }
  }
 ]
}
```

Creating a service-linked role for RUM

You do not need to manually create the service-linked role for CloudWatch RUM. The first time that you create an app monitor with X-Ray tracing enabled, or update an app monitor to use X-Ray tracing, RUM creates **AWSServiceRoleForCloudWatchRUM** for you.

For more information, see Creating a Service-Linked Role in the *IAM User Guide*.

Editing a service-linked role for RUM

CloudWatch RUM does not allow you to edit the **AWSServiceRoleForCloudWatchRUM** role. After you create these roles, you cannot change their names because various entities might reference these roles. However, you can edit the description of these roles using IAM.

Editing a service-linked role description (IAM console)

You can use the IAM console to edit the description of a service-linked role.

To edit the description of a service-linked role (console)

1. In the navigation pane of the IAM console, choose **Roles**.
2. Choose the name of the role to modify.
3. To the far right of **Role description**, choose **Edit**.
4. Type a new description in the box, and choose **Save**.

Editing a service-linked role description (AWS CLI)

You can use IAM commands from the AWS Command Line Interface to edit the description of a service-linked role.

To change the description of a service-linked role (AWS CLI)

1. (Optional) To view the current description for a role, use the following commands:

   ```
   $ aws iam get-role --role-name role-name
   ```

   Use the role name, not the ARN, to refer to roles with the AWS CLI commands. For example, if a role has the following ARN: `arn:aws:iam::123456789012:role/myrole`, you refer to the role as **`myrole`**.

2. To update a service-linked role's description, use the following command:

```
$ aws iam update-role-description --role-name role-name --description description
```

Editing a service-linked role description (IAM API)

You can use the IAM API to edit the description of a service-linked role.

To change the description of a service-linked role (API)

1. (Optional) To view the current description for a role, use the following command:

   GetRole
2. To update a role's description, use the following command:

   UpdateRoleDescription

Deleting a service-linked role for RUM

If you no longer have app monitors with X-Ray enabled, we recommend that you delete the **AWSServiceRoleForCloudWatchRUM** role.

That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up your service-linked role before you can delete it.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

To check whether the service-linked role has an active session in the IAM console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**. Choose the name (not the check box) of the **AWSServiceRoleForCloudWatchRUM** role.
3. On the **Summary** page for the selected role, choose **Access Advisor** and review the recent activity for the service-linked role.

> **Note**
>
> If you are unsure whether RUM is using the **AWSServiceRoleForCloudWatchRUM** role, try to delete the role. If the service is using the role, then the deletion fails and you can view the Regions where the role is being used. If the role is being used, then you must wait for the session to end before you can delete the role. You cannot revoke the session for a service-linked role.

Deleting a service-linked role (IAM console)

You can use the IAM console to delete a service-linked role.

To delete a service-linked role (console)

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**. Select the check box next to the name of the role you want to delete, not the name or row itself.
3. For **Role actions**, choose **Delete role**.
4. In the confirmation dialog box, review the service last accessed data, which shows when each of the selected roles last accessed an AWS service. This helps you to confirm whether the role is currently active. To proceed, choose **Yes, Delete**.
5. Watch the IAM console notifications to monitor the progress of the service-linked role deletion. Because the IAM service-linked role deletion is asynchronous, the deletion task can succeed or fail after you submit the role for deletion. If the task fails, choose **View details** or **View Resources** from the notifications to learn why the deletion failed. If the deletion fails because there are resources in the service that are being used by the role, then the reason for the failure includes a list of resources.

Deleting a service-linked role (AWS CLI)

You can use IAM commands from the AWS Command Line Interface to delete a service-linked role.

To delete a service-linked role (AWS CLI)

1. Because a service-linked role cannot be deleted if it is being used or has associated resources, you must submit a deletion request. That request can be denied if these conditions are not

met. You must capture the `deletion-task-id` from the response to check the status of the deletion task. Type the following command to submit a service-linked role deletion request:

```
$ aws iam delete-service-linked-role --role-name service-linked-role-name
```

2. Type the following command to check the status of the deletion task:

```
$ aws iam get-service-linked-role-deletion-status --deletion-task-id deletion-task-id
```

The status of the deletion task can be `NOT_STARTED`, `IN_PROGRESS`, `SUCCEEDED`, or `FAILED`. If the deletion fails, the call returns the reason that it failed so that you can troubleshoot.

Deleting a service-linked role (IAM API)

You can use the IAM API to delete a service-linked role.

To delete a service-linked role (API)

1. To submit a deletion request for a service-linked role, call DeleteServiceLinkedRole. In the request, specify the role name that you want to delete.

   Because a service-linked role cannot be deleted if it is being used or has associated resources, you must submit a deletion request. That request can be denied if these conditions are not met. You must capture the `DeletionTaskId` from the response to check the status of the deletion task.

2. To check the status of the deletion, call GetServiceLinkedRoleDeletionStatus. In the request, specify the `DeletionTaskId`.

   The status of the deletion task can be `NOT_STARTED`, `IN_PROGRESS`, `SUCCEEDED`, or `FAILED`. If the deletion fails, the call returns the reason that it failed so that you can troubleshoot.

Supported Regions for CloudWatch RUM service-linked roles

CloudWatch RUM supports using service-linked roles in all of the AWS Regions where the service is available. For more information, see CloudWatch RUM service endpoints.

Using service-linked roles for CloudWatch Application Insights

CloudWatch Application Insights uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to CloudWatch Application Insights. Service-linked roles are predefined by CloudWatch Application Insights and include all of the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up CloudWatch Application Insights easier because you don't have to manually add the necessary permissions. CloudWatch Application Insights defines the permissions of its service-linked roles, and unless defined otherwise, only CloudWatch Application Insights can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

For information about other services that support service-linked roles, see AWS Services That Work with IAM and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** link to view the service-linked role documentation for that service.

Service-linked role permissions for CloudWatch Application Insights

CloudWatch Application Insights uses the service-linked role named **AWSServiceRoleForApplicationInsights**. Application Insights uses this role to perform operations such as analyzing the resource groups of the customer, creating CloudFormation stacks to create alarms on metrics, and configuring the CloudWatch Agent on EC2 instances. This service-linked role has an IAM policy attached to it named `CloudwatchApplicationInsightsServiceLinkedRolePolicy`. For updates to this policy, see Application Insights updates to AWS managed policies.

The role permissions policy allows CloudWatch Application Insights to complete the following actions on resources.

JSON

        "*"
      ]
    }
  ]
}
```

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-Linked Role Permissions in the *IAM User Guide*.

Creating a service-linked role for CloudWatch Application Insights

You don't need to manually create a service-linked role. When you create a new Application Insights application in the AWS Management Console, CloudWatch Application Insights creates the service-linked role for you.

If you delete this service-linked role, and then want to create it again, you can use the same process to recreate the role in your account. When you create a new Application Insights application, CloudWatch Application Insights creates the service-linked role for you again.

Editing a service-linked role for CloudWatch Application Insights

CloudWatch Application Insights does not allow you to edit the AWSServiceRoleForApplicationInsights service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a Service-Linked Role in the *IAM User Guide*.

Deleting a service-linked role for CloudWatch Application Insights

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you avoid having an unused entity that is not actively monitored or maintained. However, you must delete all applications in Application Insights before you can manually delete the role.

> **Note**
>
> If the CloudWatch Application Insights service is using the role when you try to delete the resources, the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete CloudWatch Application Insights resources used by the AWSServiceRoleForApplicationInsights

- Delete all of your CloudWatch Application Insights applications. For more information, see "Deleting Your Application(s)" in the CloudWatch Application Insights User Guide.

To manually delete the service-linked role using IAM

Use the IAM console, the AWS CLI, or the AWS API to delete the AWSServiceRoleForApplicationInsights service-linked role. For more information, see Deleting a Service-Linked Role in the *IAM User Guide*.

Supported Regions for CloudWatch Application Insights service-linked roles

CloudWatch Application Insights supports using service-linked roles in all of the AWS Regions where the service is available. For more information, see CloudWatch Application Insights Regions and Endpoints.

AWS managed policies for Amazon CloudWatch Application Insights

An AWS managed policy is a standalone policy that is created and administered by AWS. AWS managed policies are designed to provide permissions for many common use cases so that you can start assigning permissions to users, groups, and roles.

Keep in mind that AWS managed policies might not grant least-privilege permissions for your specific use cases because they're available for all AWS customers to use. We recommend that you reduce permissions further by defining customer managed policies that are specific to your use cases.

You cannot change the permissions defined in AWS managed policies. If AWS updates the permissions defined in an AWS managed policy, the update affects all principal identities (users,

groups, and roles) that the policy is attached to. AWS is most likely to update an AWS managed policy when a new AWS service is launched or new API operations become available for existing services.

For more information, see AWS managed policies in the *IAM User Guide*.

AWS managed policy: CloudWatchApplicationInsightsFullAccess

You can attach the `CloudWatchApplicationInsightsFullAccess` policy to your IAM identities.

This policy grants administrative permissions that allow full access to Application Insights functionality.

Permissions details

This policy includes the following permissions.

- `applicationinsights` – Allows full access to Application Insights functionality.
- `iam` – Allows Application Insights to create the service-linked role, AWSServiceRoleForApplicationInsights. This is required so that Application Insights can perform operations such as analyze the resource groups of a customer, create CloudFormation stacks to create alarms on metrics, and configure the CloudWatch Agent on EC2 instances. For more information, see Using service-linked roles for CloudWatch Application Insights.

    }
  ]
}
```

AWS managed policy: CloudWatchApplicationInsightsReadOnlyAccess

You can attach the `CloudWatchApplicationInsightsReadOnlyAccess` policy to your IAM identities.

This policy grants administrative permissions that allow read-only access to all Application Insights functionality.

Permissions details

This policy includes the following permissions.

- `applicationinsights` – Allows read-only access to Application Insights functionality.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "applicationinsights:Describe*",
                "applicationinsights:List*"
            ],
            "Resource": "*"
        }
    ]
}
```

AWS managed policy: CloudwatchApplicationInsightsServiceLinkedRolePolicy

You can't attach CloudwatchApplicationInsightsServiceLinkedRolePolicy to your IAM entities. This policy is attached to a service-linked role that allows Application Insights to monitor customer resources. For more information, see Using service-linked roles for CloudWatch Application Insights.

Application Insights updates to AWS managed policies

View details about updates to AWS managed policies for Application Insights since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the Application Insights Document history page.

Change	Description	Date
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added a new permission. The policy change allows Amazon CloudWatch Application Insights to enable and disable termination protection on CloudFormation stacks to manage SSM resources used to install and configure CloudWatch agents.	July 25, 2024
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to list CloudFormation stacks. These permissions are required for Amazon CloudWatch Application Insights to analyze and	April 24, 2023

Change	Description	Date
	monitor AWS resources nested in the CloudFormation stack.	
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to get list of Amazon VPC and Route 53 resources. These permissions are required for Amazon CloudWatch Application Insights to automatically set up best practice network monitoring with Amazon CloudWatch.	January 23, 2023
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to get SSM command invocation results. These permissions are required for Amazon CloudWatch Application Insights to automatically detect and monitor workloads running on Amazon EC2 instances.	December 19, 2022

Change	Description	Date
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to describe Amazon VPC and Route 53 resources. These permissions are required for Amazon CloudWatch Application Insights to read customer Amazon VPC and Route 53 resource configurations, and to help customers automatically set up best practice network monitoring with Amazon CloudWatch.	December 19, 2022
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to describe EFS resources. These permissions are required for Amazon CloudWatch Application Insights to read Amazon EFS customer resource configurations, and to help customers automatically set up best practices for EFS monitoring with CloudWatch.	October 3, 2022

Change	Description	Date
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to describe the EFS file system. These permissions are required for Amazon CloudWatch Application Insights to create account-based applications by querying all of the supported resources in an account.	October 3, 2022
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to retrieve information about FSx resources. These permissions are required for Amazon CloudWatch Application Insights to monitor workloads by retrieving sufficient information about the underlying FSx volumes.	September 12, 2022
AWS managed policy: CloudWatchApplicationInsightsFullAccess – Update to an existing policy	Application Insights added a new permission to describe log groups. This permissions is required for Amazon CloudWatch Application Insights to ensure that the correct permissions for monitoring log groups are in an account when creating a new application.	January 24, 2022

Change	Description	Date
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to create and delete CloudWatch Log Subscription Filters. These permissions are required for Amazon CloudWatch Application Insights to create Subscription Filters to facilitate log monitoring of resources within configured applications.	January 24, 2022
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to describe target groups and target health for Elastic Load Balancers. These permissions are required for Amazon CloudWatch Application Insights to create account-based applications by querying all of the supported resources in an account.	November 4, 2021

Change	Description	Date
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to run the `AmazonCloudWatch-ManageAgent` SSM document on Amazon EC2 instances. This permissions is required for Amazon CloudWatch Application Insights to clean up CloudWatch agent configuration files created by Application Insights.	September 30, 2021

Change	Description	Date
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to support account-based applicati on monitoring to onboard and monitor all supported resources in your account. These permissions are required for Amazon CloudWatch Applicati on Insights to query, tag resources, and create groups for these resources. Application Insights added new permissions to support monitoring of SNS topics. These permissions are required for Amazon CloudWatch Application Insights to gather metadata from SNS resources to configure monitoring for SNS topics.	September 15, 2021

Change	Description	Date
AWS managed policy: CloudWatchApplicationInsightsFullAccess – Update to an existing policy	Application Insights added new permissions to describe and list supported resources. These permissions are required for Amazon CloudWatch Application Insights to create account-based applications by querying all of the supported resources in an account.	September 15, 2021
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to describe FSx resources. These permissions are required for Amazon CloudWatch Application Insights to read customer FSx resource configurations, and to help customers automatically set up best practice FSx monitoring with CloudWatch.	August 31, 2021

Change	Description	Date
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to describe and list ECS and EKS service resources. This permission is required for Amazon CloudWatch Application Insights to read customer container resources configuration, and to help customers automatically set up best practice container monitoring with CloudWatch.	May 18, 2021
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to allow OpsCenter to tag OpsItems using the `ssm:AddTagsToResource` action on resources with the `opsitem` resource type. This permission is required by OpsCenter. Amazon CloudWatch Application Insights creates OpsItems so that the customer can resolve problems using AWS SSM OpsCenter.	April 13, 2021
Application Insights started tracking changes	Application Insights started tracking changes for its AWS managed policies.	April 13, 2021

Amazon CloudWatch permissions reference

The following table lists each CloudWatch API operation and the corresponding actions for which you can grant permissions to perform the action. You specify the actions in the policy's `Action` field, and you specify a wildcard character (*) as the resource value in the policy's `Resource` field.

You can use AWS-wide condition keys in your CloudWatch policies to express conditions. For a complete list of AWS-wide keys, see AWS Global and IAM Condition Context Keys in the *IAM User Guide*.

> **Note**
>
> To specify an action, use the `cloudwatch:` prefix followed by the API operation name. For example: `cloudwatch:GetMetricData`, `cloudwatch:ListMetrics`, or `cloudwatch:*` (for all CloudWatch actions).

Topics

- CloudWatch API operations and required permissions for actions
- CloudWatch Application Signals API operations and required permissions for actions
- CloudWatch Contributor Insights API operations and required permissions for actions
- CloudWatch Events API operations and required permissions for actions
- CloudWatch Logs API operations and required permissions for actions
- Amazon EC2 API operations and required permissions for actions
- Amazon EC2 Auto Scaling API operations and required permissions for actions

CloudWatch API operations and required permissions for actions

CloudWatch API operations	Required permissions (API actions)
DeleteAlarms	`cloudwatch:DeleteAlarms` Required to delete an alarm.
DeleteDashboards	`cloudwatch:DeleteDashboards`

CloudWatch API operations	Required permissions (API actions)
	Required to delete a dashboard.
DeleteMetricStream	`cloudwatch:DeleteMetricStream` Required to delete a metric stream.
DescribeAlarmHistory	`cloudwatch:DescribeAlarmHistory` Required to view alarm history. To retrieve information about composite alarms, your `cloudwatch:DescribeAlarmHistory` permission must have a * scope. You can't return information about composite alarms if your `cloudwatch:DescribeAlarmHistory` permission has a narrower scope.
DescribeAlarms	`cloudwatch:DescribeAlarms` Required to retrieve information about alarms. To retrieve information about composite alarms, your `cloudwatch:DescribeAlarms` permission must have a * scope. You can't return information about composite alarms if your `cloudwatch:DescribeAlarms` permission has a narrower scope.
DescribeAlarmsForMetric	`cloudwatch:DescribeAlarmsForMetric` Required to view alarms for a metric.

CloudWatch API operations	Required permissions (API actions)
DisableAlarmActions	`cloudwatch:DisableAlarmActions` Required to disable an alarm action.
EnableAlarmActions	`cloudwatch:EnableAlarmActions` Required to enable an alarm action.
GetDashboard	`cloudwatch:GetDashboard` Required to display data about existing dashboards.
GetMetricData	`cloudwatch:GetMetricData` Required to graph metric data in the CloudWatch console, to retrieve large batches of metric data, and perform metric math on that data.
GetMetricStatistics	`cloudwatch:GetMetricStatistics` Required to view graphs in other parts of the CloudWatch console and in dashboard widgets.
GetMetricStream	`cloudwatch:GetMetricStream` Required to view information about a metric stream.

CloudWatch API operations	Required permissions (API actions)
GetMetricWidgetImage	`cloudwatch:GetMetricWidgetImage` Required to retrieve a snapshot graph of one or more CloudWatch metrics as a bitmap image.
GetOTelEnrichment	`cloudwatch:GetOTelEnrichment` Required to retrieve the status of OpenTelemetry enrichment for vended metrics.
ListDashboards	`cloudwatch:ListDashboards` Required to view the list of CloudWatch dashboards in your account.
ListEntitiesForMetric (CloudWatch console-only permission)	`cloudwatch:ListEntitiesForMetric` Required to find the entities associated with a metric. Required to explore related telemetry within the CloudWatch console.
ListMetrics	`cloudwatch:ListMetrics` Required to view or search metric names within the CloudWatch console and in the CLI. Required to select metrics on dashboard widgets.
ListMetricStreams	`cloudwatch:ListMetricStreams` Required to view or search the list of metric streams in the account.

CloudWatch API operations	Required permissions (API actions)
ListTagsForResource	`cloudwatch:ListTagsForResource` Required to list the tags associated with a CloudWatch resource.
PutCompositeAlarm	`cloudwatch:PutCompositeAlarm` Required to create a composite alarm. To create a composite alarm, your `cloudwatch:PutCompositeAlarm` permission must have a * scope. You can't return information about composite alarms if your `cloudwatch:PutCompositeAlarm` permission has a narrower scope.
PutDashboard	`cloudwatch:PutDashboard` Required to create a dashboard or update an existing dashboard.
PutMetricAlarm	`cloudwatch:PutMetricAlarm` Required to create or update an alarm.
PutMetricData	`cloudwatch:PutMetricData` Required to create metrics.
PutMetricStream	`cloudwatch:PutMetricStream` Required to create a metric stream.

CloudWatch API operations	Required permissions (API actions)
SetAlarmState	`cloudwatch:SetAlarmState` Required to manually set an alarm's state.
StartMetricStreams	`cloudwatch:StartMetricStreams` Required to start the flow of metrics in a metric stream.
StartOTelEnrichment	`cloudwatch:StartOTelEnrichment` Required to enable OpenTelemetry enrichment for vended metrics, making them queryable via PromQL.
StopMetricStreams	`cloudwatch:StopMetricStreams` Required to temporarily stop the flow of metrics in a metric stream.
StopOTelEnrichment	`cloudwatch:StopOTelEnrichment` Required to disable OpenTelemetry enrichment for vended metrics.
TagResource	`cloudwatch:TagResource` Required to add or update tags on CloudWatch resources such as alarms and Contributor Insights rules.

CloudWatch API operations	Required permissions (API actions)
UntagResource	`cloudwatch:UntagResource` Required to remove tags from CloudWatch resources .

CloudWatch Application Signals API operations and required permissions for actions

CloudWatch Application Signals API operations	Required permissions (API actions)
BatchGetServiceLevelObjectiveBudgetReport	`application-signals:BatchGetServiceLevelObjectiveBudgetReport` Required to retrieve service level objective budget reports.
CreateServiceLevelObjective	`application-signals:CreateServiceLevelObjective` Required to create a service level objective (SLO).
DeleteServiceLevelObjective	`application-signals:DeleteServiceLevelObjective` Required to delete a service level objective (SLO).
GetService	`application-signals:GetService` Required to retrieve information about a service discovered by Application Signals.

CloudWatch Application Signals API operations	Required permissions (API actions)
GetServiceLevelObjective	`application-signals:GetServiceLevelObjective` Required to retrieve information about a service level objective (SLO).
ListObservedEntities	`application-signals:ListObservedEntities` Grants permission to list entities that are associated with other entities.
ListServiceDependencies	`application-signals:ListServiceDependencies` Required to retrieve a list of service dependencies of a service that you specify. This service and the dependencies were discovered by Application Signals.
ListServiceDependents	`application-signals:ListServiceDependents` Required to retrieve a list of dependents that invoked a service that you specify. This service and the dependents were discovered by Application Signals.
ListServiceLevelObjectives	`application-signals:ListServiceLevelObjectives` Required to retrieve a list of service level objectives (SLOs) in the account.

CloudWatch Application Signals API operations	Required permissions (API actions)
ListServiceOperations	`application-signals:ListServiceOperations` Required to retrieve a list of service operations of a service that you specify. This service and the dependencies were discovered by Application Signals.
ListServices	`application-signals:ListServices` Required to retrieve a list of services discovered by Application Signals.
ListTagsForResource	`application-signals:ListTagsForResource` Required to retrieve a list of the tags associated with a resource.
StartDiscovery	`application-signals:StartDiscovery` Required to be able to enable Application Signals in the account and create the required service-linked role.
TagResource	`application-signals:TagResource` Required to be able to add tags to resources.

CloudWatch Application Signals API operations	Required permissions (API actions)
UntagResource	`application-signals:UntagResource` Required to be able to remove tags from resources.
UpdateServiceLevelObjective	`application-signals:UpdateServiceLevelObjective` Required to update an existing service level objective

CloudWatch Contributor Insights API operations and required permissions for actions

> **Important**
>
> When you grant a user the `cloudwatch:PutInsightRule` permission, by default that user can create a rule that evaluates any log group in CloudWatch Logs. You can add IAM policy conditions that limit these permissions for a user to include and exclude specific log groups. For more information, see Condition keys for Contributor Insights log group access.

CloudWatch Contributor Insights API operations	Required permissions (API actions)
DeleteInsightRules	`cloudwatch:DeleteInsightRules` Required to delete Contributor Insights rules.
DescribeInsightRules	`cloudwatch:DescribeInsightRules`

CloudWatch Contributor Insights API operations	Required permissions (API actions)
	Required to view the Contributor Insights rules in your account.
EnableInsightRules	`cloudwatch:EnableInsightRules` Required to enable Contributor Insights rules.
GetInsightRuleReport	`cloudwatch:GetInsightRuleReport` Required to retrieve time series data and other statistics collectd by Contributor Insights rules.
PutInsightRule	`cloudwatch:PutInsightRule` Required to create Contributor Insights rules. See the **Important** note at the beginning of this table.

CloudWatch Events API operations and required permissions for actions

CloudWatch Events API operations	Required permissions (API actions)
DeleteRule	`events:DeleteRule` Required to delete a rule.
DescribeRule	`events:DescribeRule` Required to list the details about a rule.
DisableRule	`events:DisableRule`

CloudWatch Events API operations	Required permissions (API actions)
	Required to disable a rule.
EnableRule	`events:EnableRule` Required to enable a rule.
ListRuleNamesByTarget	`events:ListRuleNamesByTarget` Required to list rules associated with a target.
ListRules	`events:ListRules` Required to list all rules in your account.
ListTargetsByRule	`events:ListTargetsByRule` Required to list all targets associated with a rule.
PutEvents	`events:PutEvents` Required to add custom events that can be matched to rules.
PutRule	`events:PutRule` Required to create or update a rule.
PutTargets	`events:PutTargets` Required to add targets to a rule.

CloudWatch Events API operations	Required permissions (API actions)
RemoveTargets	`events:RemoveTargets` Required to remove a target from a rule.
TestEventPattern	`events:TestEventPattern` Required to test an event pattern against a given event.

CloudWatch Logs API operations and required permissions for actions

> **Note**
>
> CloudWatch Logs permissions can be found in the CloudWatch Logs user guide.

Amazon EC2 API operations and required permissions for actions

Amazon EC2 API operations	Required permissions (API actions)
DescribeInstanceStatus	`ec2:DescribeInstanceStatus` Required to view EC2 instance status details.
DescribeInstances	`ec2:DescribeInstances` Required to view EC2 instance details.
RebootInstances	`ec2:RebootInstances` Required to reboot an EC2 instance.
StopInstances	`ec2:StopInstances`

Amazon EC2 API operations	Required permissions (API actions)
	Required to stop an EC2 instance.
TerminateInstances	`ec2:TerminateInstances` Required to terminate an EC2 instance.

Amazon EC2 Auto Scaling API operations and required permissions for actions

Amazon EC2 Auto Scaling API operations	Required permissions (API actions)
Scaling	`autoscaling:Scaling` Required to scale an Auto Scaling group.
Trigger	`autoscaling:Trigger` Required to trigger an Auto Scaling action.

Compliance validation for Amazon CloudWatch

To learn whether an AWS service is within the scope of specific compliance programs, see AWS services in Scope by Compliance Program and choose the compliance program that you are interested in. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. For more information about your compliance responsibility when using AWS services, see AWS Security Documentation.

Resilience in Amazon CloudWatch

The AWS global infrastructure is built around AWS Regions and Availability Zones. Regions provide multiple physically separated and isolated Availability Zones, which are connected through low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see AWS Global Infrastructure.

Infrastructure security in Amazon CloudWatch

As a managed service, Amazon CloudWatch is protected by AWS global network security. For information about AWS security services and how AWS protects infrastructure, see AWS Cloud Security. To design your AWS environment using the best practices for infrastructure security, see Infrastructure Protection in *Security Pillar AWS Well-Architected Framework*.

You use AWS published API calls to access CloudWatch through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Network isolation

A virtual private cloud (VPC) is a virtual network in your own logically isolated area in the Amazon Web Services Cloud. A subnet is a range of IP addresses in a VPC. You can deploy a variety of AWS resources in the subnets of your VPCs. For example, you can deploy Amazon EC2 instances, EMR clusters, and DynamoDB tables in subnets. For more information, see the Amazon VPC User Guide.

To enable CloudWatch to communicate with resources in a VPC without going through the public internet, use AWS PrivateLink. For more information, see Using CloudWatch, CloudWatch Synthetics, and CloudWatch Network Monitoring with interface VPC endpoints.

A private subnet is a subnet with no default route to the public internet. Deploying an AWS resource in a private subnet does not prevent Amazon CloudWatch from collecting built-in metrics from the resource.

If you need to publish custom metrics from an AWS resource in a private subnet, you can do so using a proxy server. The proxy server forwards those HTTPS requests to the public API endpoints for CloudWatch.

AWS Security Hub

Monitor your usage of CloudWatch as it relates to security best practices by using AWS Security Hub. Security Hub uses *security controls* to evaluate resource configurations and *security standards* to help you comply with various compliance frameworks. For more information about using Security Hub to evaluate CloudWatch resources, see Amazon CloudWatch controls in the AWS Security Hub User Guide.

Using CloudWatch, CloudWatch Synthetics, and CloudWatch Network Monitoring with interface VPC endpoints

If you use Amazon Virtual Private Cloud (Amazon VPC) to host your AWS resources, you can establish a private connection between your VPC, CloudWatch, CloudWatch Synthetics, and CloudWatch Network Monitoring features. You can use these connections to enable these services to communicate with resources in your VPC without going through the public internet.

Amazon VPC is an AWS service that you can use to launch AWS resources in a virtual network that you define. With a VPC, you have control over your network settings, such the IP address range, subnets, route tables, and network gateways. To connect your VPC to CloudWatch services, you define an *interface VPC endpoint* for your VPC. The endpoint provides reliable, scalable connectivity to CloudWatch and supported CloudWatch services without requiring an internet gateway, network address translation (NAT) instance, or VPN connection. For more information, see What is Amazon VPC in the *Amazon VPC User Guide*.

Interface VPC endpoints are powered by AWS PrivateLink, an AWS technology that enables private communication between AWS services using an elastic network interface with private IP addresses. For more information, see the following blog post: New – AWS PrivateLink for AWS Services

The following steps are for users of Amazon VPC. For more information, see Getting Started in the *Amazon VPC User Guide*.

CloudWatch VPC endpoints

CloudWatch currently supports VPC endpoints, including IPv6-only and dual stack enabled endpoints, in all AWS Regions, including the AWS GovCloud (US) Regions. For information on endpoints URL, see CloudWatch endpoints and quotas .

Creating a VPC endpoint for CloudWatch

To start using CloudWatch with your VPC, create an interface VPC endpoint for CloudWatch. The service name to choose is `com.amazonaws.region.monitoring`. For more information, see Creating an interface endpoint in the *Amazon VPC User Guide*.

You do not need to change the settings for CloudWatch. CloudWatch calls other AWS services using either public endpoints or private interface VPC endpoints, whichever are in use. For example, if you create an interface VPC endpoint for CloudWatch, and you already have metrics flowing to CloudWatch from resources located on your VPC, these metrics begin flowing through the interface VPC endpoint by default.

Controlling access to your CloudWatch VPC endpoint

A VPC endpoint policy is an IAM resource policy that you attach to an endpoint when you create or modify the endpoint. If you don't attach a policy when you create an endpoint, Amazon VPC attaches a default policy for you that allows full access to the service. An endpoint policy doesn't override or replace user policies or service-specific policies. It's a separate policy for controlling access from the endpoint to the specified service.

Endpoint policies must be written in JSON format.

For more information, see Controlling access to services with VPC endpoints in the *Amazon VPC User Guide*.

The following is an example of an endpoint policy for CloudWatch. This policy allows users connecting to CloudWatch through the VPC to send metric data to CloudWatch and prevents them from performing other CloudWatch actions.

```
{
  "Statement": [
    {
      "Sid": "PutOnly",
      "Principal": "*",
      "Action": [
```

```
        "cloudwatch:PutMetricData"
      ],
      "Effect": "Allow",
      "Resource": "*"
    }
  ]
}
```

To edit the VPC endpoint policy for CloudWatch

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoints**.
3. If you have not already created the endpoint for CloudWatch, choose **Create endpoint**. Select **com.amazonaws.*region*.monitoring**, and then choose **Create endpoint**.
4. Select the **com.amazonaws.*region*.monitoring** endpoint, and then choose the **Policy** tab.
5. Choose **Edit policy**, and then make your changes.

CloudWatch Synthetics VPC endpoint

CloudWatch Synthetics currently supports VPC endpoints in the following AWS Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)

- Europe (Paris)
- South America (São Paulo)

Creating a VPC endpoint for CloudWatch Synthetics

To start using CloudWatch Synthetics with your VPC, create an interface VPC endpoint for CloudWatch Synthetics. The service name to choose is `com.amazonaws.region.synthetics`. For more information, see Creating an interface endpoint in the *Amazon VPC User Guide*.

You do not need to change the settings for CloudWatch Synthetics. CloudWatch Synthetics communicates with other AWS services using either public endpoints or private interface VPC endpoints, whichever are in use. For example, if you create an interface VPC endpoint for CloudWatch Synthetics, and you already have an interface endpoint for Amazon S3, CloudWatch Synthetics begins communicating with Amazon S3 through the interface VPC endpoint by default.

Controlling access to your CloudWatch Synthetics VPC endpoint

A VPC endpoint policy is an IAM resource policy that you attach to an endpoint when you create or modify the endpoint. If you don't attach a policy when you create an endpoint, we attach a default policy for you that allows full access to the service. An endpoint policy doesn't override or replace user policies or service-specific policies. It's a separate policy for controlling access from the endpoint to the specified service.

Endpoint policies affect canaries that are managed privately by VPC. They are not needed for canaries that run on private subnets.

Endpoint policies must be written in JSON format.

For more information, see Controlling access to services with VPC endpoints in the *Amazon VPC User Guide*.

The following is an example of an endpoint policy for CloudWatch Synthetics. This policy enables users connecting to CloudWatch Synthetics through the VPC to view information about canaries and their runs, but not to create, modify, or delete canaries.

```
{
    "Statement": [
        {
            "Action": [
                "synthetics:DescribeCanaries",
```

```
                "synthetics:GetCanaryRuns"
            ],
            "Effect": "Allow",
            "Resource": "*",
            "Principal": "*"
        }
    ]
}
```

To edit the VPC endpoint policy for CloudWatch Synthetics

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoints**.
3. If you have not already created the endpoint for CloudWatch Synthetics, choose **Create endpoint**. Select **com.amazonaws.*region*.synthetics** and then choose **Create endpoint**.
4. Select the **com.amazonaws.*region*.synthetics** endpoint, and then choose the **Policy** tab.
5. Choose **Edit policy**, and then make your changes.

CloudWatch Network Monitoring feature VPC endpoints

CloudWatch Network Monitoring includes the following features: Network Flow Monitor, Internet Monitor, and Network Synthetic Monitor. These features each support VPC endpoints in the AWS Regions where the Network Monitoring feature is supported.

To see a list of supported Regions for each Network Monitoring feature, see the following topics:

- **Network Flow Monitor:** Supported AWS Regions for Network Flow Monitor
- **Internet Monitor:** Supported AWS Regions for Internet Monitor
- **Network Synthetic Monitor:** Supported AWS Regions for Network Synthetic Monitor

Creating a VPC endpoint for a CloudWatch Network Monitoring feature

To start using CloudWatch Network Monitoring features with your VPC, create an interface VPC endpoint for the feature that you want to use. For Network Monitoring, the following service names are available:

- `com.amazonaws.region.networkflowmonitor`
- `com.amazonaws.region.networkflowmonitorreports`

- com.amazonaws.*region*.internetmonitor
- com.amazonaws.*region*.internetmonitor-fips
- com.amazonaws.*region*.networkmonitor

For more information, see Creating an interface endpoint in the *Amazon VPC User Guide*.

You don't need to change the settings for Network Monitoring services. Network Monitoring services communicate with other AWS services using either public endpoints or private interface VPC endpoints, whichever are being used. For example, if you create an interface VPC endpoint for a Network Monitoring service, and you already have metrics flowing to the service from resources located on your VPC, the metrics begin flowing through the interface VPC endpoint by default.

Controlling access to your CloudWatch Network Monitoring feature VPC endpoints

A VPC endpoint policy is an IAM resource policy that you attach to an endpoint when you create or modify the endpoint. An endpoint policy doesn't override or replace user policies or service-specific policies. It's a separate policy for controlling access from the endpoint to the specified service.

If you don't attach a policy when you create an endpoint, Amazon VPC attaches a default policy for you that allows full access and does not restrict access to a specific service. For additional security, you can attach a policy to the endpoint to specifically limit access to the feature. For example, for Internet Monitor, you could allow full access to just Internet Monitor by attaching the AWS managed policy that enables full access to the feature, CloudWatchInternetMonitorFullAccess. Or, you can further limit permissions to just specific actions for the endpoint.

For more information, see Controlling access to services with VPC endpoints in the *Amazon VPC User Guide*.

The following is an example of an endpoint policy that you could create for Network Flow Monitor to limit actions for the endpoint. This policy allows requests to Network Flow Monitor through the VPC to use only the `Publish` action, which enables requests to publish metrics to Network Flow Monitor backend ingestion.

```
{
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": "*",
            "Action": "networkflowmonitor:Publish",
            "Resource": "*"
```

```
        }
    ]
}
```

If you want to use a specific VPC endpoint policy with an interface VPC endpoint for a Network Monitoring feature, use steps similar to the following example for adding a policy for Network Flow Monitor.

To edit a VPC endpoint policy for Network Flow Monitor

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoints**.
3. If you have not already created the endpoint for Internet Monitor, choose **Create endpoint**.
4. Select **com.amazonaws.*region*.networkflowmonitor**, and then choose **Create endpoint**.
5. Select the **com.amazonaws.*region*.networkflowmonitor** endpoint, and then choose the **Policy** tab.
6. Choose **Edit policy**, and then make your changes.

Security considerations for Synthetics canaries

The following sections explain security issues that you should consider when creating and running canaries in Synthetics.

Use secure connections

Because canary code and the results from canary test runs can contain sensitive information, do not have your canary connect to endpoints over unencrypted connections. Always use encrypted connections, such as those that begin with `https://`.

Canary naming considerations

The Amazon Resource Name (ARN) of a canary is included in the user-agent header as a part of outbound calls made from the Puppeteer-driven Chromium browser that is included as a part of the CloudWatch Synthetics wrapper library. This helps identify CloudWatch Synthetics canary traffic and relate it back to the canaries that are making calls.

The canary ARN includes the canary name. Choose canary names that do not reveal proprietary information.

Additionally, be sure to point your canaries only at websites and endpoints that you control.

Secrets and sensitive information in canary code

If you pass your canary code directly into the canary using a zip file, the contents of the script can be seen in AWS CloudTrail logs.

If you have sensitive information or secrets (such as access keys or database credentials) in a canary script, we strongly recommend that you store the script as a versioned object in Amazon S3 and pass the Amazon S3 location into the canary, instead of passing the canary code by a zip file.

If you do use a zip file to pass the canary script, we strongly recommend that you don't include secrets or sensitive information in your canary source code. For more information about how to use AWS Secrets Manager to help keep your secrets safe, see What is AWS Secrets Manager?.

Permissions considerations

We recommend that you restrict access to resources that are created or used by CloudWatch Synthetics. Use tight permissions on the Amazon S3 buckets where canaries store test run results and other artifacts, such as logs and screenshots.

Similarly, keep tight permissions on the locations where your canary source code is stored, so that no user accidentally or maliciously deletes the Lambda layers or Lambda functions used for the canary.

To help make sure you run the canary code you intend, you can use object versioning on the Amazon S3 bucket where your canary code is stored. Then when you specify this code to run as a canary, you can include the object `versionId` as part of the path, as in the following examples.

```
https://bucket.s3.amazonaws.com/path/object.zip?versionId=version-id
https://s3.amazonaws.com/bucket/path/object.zip?versionId=version-id
https://bucket.s3-region.amazonaws.com/path/object.zip?versionId=version-id
```

Stack traces and exception messages

By default, CloudWatch Synthetics canaries capture any exception thrown by your canary script, no matter whether the script is custom or is from a blueprint. CloudWatch Synthetics logs both the exception message and the stack trace to three locations:

- Back into the CloudWatch Synthetics service to speed up debugging when you describe test runs

- Into CloudWatch Logs according to the configuration that your Lambda functions are created with
- Into the Synthetics log file, which is a plaintext file that is uploaded to the Amazon S3 location specified by the value you set for the `resultsLocation` of the canary

If you want to send and store less information, you can capture exceptions before they return to the CloudWatch Synthetics wrapper library.

You can also have request URLs in your errors. CloudWatch Synthetics scans for any URLs in the error thrown by your script and redacts restricted URL parameters from them based on the **restrictedUrlParameters** configuration. If you are logging error messages in your script, you can use getSanitizedErrorMessage to redact URLs before logging.

Scope your IAM roles narrowly

We recommend that you do not configure your canary to visit potentially malicious URLs or endpoints. Pointing your Canary to untrusted or unknown websites or endpoints could expose your Lambda function code to malicious user's scripts. Assuming a malicious website can break out of Chromium, it could have access to your Lambda code in a similar way to if you connected to it using an internet browser.

Run your Lambda function with an IAM execution role that has scoped-down permissions. This way, if your Lambda function is compromised by a malicious script, it is limited in the actions it can take when running as your canary's AWS account.

When you use the CloudWatch console to create a canary, it is created with a scoped-down IAM execution role.

Sensitive data redaction

CloudWatch Synthetics captures URLs, status code, failure reason (if any), and headers and bodies of requests and responses. This enables a canary user to understand, monitor, and debug canaries.

The configurations described in the following sections can be set at any point in canary execution. You can also choose to apply different configurations to different synthetics steps.

Request URLs

By default, CloudWatch Synthetics logs request URLs, status codes, and the status reason for each URL in canary logs. Request URLs can also appear in canary execution reports, HAR files, and so on.

Your request URL might contain sensitive query parameters, such as access tokens or passwords. You can redact sensitive information from being logged by CloudWatch Synthetics.

To redact sensitive information, set the configuration property **restrictedUrlParameters**. For more information, see SyntheticsConfiguration class. This causes CloudWatch Synthetics to redact URL parameters, including path and query parameter values, based on **restrictedUrlParameters** before logging. If you are logging URLs in your script, you can use getSanitizedUrl(url, stepConfig = null) to redact URLs before logging. For more information, see SyntheticsLogHelper class.

Headers

By default, CloudWatch Synthetics doesn't log request/response headers. For UI canaries, this is the default behavior for canaries using runtime version `syn-nodejs-puppeteer-3.2` and later.

If your headers don't contain sensitive information, you can enable headers in HAR file and HTTP reports by setting the **includeRequestHeaders** and **includeResponseHeaders** properties to `true`. You can enable all headers but choose to restrict values of sensitive header keys. For example, you can choose to only redact `Authorization` headers from artifacts produced by canaries.

Request and response body

By default, CloudWatch Synthetics doesn't log the request/response body in canary logs or reports. This information is particularly useful for API canaries. Synthetics captures all HTTP requests and can show headers, request and response bodies. For more information, see executeHttpStep(stepName, requestOptions, [callback], [stepConfig]). You can choose to enable request/response body by setting the **includeRequestBody** and **includeResponseBody** properties to `true`.

Code examples for CloudWatch using AWS SDKs

The following code examples show how to use CloudWatch with an AWS software development kit (SDK).

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

For a complete list of AWS SDK developer guides and code examples, see Using CloudWatch with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Hello CloudWatch

The following code examples show how to get started using CloudWatch.

.NET

SDK for .NET (v4)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
using Amazon.CloudWatch;
using Amazon.CloudWatch.Model;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Hosting;

namespace CloudWatchActions;

public static class HelloCloudWatch
{
    static async Task Main(string[] args)
    {
```

```
        // Use the AWS .NET Core Setup package to set up dependency injection for
 the Amazon CloudWatch service.
        // Use your AWS profile name, or leave it blank to use the default
 profile.
        using var host = Host.CreateDefaultBuilder(args)
            .ConfigureServices((_, services) =>
                services.AddAWSService<IAmazonCloudWatch>()
            ).Build();

        // Now the client is available for injection.
        var cloudWatchClient =
 host.Services.GetRequiredService<IAmazonCloudWatch>();

        // You can use await and any of the async methods to get a response.
        var metricNamespace = "AWS/Billing";
        var response = await cloudWatchClient.ListMetricsAsync(new
 ListMetricsRequest
        {
            Namespace = metricNamespace
        });
        Console.WriteLine($"Hello Amazon CloudWatch! Following are some metrics
 available in the {metricNamespace} namespace:");
        Console.WriteLine();
        if (response.Metrics != null)
        {
            foreach (var metric in response.Metrics.Take(5))
            {
                Console.WriteLine($"\tMetric: {metric.MetricName}");
                Console.WriteLine($"\tNamespace: {metric.Namespace}");
                Console.WriteLine(
                    $"\tDimensions: {string.Join(", ", metric.Dimensions.Select(m
 => $"{m.Name}:{m.Value}"))}");
                Console.WriteLine();
            }
        }
    }
}
```

- For API details, see ListMetrics in *AWS SDK for .NET API Reference*.

Java

SDK for Java 2.x

        cwClient
            .listMetricsPaginated(request)
            .transform { it.metrics?.forEach { obj -> emit(obj) } }
            .collect { obj ->
                println("Name is ${obj.metricName}")
                println("Namespace is ${obj.namespace}")
            }
    }
}
```

- For API details, see ListMetrics in *AWS SDK for Kotlin API reference*.

For a complete list of AWS SDK developer guides and code examples, see Using CloudWatch with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Learn core operations for CloudWatch using an AWS SDK

The following code examples show how to:

- List CloudWatch namespaces and metrics.
- Get statistics for a metric and for estimated billing.
- Create and update a dashboard.
- Create and add data to a metric.
- Create and trigger an alarm, then view alarm history.
- Add an anomaly detector.
- Get a metric image, then clean up resources.

.NET

SDK for .NET (v4)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario at a command prompt.

```
public class CloudWatchScenario
{
    /*
    Before running this .NET code example, set up your development environment,
 including your credentials.

    To enable billing metrics and statistics for this example, make sure billing
 alerts are enabled for your account:
```

```
    https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/
monitor_estimated_charges_with_cloudwatch.html#turning_on_billing_metrics

    This .NET example performs the following tasks:
        1. List and select a CloudWatch namespace.
        2. List and select a CloudWatch metric.
        3. Get statistics for a CloudWatch metric.
        4. Get estimated billing statistics for the last week.
        5. Create a new CloudWatch dashboard with two metrics.
        6. List current CloudWatch dashboards.
        7. Create a CloudWatch custom metric and add metric data.
        8. Add the custom metric to the dashboard.
        9. Create a CloudWatch alarm for the custom metric.
       10. Describe current CloudWatch alarms.
       11. Get recent data for the custom metric.
       12. Add data to the custom metric to trigger the alarm.
       13. Wait for an alarm state.
       14. Get history for the CloudWatch alarm.
       15. Add an anomaly detector.
       16. Describe current anomaly detectors.
       17. Get and display a metric image.

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-
started.html
 *
 * To enable billing metrics and statistics for this example, make sure billing
 * alerts are enabled for your account:
 * https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/
monitor_estimated_charges_with_cloudwatch.html#turning_on_billing_metrics
 *
 * This Java code example performs the following tasks:
 *
 * 1. List available namespaces from Amazon CloudWatch.
 * 2. List available metrics within the selected Namespace.
 * 3. Get statistics for the selected metric over the last day.
 * 4. Get CloudWatch estimated billing for the last week.
 * 5. Create a new CloudWatch dashboard with metrics.
 * 6. List dashboards using a paginator.
 * 7. Create a new custom metric by adding data for it.
```

```
 * 8. Add the custom metric to the dashboard.
 * 9. Create an alarm for the custom metric.
 * 10. Describe current alarms.
 * 11. Get current data for the new custom metric.
 * 12. Push data into the custom metric to trigger the alarm.
 * 13. Check the alarm state using the action DescribeAlarmsForMetric.
 * 14. Get alarm history for the new alarm.
 * 15. Add an anomaly detector for the custom metric.
 * 16. Describe current anomaly detectors.
 * 17. Get a metric image for the custom metric.
 * 18. Clean up the Amazon CloudWatch resources.

            Amazon CloudWatch is a comprehensive monitoring and observability
service
            provided by Amazon Web Services (AWS). It is designed to help you
monitor your
            AWS resources, applications, and services, as well as on-premises
resources,
            in real-time.

            CloudWatch collects and tracks various types of data, including
metrics,
            logs, and events, from your AWS and on-premises resources. It allows
you to set
            alarms and automatically respond to changes in your environment,
            enabling you to quickly identify and address issues before they
impact your
            applications or services.

            With CloudWatch, you can gain visibility into your entire
infrastructure, from the cloud
            to the edge, and use this information to make informed decisions and
optimize your
            resource utilization.

            This scenario guides you through how to perform Amazon CloudWatch
tasks by using the
            AWS SDK for Java v2. Let's get started...

Kotlin

SDK for Kotlin

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario demonstrating CloudWatch features.

```
/**
 Before running this Kotlin code example, set up your development environment,
 including your credentials.

 For more information, see the following documentation topic:
 https://docs.aws.amazon.com/sdk-for-kotlin/latest/developer-guide/setup.html

 To enable billing metrics and statistics for this example, make sure billing
 alerts are enabled for your account:
 https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/
monitor_estimated_charges_with_cloudwatch.html#turning_on_billing_metrics

 This Kotlin code example performs the following tasks:

 1. List available namespaces from Amazon CloudWatch. Select a namespace from the
 list.
 2. List available metrics within the selected namespace.
 3. Get statistics for the selected metric over the last day.
 4. Get CloudWatch estimated billing for the last week.
 5. Create a new CloudWatch dashboard with metrics.
 6. List dashboards using a paginator.
 7. Create a new custom metric by adding data for it.
 8. Add the custom metric to the dashboard.
 9. Create an alarm for the custom metric.
 10. Describe current alarms.
 11. Get current data for the new custom metric.
 12. Push data into the custom metric to trigger the alarm.
 13. Check the alarm state using the action DescribeAlarmsForMetric.
 14. Get alarm history for the new alarm.
 15. Add an anomaly detector for the custom metric.
```

```
 16. Describe current anomaly detectors.
 17. Get a metric image for the custom metric.
 18. Clean up the Amazon CloudWatch resources.

Actions for CloudWatch using AWS SDKs

The following code examples demonstrate how to perform individual CloudWatch actions with AWS SDKs. Each example includes a link to GitHub, where you can find instructions for setting up and running the code.

These excerpts call the CloudWatch API and are code excerpts from larger programs that must be run in context. You can see actions in context in Scenarios for CloudWatch using AWS SDKs.

The following examples include only the most commonly used actions. For a complete list, see the Amazon CloudWatch API Reference.

Examples

- Use DeleteAlarms with an AWS SDK or CLI
- Use DeleteAnomalyDetector with an AWS SDK or CLI
- Use DeleteDashboards with an AWS SDK or CLI
- Use DescribeAlarmHistory with an AWS SDK or CLI
- Use DescribeAlarms with an AWS SDK or CLI
- Use DescribeAlarmsForMetric with an AWS SDK or CLI
- Use DescribeAnomalyDetectors with an AWS SDK or CLI
- Use DisableAlarmActions with an AWS SDK or CLI
- Use EnableAlarmActions with an AWS SDK or CLI
- Use GetDashboard with an AWS SDK or CLI
- Use GetMetricData with an AWS SDK or CLI
- Use GetMetricStatistics with an AWS SDK or CLI
- Use GetMetricWidgetImage with an AWS SDK or CLI
- Use ListDashboards with an AWS SDK or CLI
- Use ListMetrics with an AWS SDK or CLI
- Use PutAnomalyDetector with an AWS SDK or CLI
- Use PutDashboard with an AWS SDK or CLI
- Use PutMetricAlarm with an AWS SDK or CLI
- Use PutMetricData with an AWS SDK or CLI

Use `DeleteAlarms` with an AWS SDK or CLI

The following code examples show how to use `DeleteAlarms`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- Learn the basics
- Get started with alarms
- Manage metrics and alarms
- Run CPU stress tests on virtual machine instances using fault injection

.NET

SDK for .NET (v4)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
/// <summary>
/// Delete a list of alarms from CloudWatch.
/// </summary>
/// <param name="alarmNames">A list of names of alarms to delete.</param>
/// <returns>True if successful.</returns>
public async Task<bool> DeleteAlarms(List<string> alarmNames)
{
    var deleteAlarmsResult = await _amazonCloudWatch.DeleteAlarmsAsync(
        new DeleteAlarmsRequest()
        {
            AlarmNames = alarmNames
        });

    return deleteAlarmsResult.HttpStatusCode == HttpStatusCode.OK;
}
```

- For API details, see DeleteAlarms in *AWS SDK for .NET API Reference*.

C++

SDK for C++

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Include the required files.

```
#include <aws/core/Aws.h>
#include <aws/monitoring/CloudWatchClient.h>
#include <aws/monitoring/model/DeleteAlarmsRequest.h>
#include <iostream>
```

Delete the alarm.

```
        Aws::CloudWatch::CloudWatchClient cw;
        Aws::CloudWatch::Model::DeleteAlarmsRequest request;
        request.AddAlarmNames(alarm_name);

        auto outcome = cw.DeleteAlarms(request);
        if (!outcome.IsSuccess())
        {
            std::cout << "Failed to delete CloudWatch alarm:" <<
                outcome.GetError().GetMessage() << std::endl;
        }
        else
        {
            std::cout << "Successfully deleted CloudWatch alarm " << alarm_name
                << std::endl;
        }
```

- For API details, see DeleteAlarms in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To delete an alarm

The following example uses the `delete-alarms` command to delete the Amazon CloudWatch alarm named "myalarm":

```
aws cloudwatch delete-alarms --alarm-names myalarm
```

Output:

```
This command returns to the prompt if successful.
```

- For API details, see DeleteAlarms in *AWS CLI Command Reference*.

Java

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   /**
    * Deletes a CloudWatch alarm.
    *
    * @param alarmName the name of the alarm to be deleted
    * @return a {@link CompletableFuture} representing the asynchronous
operation to delete the alarm
    * the {@link DeleteAlarmsResponse} is returned when the operation completes
successfully,
    * or a {@link RuntimeException} is thrown if the operation fails
    */
   public CompletableFuture<DeleteAlarmsResponse> deleteCWAlarmAsync(String
alarmName) {
       DeleteAlarmsRequest request = DeleteAlarmsRequest.builder()
           .alarmNames(alarmName)
           .build();

       return getAsyncClient().deleteAlarms(request)
           .whenComplete((response, exception) -> {
               if (exception != null) {
                   throw new RuntimeException("Failed to delete the alarm:{} " +
alarmName, exception);
               } else {
                   logger.info("Successfully deleted alarm {} ", alarmName);
               }
           });
   }
```

- For API details, see DeleteAlarms in *AWS SDK for Java 2.x API Reference*.

JavaScript

SDK for JavaScript (v3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Import the SDK and client modules and call the API.

```
import { DeleteAlarmsCommand } from "@aws-sdk/client-cloudwatch";
import { client } from "../libs/client.js";

const run = async () => {
  const command = new DeleteAlarmsCommand({
    AlarmNames: [process.env.CLOUDWATCH_ALARM_NAME], // Set the value of
 CLOUDWATCH_ALARM_NAME to the name of an existing alarm.
  });

  try {
    return await client.send(command);
  } catch (err) {
    console.error(err);
  }
};

export default run();
```

Create the client in a separate module and export it.

```
import { CloudWatchClient } from "@aws-sdk/client-cloudwatch";

export const client = new CloudWatchClient({});
```

- For more information, see AWS SDK for JavaScript Developer Guide.
- For API details, see DeleteAlarms in *AWS SDK for JavaScript API Reference*.

SDK for JavaScript (v2)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Import the SDK and client modules and call the API.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create CloudWatch service object
var cw = new AWS.CloudWatch({ apiVersion: "2010-08-01" });

var params = {
  AlarmNames: ["Web_Server_CPU_Utilization"],
};

Use `DeleteAnomalyDetector` with an AWS SDK or CLI

The following code examples show how to use `DeleteAnomalyDetector`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Learn the basics

.NET

SDK for .NET (v4)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    /// <summary>
    /// Delete a single metric anomaly detector.
    /// </summary>
    /// <param name="anomalyDetector">The anomaly detector to delete.</param>
    /// <returns>True if successful.</returns>
```

```
    public async Task<bool> DeleteAnomalyDetector(SingleMetricAnomalyDetector
anomalyDetector)
    {
        var deleteAnomalyDetectorResponse = await
_amazonCloudWatch.DeleteAnomalyDetectorAsync(
            new DeleteAnomalyDetectorRequest()
            {
                SingleMetricAnomalyDetector = anomalyDetector
            });

        return deleteAnomalyDetectorResponse.HttpStatusCode == HttpStatusCode.OK;
    }
```

- For API details, see DeleteAnomalyDetector in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To delete a specified anomaly detection model

The following `delete-anomaly-detector` example deletes an anomaly detector model in the specified account.

```
aws cloudwatch delete-anomaly-detector \
    --namespace AWS/Logs \
    --metric-name IncomingBytes \
    --stat SampleCount
```

This command produces no output.

For more information, see Deleting an anomaly detection model in the *Amazon CloudWatch User Guide*.

- For API details, see DeleteAnomalyDetector in *AWS CLI Command Reference*.

Java

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```

}
```

- For API details, see DeleteAnomalyDetector in *AWS SDK for Kotlin API reference*.

For a complete list of AWS SDK developer guides and code examples, see Using CloudWatch with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use `DeleteDashboards` with an AWS SDK or CLI

The following code examples show how to use `DeleteDashboards`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- Learn the basics
- Creating a monitoring dashboard with function name as a variable
- Using property variables in monitoring dashboards to monitor multiple serverless functions

.NET

SDK for .NET (v4)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    /// <summary>
    /// Delete a list of CloudWatch dashboards.
    /// </summary>
    /// <param name="dashboardNames">List of dashboard names to delete.</param>
    /// <returns>True if successful.</returns>
    public async Task<bool> DeleteDashboards(List<string> dashboardNames)
    {
        var deleteDashboardsResponse = await
_amazonCloudWatch.DeleteDashboardsAsync(
            new DeleteDashboardsRequest()
            {
                DashboardNames = dashboardNames
            });

        return deleteDashboardsResponse.HttpStatusCode == HttpStatusCode.OK;
    }
```

- For API details, see DeleteDashboards in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To delete specified dashboards

The following `delete-dashboards` example deletes two dashboards named `Dashboard-A` and `Dashboard-B` in the specified account.

```
aws cloudwatch delete-dashboards \
    --dashboard-names Dashboard-A Dashboard-B
```

This command produces no output.

For more information, see Amazon CloudWatch dashboards in the *Amazon CloudWatch User Guide*.

- For API details, see DeleteDashboards in *AWS CLI Command Reference*.

Java

SDK for Java 2.x

```
suspend fun deleteDashboard(dashboardName: String) {
    val dashboardsRequest =
        DeleteDashboardsRequest {
            dashboardNames = listOf(dashboardName)
        }
    CloudWatchClient.fromEnvironment { region = "us-east-1" }.use { cwClient ->
        cwClient.deleteDashboards(dashboardsRequest)
        println("$dashboardName was successfully deleted.")
    }
}
```

- For API details, see DeleteDashboards in *AWS SDK for Kotlin API reference*.

PowerShell

Tools for PowerShell V4

Example 1: Deletes the specified dashboard, promoting for confirmation before proceeding. To bypass confirmation add the -Force switch to the command.

```
Remove-CWDashboard -DashboardName Dashboard1
```

- For API details, see DeleteDashboards in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: Deletes the specified dashboard, promoting for confirmation before proceeding. To bypass confirmation add the -Force switch to the command.

```
Remove-CWDashboard -DashboardName Dashboard1
```

- For API details, see DeleteDashboards in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see Using CloudWatch with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Use `DescribeAlarmHistory` with an AWS SDK or CLI

The following code examples show how to use `DescribeAlarmHistory`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Learn the basics

.NET

SDK for .NET (v4)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    /// <summary>
    /// Describe the history of an alarm for a number of days in the past.
    /// </summary>
    /// <param name="alarmName">The name of the alarm.</param>
    /// <param name="historyDays">The number of days in the past.</param>
    /// <returns>The list of alarm history data.</returns>
    public async Task<List<AlarmHistoryItem>> DescribeAlarmHistory(string
alarmName, int historyDays)
```

```
    {
        List<AlarmHistoryItem> alarmHistory = new List<AlarmHistoryItem>();
        var paginatedAlarmHistory =
 _amazonCloudWatch.Paginators.DescribeAlarmHistory(
            new DescribeAlarmHistoryRequest()
            {
                AlarmName = alarmName,
                EndDateUtc = DateTime.UtcNow,
                HistoryItemType = HistoryItemType.StateUpdate,
                StartDateUtc = DateTime.UtcNow.AddDays(-historyDays)
            });

        await foreach (var data in paginatedAlarmHistory.AlarmHistoryItems)
        {
            alarmHistory.Add(data);
        }
        return alarmHistory;
    }
```

- For API details, see DescribeAlarmHistory in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To retrieve history for an alarm

The following example uses the `describe-alarm-history` command to retrieve history for the Amazon CloudWatch alarm named "myalarm":

```
aws cloudwatch describe-alarm-history --alarm-name "myalarm" --history-item-
type StateUpdate
```

Output:

```
{
    "AlarmHistoryItems": [
        {
            "Timestamp": "2014-04-09T18:59:06.442Z",
            "HistoryItemType": "StateUpdate",
            "AlarmName": "myalarm",
```

```
            "HistoryData": "{\"version\":\"1.0\",\"oldState\":{\"stateValue
\":\"ALARM\",\"stateReason\":\"testing purposes\"},\"newState\":{\"stateValue
\":\"OK\",\"stateReason\":\"Threshold Crossed: 2 datapoints were not

PowerShell

Tools for PowerShell V4

Example 1: Returns all the alarms including Composite and Metric Alarms from CloudWatch.

```
Get-CWAlarm -MaxRecords 1
```

Output:

```
CompositeAlarms MetricAlarms         NextToken
--------------- ------------         ---------
                {MetricAlarms-01}    NextToken-01
                {MetricAlarms-02}    NextToken-02
                {MetricAlarms-03}    NextToken-03
```

Example 2: Returns only the composite alarms data from CloudWatch after setting -AlarmType parameter to CompositeAlarms.

```
Get-CWAlarm -AlarmType 'CompositeAlarms'
```

Output:

```
CompositeAlarms        MetricAlarms NextToken
---------------        ------------ ---------
{CompositeAlarms-01}
{CompositeAlarms-02}
{CompositeAlarms-03}
```

- For API details, see DescribeAlarmsForMetric in *AWS SDK for Java 2.x API Reference*.

JavaScript

SDK for JavaScript (v3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Import the SDK and client modules and call the API.

```
import { DescribeAlarmsCommand } from "@aws-sdk/client-cloudwatch";
import { client } from "../libs/client.js";

const run = async () => {
  const command = new DescribeAlarmsCommand({
    AlarmNames: [process.env.CLOUDWATCH_ALARM_NAME], // Set the value of
 CLOUDWATCH_ALARM_NAME to the name of an existing alarm.
  });

  try {
    return await client.send(command);
  } catch (err) {
    console.error(err);
  }
};
```

```
export default run();
```

Create the client in a separate module and export it.

```
import { CloudWatchClient } from "@aws-sdk/client-cloudwatch";

export const client = new CloudWatchClient({});
```

- For more information, see AWS SDK for JavaScript Developer Guide.
- For API details, see DescribeAlarmsForMetric in *AWS SDK for JavaScript API Reference*.

SDK for JavaScript (v2)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create CloudWatch service object
var cw = new AWS.CloudWatch({ apiVersion: "2010-08-01" });

cw.describeAlarms({ StateValue: "INSUFFICIENT_DATA" }, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    // List the names of all current alarms in the console
    data.MetricAlarms.forEach(function (item, index, array) {
      console.log(item.AlarmName);
    });
  }
});
```

- For more information, see AWS SDK for JavaScript Developer Guide.
- For API details, see DescribeAlarmsForMetric in *AWS SDK for JavaScript API Reference*.

Use `DisableAlarmActions` with an AWS SDK or CLI

The following code examples show how to use `DisableAlarmActions`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- Get started with alarms
- Manage metrics and alarms

.NET

SDK for .NET (v4)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    /// <summary>
    /// Disable the actions for a list of alarms from CloudWatch.
    /// </summary>
    /// <param name="alarmNames">A list of names of alarms.</param>
    /// <returns>True if successful.</returns>
    public async Task<bool> DisableAlarmActions(List<string> alarmNames)
    {
        var disableAlarmActionsResult = await
_amazonCloudWatch.DisableAlarmActionsAsync(
            new DisableAlarmActionsRequest()
            {
                AlarmNames = alarmNames
            });

        return disableAlarmActionsResult.HttpStatusCode == HttpStatusCode.OK;
    }
```

- For API details, see DisableAlarmActions in *AWS SDK for .NET API Reference*.

C++

SDK for C++

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Include the required files.

```
#include <aws/core/Aws.h>
#include <aws/monitoring/CloudWatchClient.h>
#include <aws/monitoring/model/DisableAlarmActionsRequest.h>
#include <iostream>
```

Disable the alarm actions.

```
        Aws::CloudWatch::CloudWatchClient cw;

        Aws::CloudWatch::Model::DisableAlarmActionsRequest
 disableAlarmActionsRequest;
        disableAlarmActionsRequest.AddAlarmNames(alarm_name);

        auto disableAlarmActionsOutcome =
 cw.DisableAlarmActions(disableAlarmActionsRequest);
        if (!disableAlarmActionsOutcome.IsSuccess())
        {
            std::cout << "Failed to disable actions for alarm " << alarm_name <<
                ": " << disableAlarmActionsOutcome.GetError().GetMessage() <<
                std::endl;
        }
        else
        {
            std::cout << "Successfully disabled actions for alarm " <<
                alarm_name << std::endl;
        }
```

- For API details, see DisableAlarmActions in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To disable actions for an alarm

The following example uses the `disable-alarm-actions` command to disable all actions for the alarm named myalarm.:

```
aws cloudwatch disable-alarm-actions --alarm-names myalarm
```

This command returns to the prompt if successful.

- For API details, see DisableAlarmActions in *AWS CLI Command Reference*.

SDK for JavaScript (v3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Import the SDK and client modules and call the API.

```
import { DisableAlarmActionsCommand } from "@aws-sdk/client-cloudwatch";
import { client } from "../libs/client.js";

const run = async () => {
  const command = new DisableAlarmActionsCommand({
    AlarmNames: process.env.CLOUDWATCH_ALARM_NAME, // Set the value of
 CLOUDWATCH_ALARM_NAME to the name of an existing alarm.
  });

  try {
    return await client.send(command);
  } catch (err) {
    console.error(err);
  }
};

export default run();
```

Create the client in a separate module and export it.

```
import { CloudWatchClient } from "@aws-sdk/client-cloudwatch";

export const client = new CloudWatchClient({});
```

- For more information, see AWS SDK for JavaScript Developer Guide.
- For API details, see DisableAlarmActions in *AWS SDK for JavaScript API Reference*.

SDK for JavaScript (v2)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Import the SDK and client modules and call the API.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create CloudWatch service object
var cw = new AWS.CloudWatch({ apiVersion: "2010-08-01" });

cw.disableAlarmActions(
  { AlarmNames: ["Web_Server_CPU_Utilization"] },
  function (err, data) {
    if (err) {
      console.log("Error", err);
    } else {
      console.log("Success", data);
    }
  }
);
```

- For more information, see AWS SDK for JavaScript Developer Guide.
- For API details, see DisableAlarmActions in *AWS SDK for JavaScript API Reference*.

Kotlin

SDK for Kotlin

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
suspend fun disableActions(alarmName: String) {
    val request =
        DisableAlarmActionsRequest {
            alarmNames = listOf(alarmName)
        }
    CloudWatchClient.fromEnvironment { region = "us-east-1" }.use { cwClient ->
        cwClient.disableAlarmActions(request)
        println("Successfully disabled actions on alarm $alarmName")
    }
}
```

- For API details, see DisableAlarmActions in *AWS SDK for Kotlin API reference*.

C++

SDK for C++

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Include the required files.

```
#include <aws/core/Aws.h>
#include <aws/monitoring/CloudWatchClient.h>
#include <aws/monitoring/model/EnableAlarmActionsRequest.h>
#include <aws/monitoring/model/PutMetricAlarmRequest.h>
#include <iostream>
```

Enable the alarm actions.

```
    Aws::CloudWatch::CloudWatchClient cw;
    Aws::CloudWatch::Model::PutMetricAlarmRequest request;
    request.SetAlarmName(alarm_name);
    request.SetComparisonOperator(
        Aws::CloudWatch::Model::ComparisonOperator::GreaterThanThreshold);
    request.SetEvaluationPeriods(1);
    request.SetMetricName("CPUUtilization");
    request.SetNamespace("AWS/EC2");
    request.SetPeriod(60);
    request.SetStatistic(Aws::CloudWatch::Model::Statistic::Average);
    request.SetThreshold(70.0);
    request.SetActionsEnabled(false);
    request.SetAlarmDescription("Alarm when server CPU exceeds 70%");
    request.SetUnit(Aws::CloudWatch::Model::StandardUnit::Seconds);
    request.AddAlarmActions(actionArn);

    Aws::CloudWatch::Model::Dimension dimension;
    dimension.SetName("InstanceId");
    dimension.SetValue(instanceId);
    request.AddDimensions(dimension);
```

```
    auto outcome = cw.PutMetricAlarm(request);
    if (!outcome.IsSuccess())
    {
        std::cout << "Failed to create CloudWatch alarm:" <<
            outcome.GetError().GetMessage() << std::endl;
        return;
    }

    Aws::CloudWatch::Model::EnableAlarmActionsRequest enable_request;
    enable_request.AddAlarmNames(alarm_name);

    auto enable_outcome = cw.EnableAlarmActions(enable_request);
    if (!enable_outcome.IsSuccess())
    {
        std::cout << "Failed to enable alarm actions:" <<
            enable_outcome.GetError().GetMessage() << std::endl;
        return;
    }

    std::cout << "Successfully created alarm " << alarm_name <<
        " and enabled actions on it." << std::endl;
```

- For API details, see EnableAlarmActions in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To enable all actions for an alarm

The following example uses the `enable-alarm-actions` command to enable all actions for the alarm named myalarm.:

```
aws cloudwatch enable-alarm-actions --alarm-names myalarm
```

This command returns to the prompt if successful.

- For API details, see EnableAlarmActions in *AWS CLI Command Reference*.

Use `GetDashboard` with an AWS SDK or CLI

The following code examples show how to use `GetDashboard`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- Creating a monitoring dashboard with function name as a variable
- Using property variables in monitoring dashboards to monitor multiple serverless functions

.NET

SDK for .NET (v4)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    /// <summary>
    /// Get information on a dashboard.
    /// </summary>
    /// <param name="dashboardName">The name of the dashboard.</param>
    /// <returns>A JSON object with dashboard information.</returns>
    public async Task<string> GetDashboard(string dashboardName)
    {
        var dashboardResponse = await _amazonCloudWatch.GetDashboardAsync(
            new GetDashboardRequest()
            {
                DashboardName = dashboardName
            });

        return dashboardResponse.DashboardBody;
    }
```

- For API details, see GetDashboard in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To retrieve information about a Dashboard

The following `get-dashboard` example displays information about the dashboard named `Dashboard-A` in the specified account.

```
aws cloudwatch get-dashboard \
    --dashboard-name Dashboard-A
```

Output:

```
{
    "DashboardArn": "arn:aws:cloudwatch::123456789012:dashboard/Dashboard-A",
    "DashboardBody": "{\"widgets\":[{\"type\":\"metric\",\"x\":0,\"y\":0,\"width
\":6,\"height\":6,\"properties\":{\"view\":\"timeSeries\",\"stacked\":false,
\"metrics\":[[\"AWS/EC2\",\"NetworkIn\",\"InstanceId\",\"i-0131f062232ade043\"],
[\".\",\"NetworkOut\",\".\",\".\"]],\"region\":\"us-east-1\"}}]}",
    "DashboardName": "Dashboard-A"
}
```

For more information, see Amazon CloudWatch dashboards in the *Amazon CloudWatch User Guide*.

- For API details, see GetDashboard in *AWS CLI Command Reference*.

PowerShell

Tools for PowerShell V4

Example 1: Returns the arn the body of the specified dashboard.

```
Get-CWDashboard -DashboardName Dashboard1
```

Output:

```
DashboardArn                                              DashboardBody
------------                                              -------------
arn:aws:cloudwatch::123456789012:dashboard/Dashboard1 {...
```

- For API details, see GetDashboard in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: Returns the arn the body of the specified dashboard.

```
Get-CWDashboard -DashboardName Dashboard1
```

Output:

```
DashboardArn                                              DashboardBody
```

```
------------                                                  -------------
arn:aws:cloudwatch::123456789012:dashboard/Dashboard1 {...
```

- For API details, see GetDashboard in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

CLI

AWS CLI

Example 1: To get the Average Total IOPS for the specified EC2 using math expression

The following `get-metric-data` example retrieves CloudWatch metric values for the EC2 instance with InstanceID `i-abcdef` using metric math exprssion that combines `EBSReadOps` and `EBSWriteOps` metrics.

```
aws cloudwatch get-metric-data \
    --metric-data-queries file://file.json \
    --start-time 2024-09-29T22:10:00Z \
    --end-time 2024-09-29T22:15:00Z
```

Contents of `file.json`:

```
[
    {
        "Id": "m3",
        "Expression": "(m1+m2)/300",
        "Label": "Avg Total IOPS"
    },
    {
        "Id": "m1",
        "MetricStat": {
            "Metric": {
                "Namespace": "AWS/EC2",
                "MetricName": "EBSReadOps",
                "Dimensions": [
                    {
                        "Name": "InstanceId",
                        "Value": "i-abcdef"
                    }
                ]
            },
            "Period": 300,
            "Stat": "Sum",
            "Unit": "Count"
        },
        "ReturnData": false
    },
    {
```

```
        "Id": "m2",
        "MetricStat": {
            "Metric": {
                "Namespace": "AWS/EC2",
                "MetricName": "EBSWriteOps",
                "Dimensions": [
                    {
                        "Name": "InstanceId",
                        "Value": "i-abcdef"
                    }
                ]
            },
            "Period": 300,
            "Stat": "Sum",
            "Unit": "Count"
        },
        "ReturnData": false
    }
]
```

Output:

```
{
    "MetricDataResults": [
        {
            "Id": "m3",
            "Label": "Avg Total IOPS",
            "Timestamps": [
                "2024-09-29T22:10:00+00:00"
            ],
            "Values": [
                96.85
            ],
            "StatusCode": "Complete"
        }
    ],
    "Messages": []
}
```

Example 2: To monitor the estimated AWS charges using CloudWatch billing metrics

The following `get-metric-data` example retrieves `EstimatedCharges` CloudWatch metric from AWS/Billing namespace.

```
aws cloudwatch get-metric-data \
    --metric-data-queries '[{"Id":"m1","MetricStat":{"Metric":
{"Namespace":"AWS/Billing","MetricName":"EstimatedCharges","Dimensions":
[{"Name":"Currency","Value":"USD"}]},"Period":21600,"Stat":"Maximum"}}]' \
    --start-time 2024-09-26T12:00:00Z \
    --end-time 2024-09-26T18:00:00Z \
    --region us-east-1
```

Output:

```
{
    "MetricDataResults": [
        {
            "Id": "m1",
            "Label": "EstimatedCharges",
            "Timestamps": [
                "2024-09-26T12:00:00+00:00"
            ],
            "Values": [
                542.38
            ],
            "StatusCode": "Complete"
        }
    ],
    "Messages": []
}
```

CLI

AWS CLI

To get the CPU utilization per EC2 instance

The following example uses the `get-metric-statistics` command to get the CPU utilization for an EC2 instance with the ID i-abcdef.

```
aws cloudwatch get-metric-statistics --metric-name CPUUtilization --start-
time 2014-04-08T23:18:00Z --end-time 2014-04-09T23:18:00Z --period 3600 --
namespace AWS/EC2 --statistics Maximum --dimensions Name=InstanceId,Value=i-
abcdef
```

Output:

```
{
    "Datapoints": [
        {
            "Timestamp": "2014-04-09T11:18:00Z",
            "Maximum": 44.79,

            "Unit": "Percent"
        }
    ],
    "Label": "CPUUtilization"
}
```

Specifying multiple dimensions

The following example illustrates how to specify multiple dimensions. Each dimension is specified as a Name/Value pair, with a comma between the name and the value. Multiple dimensions are separated by a space. If a single metric includes multiple dimensions, you must specify a value for every defined dimension.

For more examples using the `get-metric-statistics` command, see Get Statistics for a Metric in the *Amazon CloudWatch Developer Guide*.

```
aws cloudwatch get-metric-statistics --metric-name Buffers --
namespace MyNameSpace --dimensions Name=InstanceID,Value=i-
abcdef Name=InstanceType,Value=m1.small --start-time 2016-10-15T04:00:00Z --end-
time 2016-10-19T07:00:00Z --statistics Average --period 60
```

- For API details, see GetMetricStatistics in *AWS CLI Command Reference*.

Python

SDK for Python (Boto3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
class CloudWatchWrapper:
    """Encapsulates Amazon CloudWatch functions."""

    def __init__(self, cloudwatch_resource):
        """
        :param cloudwatch_resource: A Boto3 CloudWatch resource.
        """
        self.cloudwatch_resource = cloudwatch_resource

    def get_metric_statistics(self, namespace, name, start, end, period,
 stat_types):
        """
        Gets statistics for a metric within a specified time span. Metrics are
 grouped
        into the specified period.

        :param namespace: The namespace of the metric.
        :param name: The name of the metric.
        :param start: The UTC start time of the time span to retrieve.
        :param end: The UTC end time of the time span to retrieve.
```

```
        :param period: The period, in seconds, in which to group metrics. The
period
                       must match the granularity of the metric, which depends on
                       the metric's age. For example, metrics that are older than
                       three hours have a one-minute granularity, so the period
must
                       be at least 60 and must be a multiple of 60.
        :param stat_types: The type of statistics to retrieve, such as average
value
                           or maximum value.
        :return: The retrieved statistics for the metric.

    public string SaveMetricImage(MemoryStream memoryStream, string metricName)
    {
        var metricFileName = $"{metricName}_{DateTime.Now.Ticks}.png";
```

```
        using var sr = new StreamReader(memoryStream);
        // Writes the memory stream to a file.
        File.WriteAllBytes(metricFileName, memoryStream.ToArray());
        var filePath = Path.Join(AppDomain.CurrentDomain.BaseDirectory,
            metricFileName);
        return filePath;
    }
```

- For API details, see GetMetricWidgetImage in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To retrieve a snapshot graph of CPUUtilization

The following `get-metric-widget-image` example retrieves snapshot graph for the metric `CPUUtilization` of the EC2 instance with the ID `i-abcde` and saves the retrieved image as a file named "image.png" on your local machine.

```
aws cloudwatch get-metric-widget-image \
    --metric-widget '{"metrics":[["AWS/EC2","CPUUtilization","InstanceId","i-abcde"]]}' \
    --output-format png \
    --output text | base64 --decode > image.png
```

This command produces no output.

- For API details, see GetMetricWidgetImage in *AWS CLI Command Reference*.

Use `ListDashboards` with an AWS SDK or CLI

The following code examples show how to use `ListDashboards`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Creating a monitoring dashboard with function name as a variable

.NET

SDK for .NET (v4)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
/// <summary>
/// Get a list of dashboards.
/// </summary>
/// <returns>A list of DashboardEntry objects.</returns>
public async Task<List<DashboardEntry>> ListDashboards()
{
    var results = new List<DashboardEntry>();
    var paginateDashboards = _amazonCloudWatch.Paginators.ListDashboards(
        new ListDashboardsRequest());
    // Get the entire list using the paginator.
    await foreach (var data in paginateDashboards.DashboardEntries)
    {
        results.Add(data);
    }

    return results;
}
```

- For API details, see ListDashboards in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To retrieve a list of Dashboards

The following `list-dashboards` example lists all the Dashboards in the specified account.

```
aws cloudwatch list-dashboards
```

Output:

```
{
    "DashboardEntries": [
        {
            "DashboardName": "Dashboard-A",
            "DashboardArn": "arn:aws:cloudwatch::123456789012:dashboard/
Dashboard-A",
            "LastModified": "2024-10-11T18:40:11+00:00",
            "Size": 271
        },
        {
            "DashboardName": "Dashboard-B",
            "DashboardArn": "arn:aws:cloudwatch::123456789012:dashboard/
Dashboard-B",
            "LastModified": "2024-10-11T18:44:41+00:00",
            "Size": 522
        }
    ]
}
```

For more information, see Amazon CloudWatch dashboards in the *Amazon CloudWatch User Guide*.

- For API details, see ListDashboards in *AWS CLI Command Reference*.

                println("Name is ${obj.dashboardName}")
                println("Dashboard ARN is ${obj.dashboardArn}")
            }
```

```
    }
}
```

- For API details, see ListDashboards in *AWS SDK for Kotlin API reference*.

PowerShell

Tools for PowerShell V4

Example 1: Returns the collection of dashboards for your account.

```
Get-CWDashboardList
```

Output:

```
DashboardArn DashboardName LastModified        Size
------------ ------------- ------------        ----
arn:...      Dashboard1    7/6/2017 8:14:15 PM 252
```

Example 2: Returns the collection of dashboards for your account whose names start with the prefix 'dev'.

```
Get-CWDashboardList -DashboardNamePrefix dev
```

- For API details, see ListDashboards in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: Returns the collection of dashboards for your account.

```
Get-CWDashboardList
```

Output:

```
DashboardArn DashboardName LastModified        Size
------------ ------------- ------------        ----
arn:...      Dashboard1    7/6/2017 8:14:15 PM 252
```

Example 2: Returns the collection of dashboards for your account whose names start with the prefix 'dev'.

```
Get-CWDashboardList -DashboardNamePrefix dev
```

- For API details, see ListDashboards in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

CLI

AWS CLI

To list the metrics for Amazon SNS

The following `list-metrics` example displays the metrics for Amazon SNS.

```
aws cloudwatch list-metrics \
    --namespace "AWS/SNS"
```

Output:

```
{
    "Metrics": [
        {
            "Namespace": "AWS/SNS",
            "Dimensions": [
                {
                    "Name": "TopicName",
                    "Value": "NotifyMe"
                }
            ],
            "MetricName": "PublishSize"
```

```
        },
        {
            "Namespace": "AWS/SNS",
            "Dimensions": [
                {
                    "Name": "TopicName",
                    "Value": "CFO"
                }
            ],
            "MetricName": "PublishSize"
        },
        {
            "Namespace": "AWS/SNS",

JavaScript

SDK for JavaScript (v3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Import the SDK and client modules and call the API.

```
import {
  CloudWatchServiceException,
  ListMetricsCommand,
} from "@aws-sdk/client-cloudwatch";
import { client } from "../libs/client.js";

export const main = async () => {
  // Use the AWS console to see available namespaces and metric names. Custom
 metrics can also be created.
  // https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/
viewing_metrics_with_cloudwatch.html
  const command = new ListMetricsCommand({
    Dimensions: [
      {
        Name: "LogGroupName",
      },
    ],
    MetricName: "IncomingLogEvents",
    Namespace: "AWS/Logs",
  });

  try {
    const response = await client.send(command);
    console.log(`Metrics count: ${response.Metrics?.length}`);
    return response;
  } catch (caught) {
    if (caught instanceof CloudWatchServiceException) {
      console.error(`Error from CloudWatch. ${caught.name}: ${caught.message}`);
    } else {
      throw caught;
    }
```

```
  }
};
```

Create the client in a separate module and export it.

```
import { CloudWatchClient } from "@aws-sdk/client-cloudwatch";

export const client = new CloudWatchClient({});
```

- For more information, see AWS SDK for JavaScript Developer Guide.
- For API details, see ListMetrics in *AWS SDK for JavaScript API Reference*.

SDK for JavaScript (v2)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create CloudWatch service object
var cw = new AWS.CloudWatch({ apiVersion: "2010-08-01" });

var params = {
  Dimensions: [
    {
      Name: "LogGroupName" /* required */,
    },
  ],
  MetricName: "IncomingLogEvents",
  Namespace: "AWS/Logs",
};

cw.listMetrics(params, function (err, data) {
```

```
  if (err) {
    console.log("Error", err);
  } else {
    console.log("Metrics", JSON.stringify(data.Metrics));
  }
});
```

Use `PutAnomalyDetector` with an AWS SDK or CLI

The following code examples show how to use `PutAnomalyDetector`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Learn the basics

.NET

SDK for .NET (v4)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   /// <summary>
   /// Add an anomaly detector for a single metric.
   /// </summary>
   /// <param name="anomalyDetector">A single metric anomaly detector.</param>
   /// <returns>True if successful.</returns>
   public async Task<bool> PutAnomalyDetector(SingleMetricAnomalyDetector
anomalyDetector)
   {
       var putAlarmDetectorResult = await
_amazonCloudWatch.PutAnomalyDetectorAsync(
           new PutAnomalyDetectorRequest()
           {
               SingleMetricAnomalyDetector = anomalyDetector
           });

       return putAlarmDetectorResult.HttpStatusCode == HttpStatusCode.OK;
   }
```

- For API details, see PutAnomalyDetector in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To create an anomaly detection model

The following `put-anomaly-detector` example creates an anomaly detection model for a CloudWatch metric.

```
aws cloudwatch put-anomaly-detector \
    --namespace AWS/Logs \
    --metric-name IncomingBytes \
    --stat SampleCount
```

This command produces no output.

For more information, see Using CloudWatch anomaly detection in the *Amazon CloudWatch User Guide*.

- For API details, see PutAnomalyDetector in *AWS CLI Command Reference*.

CLI

AWS CLI

To create a dashboard

The following `put-dashboard` example creates a dashboard named `Dashboard-A` in the specified account.

```
aws cloudwatch put-dashboard \
    --dashboard-name Dashboard-A \
    --dashboard-body '{"widgets":
[{"height":6,"width":6,"y":0,"x":0,"type":"metric","properties":
{"view":"timeSeries","stacked":false,"metrics":
```

```
[["Namespace","CPUUtilization","Environment","Prod","Type","App"]],"region":"us-east-1"}}]}'
```

Output:

```
{
    "DashboardValidationMessages": []
}
```

For more information, see Creating a CloudWatch dashboard in the *Amazon CloudWatch User Guide*.

- For API details, see PutDashboard in *AWS CLI Command Reference*.

C++

SDK for C++

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Include the required files.

```
#include <aws/core/Aws.h>
#include <aws/monitoring/CloudWatchClient.h>
#include <aws/monitoring/model/PutMetricAlarmRequest.h>
#include <iostream>
```

Create the alarm to watch the metric.

```
        Aws::CloudWatch::CloudWatchClient cw;
        Aws::CloudWatch::Model::PutMetricAlarmRequest request;
        request.SetAlarmName(alarm_name);
        request.SetComparisonOperator(
            Aws::CloudWatch::Model::ComparisonOperator::GreaterThanThreshold);
        request.SetEvaluationPeriods(1);
        request.SetMetricName("CPUUtilization");
        request.SetNamespace("AWS/EC2");
        request.SetPeriod(60);
        request.SetStatistic(Aws::CloudWatch::Model::Statistic::Average);
        request.SetThreshold(70.0);
        request.SetActionsEnabled(false);
```

```
        request.SetAlarmDescription("Alarm when server CPU exceeds 70%");
        request.SetUnit(Aws::CloudWatch::Model::StandardUnit::Seconds);

        Aws::CloudWatch::Model::Dimension dimension;
        dimension.SetName("InstanceId");
        dimension.SetValue(instanceId);

        request.AddDimensions(dimension);

        auto outcome = cw.PutMetricAlarm(request);
        if (!outcome.IsSuccess())
        {
            std::cout << "Failed to create CloudWatch alarm:" <<
                outcome.GetError().GetMessage() << std::endl;
        }
        else
        {
            std::cout << "Successfully created CloudWatch alarm " << alarm_name
                << std::endl;
        }
```

- For API details, see PutMetricAlarm in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To send an Amazon Simple Notification Service email message when CPU utilization exceeds 70 percent

The following example uses the `put-metric-alarm` command to send an Amazon Simple Notification Service email message when CPU utilization exceeds 70 percent:

```
aws cloudwatch put-metric-alarm --alarm-name cpu-mon --alarm-description "Alarm
 when CPU exceeds 70 percent" --metric-name CPUUtilization --namespace AWS/
EC2 --statistic Average --period 300 --threshold 70 --comparison-
operator GreaterThanThreshold  --dimensions "Name=InstanceId,Value=i-12345678" --
evaluation-periods 2 --alarm-actions arn:aws:sns:us-east-1:111122223333:MyTopic
 --unit Percent
```

This command returns to the prompt if successful. If an alarm with the same name already exists, it will be overwritten by the new alarm.

To specify multiple dimensions

The following example illustrates how to specify multiple dimensions. Each dimension is specified as a Name/Value pair, with a comma between the name and the value. Multiple dimensions are separated by a space:

```
aws cloudwatch put-metric-alarm --alarm-name "Default_Test_Alarm3" --alarm-
description "The default example alarm" --namespace "CW EXAMPLE METRICS"
 --metric-name Default_Test --statistic Average --period 60 --evaluation-
periods 3 --threshold 50 --comparison-operator GreaterThanOrEqualToThreshold --
dimensions Name=key1,Value=value1 Name=key2,Value=value2
```

- For API details, see PutMetricAlarm in *AWS CLI Command Reference*.

JavaScript

SDK for JavaScript (v3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Import the SDK and client modules and call the API.

```
import { PutMetricAlarmCommand } from "@aws-sdk/client-cloudwatch";
import { client } from "../libs/client.js";

const run = async () => {
  // This alarm triggers when CPUUtilization exceeds 70% for one minute.
  const command = new PutMetricAlarmCommand({
    AlarmName: process.env.CLOUDWATCH_ALARM_NAME, // Set the value of
 CLOUDWATCH_ALARM_NAME to the name of an existing alarm.
    ComparisonOperator: "GreaterThanThreshold",
    EvaluationPeriods: 1,
    MetricName: "CPUUtilization",
    Namespace: "AWS/EC2",
    Period: 60,
    Statistic: "Average",
    Threshold: 70.0,
    ActionsEnabled: false,
    AlarmDescription: "Alarm when server CPU exceeds 70%",
    Dimensions: [
      {
```

```
        Name: "InstanceId",
        Value: process.env.EC2_INSTANCE_ID, // Set the value of EC_INSTANCE_ID to
 the Id of an existing Amazon EC2 instance.
      },
    ],
    Unit: "Percent",
  });

  try {
    return await client.send(command);
  } catch (err) {
    console.error(err);
  }
};

export default run();
```

Create the client in a separate module and export it.

```
import { CloudWatchClient } from "@aws-sdk/client-cloudwatch";

export const client = new CloudWatchClient({});
```

> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Include the required files.

```
#include <aws/core/Aws.h>
#include <aws/monitoring/CloudWatchClient.h>
#include <aws/monitoring/model/PutMetricDataRequest.h>
#include <iostream>
```

Put data into the metric.

```
        Aws::CloudWatch::CloudWatchClient cw;

        Aws::CloudWatch::Model::Dimension dimension;
        dimension.SetName("UNIQUE_PAGES");
        dimension.SetValue("URLS");

        Aws::CloudWatch::Model::MetricDatum datum;
        datum.SetMetricName("PAGES_VISITED");
        datum.SetUnit(Aws::CloudWatch::Model::StandardUnit::None);
        datum.SetValue(data_point);
        datum.AddDimensions(dimension);

        Aws::CloudWatch::Model::PutMetricDataRequest request;
        request.SetNamespace("SITE/TRAFFIC");
        request.AddMetricData(datum);

        auto outcome = cw.PutMetricData(request);
        if (!outcome.IsSuccess())
        {
            std::cout << "Failed to put sample metric data:" <<
                outcome.GetError().GetMessage() << std::endl;
        }
```

```
        else
        {
            std::cout << "Successfully put sample metric data" << std::endl;
        }
```

- For API details, see PutMetricData in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To publish a custom metric to Amazon CloudWatch

The following example uses the `put-metric-data` command to publish a custom metric to Amazon CloudWatch:

```
aws cloudwatch put-metric-data --namespace "Usage Metrics" --metric-data file://
metric.json
```

The values for the metric itself are stored in the JSON file, `metric.json`.

Here are the contents of that file:

```
[
  {
    "MetricName": "New Posts",
    "Timestamp": "Wednesday, June 12, 2013 8:28:20 PM",
    "Value": 0.50,
    "Unit": "Count"
  }
]
```

For more information, see Publishing Custom Metrics in the *Amazon CloudWatch Developer Guide*.

To specify multiple dimensions

The following example illustrates how to specify multiple dimensions. Each dimension is specified as a Name=Value pair. Multiple dimensions are separated by a comma.:

```
aws cloudwatch put-metric-data --metric-name Buffers --
namespace MyNameSpace --unit Bytes --value 231434333 --
dimensions InstanceID=1-23456789,InstanceType=m1.small
```

- For API details, see PutMetricData in *AWS CLI Command Reference*.

JavaScript

SDK for JavaScript (v3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Import the SDK and client modules and call the API.

```
import { PutMetricDataCommand } from "@aws-sdk/client-cloudwatch";
import { client } from "../libs/client.js";

const run = async () => {
  // See https://docs.aws.amazon.com/AmazonCloudWatch/latest/APIReference/
API_PutMetricData.html#API_PutMetricData_RequestParameters
  // and https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/
publishingMetrics.html
  // for more information about the parameters in this command.
  const command = new PutMetricDataCommand({
    MetricData: [
      {
        MetricName: "PAGES_VISITED",
        Dimensions: [
          {
            Name: "UNIQUE_PAGES",
            Value: "URLS",
```

```
          },
        ],
        Unit: "None",
        Value: 1.0,
      },
    ],
    Namespace: "SITE/TRAFFIC",
  });

  try {
    return await client.send(command);
  } catch (err) {
    console.error(err);
  }
};

export default run();
```

Create the client in a separate module and export it.

```
import { CloudWatchClient } from "@aws-sdk/client-cloudwatch";

export const client = new CloudWatchClient({});
```

- For more information, see AWS SDK for JavaScript Developer Guide.
- For API details, see PutMetricData in *AWS SDK for JavaScript API Reference*.

SDK for JavaScript (v2)

> **Note**
>

PowerShell

Tools for PowerShell V4

Example 1: Creates a new MetricDatum object, and writes it to Amazon Web Services CloudWatch Metrics.

```
### Create a MetricDatum .NET object
$Metric = New-Object -TypeName Amazon.CloudWatch.Model.MetricDatum
$Metric.Timestamp = [DateTime]::UtcNow
$Metric.MetricName = 'CPU'
$Metric.Value = 50

### Write the metric data to the CloudWatch service
Write-CWMetricData -Namespace instance1 -MetricData $Metric
```

- For API details, see PutMetricData in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: Creates a new MetricDatum object, and writes it to Amazon Web Services CloudWatch Metrics.

```
### Create a MetricDatum .NET object
$Metric = New-Object -TypeName Amazon.CloudWatch.Model.MetricDatum
$Metric.Timestamp = [DateTime]::UtcNow
$Metric.MetricName = 'CPU'
$Metric.Value = 50

### Write the metric data to the CloudWatch service
Write-CWMetricData -Namespace instance1 -MetricData $Metric
```

- For API details, see PutMetricData in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see Using CloudWatch with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Scenarios for CloudWatch using AWS SDKs

The following code examples show you how to implement common scenarios in CloudWatch with AWS SDKs. These scenarios show you how to accomplish specific tasks by calling multiple functions within CloudWatch or combined with other AWS services. Each scenario includes a link to the complete source code, where you can find instructions on how to set up and run the code.

Scenarios target an intermediate level of experience to help you understand service actions in context.

Examples

- Creating a monitoring dashboard with function name as a variable
- Get started with CloudWatch alarms using an AWS SDK
- Manage CloudWatch metrics and alarms using an AWS SDK
- Monitor performance of Amazon DynamoDB using an AWS SDK
- Run CPU stress tests on virtual machine instances using fault injection
- Using property variables in monitoring dashboards to monitor multiple serverless functions

Creating a monitoring dashboard with function name as a variable

The following code example shows how to:

- Create a CloudWatch dashboard
- Add Lambda metrics widgets with a function name variable
- Verify the dashboard
- Clean up resources

Bash

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# Script to create a CloudWatch dashboard with Lambda function name as a variable
# This script creates a CloudWatch dashboard that allows you to switch between
 different Lambda functions

Get started with CloudWatch alarms using an AWS SDK

The following code example shows how to:

- Create an alarm.
- Disable alarm actions.
- Describe an alarm.
- Delete an alarm.

SAP ABAP

SDK for SAP ABAP

> **Note**

Monitor performance of Amazon DynamoDB using an AWS SDK

The following code example shows how to configure an application's use of DynamoDB to monitor performance.

Java

SDK for Java 2.x

This example shows how to configure a Java application to monitor the performance of DynamoDB. The application sends metric data to CloudWatch where you can monitor the performance.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- CloudWatch
- DynamoDB

For a complete list of AWS SDK developer guides and code examples, see Using CloudWatch with an AWS SDK. This topic also includes information about getting started and details about previous SDK versions.

Run CPU stress tests on virtual machine instances using fault injection

The following code example shows how to:

- Create IAM roles
- Create a CloudWatch alarm
- Create an experiment template
- Run the experiment
- Verify the results
- Clean up resources

Bash

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

Using property variables in monitoring dashboards to monitor multiple serverless functions

The following code example shows how to:

- Create Lambda functions for monitoring
- Create a CloudWatch dashboard
- Add a property variable to the dashboard
- Clean up resources

Bash

AWS CLI with Bash script

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Sample developer tutorials repository.

```
#!/bin/bash

# CloudWatch Dashboard with Lambda Function Variable Script
# This script creates a CloudWatch dashboard with a property variable for Lambda
 function names

set -euo pipefail

# Security: Set restrictive umask

Logging Amazon CloudWatch API and console operations with AWS CloudTrail

Amazon CloudWatch, CloudWatch Synthetics, CloudWatch RUM, Amazon Q Developer operational investigations, Network Flow Monitor, and Internet Monitor are integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures API calls made by or on behalf of your AWS account. The captured calls include calls from the CloudWatch console and code calls to CloudWatch API operations. Using the information collected by CloudTrail, you can determine the request that was made to CloudWatch, the IP address from which the request was made, when it was made, and additional details.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root user or user credentials.
- Whether the request was made on behalf of an IAM Identity Center user.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

CloudTrail is active in your AWS account when you create the account and you automatically have access to the CloudTrail **Event history**. The CloudTrail **Event history** provides a viewable, searchable, downloadable, and immutable record of the past 90 days of recorded management events in an AWS Region. For more information, see Working with CloudTrail Event history in the *AWS CloudTrail User Guide*. There are no CloudTrail charges for viewing the **Event history**.

For an ongoing record of events in your AWS account past 90 days, create a trail or a CloudTrail Lake event data store.

CloudTrail trails

A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. All trails created using the AWS Management Console are multi-Region. You can create a single-Region or a multi-Region trail by using the AWS CLI. Creating a multi-Region trail is recommended because you capture activity in all AWS Regions in your account. If you create a single-Region trail, you can view only the events logged in the trail's AWS Region. For more information about trails, see Creating a

trail for your AWS account and Creating a trail for an organization in the *AWS CloudTrail User Guide*.

You can deliver one copy of your ongoing management events to your Amazon S3 bucket at no charge from CloudTrail by creating a trail, however, there are Amazon S3 storage charges. For more information about CloudTrail pricing, see AWS CloudTrail Pricing. For information about Amazon S3 pricing, see Amazon S3 Pricing.

CloudTrail Lake event data stores

CloudTrail Lake lets you run SQL-based queries on your events. CloudTrail Lake converts existing events in row-based JSON format to Apache ORC format. ORC is a columnar storage format that is optimized for fast retrieval of data. Events are aggregated into *event data stores*, which are immutable collections of events based on criteria that you select by applying advanced event selectors. The selectors that you apply to an event data store control which events persist and are available for you to query. For more information about CloudTrail Lake, see Working with AWS CloudTrail Lake in the *AWS CloudTrail User Guide*.

CloudTrail Lake event data stores and queries incur costs. When you create an event data store, you choose the pricing option you want to use for the event data store. The pricing option determines the cost for ingesting and storing events, and the default and maximum retention period for the event data store. For more information about CloudTrail pricing, see AWS CloudTrail Pricing.

> **Note**
>
> For information about CloudWatch Logs API calls that are logged in CloudTrail, see CloudWatch Logs information in CloudTrail.

CloudWatch data events in CloudTrail

CloudTrail can capture API activities related to the CloudWatch data plane operations on metrics GetMetricData, GetMetricWidgetImage, PutMetricData, GetMetricStatistics, and ListMetrics APIs.

> **Note**
>
> PromQL queries are not supported for CloudTrail data events. Only the CloudWatch APIs listed above can be logged as data events in CloudTrail.

Data events, also known as data plane operations, give you insight into the resource operations performed on or within a resource. Data events are often high-volume activities.

By default, CloudTrail doesn't log data events. The CloudTrail **Event history** doesn't record data events.

Additional charges apply for data events. For more information about CloudTrail pricing, see AWS CloudTrail Pricing.

You can log data events for the CloudWatch resource types by using the CloudTrail console, AWS CLI, or CloudTrail API operations. For more information about how to log data events, see Logging data events with the AWS Management Console and Logging data events with the AWS Command Line Interface in the *AWS CloudTrail User Guide*.

Data plane events can be filtered by resource type. Because there are additional costs for using data events in CloudTrail, filtering by resource allows you to have more control over what you log and pay for.

Using the information that CloudTrail collects, you can identify any of the metric APIs, the IP address of the requester, the requester's identity, and the date and time of the request. Logging the **GetMetricData**, **GetMetricWidgetImage**, **PutMetricData**, **GetMetricStatistics**, and **ListMetrics** APIs using CloudTrail helps you enable operational and risk auditing, governance, and compliance of your AWS account.

> **Note**
>
> When you view the **GetMetricData** events in CloudTrail, you might see more calls than the calls that you initiated. This is because CloudWatch logs events to CloudTrail for **GetMetricData** actions that are initiated by internal components. For example, you'll see **GetMetricData** calls initiated by CloudWatch dashboards to refresh widget data, and **GetMetricData** calls initiated by a monitoring account to retrieve data from a source account, in cross-account observability. These internally-initiated calls don't incur CloudWatch charges, but they do count toward the number of events logged in CloudTrail, and CloudTrail charges according to the number of events logged.

The following is an example of a CloudTrail event for a **GetMetricData** operation.

```
{
    "eventVersion": "1.09",
    "userIdentity": {
        "type": "IAMUser",
        "principalId": "AIDA2NYTR2EPCTNY7AF3L",

    }
  }
```

Query generation information in CloudTrail

CloudTrail logging for Query generator console events is also supported. Query generator is currently supported for CloudWatch Metric Insights and CloudWatch Logs Insights. In these CloudTrail events, the `eventSource` is `monitoring.amazonaws.com`.

The following example shows a CloudTrail log entry that demonstrates the **GenerateQuery** action in CloudWatch Metrics Insights.

```
{
    "eventVersion": "1.09",
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "EX_PRINCIPAL_ID",
        "arn": "arn:aws:iam::123456789012:assumed-role/role_name",
        "accountId": "123456789012",
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "sessionContext": {
            "sessionIssuer": {
                "type": "Role",
                "principalId": "EX_PRINCIPAL_ID",
                "arn": "arn:aws:iam::111222333444:role/Administrator",
                "accountId": "123456789012",
                "userName": "SAMPLE_NAME"
            },
            "attributes": {
                "creationDate": "2020-04-08T21:43:24Z",

Amazon Q Developer operational investigations events in CloudTrail

Amazon Q Developer operational investigations supports logging the following actions as events in CloudTrail log files.

- CreateInvestigationGroup
- GetInvestigationGroup
- DeleteInvestigationGroup
- ListInvestigationGroup
- PutInvestigationGroupPolicy
- DeleteInvestigationGroupPolicy
- ListTagsForResource
- GetInvestigationGroupPolicy
- TagResource
- UntagResource
- UpdateInvestigationGroup

Example: Amazon Q Developer operational investigations log file entries

The following example shows a Amazon Q Developer operational investigations log entry that demonstrates the `CreateInvestigationGroup` action.

```
{
```

```
 "eventVersion": "1.09",
 "userIdentity": {
  "type": "AssumedRole",
  "principalId": "EX_PRINCIPAL_ID",
  "arn": "arn:aws:iam::123456789012:assumed-role/role_name",
  "accountId": "123456789012",
  "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
  "sessionContext": {
   "sessionIssuer": {
    "type": "Role",
    "principalId": "EX_PRINCIPAL_ID",
    "arn": "arn:aws:iam::123456789012:role/role_name",
    "accountId": "123456789012",
    "userName": "SAMPLE_NAME"
   },
   "attributes": {
    "creationDate": "2024-10-30T18:42:05Z",

Network Flow Monitor in CloudTrail

Network Flow Monitor supports logging the following actions as events in CloudTrail log files.

- CreateMonitor
- CreateScope
- DeleteMonitor
- DeleteScope
- GetMonitor
- GetScope
- ListMonitors
- ListScopes
- ListTagsForResource

- TagResource
- UntagResource
- UpdateMonitor
- UpdateScope

Example: Network Flow Monitor log file entry

The following example shows a Network Flow Monitor CloudTrail log file entry that demonstrates the `CreateMonitor` action.

```
{
    "eventVersion": "1.09",
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "EX_PRINCIPAL_ID",
        "arn": "arn:aws:iam::000000000000:assumed-role/role_name",
        "accountId": "123456789012",
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "sessionContext": {
            "sessionIssuer": {
                "type": "Role",

```

Network Flow Monitor data plane events in CloudTrail

CloudTrail can capture API activities related to the CloudWatch-NetworkFlowMonitor data plane operations.

Data events, also known as data plane operations, give you insight into the resource operations performed on or within a resource. Data events are often high-volume activities.

To enable logging of Network Flow Monitor data events in CloudTrail files, you'll need to enable the logging of data plane API activity in CloudTrail. See Logging data events for trails for more information.

Data plane events can be filtered by resource type. Because there are additional costs for using data events in CloudTrail, filtering by resource allows you to have more control over what you log and pay for.

Using the information that CloudTrail collects, you can identify a specific request to the CloudWatch-NetworkFlowMonitor data plane APIs, the IP address of the requester, the requester's identity, and the date and time of the request. Logging the data plane APIs using CloudTrail can help you with operational and risk auditing, governance, and compliance of your AWS account.

The following are data plane APIs in Network Flow Monitor.

- GetQueryResultsMonitorTopContributors
- GetQueryResultsMonitorsTopContributors
- GetQueryResultsWorkloadInsightsTopContributors
- GetQueryResultsWorkloadInsightsTopContributorsData
- GetQueryStatusMonitorTopContributors
- GetQueryStatusMonitorsTopContributors
- GetQueryStatusWorkloadInsightsTopContributors
- GetQueryStatusWorkloadInsightsTopContributorsData
- StartQueryMonitorTopContributors
- StartQueryMonitorsTopContributors
- StartQueryWorkloadInsightsTopContributors
- StartQueryWorkloadInsightsTopContributorsData
- StopQueryMonitorTopContributors

- StopQueryMonitorsTopContributors
- StopQueryWorkloadInsightsTopContributors
- StopQueryWorkloadInsightsTopContributorsData

The following example shows a CloudTrail log entry that demonstrates the GetQueryResultsMonitorsTopContributors action.

```
{
  "eventVersion": "1.09",
  "userIdentity": {
    "type": "AssumedRole",
    "principalId": "EX_PRINCIPAL_ID",
    "arn": "arn:aws:iam::000000000000:assumed-role/role_name",
    "accountId": "123456789012",
    "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
    "sessionContext": {
      "sessionIssuer": {
        "type": "Role",

Internet Monitor in CloudTrail

Internet Monitor supports logging the following actions as events in CloudTrail log files.

- CreateMonitor
- DeleteMonitor
- GetHealthEvent
- GetMonitor
- GetQueryResults
- GetQueryStatus
- ListHealthEvents
- ListInternetEvents

- ListMonitors
- ListTagsForResource
- StartQuery
- StopQuery
- TagResource
- UntagResource
- UpdateMonitor

Example: Internet Monitor log file entries

The following example shows a CloudTrail Internet Monitor log entry that demonstrates the `ListMonitors` action.

```
{
        "eventVersion": "1.08",
        "userIdentity": {
            "type": "AssumedRole",
            "principalId": "EX_PRINCIPAL_ID",
            "arn": "arn:aws:iam::000000000000:assumed-role/role_name",
            "accountId":"123456789012",
            "accessKeyId":"AKIAIOSFODNN7EXAMPLE",
            "sessionContext": {
                "sessionIssuer": {
                "type": "Role",
                "principalId": "EX_PRINCIPAL_ID",
                "arn": "arn:aws:iam::000000000000:role/Admin",
                "accountId":"123456789012",
                "userName": "SAMPLE_NAME"
                },
                "webIdFederationData": {},
                "attributes": {
                    "creationDate": "2022-10-11T17:25:41Z",
                    "mfaAuthenticated": "false"
                }
            }
        },
        "eventTime": "2022-10-11T17:30:18Z",
        "eventSource": "internetmonitor.amazonaws.com",
        "eventName": "ListMonitors",
        "awsRegion": "us-east-2",
```

```
        "sourceIPAddress": "192.0.2.0",
        "userAgent": "Mozilla/5.0 (Macintosh; Intel Mac OS X 10_15_7)",
        "requestParameters": null,
        "responseElements": null,
        "requestID": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",

        "requestID": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
        "eventID": "a1b2c3d4-5678-90ab-cdef-EXAMPLEbbbbb",
        "readOnly": false,
        "eventType": "AwsApiCall",
        "managementEvent": true,
        "recipientAccountId": "111122223333",
        "eventCategory": "Management"
    }
```

CloudWatch Synthetics information in CloudTrail

CloudWatch Synthetics supports logging the following actions as events in CloudTrail log files:

- AssociateResource
- CreateCanary
- CreateGroup
- DeleteCanary
- DeleteGroup
- DescribeCanaries
- DescribeCanariesLastRun
- DescribeRuntimeVersions
- DisassociateResource
- GetCanary
- GetCanaryRuns
- GetGroup

- ListAssociatedGroups
- ListGroupResources
- ListGroups
- ListTagsForResource
- StartCanary
- StartCanaryDryRun
- StopCanary
- TagResource
- UntagResource
- UpdateCanary

Example: CloudWatch Synthetics log file entries

The following example shows a CloudTrail Synthetics log entry that demonstrates the `DescribeCanaries` action.

```
{
    "eventVersion": "1.05",
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "EX_PRINCIPAL_ID",
        "arn": "arn:aws:iam::123456789012:assumed-role/role_name",
        "accountId":"123456789012",
        "accessKeyId":"AKIAIOSFODNN7EXAMPLE",
        "sessionContext": {
            "sessionIssuer": {
                "type": "Role",
                "principalId": "EX_PRINCIPAL_ID",
                "arn": "arn:aws:iam::111222333444:role/Administrator",
                "accountId":"123456789012",
                "userName": "SAMPLE_NAME"
            },

CloudWatch RUM information in CloudTrail

CloudWatch RUM supports logging the following actions as events in CloudTrail log files:

- BatchCreateRumMetricDefinitions
- BatchDeleteRumMetricDefinitions
- BatchGetRumMetricDefinitions

- CreateAppMonitor
- DeleteAppMonitor
- DeleteResourcePolicy
- DeleteRumMetricsDestination
- GetAppMonitor
- GetAppMonitorData
- GetResourcePolicy
- ListAppMonitors
- ListRumMetricsDestinations
- ListTagsForResource
- PutResourcePolicy
- PutRumMetricsDestination
- TagResource
- UntagResource
- UpdateAppMonitor
- UpdateRumMetricDefinition

Example: CloudWatch RUM log file entries

This section contains example CloudTrail entries for some CloudWatch RUM APIs.

The following example shows a CloudTrail log entry that demonstrates the CreateAppMonitor action.

```
{
    "eventVersion": "1.09",
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "EXAMPLE_PRINCIPAL_ID",
        "arn": "arn:aws:sts::777777777777:assumed-role/EXAMPLE",
        "accountId": "777777777777",
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "sessionContext": {
            "sessionIssuer": {
                "type": "Role",
                "principalId": "EXAMPLE_PRINCIPAL_ID",
```

```
                "arn": "arn:aws:iam::777777777777:role/EXAMPLE",
                "accountId": "777777777777",
                "userName": "USERNAME_EXAMPLE"
            },
            "attributes": {
                "creationDate": "2024-07-23T16:48:47Z",
                "mfaAuthenticated": "false"
            }
        }
    },

```

CloudWatch RUM data plane events in CloudTrail

CloudTrail can capture API activities related to the CloudWatch RUM data plane operation PutRumEvents.

Data events, also known as data plane operations, give you insight into the resource operations performed on or within a resource. Data events are often high-volume activities.

To enable logging of the **PutRumEvents** data events in CloudTrail files, you'll need to enable the logging of data plane API activity in CloudTrail. See Logging data events for trails for more information.

Data plane events can be filtered by resource type. Because there are additional costs for using data events in CloudTrail, filtering by resource allows you to have more control over what you log and pay for.

Using the information that CloudTrail collects, you can identify a specific request to the CloudWatch RUM **PutRumEvents** API, the IP address of the requester, the requester's identity, and the date and time of the request. Logging the **PutRumEvents** API using CloudTrail helps you enable operational and risk auditing, governance, and compliance of your AWS account.

The following example shows a CloudTrail log entry that demonstrates the PutRumEvents action.

```
{
 "Records": [
     {
         "eventVersion": "1.09",
         "userIdentity": {
             "type": "AssumedRole",

Network Synthetic Monitor information in CloudTrail

Network Synthetic Monitor supports logging the following actions as events in CloudTrail log files:

- CreateMonitor
- CreateProbe
- DeleteMonitor
- DeleteProbe
- GetMonitor
- GetProbe
- ListMonitors
- ListTagsForResource
- TagResource
- UntagResource
- UpdateMonitor
- UpdateProbe

Example: Network Synthetic Monitor log file entries

The following example shows a Network Synthetic Monitor CloudTrail log entry that demonstrates the `CreateMonitor` action.

```
{
    "eventVersion": "1.09",
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "EX_PRINCIPAL_ID",
```

```
        "arn": "arn:aws:iam::111122223333:assumed-role/role_name",
        "accountId": "111122223333",
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "sessionContext": {
            "sessionIssuer": {
                "type": "Role",
                "principalId": "EX_PRINCIPAL_ID",
                "arn": "arn:aws:iam::111122223333:role/Admin",
                "accountId": "111122223333",
                "userName": "SAMPLE_NAME"
            },
            "attributes": {
                "creationDate": "2024-11-03T15:43:27Z",
                "mfaAuthenticated": "false"
            }
        }
    },
    "eventTime": "2024-11-03T15:58:11Z",
    "eventSource": "networksynthetics.amazonaws.com",
    "eventName": "CreateMonitor",
    "awsRegion": "us-east-1",
    "sourceIPAddress": "192.0.2.0",
    "userAgent": "Mozilla/5.0 (Macintosh; Intel Mac OS X 10_15_7)",
    "requestParameters": {

CloudWatch Observability Access Manager information in CloudTrail

CloudWatch Observability Access Manager supports logging the following actions as events in CloudTrail log files:

- CreateLink
- CreateSink
- DeleteLink
- DeleteSink
- GetLink
- GetSink
- GetSinkPolicy
- ListAttachedLinks
- ListLinks
- ListSinks
- ListTagsForResource
- PutSinkPolicy
- TagResource
- UntagResource
- UpdateLink

Example: CloudWatch Observability Access Manager log file entries

The following example shows a CloudWatch Observability Access Manager CloudTrail log entry that demonstrates the `CreateSink` action.

```
{
    "eventVersion": "1.09",
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "EX_PRINCIPAL_ID",
        "arn": "arn:aws:iam::111122223333:assumed-role/role_name",
```

```
        "accountId": "111122223333",
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "sessionContext": {
            "sessionIssuer": {
                "type": "Role",
                "principalId": "EX_PRINCIPAL_ID",
                "arn": "arn:aws:iam::111122223333:role/Admin",
                "accountId": "111122223333",
                "userName": "SAMPLE_NAME"
            },
            "attributes": {
                "creationDate": "2024-11-03T15:43:27Z",
                "mfaAuthenticated": "false"
            }
        }
    },
    "eventTime": "2024-11-03T15:58:11Z",
    "eventSource": "oam.amazonaws.com",
    "eventName": "CreateSink",
    "awsRegion": "us-east-1",
    "sourceIPAddress": "192.0.2.0",
    "userAgent": "Mozilla/5.0 (Macintosh; Intel Mac OS X 10_15_7)",
    "requestParameters": {
        "Name": "TestObservabilitySink"
    },
    "responseElements": {
        "Arn": "arn:aws:oam:us-east-1:111122223333:sink/TestObservabilitySink",
        "Id": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
        "Name": "TestObservabilitySink"
    },
    "requestID": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
    "eventID": "a1b2c3d4-5678-90ab-cdef-EXAMPLEbbbbb",
    "readOnly": false,
    "eventType": "AwsApiCall",
    "managementEvent": true,
    "recipientAccountId": "111122223333",
    "eventCategory": "Management"
}
```

CloudWatch Observability Admin information in CloudTrail

CloudWatch Observability Admin supports logging the following actions as events in CloudTrail log files:

- GetTelemetryEvaluationStatus
- GetTelemetryEvaluationStatusForOrganization
- ListResourceTelemetry
- ListResourceTelemetryForOrganization
- StartTelemetryEvaluation
- StartTelemetryEvaluationForOrganization
- StopTelemetryEvaluation
- StopTelemetryEvaluationForOrganization

Example: CloudWatch Observability Admin log file entries

The following example shows a CloudWatch Observability Admin CloudTrail log entry that demonstrates the `StartTelemetryEvaluation` action.

```
{
    "eventVersion": "1.09",
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "EX_PRINCIPAL_ID",
        "arn": "arn:aws:iam::111122223333:assumed-role/role_name",
        "accountId": "111122223333",
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "sessionContext": {
            "sessionIssuer": {
                "type": "Role",
                "principalId": "EX_PRINCIPAL_ID",
                "arn": "arn:aws:iam::111122223333:role/Admin",
                "accountId": "111122223333",
                "userName": "SAMPLE_NAME"
            },
            "attributes": {
                "creationDate": "2024-11-03T15:43:27Z",
                "mfaAuthenticated": "false"
            }
        }
    },
    "eventTime": "2024-11-03T15:58:11Z",
    "eventSource": "observabilityadmin.amazonaws.com",
    "eventName": "StartTelemetryEvaluation",
```

```
    "awsRegion": "us-east-1",
    "sourceIPAddress": "192.0.2.0",
    "userAgent": "Mozilla/5.0 (Macintosh; Intel Mac OS X 10_15_7)",
    "requestParameters": {},
    "responseElements": null,
    "requestID": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
    "eventID": "a1b2c3d4-5678-90ab-cdef-EXAMPLEbbbbb",
    "readOnly": false,
    "eventType": "AwsApiCall",
    "managementEvent": true,
    "recipientAccountId": "111122223333",
    "eventCategory": "Management"
}
```

CloudWatch Application Signals information in CloudTrail

CloudWatch Application Signals supports logging the following actions as events in CloudTrail log files:

- BatchGetServiceLevelObjectiveBudgetReport
- BatchUpdateExclusionWindows
- CreateServiceLevelObjective
- DeleteServiceLevelObjective
- GetService
- GetServiceLevelObjective
- ListServiceDependencies
- ListServiceDependents
- ListServiceLevelObjectives
- ListServiceOperations
- ListServices
- ListTagsForResource
- StartDiscovery
- TagResource
- UntagResource
- UpdateServiceLevelObjective

Example: CloudWatch Application Signals log file entries

The following example shows a CloudWatch Application Signals CloudTrail log entry that demonstrates the `CreateServiceLevelObjective` action.

```
{
    "eventVersion": "1.09",
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "EX_PRINCIPAL_ID",
        "arn": "arn:aws:iam::111122223333:assumed-role/role_name",
        "accountId": "111122223333",
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "sessionContext": {
            "sessionIssuer": {
                "type": "Role",
                "principalId": "EX_PRINCIPAL_ID",
                "arn": "arn:aws:iam::111122223333:role/Admin",
                "accountId": "111122223333",
                "userName": "SAMPLE_NAME"
            },
            "attributes": {
                "creationDate": "2024-11-03T15:43:27Z",
                "mfaAuthenticated": "false"
            }
        }
    },
    "eventTime": "2024-11-03T15:58:11Z",
    "eventSource": "applicationsignals.amazonaws.com",
    "eventName": "CreateServiceLevelObjective",
    "awsRegion": "us-east-1",
    "sourceIPAddress": "192.0.2.0",
    "userAgent": "Mozilla/5.0 (Macintosh; Intel Mac OS X 10_15_7)",
    "requestParameters": {
        "Name": "TestSLO",
        "Description": "Test Service Level Objective"
    },
    "responseElements": {
        "Arn": "arn:aws:applicationsignals:us-east-1:111122223333:slo/TestSLO"
    },
    "requestID": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
    "eventID": "a1b2c3d4-5678-90ab-cdef-EXAMPLEbbbbb",
    "readOnly": false,
```

```
    "eventType": "AwsApiCall",
    "managementEvent": true,
    "recipientAccountId": "111122223333",
    "eventCategory": "Management"
}
```

CloudWatch Application Insights information in CloudTrail

CloudWatch Application Insights supports logging the following actions as events in CloudTrail log files:

- AddWorkload
- CreateApplication
- CreateComponent
- CreateLogPattern
- DeleteApplication
- DeleteComponent
- DeleteLogPattern
- DescribeApplication
- DescribeComponent
- DescribeComponentConfiguration
- DescribeComponentConfigurationRecommendation
- DescribeLogPattern
- DescribeObservation
- DescribeProblem
- DescribeProblemObservations
- DescribeWorkload
- ListApplications
- ListComponents
- ListConfigurationHistory
- ListLogPatterns
- ListLogPatternSets
- ListProblems

- ListTagsForResource
- ListWorkloads
- RemoveWorkload
- TagResource
- UntagResource
- UpdateApplication
- UpdateComponent
- UpdateComponentConfiguration
- UpdateLogPattern
- UpdateProblem
- UpdateWorkload

Example: CloudWatch Application Insights log file entries

The following example shows a CloudWatch Application Insights CloudTrail log entry that demonstrates the `CreateApplication` action.

```
{
    "eventVersion": "1.09",
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "EX_PRINCIPAL_ID",
        "arn": "arn:aws:iam::111122223333:assumed-role/role_name",
        "accountId": "111122223333",
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "sessionContext": {
            "sessionIssuer": {
                "type": "Role",
                "principalId": "EX_PRINCIPAL_ID",
                "arn": "arn:aws:iam::111122223333:role/Admin",
                "accountId": "111122223333",
                "userName": "SAMPLE_NAME"
            },
            "attributes": {
                "creationDate": "2024-11-03T15:43:27Z",
                "mfaAuthenticated": "false"
            }
        }
```

```
    },
    "eventTime": "2024-11-03T15:58:11Z",
    "eventSource": "applicationinsights.amazonaws.com",
    "eventName": "CreateApplication",
    "awsRegion": "us-east-1",
    "sourceIPAddress": "192.0.2.0",
    "userAgent": "Mozilla/5.0 (Macintosh; Intel Mac OS X 10_15_7)",
    "requestParameters": {
        "ResourceGroupName": "TestApplicationResourceGroup"
    },
    "responseElements": {
        "ApplicationInfo": {
            "ResourceGroupName": "TestApplicationResourceGroup",
            "LifeCycle": "ACTIVE"
        }
    },
    "requestID": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
    "eventID": "a1b2c3d4-5678-90ab-cdef-EXAMPLEbbbbb",
    "readOnly": false,
    "eventType": "AwsApiCall",
    "managementEvent": true,
    "recipientAccountId": "111122223333",
    "eventCategory": "Management"
}
```

Tagging your Amazon CloudWatch resources

A *tag* is a custom attribute label that you or AWS assigns to an AWS resource.

Tags help you do the following:

- Identify and organize your AWS resources. Many AWS services support tagging. You can assign the same tag to resources from different services to indicate the resources are related. For example, you can assign the tag that you assigned to a CloudWatch rule to an EC2 instance.

Tags have two parts:

- A *tag key* (for example, `CostCenter`, `Environment`, or `Project`). Tag keys are case sensitive.
- An optional field known as a *tag value* (for example, `111122223333` or `Production`). Omitting the tag value is the same as using an empty string. Like tag keys, tag values are case sensitive.

The following sections provide more information about tags for CloudWatch.

Supported resources in CloudWatch

The following resources in CloudWatch support tagging:

- Alarms – You can tag alarms using the tag-resource AWS CLI command and the TagResource API. You can also view and manage your alarm tags using the *Alarms* details page in the CloudWatch console.
- Canaries – You can tag canaries using the CloudWatch console. For more information, see Creating a canary.
- Contributor Insights rules – You can tag Contributor Insights rules when you create them by using the put-insight-rule AWS CLI command and the PutInsightRule API. You can add tags to existing rules by using the tag-resource AWS CLI command and the TagResource API.
- Dashboards – You can tag dashboards when you create them by using the put-dashboard AWS CLI command and the PutDashboard API. You can add tags to existing dashboards by using the tag-resource AWS CLI command and the TagResource API.
- Metric streams – You can tag metric streams when you create them by using the put-metric-stream AWS CLI command and the PutMetricStream API. You can add tags to existing metric streams by using the tag-resource AWS CLI command and the TagResource API.

For information about adding and managing tags, see Managing tags.

Managing tags

Tags consist of the `Key` and `Value` properties on a resource. You can use the CloudWatch console, the AWS CLI, or the CloudWatch API to add, edit, or delete the values for these properties. For information about working with tags, see the following:

- TagResource, UntagResource, and ListTagsForResource in the *Amazon CloudWatch API Reference*
- tag-resource, untag-resource, and list-tags-for-resource in the *Amazon CloudWatch CLI Reference*
- Working with Tag Editor in the *Resource Groups User Guide*

Tag naming and usage conventions

The following basic naming and usage conventions apply to using tags with CloudWatch resources:

- Each resource can have a maximum of 50 tags.
- For each resource, each tag key must be unique, and each tag key can have only one value.
- The maximum tag key length is 128 Unicode characters in UTF-8.
- The maximum tag value length is 256 Unicode characters in UTF-8.
- Allowed characters are letters, numbers, spaces representable in UTF-8, and the following characters: ***. : + = @ _ / -*** (hyphen).
- Tag keys and values are case sensitive. As a best practice, decide on a strategy for capitalizing tags and consistently implement that strategy across all resource types. For example, decide whether to use `Costcenter`, `costcenter`, or `CostCenter` and use the same convention for all tags. Avoid using similar tags with inconsistent case treatment.
- The `aws:` prefix is prohibited for tags because it's reserved for AWS use. You can't edit or delete tag keys or values with this prefix. Tags with this prefix don't count against your tags per resource limit.

CloudWatch service quotas

Amazon CloudWatch provides monitoring and observability for your AWS resources and applications. To ensure optimal performance and prevent abuse, CloudWatch imposes service quotas on various aspects of its functionality. This chapter outlines the key quotas for CloudWatch services, including metrics, alarms, API requests, and notifications. Understanding these quotas is crucial for effectively planning and managing your CloudWatch usage.

> **Note**
>
> For some AWS services including CloudWatch, you can use the CloudWatch usage metrics to visualize your current service usage on CloudWatch graphs and dashboards. You can use a CloudWatch metric math function to display the service quotas for those resources on your graphs. You can also configure alarms that alert you when your usage approaches a service quota. For more information, see Visualizing your service quotas and setting alarms.

Topics

- CloudWatch
- CloudWatch investigations (Amazon AI Operations)
- CloudWatch Application Insights
- CloudWatch Application Signals
- Internet Monitor
- Network Flow Monitor
- Network Synthetic Monitor
- CloudWatch Observability Access Manager
- CloudWatch Observability Admin
- CloudWatch RUM
- Managing your CloudWatch service quotas

CloudWatch

This section details the service quotas specifically for core CloudWatch functionality. These quotas cover aspects such as metrics, alarms, API requests, and dashboards. Familiarizing yourself with

these limits helps you optimize your CloudWatch configuration and avoid potential throttling or service disruptions.

Name	Default	Adjustable	Description
Canary limit	us-east-1: 300 ap-east-2: 200 ap-northeast-1: 300 Each of the other supported Regions: 500	Yes	The maximum number of canaries per account per region.
Minimum frequency	Each supported Region: 60,000 Milliseconds	No	The minimum time, in milliseconds, between runs of the same canary.
Number of Alarm Mute Rules	Each supported Region: 2,000	No	The maximum number of Alarm Mute Rules that you can have in this account in the current region.
Number of Contributor Insights rules	Each supported Region: 100	Yes	The maximum number of Contributor Insights rules you can have in this account.
Number of Metrics Insights alarms	Each supported Region: 200	No	The maximum number of Metrics Insights alarms that you can have in this account in the current region.

Name	Default	Adjustable	Description
Rate of ANOMALY_DETECTION_BAND usage in GetMetricData	Each supported Region: 1,000	No	The maximum number of times the ANOMALY_DETECTION_BAND function can be used in all GetMetricData requests, per second, in this account in the current region.
Rate of DB_PERF_INSIGHTS usage in GetMetricData	Each supported Region: 4	No	The maximum number of times the DB_PERF_INSIGHTS function can be used in all GetMetricData requests, per second, in this account in the current region.
Rate of DeleteAlarmMuteRule requests	Each supported Region: 3 per second	No	The maximum number of DeleteAlarmMuteRule requests that you can make, per second, in this account in the current region.
Rate of DeleteAlarms requests	Each supported Region: 3 per second	No	The maximum number of DeleteAlarms requests that you can make, per second, in this account in the current region.

Name	Default	Adjustable	Description
Rate of DeleteAnomalyDetector requests	Each supported Region: 5 per second	No	The maximum number of DeleteAnomalyDetector requests that you can make, per second, in this account in the current region.
Rate of DeleteDashboards requests	Each supported Region: 10 per second	Yes	The maximum number of DeleteDashboards requests that you can make, per second, in this account in the current region.
Rate of DeleteInsightRules requests	Each supported Region: 5 per second	No	The maximum number of DeleteInsightRules requests you can make per second in this account.
Rate of DeleteMetricStream requests	Each supported Region: 10 per second	Yes	The maximum number of DeleteMetricStream requests that you can make, per second, in this account in the current region.
Rate of DescribeAlarmContributors requests	Each supported Region: 9 per second	Yes	The maximum number of DescribeAlarmContributors requests that you can make, per second, in this account in the current region.

Name	Default	Adjustable	Description
Rate of DescribeAlarmHistory requests	Each supported Region: 20 per second	No	The maximum number of DescribeAlarmHistory requests that you can make, per second, in this account in the current region.
Rate of DescribeAlarms requests	Each supported Region: 9 per second	Yes	The maximum number of DescribeAlarms requests that you can make, per second, in this account in the current region.
Rate of DescribeAlarmsForMetric requests	Each supported Region: 9 per second	No	The maximum number of DescribeAlarmsForMetric requests that you can make, per second, in this account in the current region.
Rate of DescribeAnomalyDetectors requests	Each supported Region: 10 per second	Yes	The maximum number of DescribeAnomalyDetectors requests that you can make, per second, in this account in the current region.
Rate of DescribeInsightRules requests	Each supported Region: 20 per second	No	The maximum number of DescribeInsightRules requests you can make per second in this account.

Name	Default	Adjustable	Description
Rate of DisableAlarmActions requests	Each supported Region: 3 per second	No	The maximum number of DisableAlarmActions requests that you can make, per second, in this account in the current region.
Rate of DisableInsightRules requests	Each supported Region: 1 per second	No	The maximum number of DisableInsightRules requests you can make per second in this account.
Rate of EnableAlarmActions requests	Each supported Region: 3 per second	No	The maximum number of EnableAlarmActions requests that you can make, per second, in this account in the current region.
Rate of EnableInsightRules requests	Each supported Region: 1 per second	No	The maximum number of EnableInsightRules requests you can make per second in this account.
Rate of GetAlarmMuteRule requests	Each supported Region: 20 per second	Yes	The maximum number of GetAlarmMuteRule requests that you can make, per second, in this account in the current region.

Name	Default	Adjustable	Description
Rate of GetDashboard requests	Each supported Region: 10 per second	Yes	The maximum number of GetDashboard requests that you can make, per second, in this account in the current region.
Rate of GetInsightRuleReport requests	Each supported Region: 20 per second	Yes	The maximum number of GetInsightRuleReport requests you can make, per second in this account.
Rate of GetMetricData datapoints for metrics older than three hours	Each supported Region: 396,000	No	The maximum number of GetMetricData datapoints that you can fetch, per second, for a request with a StartTime of more than three hours in this account in the current region.
Rate of GetMetricData datapoints for the last three hours of metrics	Each supported Region: 180,000	No	The maximum number of GetMetricData datapoints that you can fetch, per second, for a request with a StartTime of less than or equal to three hours in this account in the current region.

Name	Default	Adjustable	Description
Rate of GetMetricData datapoints using Metrics Insights	Each supported Region: 4,300,000	No	The maximum number of GetMetricData datapoints that you can fetch using Metrics Insights, per second, for a request with a StartTime of less than or equal to three hours in this account in the current region.
Rate of GetMetricData requests	Each supported Region: 500 per second	Yes	The maximum number of GetMetricData requests that you can make, per second, in this account in the current region.
Rate of GetMetricStatistics requests	Each supported Region: 400 per second	Yes	The maximum number of GetMetricStatistics requests that you can make, per second, in this account in the current region.
Rate of GetMetricStream requests	Each supported Region: 10 per second	Yes	The maximum number of GetMetricStream requests that you can make, per second, in this account in the current region.

Name	Default	Adjustable	Description
Rate of GetMetricWidgetImage requests	Each supported Region: 20 per second	Yes	The maximum number of GetMetricWidgetImage requests that you can make, per second, in this account in the current region.
Rate of INSIGHT_RULE_METRIC usage in GetMetricData	Each supported Region: 20	No	The maximum number of times the INSIGHT_RULE_METRIC function can be used in all GetMetricData requests, per second, in this account in the current region.
Rate of LAMBDA usage in GetMetricData	Each supported Region: 5	No	The maximum number of times the LAMBDA function can be used in all GetMetricData requests, per second, in this account in the current region.
Rate of ListAlarmMuteRules requests	Each supported Region: 50 per second	Yes	The maximum number of ListAlarmMuteRules requests that you can make, per second, in this account in the current region.

Name	Default	Adjustable	Description
Rate of ListDashboards requests	Each supported Region: 10 per second	Yes	The maximum number of ListDashboards requests that you can make, per second, in this account in the current region.
Rate of ListMetricStreams requests	Each supported Region: 10 per second	Yes	The maximum number of ListMetricStreams requests that you can make, per second, in this account in the current region.
Rate of ListMetrics requests	Each supported Region: 25 per second	Yes	The maximum number of ListMetrics requests that you can make, per second, in this account in the current region.
Rate of ListTagsForResource requests	Each supported Region: 10 per second	No	The maximum number of ListTagsForResource requests that you can make, per second, in this account in the current region.
Rate of Metrics Insights usage in GetMetricData	Each supported Region: 10	No	The maximum number of times Metrics Insights can be used in all GetMetricData requests, per second, in this account in the current region.

Name	Default	Adjustable	Description
Rate of PutAlarmMuteRule requests	Each supported Region: 3 per second	Yes	The maximum number of PutAlarmMuteRule requests that you can make, per second, in this account in the current region.
Rate of PutAnomalyDetector requests	Each supported Region: 10 per second	Yes	The maximum number of PutAnomalyDetector requests that you can make, per second, in this account in the current region.
Rate of PutCompositeAlarm requests	Each supported Region: 3 per second	Yes	The maximum number of PutCompositeAlarm requests that you can make, per second, in this account in the current region.
Rate of PutDashboard requests	Each supported Region: 10 per second	Yes	The maximum number of PutDashboard requests that you can make, per second, in this account in the current region.
Rate of PutInsightRule requests	Each supported Region: 5 per second	No	The maximum number of PutInsightRule requests you can make, per second in this account.

Name	Default	Adjustable	Description
Rate of PutLogAlarm requests	Each supported Region: 3 per second	No	The maximum number of PutLogAlarm requests that you can make, per second, in this account in the current region.
Rate of PutMetricAlarm requests	Each supported Region: 3 per second	Yes	The maximum number of PutMetricAlarm requests that you can make, per second, in this account in the current region.
Rate of PutMetricData requests	Each supported Region: 500 per second	Yes	The maximum number of PutMetricData requests that you can make, per second, in this account in the current region.
Rate of PutMetricStream requests	Each supported Region: 10 per second	Yes	The maximum number of PutMetricStream requests that you can make, per second, in this account in the current region.
Rate of SEARCH usage in GetMetricData	Each supported Region: 50	No	The maximum number of times the SEARCH function can be used in all GetMetricData requests, per second, in this account in the current region.

Name	Default	Adjustable	Description
Rate of SERVICE_QUOTA usage in GetMetricData	Each supported Region: 1,000	No	The maximum number of times the SERVICE_QUOTA function can be used in all GetMetricData requests, per second, in this account in the current region.
Rate of SetAlarmState requests	Each supported Region: 3 per second	No	The maximum number of SetAlarmState requests that you can make, per second, in this account in the current region.
Rate of StartMetricStreams requests	Each supported Region: 10 per second	Yes	The maximum number of StartMetricStreams requests that you can make, per second, in this account in the current region.
Rate of StopMetricStreams requests	Each supported Region: 10 per second	Yes	The maximum number of StopMetricStreams requests that you can make, per second, in this account in the current region.
Rate of TagResource requests	Each supported Region: 20 per second	No	The maximum number of TagResource requests that you can make, per second, in this account in the current region.

Name	Default	Adjustable	Description
Rate of UntagResource requests	Each supported Region: 20 per second	No	The maximum number of UntagResource requests that you can make, per second, in this account in the current region.

CloudWatch investigations (Amazon AI Operations)

CloudWatch investigations (Amazon AI Operations) enables intelligent problem detection and root cause analysis. This section outlines the quotas related to concurrent investigations, investigation groups, and AI-assisted analyses.

Name	Default	Adjustable	Description
Concurrent active investigations	Each supported Region: 2	No	The maximum number of concurrent investigations with active AI analysis per account per region.
Investigation groups	Each supported Region: 1	No	The maximum number of investigation groups that can be created per account in a region.
Monthly investigations	Each supported Region: 150	No	The maximum number of AI-assisted investigations per month in this account in the current region.

CloudWatch Application Insights

CloudWatch Application Insights helps you monitor your applications and troubleshoot issues quickly. This section presents the quotas for CloudWatch Application Insights, including limits on API requests, applications, log streams, and metrics. Knowing these quotas allows you to effectively plan your application monitoring setup.

Resource	Default quota	Adjustable
API requests	All API actions are throttled to 5 TPS	No
Resource Group applications	100 per account	No
Account applications	1 per account	No
Log Streams	5 per resource	No
Observations per problem	20 per dashboard 40 per DescribeProblemObservations action	No
Metrics	60 per resource	No

CloudWatch Application Signals

CloudWatch Application Signals provides deep insights into your application's performance and dependencies. This section covers the quotas for Application Signals, including API request limits and service-level objective (SLO) constraints. Understanding these quotas is crucial for implementing effective application performance monitoring.

Name	Default	Adjustable	Description
Number of SLOs per Region	Each supported Region: 250	Yes	The maximum number of SLOs that you can have

Name	Default	Adjustable	Description
			in this account in the current region.
Number of SLOs per Service	Each supported Region: 100	Yes	The maximum number of SLOs that you can have per service in the current region.
Rate of BatchGetServiceLevelObjectiveBudgetReport requests	Each supported Region: 10 per second	Yes	The maximum number of BatchGetServiceLevelObjectiveBudgetReport requests you can make per second in this Region.
Rate of BatchUpdateExclusionWindows requests	Each supported Region: 5 per second	Yes	The maximum number of BatchUpdateExclusionWindows requests you can make per second in this Region.
Rate of CreateServiceLevelObjective requests	Each supported Region: 5 per second	Yes	The maximum number of CreateServiceLevelObjective requests you can make per second in this Region.
Rate of DeleteGroupingConfiguration requests	Each supported Region: 10 per second	Yes	The maximum number of DeleteGroupingConfiguration requests you can make per second in this Region.

Name	Default	Adjustable	Description
Rate of DeleteServiceLevelObjective requests	Each supported Region: 5 per second	Yes	The maximum number of DeleteServiceLevelObjective requests you can make per second in this Region.
Rate of GetService requests	Each supported Region: 10 per second	Yes	The maximum number of GetService requests you can make per second in this Region.
Rate of GetServiceLevelObjective requests	Each supported Region: 5 per second	Yes	The maximum number of GetServiceLevelObjective requests you can make per second in this Region.
Rate of ListAuditFindings requests	Each supported Region: 1 per second	Yes	The maximum number of ListAuditFindings requests you can make per second in this Region.
Rate of ListEntityEvents requests	Each supported Region: 10 per second	Yes	The maximum number of ListEntityEvents requests you can make per second in this Region.
Rate of ListGroupingAttributeDefinitions requests	Each supported Region: 10 per second	Yes	The maximum number of ListGroupingAttributeDefinitions requests you can make per second in this Region.

Name	Default	Adjustable	Description
Rate of ListServiceDependencies requests	Each supported Region: 10 per second	Yes	The maximum number of ListServiceDependencies requests you can make per second in this Region.
Rate of ListServiceDependents requests	Each supported Region: 10 per second	Yes	The maximum number of ListServiceDependents requests you can make per second in this Region.
Rate of ListServiceLevelObjectiveExclusionWindows requests	Each supported Region: 5 per second	Yes	The maximum number of ListServiceLevelObjectiveExclusionWindows requests you can make per second in this Region.
Rate of ListServiceLevelObjectives requests	Each supported Region: 5 per second	Yes	The maximum number of ListServiceLevelObjectives requests you can make per second in this Region.
Rate of ListServiceOperations requests	Each supported Region: 10 per second	Yes	The maximum number of ListServiceOperations requests you can make per second in this Region.

Name	Default	Adjustable	Description
Rate of ListServiceStates requests	Each supported Region: 5 per second	Yes	The maximum number of ListServiceStates requests you can make per second in this Region.
Rate of ListServices requests	Each supported Region: 10 per second	Yes	The maximum number of ListServices requests you can make per second in this Region.
Rate of ListTagsForResource requests	Each supported Region: 5 per second	Yes	The maximum number of ListTagsForResource requests you can make per second in this Region.
Rate of PutGroupingConfiguration requests	Each supported Region: 10 per second	Yes	The maximum number of PutGroupingConfiguration requests you can make per second in this Region.
Rate of StartDiscovery requests	Each supported Region: 5 per second	Yes	The maximum number of StartDiscovery requests you can make per second in this Region.
Rate of TagResource requests	Each supported Region: 5 per second	Yes	The maximum number of TagResource requests you can make per second in this Region.

Name	Default	Adjustable	Description
Rate of UntagResource requests	Each supported Region: 5 per second	Yes	The maximum number of UntagResource requests you can make per second in this Region.
Rate of UpdateServiceLevelObjective requests	Each supported Region: 5 per second	Yes	The maximum number of UpdateServiceLevel Objective requests you can make per second in this Region.

Internet Monitor

Internet Monitor, a feature of CloudWatch Network Monitoring, helps you understand how internet issues impact your application's performance. This section provides the quotas specific to Internet Monitor, to help you to plan an effective internet performance monitoring strategy.

Name	Default	Adjustable	Description
Days that health events are retained	Each supported Region: 400	No	The number of days that AWS keeps information about a resolved Internet Monitor health event.
Monitors per account per AWS Region	Each supported Region: 50	No	The maximum number of monitors in an account in one AWS Region.
Resources per monitor	Each supported Region: 50	No	The maximum number of resources that a monitor can have.

Network Flow Monitor

Network Flow Monitor, a feature of CloudWatch Network Monitoring, provides near real-time visibility into network performance, such as packet loss and latency, for traffic between Amazon EC2 instances, as well as traffic toward certain other AWS services. It also helps you to determine if AWS issues are causing network performance degradation for your application. This section provides the quotas for Network Flow Monitor, including limits on monitored flows, data retention, and API requests. Understanding these quotas can help you to plan an effective network flow monitoring strategy.

Resource	Default quota	Adjustable?
Scopes per account per AWS Region	1	No
Monitors per account per AWS Region	20	Yes
Local resources per monitor	25	No
Remote resources per monitor	25	No

Network Synthetic Monitor

Network Synthetic Monitor, a feature of CloudWatch Network Monitoring, enables you to proactively monitor your network endpoints and API operations using configurable tests. This section details the quotas for Network Synthetic Monitor, including limits on synthetic monitors, test frequency, and script execution. These quotas are important for planning your network testing strategy and maintaining reliable endpoint monitoring.

Name	Default	Adjuse	Description
Number of monitors per account per AWS region	Each supported Region: 100	Yes	The maximum number of monitors in an account in one AWS Region.
Number of probes per monitor	Each supported Region: 24	Yes	The maximum number of probes that a monitor can have.
Number of probes per subnet for each monitor	Each supported Region: 4	Yes	The maximum number of probes that a subnet in a monitor can have.

CloudWatch Observability Access Manager

CloudWatch Observability Access Manager allows you to securely share CloudWatch resources across accounts. This section details the quotas for Observability Access Manager, including limits on API requests, source account links, and sinks. Understanding these quotas is essential for implementing cross-account observability effectively.

Name	Default	Adjuse	Description
Links per sink	Each supported Region: 100,000	No	Maximum number of links that can be attached to a sink
Number of links	Each supported Region: 5	No	Maximum number of links in your account
Number of sinks	Each supported Region: 1	No	Maximum number of sinks in your account

Name	Default	Adjustable	Description
Rate of CreateLink requests	Each supported Region: 10 per second	No	Maximum number of CreateLink requests you can make per second, in this account in the current region
Rate of CreateSink requests	Each supported Region: 10 per second	No	Maximum number of CreateSink requests you can make per second, in this account in the current region
Rate of DeleteLink requests	Each supported Region: 10 per second	No	Maximum number of DeleteLink requests you can make per second, in this account in the current region
Rate of DeleteSink requests	Each supported Region: 10 per second	No	Maximum number of DeleteSink requests you can make per second, in this account in the current region
Rate of GetLink requests	Each supported Region: 10 per second	No	Maximum number of GetLink requests you can make per second, in this account in the current region
Rate of GetSink requests	Each supported Region: 10 per second	No	Maximum number of GetSink requests you can make per second, in this account in the current region

Name	Default	Adjustable	Description
Rate of GetSinkPolicy requests	Each supported Region: 10 per second	No	Maximum number of GetSinkPolicy requests you can make per second, in this account in the current region
Rate of ListAttachedLinks requests	Each supported Region: 10 per second	No	Maximum number of ListAttachedLinks requests you can make per second, in this account in the current region
Rate of ListLinks requests	Each supported Region: 10 per second	No	Maximum number of ListLinks requests you can make per second, in this account in the current region
Rate of ListSinks requests	Each supported Region: 10 per second	No	Maximum number of ListSinks requests you can make per second, in this account in the current region
Rate of ListTagsForResource requests	Each supported Region: 10 per second	No	Maximum number of ListTagsForResource requests you can make per second, in this account in the current region

Name	Default	Adjustable	Description
Rate of PutSinkPolicy requests	Each supported Region: 1 per second	No	Maximum number of PutSinkPolicy requests you can make per second, in this account in the current region
Rate of TagResource requests	Each supported Region: 10 per second	No	Maximum number of TagResource requests you can make per second, in this account in the current region
Rate of UntagResource requests	Each supported Region: 10 per second	No	Maximum number of UntagResource requests you can make per second, in this account in the current region
Rate of UpdateLink requests	Each supported Region: 10 per second	No	Maximum number of UpdateLink requests you can make per second, in this account in the current region

CloudWatch Observability Admin

CloudWatch Observability Admin helps you discover, audit, and manage CloudWatch telemetry configurations across an AWS account or organization. It provides a consolidated view of monitoring settings for resources, enabling you to ensure consistent and proper data collection by simplifying the management of telemetry across multiple accounts. Most quotas are adjustable to accommodate enterprise-scale deployments that need higher limits for managing observability rules across large organizations.

Name	Default	Adjustable	Description
CreateCentralizationRuleForOrganization throttle limit in transactions per second	Each supported Region: 5	No	The maximum number of create-centralization-rule-for-organization calls per second per account/per region
CreateTelemetryPipeline throttle limit in transactions per second	Each supported Region: 5 per second	No	The maximum number of CreateTelemetryPipeline calls per second per account and per Region
CreateTelemetryRule throttle limit in transactions per second	Each supported Region: 5	No	The maximum number of create-telemetry-rule calls per second per account/per region
CreateTelemetryRuleForOrganization throttle limit in transactions per second	Each supported Region: 5	No	The maximum number of create-telemetry-rule-for-organization calls per second per account/per region
DeleteCentralizationRuleForOrganization throttle limit in transactions per second	Each supported Region: 5	No	The maximum number of delete-centralization-rule-for-organization calls per second per account/per region
DeleteTelemetryPipeline throttle limit in transactions per second	Each supported Region: 5 per second	No	The maximum number of DeleteTelemetryPipeline calls per second per account and per Region
DeleteTelemetryRule throttle limit in transactions per second	Each supported Region: 5	No	The maximum number of delete-telemetry-r

Name	Default	Adjustable	Description
			ule calls per second per account/per region
DeleteTelemetryRuleForOrganization throttle limit in transactions per second	Each supported Region: 5	No	The maximum number of delete-telemetry-rule-for-organization calls per second per account/per region
GetCentralizationRuleForOrganization throttle limit in transactions per second	Each supported Region: 5	No	The maximum number of get-centralization-rule-for-organization calls per second per account/per region
GetTelemetryEnrichmentStatus throttle limit in transactions per second	Each supported Region: 5 per second	Yes	The maximum number of GetTelemetryEnrichmentStatus calls per second per account and per region
GetTelemetryPipeline throttle limit in transactions per second	Each supported Region: 5 per second	No	The maximum number of GetTelemetryPipeline calls per second per account and per Region
GetTelemetryRule throttle limit in transactions per second	Each supported Region: 5	No	The maximum number of get-telemetry-rule calls per second per account/per region

Name	Default	Adjustable	Description
GetTelemetryRuleForOrganization throttle limit in transactions per second	Each supported Region: 5	No	The maximum number of get-telemetry-rule-for-organization calls per second per account/per region
ListCentralizationRulesForOrganization throttle limit in transactions per second	Each supported Region: 5	No	The maximum number of list-centralization-rules-for-organization calls per second per account/per region
ListTagsForResource throttle limit in transactions per second	Each supported Region: 5	No	The maximum number of list-tags-for-resource calls per second per account/per region
ListTelemetryPipelines throttle limit in transactions per second	Each supported Region: 5 per second	No	The maximum number of ListTelemetryPipelines calls per second per account and per Region
ListTelemetryRules throttle limit in transactions per second	Each supported Region: 5	No	The maximum number of list-telemetry-rules calls per second per account/per region
ListTelemetryRulesForOrganization throttle limit in transactions per second	Each supported Region: 5	No	The maximum number of list-telemetry-rules-for-organization calls per second per account/per region

Name	Default	Adjustable	Description
Logs Centralization throughput per destination region	Each supported Region: 2.5 Gigabytes per second	No	The maximum organization-level throughput for centralization of logs per destination region
Organization Centralization Rules	Each supported Region: 50	Yes	The maximum number of organization centralization rules that you can create for an organization
Organization Telemetry Rules	Each supported Region: 50	Yes	The maximum number of organization telemetry rules that you can create for an organization
Pipelines for managed OTel metrics experience	Each supported Region: 300	Yes	The maximum number of pipelines for managed OTel metrics experience allowed per account and per Region
Pipelines with a CloudWatch Logs source	Each supported Region: 300	Yes	The maximum number of pipelines with a CloudWatch Logs source allowed per account per Region
Pipelines with a third-party integration source	Each supported Region: 30	Yes	The maximum number of pipelines with a third-party integration source allowed per account per Region

Name	Default	Adjustable	Description
StartTelemetryEnrichment throttle limit in transactions per second	Each supported Region: 1 per second	Yes	The maximum number of StartTelemetryEnrichment calls per second per account and per region
StopTelemetryEnrichment throttle limit in transactions per second	Each supported Region: 1 per second	Yes	The maximum number of StopTelemetryEnrichment calls per second per account and per region
TagResource throttle limit in transactions per second	Each supported Region: 5	No	The maximum number of tag-resource calls per second per account/per region
Telemetry Rules	Each supported Region: 20	Yes	The maximum number of telemetry rules that you can create for an account
TestTelemetryPipeline throttle limit in transactions per second	Each supported Region: 5 per second	No	The maximum number of TestTelemetryPipeline calls per second per account and per Region
UntagResource throttle limit in transactions per second	Each supported Region: 5	No	The maximum number of untag-resource calls per second per account/per region

Name	Default	Adjustable	Description
UpdateCentralizationRuleForOrganization throttle limit in transactions per second	Each supported Region: 5	No	The maximum number of update-centralization-rule-for-organization calls per second per account/per region
UpdateTelemetryPipeline throttle limit in transactions per second	Each supported Region: 5 per second	No	The maximum number of UpdateTelemetryPipeline calls per second per account and per Region
UpdateTelemetryRule throttle limit in transactions per second	Each supported Region: 5	No	The maximum number of update-telemetry-rule calls per second per account/per region
UpdateTelemetryRuleForOrganization throttle limit in transactions per second	Each supported Region: 5	No	The maximum number of update-telemetry-rule-for-organization calls per second per account/per region
ValidateTelemetryPipelineConfiguration throttle limit in transactions per second	Each supported Region: 5 per second	No	The maximum number of ValidateTelemetryPipelineConfiguration calls per second per account and per Region

CloudWatch RUM

CloudWatch RUM (Real-User Monitoring) helps you collect and analyze performance data from real user interactions with your web applications. This section presents the quotas for CloudWatch RUM, allowing you to plan your real-user monitoring strategy within the service limits.

Name	Default	Adjuse	Description
RUM AppMonitors	Each supported Region: 20	Yes	The maximum number of RUM AppMonitors that you can have in this AWS account.
RUM Events per second per AWS Account	Each supported Region: 50	Yes	The maximum number of RUM Events per second that RUM will ingest for this AWS account.

Managing your CloudWatch service quotas

Effective management of CloudWatch service quotas is crucial for maintaining optimal performance and avoiding service disruptions. This section provides guidance on viewing your current quota usage, requesting quota increases when necessary, and best practices for working within CloudWatch service limits.

CloudWatch quotas are integrated with Service Quotas, an AWS service that enables you to view and manage your quotas from a central location. For more information, see What Is Service Quotas? in the *Service Quotas User Guide*.

AWS Management Console

To view CloudWatch service quotas using the console

1. Open the Service Quotas console at https://console.aws.amazon.com/servicequotas/.
2. In the navigation pane, choose **AWS services**.
3. From the **AWS services** list, search for and select the CloudWatch service whose quotas you want to view.

   In the **Service quotas** list, you can see the service quota name, applied value (if it is available), AWS default quota, and whether the quota value is adjustable.
4. To view additional information about a service quota, such as the description, choose the quota name.

5. (Optional) To request a quota increase, select the quota that you want to increase, select **Request quota increase**, enter or select the required information, and select **Request**.

To work more with service quotas using the console see the Service Quotas User Guide. To learn more about quota increases, see Requesting a quota increase in the *Service Quotas User Guide*.

AWS CLI

To view CloudWatch service quotas using the AWS CLI

1. Run the following command to view the default CloudWatch quotas.

```
aws service-quotas list-aws-default-service-quotas \
    --query 'Quotas[*].
{Adjustable:Adjustable,Name:QuotaName,Value:Value,Code:QuotaCode}' \
    --service-code ServiceCode
    --output table
```

> **Note**
>
> The following list contains the CloudWatch **ServiceCode** values:
>
> - To see the CloudWatch quotas, use `--service-code monitoring`.
> - To see the Amazon AI Operations quotas, use `--service-code aiops`.
> - To see the CloudWatch Application Signals quotas, use `--service-code application-signals`.
> - To see the Amazon CloudWatch Internet Monitor quotas, use `--service-code internetmonitor`.
> - To see the CloudWatch Network Monitor quotas, use `--service-code networkmonitor`.
> - To see the CloudWatch Observability Access Manager quotas, use `--service-code oam`.
> - To see the CloudWatch RUM (Real-User Monitoring) quotas, use `--service-code rum`.

2. (Optional) Request a quota increase for a CloudWatch service:

   a. Identify the quota code for the quota you want to increase.

```
aws service-quotas list-service-quotas --service-code ServiceCode
```

b. Note the `QuotaCode` value for the item. For example if you wanted to increase your quota for the **Rate of PutCompositeAlarm requests** that are supported by CloudWatch for your account, you would record the **QuotaCode** `L-8742A250`.

c. Type the following command using the identified `ServiceCode` and `QuotaCode` values and providing the numeric value for the desired new quota:

```
aws service-quotas request-service-quota-increase \
    --service-code ServiceCode \
    --quota-code QuotaCode \
    --desired-value new-quota-value
```

For more details about quota increases, see the `request-service-quota-increase` command in the AWS CLI Command Reference.

To work more with service quotas using the AWS CLI, see the Service Quotas AWS CLI Command Reference.

Document history

The following table describes important changes for each release of the *Amazon CloudWatch User Guide*, beginning in June 2018. To receive notifications about updates to this documentation, you can subscribe to an RSS feed.

Change	Description	Date
Telemetry configuration adds support for Amazon S3 server access logs	CloudWatch telemetry configuration now supports discovering Amazon Simple Storage Service (Amazon S3) buckets and enabling server access log delivery to CloudWatch Logs. You can create enablement rules to automatically configure server access logs for your Amazon S3 buckets across your account or organization.	June 30, 2026
Updated CloudWatchFullAccessV2 policy	CloudWatch added two `iam:PassRole` permissions to CloudWatchFullAccessV2 to support the new `PutLogAlarm` API. The new permissions allow customers to pass a Scheduled Query Execution Role to `logs.amazonaws.com` and a Log Lines Role to `cloudwatch.amazonaws.com` .	June 15, 2026
Internet Monitor publishes local health events to Amazon EventBridge	Internet Monitor now publishes local health events to Amazon EventBridge, in addition to overall (global)	May 20, 2026

	health events. Local health events have an impact type of `LOCAL_AVAILABILITY` or `LOCAL_PERFORMANCE`.	
Updated AWSObservabilityAdminTelemetryEnablementServiceRolePolicy policy	CloudWatch updated the **AWSObservabilityAdminTelemetryEnablementServiceRolePolicy** that grants CloudWatch the permissions necessary to enable and manage telemetry configurations for the newly supported AWS resources based on telemetry rules. For more information, see AWSObservabilityAdminTelemetryEnablementServiceRolePolicy.	April 30, 2026
Updated CloudWatchSyntheticsFullAccess managed policy	The `cloudwatch:ListMetrics` permission was added to the **CloudWatchSyntheticsFullAccess** policy. Additionally, the `apigateway:GET` permission has been changed from allowing all resources to specific API Gateway resources: REST APIs, REST API stages, REST API stage Swagger exports, and HTTP APIs. For more information, see CloudWatchSyntheticsFullAccess.	March 31, 2026

Updated AWSObservabilityAdminTelemetryEnablementServiceRolePolicy policy	CloudWatch updated the **AWSObservabilityAdminTelemetryEnablementServiceRolePolicy** that grants CloudWatch the permissions necessary to enable and manage telemetry configurations for the newly supported AWS resources based on telemetry rules. For more information, see AWSObservabilityAdminTelemetryEnablementServiceRolePolicy.	March 31, 2026
Updated AWSObservabilityAdminTelemetryEnablementServiceRolePolicy policy	CloudWatch updated the **AWSObservabilityAdminTelemetryEnablementServiceRolePolicy** that grants CloudWatch the permissions necessary to enable and manage telemetry configurations for the newly supported AWS resources based on telemetry rules. For more information, see AWSObservabilityAdminTelemetryEnablementServiceRolePolicy.	March 10, 2026

Update to AIOPsAssistantPolicy managed policy	CloudWatch updated the **AIOpsAssistantPolicy** to allow CloudWatch investigations access to additional resources to assist in queries, troubleshooting, and topology mapping. For more information, see AIOpsAssistantPolicy.	February 6, 2026
Update to AIOPsAssistantPolicy managed policy	CloudWatch updated the **AIOpsAssistantPolicy** to allow CloudWatch investigations access to additional resources to assist in queries, troubleshooting, and topology mapping. For more information, see AIOpsAssistantPolicy.	December 17, 2025

Updated CloudWatchNetworkMonitorServiceRolePolicy managed policy with TGW permissions	CloudWatch added the `ec2:DescribeRouteTables` , `ec2:DescribeTransitGatewayAttachments` , `ec2:DescribeTransitGatewayRouteTables` , `ec2:SearchTransitGatewayRoutes` permissions to the CloudWatchNetworkMonitorServiceRolePolicy managed policy to grant permissions for Network Synthetic Monitor to generate the Network Health Indicator values for customers utilizing Transit Gateways.	December 12, 2025
Updated CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy managed policy with VPC Endpoints and vpce service config permissions	CloudWatch added the `ec2:DescribeVpcEndpoints` and `ec2:DescribeVpcEndpointServiceConfigurations` permissions to the CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy managed policy to grant permissions for Network Flow Monitor to generate topology snapshots of VPC endpoints and vpce service config.	December 10, 2025

Updated CloudWatchFullAccessV2 policy	Permissions for observability administration actions were added to CloudWatchFullAccessV2 to allow full access to telemetry pipelines and S3 table integrations.	December 2, 2025
Observability for Amazon Bedrock AgentCore policies	You can now monitor invocation metrics for Amazon Bedrock AgentCore policies using Amazon CloudWatch. For more information, see Gateways.	December 2, 2025
Observability for Amazon Bedrock AgentCore Evaluations	You can now monitor and assess the performance, quality, and reliability of your AI agents using the Evaluations dashboard. For more information, see Agent details - Evaluations.	December 2, 2025
New AWSObservabilityAdminTelemetryEnablementServiceRolePolicy policy	CloudWatch updated the **AWSObservabilityAdminTelemetryEnablementServiceRolePolicy** that grants CloudWatch the permissions necessary to enable and manage telemetry configurations for the newly supported AWS resources based on telemetry rules. For more information, see AWSObservabilityAdminTelemetryEnablementServiceRolePolicy.	December 2, 2025

Introduced CloudWatch pipelines	The new pipeline feature of CloudWatch connects data from a catalogue of data sources, so that you can add and configure pipeline processors from a library to parse, enrich, and standardize data. For more information, see CloudWatch pipelines.	December 2, 2025
Introduced CloudWatch pipelines	The new pipeline feature of CloudWatch connects data from a catalogue of data sources, so that you can add and configure pipeline processors from a library to parse, enrich, and standardize data. For more information, see CloudWatch pipelines.	December 2, 2025

New CloudWatch investigations feature	Amazon CloudWatch now offers interactive incident report generation, enabling customers to create comprehensive post-incident analysis reports in minutes. The new capability, available within CloudWatch investigations, automatically gathers and correlates your telemetry data, as well as your input and any actions taken during an investigation, and produces a streamlined incident report. Amazon CloudWatch enhanced incident report generation capabilities with an AI-powered root-cause workflow that guides customers through the "Five Why's" analysis technique. For more information, see Generate incident reports	November 30, 2025
Updated CloudWatchReadOnlyAccess policy	CloudWatch updated CloudWatchReadOnlyAccess to include Resource Explorer permissions to support uninstrumented service functionalities in Application Signals.	November 20, 2025

Updated CloudWatchFullAccessV2 policy	CloudWatch updated CloudWatchFullAccessV2 to include Resource Explorer permissions to support uninstrumented service functionalities in Application Signals.	November 20, 2025
Updated CloudWatchApplicationSignalsServiceRolePolicy policy	CloudWatch updated the policy to include `resource-explorer-2:Search` and `cloudtrail:CreateServiceLinkedChannel` to enable new Application Signals features. For more information, see CloudWatchApplicationSignalsServiceRolePolicy.	November 20, 2025
Updated CloudWatchApplicationSignalsReadOnlyAccess policy	CloudWatch updated CloudWatchApplicationSignalsReadOnlyAccess to include new Application Signals operation and OAM and Resource Explorer permissions to support change events, cross account and uninstrumented service functionalities in Application Signals.	November 20, 2025

Updated CloudWatchApplicationSignalsFullAccess policy	CloudWatch updated CloudWatchApplicationSignalsFullAccess to include OAM and Resource Explorer permissions to support cross account and uninstrumented service functionalities in Application Signals.	November 20, 2025
CloudWatch updated AIOpsConsoleAdminPolicy managed policy with Amazon Q permissions	CloudWatch updated the **AIOpsConsoleAdminPolicy** managed policy to include Amazon Q integration permissions. These permissions enable users to interact with CloudWatch investigations incident reports through Amazon Q's conversational interface. For more information see, AIOpsConsoleAdminPolicy.	November 17, 2025
CloudWatch updated AIOpsOperatorAccess managed policy with Amazon Q permissions	CloudWatch updated the **AIOpsOperatorAccess** managed policy to include Amazon Q integration permissions. These permissions enable users to interact with CloudWatch investigations incident reports through Amazon Q's conversational interface. For more information see, AIOpsOperatorAccess.	November 7, 2025

Updated CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy managed policy with managed prefix lists permissions	CloudWatch added the `ec2:DescribeManagedPrefixLists` and `ec2:GetManagedPrefixListEntries` permissions to the CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy managed policy to grant permissions for Network Flow Monitor to generate topology snapshots of managed prefix lists.	November 6, 2025
Updated CloudWatchReadOnlyAccess Policy with observability administration permissions	CloudWatch updated the **CloudWatchReadOnlyAccess** managed policy to include observability administration permissions. These permissions provide read-only access to telemetry rules, centralization configurations, and resource telemetry data across AWS Organizations. For more information, see CloudWatchReadOnlyAccess.	October 10, 2025

CloudWatch updated AIOpsOperatorAccess managed policy with incident report permissions	CloudWatch updated the **AIOpsOperatorAccess** managed policy to include incident report generation permissions. These permissio ns allow users to create and manage incident reports and work with AI-derived facts in CloudWatch investigations. For more information, see AIOpsOperatorAccess.	October 10, 2025
CloudWatch investigations added incident reports	CloudWatch updated CloudWatch investigations to provide incident reporting . These AI-generated reports capture investigation findings, root causes, timeline events, and recommended corrective actions in a structured format. For more information see, Generate incident reports.	October 10, 2025

CloudWatch added AIOpsAssistantIncidentReportPolicy managed policy to support CloudWatch investigations AI-generated incident reports	CloudWatch added the **AIOpsAssistantIncidentReportPolicy** managed policy to enable CloudWatch investigations to generate incident reports from investigation data. This policy provides permissions to access investigations, create and manage reports, and work with AI-derived facts that form the foundation of incident documentation. For more information, see AIOpsAssistantIncidentReportPolicy.	October 10, 2025
Updated CloudWatchReadOnlyAccess policy with CloudTrail and Service Quotas permissions	CloudWatch updated CloudWatchReadOnlyAccess to include CloudTrail and Service Quotas permissions to support top observations and change indicators functionality within Application Signals.	October 8, 2025
Updated CloudWatchFullAccessV2 policy	CloudWatch updated CloudWatchFullAccessV2 to include CloudTrail and Service Quotas permissions to support top observations and change indicators functionality within Application Signals.	October 8, 2025

Updated CloudWatchApplicationSignalsReadOnlyAccess policy	CloudWatch updated the `CloudWatchApplicationSignalsReadOnlyAccess` policy to view how resources and services change in your account and view top observations for service anomalies in your account. For more information, see CloudWatchApplicationSignalsReadOnlyAccess.	September 29, 2025
Updated CloudWatchApplicationSignalsFullAccess policy	CloudWatch updated the `CloudWatchApplicationSignalsFullAccess` policy to view how resources and services change in your account and view top observations for service anomalies in your account. For more information, see CloudWatchApplicationSignalsFullAccess.	September 29, 2025
CloudWatch Application Signals added support for dynamic service grouping and filtering, last deployment tracking, and automated audit findings	You can group and filter services with Application Signals' dynamic grouping capabilities track deployment activities through Application Signals' automatic processing of CloudTrail events, and discover critical insights through Application Signals' automated audit findings. For more information, see Application Signals.	September 29, 2025

Update to AIOPsAssistantPolicy managed policy	CloudWatch updated the **AIOpsAssistantPolicy** to allow CloudWatch investigations access to additional resources to assist in queries, troubleshooting, and topology mapping. For more information, see AIOpsAssistantPolicy.	September 24, 2025
New AWSObservabilityAdminLogsCentralizationServiceRolePolicy policy	CloudWatch added the **AWSObservabilityAdminLogsCentralizationServiceRolePolicy** that grants CloudWatch permission to use telemetry data from other AWS accounts that you specify to create CloudWatch log groups, log streams, and log events in your organization's monitoring account. The SLR only provides the assume role permission to allow the CloudWatch service to assume the role in the monitoring account. For more information, see AWSObservabilityAdminLogsCentralizationServiceRolePolicy.	September 17, 2025

CloudWatch added support for Cross-account cross-Region log centralization	CloudWatch added support for the **Cross-account cross-Region log centralization** that enables CloudWatch Logs to gather log data from AWS Organizations member accounts into a central account for analysis. For more information, see Monitor across accounts and Regions.	September 17, 2025
Collect EC2 instance store volume NVMe driver metrics	You can now use the CloudWatch agent to collect AWS NVMe driver metrics for instance store volumes attached to Nitro-based Amazon EC2 instances.	September 16, 2025
Removed AWS OpsWorks metrics and dimensions	AWS OpsWorks reached end-of-life and the service is deprecated.	August 20, 2025
New AWSObservabilityAdminTelemetryEnablementServiceRolePolicy policy	CloudWatch added the **AWSObservabilityAdminTelemetryEnablementServiceRolePolicy** that grants CloudWatch the permissions necessary to enable and manage telemetry configurations for AWS resources based on telemetry rules. For more information, see AWSObservabilityAdminTelemetryEnablementServiceRolePolicy.	July 17, 2025

Generative AI observability	With CloudWatch, you can observe generative AI workloads, including Amazon Bedrock AgentCore agents, and gain insights into AI performance, health, and accuracy. For more information, see Generative AI observability.	July 16, 2025
AIOpsReadOnlyAccess policy updated	CloudWatch updated the **AIOpsReadOnlyAccess** policy to permit validation of investigation groups across accounts. For more informati on, see AIOpsReadOnlyAccess policy.	June 23, 2025
Updated AIOpsCons oleAdminPolicy policy	CloudWatch updated the AIOpsConsoleAdminPolicy policy to permit validation of investigation groups across accounts. For more informati on, see AIOpsConsoleAdminP olicy policy.	June 13, 2025
Updated AIOpsAssistantPolicy policy	CloudWatch updated the AIOpsAssistantPolicy policy to provide additional IAM permissions. For more information, see AIOpsCons oleAdminPolicy policy.	June 13, 2025

Update managed policy	CloudWatch updated the **AIOpsOperatorAccess** policy to permit validation of investigation groups across accounts. For more informati on, see AIOpsOperatorAccess.	June 13, 2025
AmazonCloudWatchRU MReadOnlyAccess updated	The `synthetics: describeCanaries` , `synthetics:describ eCanariesLastRun` , `cloudwatch:GetMetr icData` , `cloudwatc h:DescribeAlarms` , `logs:DescribeLogGr oups` , `xray:GetT raceSummaries` , and `rum:ListTagsForRes ources` permissions was added to the CloudWatc h RUM `AmazonClo udWatchRUMReadOnly Access` policy.	June 12, 2025
Added functionality	You can now monitor Amazon Aurora PostgreSQL Limitless Databases at the instance level from the Database Instance Dashboard. For more information, see Monitorin g Aurora Limitless databases with Database Insights.	May 22, 2025

Added functionality	You can now enable Application Signals for your applications on an existing Amazon EKS cluster using CloudWatch Observability add-on Auto monitor advanced configuration. For more information, see Enable Application Signals on an Amazon EKS cluster using the CloudWatch Observability add-on advanced configuration.	May 19, 2025
CloudWatch Network Monitoring releases multiple account support for Network Flow Monitor	Network Flow Monitor, a feature of CloudWatch Network Monitoring, now supports monitoring network performance metrics for network flows for resources in multiple accounts. For more information, see Initialize Network Flow Monitor for multi-account monitoring.	May 6, 2025
AmazonCloudWatchRUMReadOnlyAccess updated	The `rum:GetResourcePolicy` permission was added so that CloudWatch RUM can view the resource policy attached to the RUM application monitor.	April 28, 2025

Updated AIOpsAssistantPolicy policy	CloudWatch added permissions to the **AIOpsAssistantPolicy** policy, which Amazon Q Developer operational investigations uses to find information during investigations.	April 11, 2025
CloudWatch Synthetics deprecates five runtime metrics on October 1, 2025	CloudWatch Synthetics metrics `syn-nodejs-puppeteer-7.0` , `syn-nodejs-puppeteer-6.2` , `syn-nodejs-puppeteer-5.2` , `syn-python-selenium-3.0` , and `syn-python-selenium-2.1` will be deprecated on October 1, 2025.	April 4, 2025
Updated CloudWatchApplicationSignalsServiceRolePolicy policy	CloudWatch updated the policy to exclude time windows from impacting the SLO attainment rate, error budget, and burn rate metrics. CloudWatch can retrieve exclusion windows on behalf of you. For more information, see CloudWatchApplicationSignalsServiceRolePolicy.	March 13, 2025

Time window exclusions	SLOs adds support for time window exclusions which is a block of time with a defined start and end date. This time period is excluded from the SLO's performance metrics and you can schedule one-time or recurring time exclusions windows. For more information, see Service level objectives (SLOs).	March 13, 2025
New AIOpsReadOnlyAccess policy	CloudWatch added the **AIOpsReadOnlyAccess** policy, which grants read-only permissions for Amazon AI Operations and other related services.	December 3, 2024
New AIOpsOperatorAccess policy	CloudWatch added the **AIOpsOperatorAccess** policy, which grants users access to Amazon AI Operations actions, and to additiona l AWS actions that are necessary for accessing investigation events.	December 3, 2024

New AIOpsConsoleAdminPolicy policy	CloudWatch added the **AIOpsConsoleAdminPolicy** policy, which grants users full administrative access for managing Amazon Q investigations, including the management of trusted identity propagation, and the management of IAM Identity Center and organizational access.	December 3, 2024
New AIOpsAssistantPolicy policy	CloudWatch added the **AIOpsAssistantBasicAccess** policy, which you can assign to the Amazon AI Operations assistant to enable the assistant to have basic functionality.	December 3, 2024
Amazon Q Developer operational investigations feature in Preview	CloudWatch released a Preview of Amazon Q Developer operational investigations. This feature is a generative AI-powered assistant that can help you respond to incidents in your system. It uses generative AI to scan your system's telemetry and quickly surface suggestions that might be related to your issue, to help you troubleshoot operational issues faster.	December 3, 2024

CloudWatchFullAccessV2 and CloudWatchFullAccess policies updated	CloudWatch updated both **CloudWatchFullAccessV2** and **CloudWatchFullAccess**. Permissions for Amazon OpenSearch Service were added to to enable CloudWatch Logs integration with OpenSearch Service for some features.	December 1, 2024
Telemetry config feature generally available	CloudWatch added the telemetry config feature to discover and understand the state of telemetry configuration for your AWS resources.	November 26, 2024
New AWSServiceRoleForObservabilityAdmin service-linked role	CloudWatch added the new AWSServiceRoleForObservabilityAdmin service-linked role and AWSObservabilityAdminServiceRolePolicy policy.	November 26, 2024
CloudWatch supports exploring related telemetry	CloudWatch supports exploring related telemetry data across interconnected resources.	November 22, 2024

Updated CloudWatchSyntheticsFullAccess IAM policy	CloudWatch updated the **CloudWatchSyntheticsFullAccess** policy to grant CloudWatch Synthetics access to get AWS Lambda functions , and perform actions on logs available in CloudWatch Logs. Additionally, Lambda layer version actions apply to all CloudWatch Synthetics layer ARNs.	November 21, 2024
New CloudWatch Synthetics support for Node.js with the Playwright runtime	CloudWatch Synthetics adds support for Node.js canary scripts that use the Playwright runtime.	November 21, 2024
CloudWatchReadOnlyAccess policy updated	The scope of the policy was changed to include the `xray:List *`, `xray:StartTraceRetrieval` , and `xray:CancelTraceRetrieval` permissions. This change allows CloudWatch to access new X-Ray read APIs. For more infomration, see CloudWatchReadOnlyAccess.	November 21, 2024

CloudWatch Transaction Search is generally available	CloudWatch releases Transaction Search, a search and analytics experience. Transaction Search provides visibility into application transaction issues. Explore interactions between application components to establish a root cause. Understand your application transactions and their impact on customers. Search transactions using terms like customer name or order. For more information, see CloudWatch Transaction Search.	November 21, 2024
Application Signals supports Lambda functions	You can now enable Application Signals for Lambda functions.	November 21, 2024
OpenTelemetry	You can use OpenTelemetry to directly send traces to an OpenTelemetry Protocol (OTLP) endpoint, and get out-of-the box application performance monitoring experiences in CloudWatch Application Signals.	November 20, 2024
Application Signals collects runtime metrics	Application Signals now collects OpenTelemetry-compatible runtime metrics from your Java and Python applications.	November 19, 2024

Application Signals collects runtime metrics	Application Signals now collects OpenTelemetry-compatible runtime metrics from your Java and Python applications.	November 19, 2024
Internet traffic monitoring for VPCs in AWS Local Zones	Internet Monitor now supports internet traffic monitoring for VPCs deployed in AWS Local Zones	November 18, 2024
Application Signals support for Node.js applications is generally available	CloudWatch supports enabling Node.js applications for Application Signals.	November 15, 2024
New CloudWatchInternetMonitorReadOnlyAccess IAM policy	CloudWatch added a **CloudWatchInternetMonitorReadOnlyAccess** policy, to grant read-only access to actions and resources available in the CloudWatch console for Internet Monitor.	November 14, 2024
CloudWatch added observability solutions	CloudWatch observability solutions offer a catalog of readily available configurations to help you quickly implement monitoring for various AWS services and common workloads, such as Java Virtual Machines (JVM), Apache Kafka, Apache Tomcat, and NGINX.	November 13, 2024

CloudWatch added burn rate monitoring for Application Signals SLOs	CloudWatch added burn rate monitoring to Application Signals SLOs. A burn rate is a metric that indicates how fast the service is consuming the error budget, relative to the attainment goal of the SLO.	November 13, 2024
New Internet Monitor latency reduction suggestions through Route 53 routing updates	Amazon CloudWatch Internet Monitor now provides actionable suggestions to help you optimize your Route 53 IP-based routing configurations. Easily identify the optimal AWS Regions for routing your end user traffic, and then configure your Route 53 IP-based routing based on the recommend ations.	November 1, 2024
New CloudWatchInternet MonitorFullAccess IAM policy	CloudWatch added a **CloudWatchInternet MonitorFullAccess** policy, to grant full access to actions and resources available in the CloudWatch console for Internet Monitor.	October 23, 2024
End of support notice	End of support notice: On October 16, 2025, AWS will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.	October 17, 2024

End of support notice	End of support notice: On October 16, 2025, AWS will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.	October 17, 2024
New CloudWatchLambdaApplicationSignalsExecutionRolePolicy IAM policy	CloudWatch added a new policy named **CloudWatchLambdaApplicationSignalsExecutionRolePolicy**. This policy is used when CloudWatch Application Signals is enabled for Lambda workloads. It enables write access to X-Ray and the log group used by CloudWatch Application Signals.	October 16, 2024
New CloudWatchLambdaApplicationSignalsExecutionRolePolicy IAM policy	CloudWatch added a new policy named **CloudWatchLambdaApplicationSignalsExecutionRolePolicy**. This policy is used when CloudWatch Application Signals is enabled for Lambda workloads. It enables write access to X-Ray and the log group used by CloudWatch Application Signals.	October 16, 2024

CloudWatchSyntheticsFullAccess policy updated	Permissions were added to the **CloudWatchSyntheticsFullAccess** IAM policy. The `lambda:ListTags` , `lambda:TagResource` , and `lambda:UntagResource` permissions were added so that when you apply or change tags on a canary, you can choose to have Synthetics also apply those same tags or changes to the Lambda function that the canary uses.	October 11, 2024
Application Signals supports request-based SLOs	Application Signals adds support for request-based service level objects (SLOs). For more information, see Service level objectives (SLOs).	September 6, 2024
Internet Monitor refreshed dashboard and latency improvement suggestions	Amazon CloudWatch Internet Monitor has launched an updated console experience, including new features for visualizing configuration changes that can help you reduce latency for your application.	August 12, 2024
Application Signals previewing support for .NET applications	CloudWatch Application Signals has added support for .NET applications, with ADOT Instrumentation for .NET on supported platforms. This feature is in preview release.	August 5, 2024

New CloudWatch Application Insights service linked role permission added	Allows CloudWatch Application Insights to enable and disable termination protection on CloudFormation stacks.	July 25, 2024
CloudWatch Metrics Insights support for natural language query generation is generally available.	CloudWatch Metrics Insights supports natural language query to generate and update queries. For more information, see Use natural language to generate and update CloudWatch Metric Insights queries.	June 10, 2024
CloudWatch Application Signals is generally available	CloudWatch Application Signals is now generally available. Use Application Signals to instrument your applications on AWS so that you can monitor current application health, create service level objectives (SLOs), and track long-term application performance against your business objectives. For more information, see Application Signals.	June 10, 2024
New CloudWatchApplicationSignalsReadOnlyAccess IAM policy	CloudWatch added a **CloudWatchApplicationSignalsReadOnlyAccess** policy to add read only actions and resources available in the CloudWatch console for Application Signals.	June 7, 2024

New CloudWatchApplicationSignalsFullAccess policy	CloudWatch added a **CloudWatchApplicationSignalsFullAccess** policy to add actions and resources available in the CloudWatch console for Application Signals.	June 7, 2024
CloudTrail now captures API activities related to CloudWatch data plane operations.	CloudTrail now logs events in CloudTrail for **GetMetricData** and **GetMetricWidgetImage** API activities.	June 6, 2024
CloudWatch Application Signals application map supports canary, RUM clients and AWS service dependency groupings.	The Application Signals preview release has added default groupings in the application map for canaries, RUM clients, and AWS service dependencies of the same type. This change reduces the number of icons in the application map default view to make it easier to view and navigate.	May 21, 2024

CloudWatchReadOnlyAccess policy updated	CloudWatch changed the scope of a permission in **CloudWatchReadOnlyAccess**. The scope of the policy added the `application-signals:BatchGet*` , `application-signals:Get*` , and `application-signals:List*` actions so that users can use CloudWatch Application Signals to view, investigate, and diagnose issues with the health of their services. CloudWatch also added an `iam:GetRole` action so that users can check if Application Signals is set up.	May 17, 2024
CloudWatchFullAccessV2 policy updated	CloudWatch changed the scope of a permission in **CloudWatchFullAccessV2**. The scope of the policy added the `application-signals:*` so that users can use CloudWatch Application Signals to view, investigate, and diagnose issues with the health of their services.	May 17, 2024
Lambda Insights supports AWS GovCloud (US-East) and AWS GovCloud (US-West)	CloudWatch Lambda Insights has added support for the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions.	April 29, 2024

CloudWatch cross-account observability supports resource filters	You can now create filters to specify which metric namespaces and log groups are shared from the source account to the monitoring account, when you create the link between the accounts.	April 26, 2024
CloudWatch Application Signals updates	The Application Signals preview release has added three features. Applicati on Signals now supports Python applications. It offers a simpler enablement process for applications on Amazon EKS architectures. And it includes new configurations that you can use to manage the cardinality of metrics that are collected.	April 26, 2024
CloudWatch Container Insights with enhanced observability for Amazon EKS can collect AWS Elastic Fabric Adapter (EFA) metrics	You can now use CloudWatc h Container Insights with enhanced observability for Amazon EKS collect AWS Elastic Fabric Adapter (EFA) metrics from Amazon EKS clusters.	April 23, 2024

Updated IAM policy	CloudWatch updated the **CloudWatchApplicationSignalsServiceRolePolicy** policy. The scoping of the `logs:StartQuery` and `logs:GetQueryResults` permissions in this policy was changed to add `arn:aws:logs:*:*:log-group:/aws/appsignals/*:*` and `"arn:aws:logs:*:*:log-group:/aws/application-signals/data:*"` to enable Application Signals on more architecures. This policy is attached to the **AWSServiceRoleForCloudWatchApplicationSignals** service-linked role.	April 18, 2024
Internet Monitor provides a global internet weather map to authenticated AWS customers	Amazon CloudWatch Internet Monitor now displays a global internet weather map that is available in the console to all authenticated AWS customers. To view the map, in the Amazon CloudWatch console, navigate to Internet Monitor.	April 16, 2024
CloudWatch Container Insights with enhanced observability for Amazon EKS can collect AWS Neuron metrics	You can now use CloudWatch Container Insights with enhanced observability for Amazon EKS collect AWS Neuron metrics from Amazon EKS clusters.	April 16, 2024

CloudWatch Application Signals adds a **Service overview** tab and more metrics to aid in diagnostics	A new **Service overview** tab displays an overview of your service, including number of operations, dependencies, synthetics, and client pages. The tab shows key metrics for your entire service, and top operations and dependencies. You can also now view X-Ray traces that are correlated with issues including faults, errors, and latency problems.	April 16, 2024
CloudWatch Container Insights with enhanced observability for Amazon EKS adds support for Windows	You can now use CloudWatch Container Insights with enhanced observability for Amazon EKS collect metrics from Windows worker nodes on Amazon EKS clusters.	April 10, 2024
CloudWatchApplicationSignalsServiceRolePolicy IAM policy updated	CloudWatch changed the scope of a permission in **CloudWatchApplicationSignalsServiceRolePolicy**. The scope of the `cloudwatch:GetMetricData` permission was changed to * so that Application Signals can retrieve metrics from sources in linked accounts.	April 8, 2024
Amazon CloudWatch Internet Monitor now supports cross-account observability	You can now use Internet Monitor cross-account observability to monitor your applications that span multiple AWS accounts within a single AWS Region.	March 29, 2024

CloudWatchAgentServerPolicy and **CloudWatchAgentAdminPolicy** policies updated	CloudWatch added permissions to both the `CloudWatchAgentServerPolicy` and `CloudWatchAgentAdminPolicy` policies to allow the CloudWatch agent to publish X-Ray traces and modify log group retention periods. In both policies, the `xray:PutTraceSegments`, `xray:PutTelemetryRecords`, `xray:GetSamplingRules`, `xray:GetSamplingTargets`, `xray:GetSamplingStatisticSummaries` and `logs:PutRetentionPolicy` permissions were added	February 12, 2024

New service linked role and IAM policy for CloudWatch Network Monitor	CloudWatch added a new service-linked role, called **AWSServiceRoleForNetworkMonitor**. CloudWatch added this new service-linked role to allow you to create monitors to fetch network metrics between source subnets and destination IP addresses. The new **CloudWatchNetworkMonitorServiceRolePolicy** IAM policy is attached to this role, and the policy grants permission to CloudWatch to fetch network metrics on your behalf.	December 22, 2023
CloudWatch releases Amazon CloudWatch Network Monitor	CloudWatch released a new feature, Amazon CloudWatch Network Monitor. This is a new active network monitoring service that identifies if a network issues exists within the AWS network or your own company network.	December 22, 2023

CloudWatchReadOnlyAccess policy updated	CloudWatch added existing read-only permissions for CloudWatch Synthetics, X-Ray, and CloudWatch RUM and new read-only permissions for CloudWatch Application Signals to **CloudWatchReadOnlyAccess** so that users with this policy can triage and diagnose service health issues as reported by CloudWatch Application Signals. The `cloudwatch:GenerateQuery` permission was added so that users with this policy can generate a CloudWatch Metrics Insights query string from a natural language prompt.	December 5, 2023
CloudWatchFullAccessV2 policy updated	CloudWatch added existing permissions to **CloudWatchFullAccessV2** for CloudWatch Synthetics, X-Ray, and CloudWatch RUM, and added new permissions for CloudWatch Application Signals so that users with this policy can fully manage Application Signals to triage and diagnose issues with service health.	December 5, 2023

New service-linked role and new IAM policy	CloudWatch added a new service-linked role, called **AWSServiceRoleForCloudWatchApplicationSignals**. CloudWatch added this new service-linked role to allow CloudWatch Application Signals to collect CloudWatch Logs data, X-Ray trace data, CloudWatch metrics data, and tagging data from applications that you have enabled for CloudWatch Application Signals. The new **CloudWatchApplicationSignalsServiceRolePolicy** IAM policy is attached to this role, and the policy grants permission to CloudWatch Application Signals to collect monitoring and tagging data from other relevant AWS services.	November 30, 2023

CloudWatch launches Preview release of Application Signals	CloudWatch Application Signals is in Preview. Use Application Signals to instrument your applicati ons on AWS so that you can monitor current applicati on health, create service level objectives (SLOs), and track long-term application performance against your business objectives. For more information, see Application Signals.	November 30, 2023
CloudWatch adds support for querying other data sources	You can use CloudWatch to query, visualize, and create alarms for metrics from other data sources For more information, see Querying metrics from other data sources.	November 26, 2023
CloudWatch Metrics Insights supports natural language query generation	CloudWatch Metrics Insights supports natural language query to generate and update queries. For more informati on, see Use natural language to generate and update CloudWatch Metric Insights queries.	November 26, 2023

CloudWatch releases Container Insights with enhanced observability for Amazon EKS	CloudWatch released a new version of Container Insights. This version supports enhanced observability for Amazon EKS clusters and can collect more detailed metrics from clusters running Amazon EKS. After installat ion, it automatically collects detailed infrastructure telemetry and container logs for your Amazon EKS clusters. You can then use curated, immediately usable dashboards to drill down into application and infrastructure telemetry.	November 6, 2023
CloudWatch metric streams adds quick partner setup	CloudWatch metric streams now provides a quick partner setup option, which you can use to quickly set up a metric stream to some third-party providers.	October 17, 2023
CloudWatch releases alarm recommendations	CloudWatch Synthetics now provides alarm recommend ations for metrics from other AWS services. These recommendations can help you identify the metrics that you should set alarms for to follow best practices for monitoring these services.	October 16, 2023

CloudWatch Synthetics releases runtime syn-nodejs-puppeteer-6.0	CloudWatch Synthetics released runtime `syn-nodejs-puppeteer-6.0` .	September 26, 2023
Adds Amazon CloudWatch Application Insights support for cross-account applications	You can now share CloudWatch Application Insights applications across account boundaries.	September 26, 2023
New service-linked role and new IAM policy	CloudWatch added a new service-linked role, called **AWSServiceRoleForCloudWatchMetrics_DbPerfInsights**. CloudWatch added this new service-linked role to allow CloudWatch to fetch Performance Insights metrics for alarming, anomaly detection, and snapshotting. The new **AWSServiceRoleForCloudWatchMetrics_DbPerfInsightsServiceRolePolicy** IAM policy is attached to this role, and the policy grants permission to CloudWatch to fetch Performance Insights metrics on your behalf.	September 20, 2023
Adds new metric math function	CloudWatch added a new metric math function, `DB_PERF_INSIGHTS` , that you can use to fetch Performance Insights metrics from AWS database services for alarming, anomaly detection, and snapshotting.	September 20, 2023

CloudWatchReadOnlyAccess policy updated	CloudWatch added the `application-autoscaling:DescribeScalingPolicies` permission to **CloudWatchReadOnlyAccess** so that users with this policy can access information about Application Auto Scaling policies.	September 14, 2023
CloudWatch agent added support for AL2023	The CloudWatch agent supports AL2023.	August 8, 2023
New managed IAM policy, CloudWatchFullAccessV2	CloudWatch added a new policy **CloudWatchFullAccessV2**. This policy grants full access to CloudWatch actions and resources while better scoping the permissions granted to other services such as Amazon SNS and Amazon EC2 Auto Scaling.	August 1, 2023
Updated service linked role for Amazon CloudWatch Internet Monitor – update to an existing policy	Adds new permissions, `elasticloadbalancing:DescribeLoadBalancers` and `ec2:DescribeNetworkInterfaces`, to the service linked role for Internet Monitor, to support monitoring traffic for specific Network Load Balancer resources.	July 25, 2023

Added support for Network Load Balancer resources in Amazon CloudWatch Internet Monitor	Adds support for creating a monitor in Internet Monitor with specific Network Load Balancer resources, to provide more granular levels of observability for your application.	July 25, 2023
Dashboard variables feature	CloudWatch released *dashboard variables*, which you can use to create flexible dashboards that can quickly display different contents depending on how you set one input field within the dashboard. For example, you can create a dashboard that can quickly switch between different Lambda functions or Amazon EC2 instance IDs, or one that can switch to different AWS Regions. For more information, see Create flexible dashboards with dashboard variables.	June 28, 2023
Internet Monitor now supports customizing the threshold for health events	Internet Monitor added the ability to customize the threshold for when a global performance score or availabil ity score triggers a heath event. For more informati on, see Tracking real-time performance and availabil ity in Amazon CloudWatch Internet Monitor.	June 26, 2023

Internet Monitor now supports all commercial Regions	Internet Monitor added seven new AWS Regions and now supports all commercial Regions.	June 19, 2023
New Lambda Insights extension versions	CloudWatch added the 1.0.229.0 version of the Lambda Insights extension for both x86-64 platforms and ARM64 platforms. For more information, see Available versions of the Lambda Insights extension.	June 12, 2023
CloudWatchReadOnlyAccess policy updated	CloudWatch added permissions to **CloudWatchReadOnlyAccess**. The `logs:StartLiveTail` and `logs:StopLiveTail` permissions were added so that users with this policy can use the console to start and stop CloudWatch Logs live tail sessions. For more information, see Use live tail to view logs in near real time.	June 6, 2023

CloudWatch RUM adds support for custom metrics	You can use CloudWatch RUM app monitors to create custom metrics and send them to CloudWatch and CloudWatch Evidently. This feature includes an update to the **AmazonCloudWatchRUMServiceRolePolicy** managed IAM policy. In that policy, a condition key was changed so that CloudWatch RUM can send custom metrics to custom metric namespaces.	February 9, 2023
New and updated managed polices for CloudWatch	To support CloudWatch cross-account observability, the `CloudWatchFullAccess` and `CloudWatchReadOnlyAccess` policies have been updated, and the following new managed policies have been added: `CloudWatchCrossAccountSharingConfiguration`, `OAMFullAccess`, and `OAMReadOnlyAccess`. For more information, see CloudWatch updates to AWS managed policies.	February 7, 2023
CloudWatch Application Insights service-linked role policy updates — update to an existing policy.	CloudWatch Application Insights updated an existing AWS service-linked role policy.	December 19, 2022

Amazon CloudWatch Application Insights support for containerized applications and microservices from the Container Insights console.	You can display CloudWatch Application Insights detected problems for Amazon ECS and Amazon EKS on your Container Insights dashboard.	November 17, 2021
Amazon CloudWatch Application Insights monitoring for SAP HANA databases.	You can monitor SAP HANA databases with Application Insights.	November 15, 2021
Amazon CloudWatch Application Insights support for monitoring all resources in an account.	You can onboard and monitor all resources in an account.	September 15, 2021
Amazon CloudWatch Application Insights support for Amazon FSx.	You can monitor metrics retrieved from Amazon FSx.	August 31, 2021
SDK Metrics is no longer supported.	CloudWatch SDK Metrics is no longer supported.	August 25, 2021
Amazon CloudWatch Application Insights support for setting up container monitoring.	You can monitor containers using best practices with Amazon CloudWatch Application Insights.	May 18, 2021
Metric streams is generally available	You can use metric streams to continually stream CloudWatch metrics to a destination of your choice. For more information, see Metric streams in the *Amazon CloudWatch User Guide*.	March 31, 2021

Amazon CloudWatch Application Insights monitoring for Oracle databases on Amazon RDS and Amazon EC2.	You can monitor metrics and logs retrieved from Oracle with Amazon CloudWatch Application Insights.	January 16, 2021
Lambda Insights is generally available	CloudWatch Lambda Insights is a monitoring and troubleshooting solution for serverless applications running on AWS Lambda. For more information, see Using Lambda Insights in the *Amazon CloudWatch User Guide*.	December 3, 2020
Amazon CloudWatch Application Insights monitoring for Prometheus JMX exporter metrics.	You can monitor metrics retrieved from Prometheus JMX exporter with Amazon CloudWatch Application Insights.	November 20, 2020
CloudWatch Synthetics releases new runtime version	CloudWatch Synthetics has released a new runtime version. For more information, see Canary Runtime Versions in the *Amazon CloudWatch User Guide*.	September 11, 2020
Amazon CloudWatch Application Insights monitoring for Postgre SQL on Amazon RDS and Amazon EC2.	You can monitor applications built with PostgreSQL running on Amazon RDS or Amazon EC2.	September 11, 2020

CloudWatch supports dashboard sharing	You can now share CloudWatch dashboards with people outside of your organization and AWS account. For more information, see Sharing CloudWatch Dashboards in the *Amazon CloudWatch User Guide*.	September 10, 2020
Set up monitors for .NET applications using SQL Server on the backend with CloudWatch Application Insights	You can use the documentation tutorial to help you to set up monitors for .NET applications using SQL Server on the backend with CloudWatch Application Insights.	August 19, 2020
CloudFormation support for Amazon CloudWatch Application Insights applications.	You can add CloudWatch Application Insights monitoring, including key metrics and telemetry, to your application, database, and web server, directly from CloudFormation templates.	July 30, 2020
Amazon CloudWatch Application Insights monitoring for Aurora for MySQL database clusters.	You can monitor Aurora for MySQL database clusters (RDS Aurora) with Amazon CloudWatch Application Insights.	July 2, 2020

CloudWatch Contributor Insights general availability	CloudWatch Contributor Insights is now generally available. It enables you to analyze log data and create time series that display contributor data. You can see metrics about the top-N contributors, the total number of unique contributors, and their usage. For more information, see Using Contributor Insights to Analyze High-Cardinality Data in the *Amazon CloudWatch User Guide*.	April 2, 2020
CloudWatch Synthetics public preview	CloudWatch Synthetics is now in public preview. It enables you to create canaries to monitor your endpoints and APIs. For more information, see Using Canaries in the *Amazon CloudWatch User Guide*.	November 25, 2019

CloudWatch Contributor Insights public preview	CloudWatch Contributor Insights is now in public preview. It enables you to analyze log data and create time series that display contributor data. You can see metrics about the top-N contributors, the total number of unique contributors, and their usage. For more information, see Using Contributor Insights to Analyze High-Cardinality Data in the *Amazon CloudWatch User Guide*.	November 25, 2019
CloudWatch launches ServiceLens feature	ServiceLens ehances the observability of your services and applications by enabling you to integrate traces, metrics, logs, and alarms into one place. ServiceLens integrates CloudWatch with AWS X-Ray to provide an end-to-end view of your application.	November 21, 2019

Use CloudWatch to proactively manage your AWS service quotas	You can use CloudWatch to proactively manage your AWS service quotas. CloudWatch usage metrics provide visibility into your account's usage of resources and API operations. For more information, see Service Quotas Integration and Usage Metrics in the *Amazon CloudWatch User Guide*.	November 19, 2019
CloudWatch sends events when alarms change state	CloudWatch now sends an event to Amazon EventBridge when any CloudWatch alarm changes state. For more information, see Alarm Events and EventBridge in the *Amazon CloudWatch User Guide*.	October 8, 2019
Container Insights	CloudWatch Container Insights is now generally available. It enables you to collect, aggregate, and summarize metrics and logs from your containerized applications and microservices. For more information, see Using Container Insights in the *Amazon CloudWatch User Guide*.	August 30, 2019

Updates for Container Insights preview metrics on Amazon EKS and Kubernetes	The Container Insights on Amazon EKS and Kubernetes public preview has been updated. InstanceId is now included as a dimension to the cluster EC2 instances. This allows alarms that have been created on these metrics to trigger the following EC2 actions: Stop, Terminate, Reboot, or Recover. Additionally, pod and service metrics are now reported by Kubernetes namespace to simplify the monitoring and alarming on metrics by namespace.	August 19, 2019
Updates for AWS Systems Manager OpsCenter integration	Updates on how CloudWatch Application Insights integrates with Systems Manager OpsCenter.	August 7, 2019
CloudWatch usage metrics	CloudWatch usage metrics help you track the usage of your CloudWatch resources and stay within your service limits. For more information, see https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/CloudWatch-Usage-Metrics.html.	August 6, 2019

CloudWatch Container Insights public preview	CloudWatch Container Insights is now in public preview. It enables you to collect, aggregate, and summarize metrics and logs from your containerized applications and microservices. For more information, see Using Container Insights in the *Amazon CloudWatch User Guide*.	July 9, 2019
CloudWatch Anomaly Detection public preview	CloudWatch anomaly detection is now in public preview. CloudWatch applies machine-learning algorithms to a metric's past data to create a model of the metric's expected values. You can use this model for visualization and for setting alarms. For more information, see Using CloudWatch Anomaly Detection in the *Amazon CloudWatch User Guide*.	July 9, 2019
CloudWatch Application Insights for .NET and SQL Server	CloudWatch Application Insights for .NET and SQL Server facilitates observability for .NET and SQL Server applications. It can help you set up the best monitors for your application resources to continuously analyze data for signs of problems with your applications.	June 21, 2019

CloudWatch agent section re-organized	The CloudWatch agent documentation has been rewritten to improve clarity, especially for customers using the command line to install and configure the agent. For more information, see Collecting Metrics and Logs from Amazon EC2 Instances and On-Premises Servers with the CloudWatch Agent in the *Amazon CloudWatch User Guide*.	March 28, 2019
SEARCH function added to metric math expressions	You can now use a SEARCH function in metric math expressions. This enables you to create dashboards that update automatically as new resources are created that match the search query. For more information, see Using Search Expressions in Graphs in the *Amazon CloudWatch User Guide*.	March 21, 2019
AWS SDK Metrics for Enterprise Support	SDK Metrics helps you assess the health of your AWS services and diagnose latency caused by reaching your account usage limits or by a service outage. For more information, see Monitor Applications Using AWS SDK Metrics in the *Amazon CloudWatch User Guide*.	December 11, 2018

Alarms on math expressions	CloudWatch supports creating alarms based on metric math expressions. For more information, see Alarms on Math Expressions in the *Amazon CloudWatch User Guide*.	November 20, 2018
New CloudWatch console home page	Amazon has created a new home page in the CloudWatch console, which automatically displays key metrics and alarms for all the AWS services you are using. For more information, see Getting Started with Amazon CloudWatch in the *Amazon CloudWatch User Guide*.	November 19, 2018
CloudFormation templates for the CloudWatch Agent	Amazon has uploaded CloudFormation templates that you can use to install and update the CloudWatch agent. For more information, see Install the CloudWatch Agent on New Instances Using CloudFormation in the *Amazon CloudWatch User Guide*.	November 9, 2018

Enhancements to the CloudWatch Agent	The CloudWatch agent has been updated to work with both the StatsD and collectd protocols. It also has improved cross-account support. For more informati on, see Retrieve Custom Metrics with StatsD, Retrieve Custom Metrics with collectd, and Sending Metrics and Logs to a Different AWS Account in the *Amazon CloudWatch User Guide*.	September 28, 2018
Support for Amazon VPC endpoints	You can now establish a private connection between your VPC and CloudWatc h. For more information, see Using CloudWatch with Interface VPC Endpoints in the *Amazon CloudWatch User Guide*.	June 28, 2018

The following table describes important changes to the *Amazon CloudWatch User Guide* before June 2018.

Change	Description	Release date
Metric math	You can now perform math expressions on CloudWatch metrics, producing new time series that you can add to graphs on your dashboard. For more information, see Math expressions with metrics.	April 4, 2018
"M out of N" alarms	You can now configure an alarm to trigger based on "M out of N" datapoints in any alarm evaluatio	December 8, 2017

Change	Description	Release date
	n interval. For more information, see Alarm evaluation.	
CloudWatch agent	A new unified CloudWatch agent was released. You can use the unified multi-platform agent to collect custom both system metrics and log files from Amazon EC2 instances and on-premises servers. The new agent supports both Windows and Linux and enables customization of metrics collected, including sub-resource metrics such as per-CPU core. For more information, see Collect metrics, logs, and traces using the CloudWatch agent.	September 7, 2017
NAT gateway metrics	Added metrics for Amazon VPC NAT gateway.	September 7, 2017
High-resolution metrics	You can now optionally set up custom metrics as high-resolution metrics, with a granularity of as low as one second. For more information, see High-resolution metrics.	July 26, 2017
Dashboard APIs	You can now create, modify, and delete dashboards using APIs and the AWS CLI. For more information, see Creating a customized CloudWatch dashboard.	July 6, 2017
Direct Connect metrics	Added metrics for Direct Connect.	June 29, 2017
Amazon VPC VPN metrics	Added metrics for Amazon VPC VPN.	May 15, 2017
WorkSpaces Applications metrics	Added metrics for WorkSpaces Applications.	March 8, 2017

Change	Description	Release date
CloudWatch console color picker	You can now choose the color for each metric on your dashboard widgets. For more information, see Editing a graph on a CloudWatch dashboard.	February 27, 2017
Alarms on dashboards	Alarms can now be added to dashboards. For more information, see Adding an alarm to a CloudWatch dashboard.	February 15, 2017
Added metrics for Amazon Polly	Added metrics for Amazon Polly.	December 1, 2016
Added metrics for Amazon Managed Service for Apache Flink	Added metrics for Amazon Managed Service for Apache Flink.	December 1, 2016
Added support for percentile statistics	You can specify any percentile, using up to two decimal places (for example, p95.45). For more information, see Percentiles.	November 17, 2016
Added metrics for Amazon Simple Email Service	Added metrics for Amazon Simple Email Service.	November 2, 2016
Updated metrics retention	Amazon CloudWatch now retains metrics data for 15 months instead of 14 days.	November 1, 2016
Updated metrics console interface	The CloudWatch console is updated with improvements to existing functionality and new functionality.	November 1, 2016
Added metrics for Amazon Elastic Transcoder	Added metrics for Amazon Elastic Transcoder.	September 20, 2016

Change	Description	Release date
Added metrics for Amazon API Gateway	Added metrics for Amazon API Gateway.	September 9, 2016
Added metrics for AWS Key Management Service	Added metrics for AWS Key Management Service.	September 9, 2016
Added metrics for the new Application Load Balancers supported by Elastic Load Balancing	Added metrics for Application Load Balancers.	August 11, 2016
Added new NetworkPacketsIn and NetworkPacketsOut metrics for Amazon EC2	Added new NetworkPacketsIn and NetworkPacketsOut metrics for Amazon EC2.	March 23, 2016
Added new metrics for Amazon EC2 Spot fleet	Added new metrics for Amazon EC2 Spot fleet.	March 21, 2016
Added new CloudWatch Logs metrics	Added new CloudWatch Logs metrics.	March 10, 2016

Change	Description	Release date
Added Amazon OpenSearch Service and AWS WAF metrics and dimensions	Added Amazon OpenSearch Service and AWS WAF metrics and dimensions.	October 14, 2015
Added support for CloudWatch dashboards	Dashboards are customizable home pages in the CloudWatch console that you can use to monitor your resources in a single view, even those that are spread out across different Regions. For more information, see Using Amazon CloudWatch dashboards.	October 8, 2015
Added AWS Lambda metrics and dimensions	Added AWS Lambda metrics and dimensions.	September 4, 2015
Added Amazon Elastic Container Service metrics and dimensions	Added Amazon Elastic Container Service metrics and dimensions.	August 17, 2015
Added Amazon Simple Storage Service metrics and dimensions	Added Amazon Simple Storage Service metrics and dimensions.	July 26, 2015
New feature: Reboot alarm action	Added the reboot alarm action and new IAM role for use with alarm actions. For more informati on, see Stop, terminate, reboot, or recover an EC2 instance.	July 23, 2015
Added Amazon WorkSpaces metrics and dimensions	Added Amazon WorkSpaces metrics and dimensions.	April 30, 2015

Change	Description	Release date
Added Amazon Machine Learning metrics and dimensions	Added Amazon Machine Learning metrics and dimensions.	April 9, 2015
New feature: Amazon EC2 instance recovery alarm actions	Updated alarm actions to include new EC2 instance recovery action. For more information, see Stop, terminate, reboot, or recover an EC2 instance.	March 12, 2015
Added Amazon CloudFront and Amazon CloudSearch metrics and dimensions	Added Amazon CloudFront and Amazon CloudSearch metrics and dimensions.	March 6, 2015
Added Amazon Simple Workflow Service metrics and dimensions	Added Amazon Simple Workflow Service metrics and dimensions.	May 9, 2014
Updated guide to add support for AWS CloudTrail	Added a new topic to explain how you can use AWS CloudTrail to log activity in Amazon CloudWatch. For more information, see Logging Amazon CloudWatch API and console operations with AWS CloudTrail.	April 30, 2014

Change	Description	Release date
Updated guide to use the new AWS Command Line Interface (AWS CLI)	The AWS CLI is a cross-service CLI with a simplified installation, unified configuration, and consistent command line syntax. The AWS CLI is supported on Linux/Unix, Windows, and Mac. The CLI examples in this guide have been updated to use the new AWS CLI. For information about how to install and configure the new AWS CLI, see Getting Set Up with the AWS CLI Interface in the *AWS Command Line Interface User Guide*.	February 21, 2014
Added Amazon Redshift and AWS OpsWorks metrics and dimensions	Added Amazon Redshift and AWS OpsWorks metrics and dimensions.	July 16, 2013
Added Amazon Route 53 metrics and dimensions	Added Amazon Route 53 metrics and dimensions.	June 26, 2013
New feature: Amazon CloudWatch Alarm Actions	Added a new section to document Amazon CloudWatch alarm actions, which you can use to stop or terminate an Amazon Elastic Compute Cloud instance. For more information, see Stop, terminate, reboot, or recover an EC2 instance.	January 8, 2013
Updated EBS metrics	Updated the EBS metrics to include two new metrics for Provisioned IOPS volumes.	November 20, 2012

Change	Description	Release date
New billing alerts	You can now monitor your AWS charges using Amazon CloudWatch metrics and create alarms to notify you when you have exceeded the specified threshold. For more information, see Create a billing alarm to monitor your estimated AWS charges.	May 10, 2012
New metrics	You can now access six new Elastic Load Balancing metrics that provide counts of various HTTP response codes.	October 19, 2011
New feature	You can now access metrics from Amazon EMR.	June 30, 2011
New feature	You can now access metrics from Amazon Simple Notification Service and Amazon Simple Queue Service.	July 14, 2011
New Feature	Added information about using the `PutMetricData` API to publish custom metrics. For more information, see Publish custom metrics (PutMetricData / EMF).	May 10, 2011
Updated metrics retention	Amazon CloudWatch now retains the history of an alarm for two weeks rather than six weeks. With this change, the retention period for alarms matches the retention period for metrics data.	April 7, 2011
New feature	Added ability to send Amazon Simple Notification Service or Auto Scaling notifications when a metric has crossed a threshold. For more information, see Alarms.	December 2, 2010
New feature	A number of CloudWatch actions now include the MaxRecords and NextToken parameters, which enable you to control pages of results to display.	December 2, 2010

Change	Description	Release date
New feature	This service now integrates with AWS Identity and Access Management (IAM).	December 2, 2010
