For more information about best practices in IAM, see Security best practices in IAM in the *IAM User Guide*.

Using the DynamoDB console

To access the Amazon DynamoDB console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the DynamoDB resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for entities (users or roles) with that policy.

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that they're trying to perform.

To ensure that users and roles can still use the DynamoDB console, also attach the DynamoDB `ConsoleAccess` or `ReadOnly` AWS managed policy to the entities. For more information, see Adding permissions to a user in the *IAM User Guide*.

Allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ViewOwnUserInfo",
            "Effect": "Allow",
            "Action": [
                "iam:GetUserPolicy",
                "iam:ListGroupsForUser",
                "iam:ListAttachedUserPolicies",
                "iam:ListUserPolicies",
                "iam:GetUser"
            ],
            "Resource": ["arn:aws:iam::*:user/${aws:username}"]
        },
        {
            "Sid": "NavigateInConsole",
            "Effect": "Allow",
            "Action": [
                "iam:GetGroupPolicy",
                "iam:GetPolicyVersion",
                "iam:GetPolicy",
                "iam:ListAttachedGroupPolicies",
                "iam:ListGroupPolicies",
                "iam:ListPolicyVersions",
                "iam:ListPolicies",
                "iam:ListUsers"
            ],
            "Resource": "*"
```

```
        }
    ]
}
```

Using identity-based policies with Amazon DynamoDB

This topic covers using identity-based AWS Identity and Access Management (IAM) policies with Amazon DynamoDB and provides examples. The examples show how an account administrator can attach permissions policies to IAM identities (users, groups, and roles) and thereby grant permissions to perform operations on Amazon DynamoDB resources.

The sections in this topic cover the following:

- IAM permissions required to use the Amazon DynamoDB console
- AWS managed (predefined) IAM policies for Amazon DynamoDB
- Customer managed policy examples

The following is an example of a permissions policy.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DescribeQueryScanBooksTable",
            "Effect": "Allow",
            "Action": [
                "dynamodb:DescribeTable",
                "dynamodb:Query",
                "dynamodb:Scan"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:account-id:table/Books"
        }
    ]
}
```

The preceding policy has one statement that grants permissions for three DynamoDB actions (`dynamodb:DescribeTable`, `dynamodb:Query`, and `dynamodb:Scan`) on a table in the `us-west-2` AWS Region, which is owned by the AWS account specified by *`account-id`*. The *Amazon Resource Name (ARN)* in the `Resource` value specifies the table that the permissions apply to.

IAM permissions required to use the Amazon DynamoDB console

To work with the DynamoDB console, a user must have a minimum set of permissions that allow the user to work with their AWS account's DynamoDB resources. In addition to these DynamoDB permissions, the console requires permissions:

- Amazon CloudWatch permissions to display metrics and graphs.
- AWS Data Pipeline permissions to export and import DynamoDB data.
- AWS Identity and Access Management permissions to access roles necessary for exports and imports.
- Amazon Simple Notification Service permissions to notify you whenever a CloudWatch alarm is triggered.
- AWS Lambda permissions to process DynamoDB Streams records.

If you create an IAM policy that is more restrictive than the minimum required permissions, the console won't function as intended for users with that IAM policy. To ensure that those users can still use the DynamoDB console, also attach the `AmazonDynamoDBReadOnlyAccess` AWS managed policy to the user, as described in AWS managed (predefined) IAM policies for Amazon DynamoDB.

You don't need to allow minimum console permissions for users who are making calls only to the AWS CLI or the Amazon DynamoDB API.

> **Note**
>
> If you refer to a VPC endpoint, you will also need to authorize the DescribeEndpoints API call for the requesting IAM principal(s) with the IAM action (dynamodb:DescribeEndpoints). For more information see Required policy for endpoints.

AWS managed (predefined) IAM policies for Amazon DynamoDB

AWS addresses some common use cases by providing standalone IAM policies that are created and administered by AWS. These AWS managed policies grant necessary permissions for common use cases so that you can avoid having to investigate which permissions are needed. For more information, see AWS Managed Policies in the *IAM User Guide*.

The following AWS managed policies, which you can attach to users in your account, are specific to DynamoDB and are grouped by use-case scenario:

- **AmazonDynamoDBReadOnlyAccess** – Grants read-only access to DynamoDB resources through the AWS Management Console.
- **AmazonDynamoDBFullAccess** – Grants full access to DynamoDB resources through the AWS Management Console.

You can review these AWS managed permissions policies by signing in to the IAM console and searching for specific policies there.

> **Important**
>
> The best practice is to create custom IAM policies that grant least-privilege to the users, roles, or groups that require them.

Customer managed policy examples

In this section, you can find policy examples that grant permissions for various DynamoDB actions. These policies work when you use AWS SDKs or the AWS CLI. When you use the console, you need to grant additional permissions that are specific to the console. For more information, see IAM permissions required to use the Amazon DynamoDB console.

> **Note**
>
> All of the following policy examples use one of the AWS Regions and contain fictitious account IDs and table names.

Examples:

- IAM policy to grant permissions to all DynamoDB actions on a table
- IAM policy to grant read-only permissions on items in a DynamoDB table
- IAM policy to grant access to a specific DynamoDB table and its indexes
- IAM policy to read, write, update, and delete access on a DynamoDB table
- IAM policy to separate DynamoDB environments in the same AWS account

- IAM policy to prevent the purchase of DynamoDB reserved capacity
- IAM policy to grant read access for a DynamoDB stream only (not for the table)
- IAM policy to allow an AWS Lambda function to access DynamoDB stream records
- IAM policy for read and write access to a DynamoDB Accelerator (DAX) cluster

The *IAM User Guide*, includes three additional DynamoDB examples:

- Amazon DynamoDB: Allows Access to a Specific Table
- Amazon DynamoDB: Allows Access to Specific Columns
- Amazon DynamoDB: Allows Row-Level Access to DynamoDB Based on an Amazon Cognito ID

IAM policy to grant permissions to all DynamoDB actions on a table

The following policy grants permissions for *all* DynamoDB actions on a table called `Books`. The resource ARN specified in the `Resource` identifies a table in a specific AWS Region. If you replace the table name `Books` in the `Resource` ARN with a wildcard character (*), *all* DynamoDB actions are allowed on *all* tables in the account. Carefully consider the possible security implications before using a wildcard character on this or any IAM policy.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllAPIActionsOnBooks",
            "Effect": "Allow",
            "Action": "dynamodb:*",
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"
        }
    ]
}
```

> **Note**
>
> This is an example of using a wildcard character (*) to allow *all* actions, including administration, data operations, monitoring, and purchase of DynamoDB reserved capacity. Instead, it is a best practice to explicitly specify each action to be granted and only what that user, role, or group needs.

IAM policy to grant read-only permissions on items in a DynamoDB table

The following permissions policy grants permissions for the `GetItem`, `BatchGetItem`, `Scan`, `Query`, and `ConditionCheckItem` DynamoDB actions only, and as a result, sets read-only access on the `Books` table.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ReadOnlyAPIActionsOnBooks",
            "Effect": "Allow",
            "Action": [
                "dynamodb:GetItem",
                "dynamodb:BatchGetItem",
                "dynamodb:Scan",
                "dynamodb:Query",
                "dynamodb:ConditionCheckItem"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"
        }
    ]
}
```

IAM policy to grant access to a specific DynamoDB table and its indexes

The following policy grants permissions for data modification actions on a DynamoDB table called `Books` and all of that table's indexes. For more information about how indexes work, see Improving data access with secondary indexes in DynamoDB.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AccessTableAllIndexesOnBooks",
            "Effect": "Allow",
            "Action": [
              "dynamodb:PutItem",
              "dynamodb:UpdateItem",
              "dynamodb:DeleteItem",
              "dynamodb:BatchWriteItem",
              "dynamodb:GetItem",
              "dynamodb:BatchGetItem",
```

```
                "dynamodb:Scan",
                "dynamodb:Query",
                "dynamodb:ConditionCheckItem"
            ],
            "Resource": [
                "arn:aws:dynamodb:us-west-2:123456789012:table/Books",
                "arn:aws:dynamodb:us-west-2:123456789012:table/Books/index/*"
            ]
        }
    ]
}
```

IAM policy to read, write, update, and delete access on a DynamoDB table

Use this policy if you need to allow your application to create, read, update, and delete data in Amazon DynamoDB tables, indexes, and streams. Substitute the AWS Region name, your account ID, and the table name or wildcard character (*) where appropriate.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DynamoDBIndexAndStreamAccess",
            "Effect": "Allow",
            "Action": [
                "dynamodb:GetShardIterator",
                "dynamodb:Scan",
                "dynamodb:Query",
                "dynamodb:DescribeStream",
                "dynamodb:GetRecords",
                "dynamodb:ListStreams"
            ],
            "Resource": [
                "arn:aws:dynamodb:us-west-2:123456789012:table/Books/index/*",
                "arn:aws:dynamodb:us-west-2:123456789012:table/Books/stream/*"
            ]
        },
        {
            "Sid": "DynamoDBTableAccess",
            "Effect": "Allow",
            "Action": [
                "dynamodb:BatchGetItem",
                "dynamodb:BatchWriteItem",
```

```
                "dynamodb:ConditionCheckItem",
                "dynamodb:PutItem",
                "dynamodb:DescribeTable",
                "dynamodb:DeleteItem",
                "dynamodb:GetItem",
                "dynamodb:Scan",
                "dynamodb:Query",
                "dynamodb:UpdateItem"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"
        },
        {
            "Sid": "DynamoDBDescribeLimitsAccess",
            "Effect": "Allow",
            "Action": "dynamodb:DescribeLimits",
            "Resource": [
                "arn:aws:dynamodb:us-west-2:123456789012:table/Books",
                "arn:aws:dynamodb:us-west-2:123456789012:table/Books/index/*"
            ]
        }
    ]
}
```

To expand this policy to cover all DynamoDB tables in all AWS Regions for this account, use a wildcard (*) for the Region and table name. For example:

```
"Resource":[
                "arn:aws:dynamodb:*:123456789012:table/*",
                "arn:aws:dynamodb:*:123456789012:table/*/index/*"
                ]
```

IAM policy to separate DynamoDB environments in the same AWS account

Suppose that you have separate environments where each environment maintains its own version of a table named `ProductCatalog`. If you create two `ProductCatalog` tables in the same AWS account, work in one environment might affect the other environment because of the way that permissions are set up. For example, quotas on the number of concurrent control plane operations (such as `CreateTable`) are set at the AWS account level.

As a result, each action in one environment reduces the number of operations available in the other environment. There is also a risk that the code in one environment might accidentally access tables in the other environment.

> **Note**
>
> If you want to separate production and test workloads to help control an event's potential "blast radius," the best practice is to create separate AWS accounts for test and production workloads. For more information, see AWS Account Management and Separation.

Suppose further that you have two developers, Amit and Alice, who are testing the `ProductCatalog` table. Instead of each developer requiring a separate AWS account, your developers can share the same test AWS account. In this test account, you can create a copy of the same table for each developer to work on, such as `Alice_ProductCatalog` and `Amit_ProductCatalog`. In this case, you can create users Alice and Amit in the AWS account that you created for the test environment. You then can grant permissions to these users to perform DynamoDB actions on the tables that they own.

To grant these IAM user permissions, you can do either of the following:

- Create a separate policy for each user, and then attach each policy to its user separately. For example, you can attach the following policy to user Alice to allow her access to DynamoDB actions on the `Alice_ProductCatalog` table:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllAPIActionsOnAliceTable",
            "Effect": "Allow",
            "Action": [
              "dynamodb:DeleteItem",
              "dynamodb:DescribeContributorInsights",
              "dynamodb:RestoreTableToPointInTime",
              "dynamodb:ListTagsOfResource",
              "dynamodb:CreateTableReplica",
              "dynamodb:UpdateContributorInsights",
              "dynamodb:CreateBackup",
              "dynamodb:DeleteTable",
              "dynamodb:UpdateTableReplicaAutoScaling",
              "dynamodb:UpdateContinuousBackups",
              "dynamodb:TagResource",
              "dynamodb:DescribeTable",
              "dynamodb:GetItem",
```

```
                "dynamodb:DescribeContinuousBackups",
                "dynamodb:BatchGetItem",
                "dynamodb:UpdateTimeToLive",
                "dynamodb:BatchWriteItem",
                "dynamodb:ConditionCheckItem",
                "dynamodb:UntagResource",
                "dynamodb:PutItem",
                "dynamodb:Scan",
                "dynamodb:Query",
                "dynamodb:UpdateItem",
                "dynamodb:DeleteTableReplica",
                "dynamodb:DescribeTimeToLive",
                "dynamodb:RestoreTableFromBackup",
                "dynamodb:UpdateTable",
                "dynamodb:DescribeTableReplicaAutoScaling",
                "dynamodb:GetShardIterator",
                "dynamodb:DescribeStream",
                "dynamodb:GetRecords",
                "dynamodb:DescribeLimits",
                "dynamodb:ListStreams"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/
Alice_ProductCatalog/*"
        }
    ]
}
```

Then, you can create a similar policy with a different resource (the `Amit_ProductCatalog` table) for user Amit.

- Instead of attaching policies to individual users, you can use IAM policy variables to write a single policy and attach it to a group. You need to create a group and, for this example, add both users Alice and Amit to the group. The following example grants permissions to perform all DynamoDB actions on the `${aws:username}_ProductCatalog` table. The policy variable `${aws:username}` is replaced by the requester's user name when the policy is evaluated. For example, if Alice sends a request to add an item, the action is allowed only if Alice is adding items to the `Alice_ProductCatalog` table.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
```

```
            "Sid": "ActionsOnUserSpecificTable",
            "Effect": "Allow",
            "Action": [
              "dynamodb:PutItem",
              "dynamodb:UpdateItem",
              "dynamodb:DeleteItem",
              "dynamodb:BatchWriteItem",
              "dynamodb:GetItem",
              "dynamodb:BatchGetItem",
              "dynamodb:Scan",
              "dynamodb:Query",
              "dynamodb:ConditionCheckItem"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/
${aws:username}_ProductCatalog"
        },
        {
            "Sid": "AdditionalPrivileges",
            "Effect": "Allow",
            "Action": [
                "dynamodb:ListTables",
                "dynamodb:DescribeTable",
                "dynamodb:DescribeContributorInsights"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/*"
        }
    ]
}
```

Note

When using IAM policy variables, you must explicitly specify the `2012-10-17` version of the IAM policy language in the policy. The default version of the IAM policy language (`2008-10-17`) does not support policy variables.

Instead of identifying a specific table as a resource as you normally would, you could use a wildcard character (*) to grant permissions on all tables where the table name is prefixed with the user that is making the request, as shown in the following example.

```
"Resource":"arn:aws:dynamodb:us-west-2:123456789012:table/${aws:username}_*"
```

IAM policy to prevent the purchase of DynamoDB reserved capacity

With Amazon DynamoDB reserved capacity, you pay a one-time, upfront fee and commit to paying for a minimum usage level at significant savings over a period of time. You can use the AWS Management Console to view and purchase reserved capacity. However, you might not want all of the users in your organization to be able to purchase reserved capacity. For more information about reserved capacity, see Amazon DynamoDB pricing.

DynamoDB provides the following API operations for controlling access to reserved capacity management:

- `dynamodb:DescribeReservedCapacity` – Returns the reserved capacity purchases that are currently in effect.
- `dynamodb:DescribeReservedCapacityOfferings` – Returns details about the reserved capacity plans that are currently offered by AWS.
- `dynamodb:PurchaseReservedCapacityOfferings` – Performs an actual purchase of reserved capacity.

The AWS Management Console uses these API actions to display reserved capacity information and make purchases. You cannot call these operations from an application program because they can be accessed only from the console. However, you can allow or deny access to these operations in an IAM permissions policy.

The following policy allows users to view reserved capacity purchases and offerings by using the AWS Management Console — but new purchases are denied.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowReservedCapacityDescriptions",
            "Effect": "Allow",
            "Action": [
                "dynamodb:DescribeReservedCapacity",
                "dynamodb:DescribeReservedCapacityOfferings"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:*"
```

```
        },
        {
            "Sid": "DenyReservedCapacityPurchases",
            "Effect": "Deny",
            "Action": "dynamodb:PurchaseReservedCapacityOfferings",
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:*"
        }
    ]
}
```

Note that this policy uses the wildcard character (*) to allow describe permissions for all, and to deny the purchase of DynamoDB reserved capacity for all.

IAM policy to grant read access for a DynamoDB stream only (not for the table)

When you enable DynamoDB Streams on a table, information is captured about every modification to items in the table. For more information, see Change data capture for DynamoDB Streams.

In some cases, you might want to prevent an application from reading data from a DynamoDB table, but still allow access to that table's streams. For example, you can configure AWS Lambda to poll a stream and invoke a Lambda function when item updates are detected, and then perform additional processing.

The following actions are available for controlling access to DynamoDB streams:

- `dynamodb:DescribeStream`
- `dynamodb:GetRecords`
- `dynamodb:GetShardIterator`
- `dynamodb:ListStreams`

The following example policy grants users permissions to access the streams of a table named `GameScores`. The wildcard character (*) in the ARN matches any stream associated with that table.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AccessGameScoresStreamOnly",
            "Effect": "Allow",
            "Action": [
```

```
                "dynamodb:DescribeStream",
                "dynamodb:GetRecords",
                "dynamodb:GetShardIterator",
                "dynamodb:ListStreams"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores/
stream/*"
        }
    ]
}
```

Note that this policy grants access to the `GameScores` table's streams, but not to the table itself.

IAM policy to allow an AWS Lambda function to access DynamoDB stream records

If you want certain actions to be performed based on events in a DynamoDB stream, you can write an AWS Lambda function that is triggered by these events. A Lambda function such as this needs permissions to read data from a DynamoDB stream. For more information about using Lambda with DynamoDB Streams, see DynamoDB Streams and AWS Lambda triggers.

To grant permissions to Lambda, use the permissions policy that is associated with the Lambda function's IAM role (also known as an execution role). Specify this policy when you create the Lambda function.

For example, you can associate the following permissions policy with an execution role to grant Lambda permissions to perform the DynamoDB Streams actions listed.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "APIAccessForDynamoDBStreams",
            "Effect": "Allow",
            "Action": [
                "dynamodb:GetRecords",
                "dynamodb:GetShardIterator",
                "dynamodb:DescribeStream",
                "dynamodb:ListStreams"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores/
stream/*"
        }
    ]
```

```
}
```

For more information, see AWS Lambda permissions in the *AWS Lambda Developer Guide*.

IAM policy for read and write access to a DynamoDB Accelerator (DAX) cluster

The following policy allows read, write, update, and delete access to a DynamoDB Accelerator (DAX) cluster, but not to the associated DynamoDB table. To use this policy, substitute the AWS Region name, your account ID, and the name of your DAX cluster.

> **Note**
>
> This policy gives access to DAX cluster, but not to the associated DynamoDB table. Make sure that your DAX cluster has the correct policy to perform these same operations on the DynamoDB table on your behalf.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AmazonDynamoDBDAXDataOperations",
            "Effect": "Allow",
            "Action": [
                "dax:GetItem",
                "dax:PutItem",
                "dax:ConditionCheckItem",
                "dax:BatchGetItem",
                "dax:BatchWriteItem",
                "dax:DeleteItem",
                "dax:Query",
                "dax:UpdateItem",
                "dax:Scan"
            ],
            "Resource": "arn:aws:dax:eu-west-1:123456789012:cache/MyDAXCluster"
        }
    ]
}
```

To expand this policy to cover DAX access for all AWS Regions for an account, use a wildcard character (*) for the Region name.

```
"Resource": "arn:aws:dax:*:123456789012:cache/MyDAXCluster"
```

Troubleshooting Amazon DynamoDB identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with DynamoDB and IAM.

Topics

- I am not authorized to perform an action in DynamoDB
- I am not authorized to perform iam:PassRole
- I want to allow people outside of my AWS account to access my DynamoDB resources

I am not authorized to perform an action in DynamoDB

If the AWS Management Console tells you that you're not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your user name and password.

The following example error occurs when the `mateojackson` user tries to use the console to view details about a fictional *`my-example-widget`* resource but does not have the fictional `aws:`*`GetWidget`* permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:
 aws:GetWidget on resource: my-example-widget
```

In this case, Mateo asks his administrator to update his policies to allow him to access the *`my-example-widget`* resource using the `aws:`*`GetWidget`* action.

I am not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, your policies must be updated to allow you to pass a role to DynamoDB.

Some AWS services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named `marymajor` tries to use the console to perform an action in DynamoDB. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform:
 iam:PassRole
```

In this case, Mary's policies must be updated to allow her to perform the `iam:PassRole` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I want to allow people outside of my AWS account to access my DynamoDB resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether DynamoDB supports these features, see How Amazon DynamoDB works with IAM.
- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the *IAM User Guide*.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see Cross account resource access in IAM in the *IAM User Guide*.

IAM policy to prevent the purchase of DynamoDB reserved capacity

With Amazon DynamoDB reserved capacity, you pay a one-time, upfront fee and commit to paying for a minimum usage level at significant savings over a period of time. You can use the AWS Management Console to view and purchase reserved capacity. However, you might not want all

of the users in your organization to be able to purchase reserved capacity. For more information about reserved capacity, see Amazon DynamoDB pricing.

DynamoDB provides the following API operations for controlling access to reserved capacity management:

- `dynamodb:DescribeReservedCapacity` – Returns the reserved capacity purchases that are currently in effect.
- `dynamodb:DescribeReservedCapacityOfferings` – Returns details about the reserved capacity plans that are currently offered by AWS.
- `dynamodb:PurchaseReservedCapacityOfferings` – Performs an actual purchase of reserved capacity.

The AWS Management Console uses these API actions to display reserved capacity information and make purchases. You cannot call these operations from an application program because they can be accessed only from the console. However, you can allow or deny access to these operations in an IAM permissions policy.

The following policy allows users to view reserved capacity purchases and offerings by using the AWS Management Console — but new purchases are denied.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowReservedCapacityDescriptions",
            "Effect": "Allow",
            "Action": [
                "dynamodb:DescribeReservedCapacity",
                "dynamodb:DescribeReservedCapacityOfferings"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:*"
        },
        {
            "Sid": "DenyReservedCapacityPurchases",
            "Effect": "Deny",
            "Action": "dynamodb:PurchaseReservedCapacityOfferings",
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:*"
        }
    ]
```

```
}
```

Note that this policy uses the wildcard character (*) to allow describe permissions for all, and to deny the purchase of DynamoDB reserved capacity for all.

Using IAM policy conditions for fine-grained access control

When you grant permissions in DynamoDB, you can specify conditions that determine how a permissions policy takes effect.

Overview

In DynamoDB, you have the option to specify conditions when granting permissions using an IAM policy (see Identity and Access Management for Amazon DynamoDB). For example, you can:

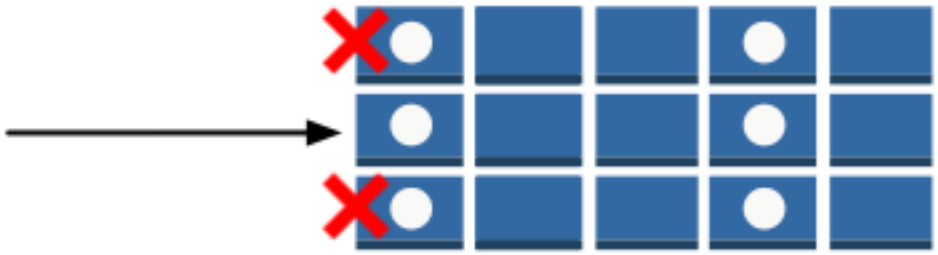
- Grant permissions to allow users read-only access to certain items and attributes in a table or a secondary index.
- Grant permissions to allow users write-only access to certain attributes in a table, based upon the identity of that user.

In DynamoDB, you can specify conditions in an IAM policy using condition keys, as illustrated in the use case in the following section.

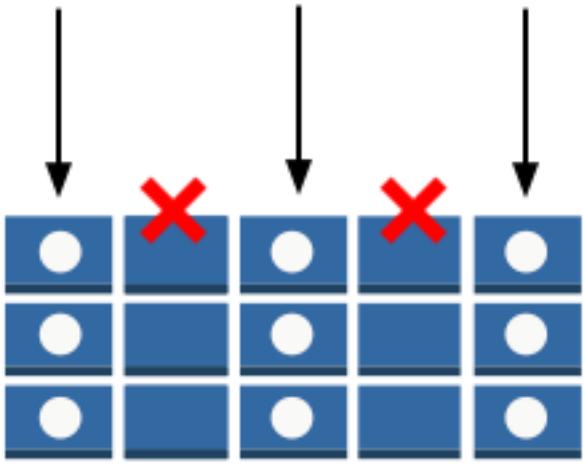
Permissions use case

In addition to controlling access to DynamoDB API actions, you can also control access to individual data items and attributes. For example, you can do the following:

- Grant permissions on a table, but restrict access to specific items in that table based on certain primary key values. An example might be a social networking app for games, where all users' saved game data is stored in a single table, but no users can access data items that they do not own, as shown in the following illustration:



- Hide information so that only a subset of attributes is visible to the user. An example might be an app that displays flight data for nearby airports, based on the user's location. Airline names, arrival and departure times, and flight numbers are all displayed. However, attributes such as pilot names or the number of passengers are hidden, as shown in the following illustration:



To implement this kind of fine-grained access control, you write an IAM permissions policy that specifies conditions for accessing security credentials and the associated permissions. You then apply the policy to users, groups, or roles that you create using the IAM console. Your IAM policy can restrict access to individual items in a table, access to the attributes in those items, or both at the same time.

You can optionally use web identity federation to control access by users who are authenticated by Login with Amazon, Facebook, or Google. For more information, see Using web identity federation.

You use the IAM `Condition` element to implement a fine-grained access control policy. By adding a `Condition` element to a permissions policy, you can allow or deny access to items and attributes in DynamoDB tables and indexes, based upon your particular business requirements.

As an example, consider a mobile gaming app that lets players select from and play a variety of different games. The app uses a DynamoDB table named `GameScores` to keep track of high scores and other user data. Each item in the table is uniquely identified by a user ID and the name of the game that the user played. The `GameScores` table has a primary key consisting of a partition key (`UserId`) and sort key (`GameTitle`). Users only have access to game data associated with their user ID. A user who wants to play a game must belong to an IAM role named `GameRole`, which has a security policy attached to it.

To manage user permissions in this app, you could write a permissions policy such as the following:

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowAccessToOnlyItemsMatchingUserID",
         "Effect":"Allow",
         "Action":[
            "dynamodb:GetItem",
            "dynamodb:BatchGetItem",
            "dynamodb:Query",
            "dynamodb:PutItem",
            "dynamodb:UpdateItem",
            "dynamodb:DeleteItem",
            "dynamodb:BatchWriteItem"
         ],
         "Resource":[
            "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores"
         ],
         "Condition":{
            "ForAllValues:StringEquals":{
               "dynamodb:LeadingKeys":[
                  "${www.amazon.com:user_id}"
               ],
               "dynamodb:Attributes":[
                  "UserId",
                  "GameTitle",
                  "Wins",
                  "Losses",
```

```
                "TopScore",
                "TopScoreDateTime"
            ]
         },
         "StringEqualsIfExists":{
            "dynamodb:Select":"SPECIFIC_ATTRIBUTES"
         }
      }
   }
]
}
```

In addition to granting permissions for specific DynamoDB actions (`Action` element) on the `GameScores` table (`Resource` element), the `Condition` element uses the following condition keys specific to DynamoDB that limit the permissions as follows:

- `dynamodb:LeadingKeys` – This condition key allows users to access only the items where the partition key value matches their user ID. This ID, `${www.amazon.com:user_id}`, is a substitution variable. For more information about substitution variables, see Using web identity federation.
- `dynamodb:Attributes` – This condition key limits access to the specified attributes so that only the actions listed in the permissions policy can return values for these attributes. In addition, the `StringEqualsIfExists` clause ensures that the app must always provide a list of specific attributes to act upon and that the app can't request all attributes.

When an IAM policy is evaluated, the result is always either true (access is allowed) or false (access is denied). If any part of the `Condition` element is false, the entire policy evaluates to false and access is denied.

> **Important**
>
> If you use `dynamodb:Attributes`, you must specify the names of all of the primary key and index key attributes for the table and any secondary indexes that are listed in the policy. Otherwise, DynamoDB can't use these key attributes to perform the requested action.

IAM policy documents can contain only the following Unicode characters: horizontal tab (U+0009), linefeed (U+000A), carriage return (U+000D), and characters in the range U+0020 to U+00FF.

Specifying conditions: Using condition keys

AWS provides a set of predefined condition keys (AWS-wide condition keys) for all AWS services that support IAM for access control. For example, you can use the `aws:SourceIp` condition key to check the requester's IP address before allowing an action to be performed. For more information and a list of the AWS-wide keys, see Available Keys for Conditions in the IAM User Guide.

The following table shows the DynamoDB service-specific condition keys that apply to DynamoDB.

DynamoDB Condition Key	Description
`dynamodb:LeadingKeys`	Represents the first key attribute of a table—in other words, the partition key. The key name `LeadingKeys` is plural, even if the key is used with single-item actions. In addition, you must use the `ForAllValues` modifier when using `LeadingKeys` in a condition.
`dynamodb:Select`	Represents the `Select` parameter of a `Query` or `Scan` request. `Select` can be any of the following values: • `ALL_ATTRIBUTES` • `ALL_PROJECTED_ATTRIBUTES` • `SPECIFIC_ATTRIBUTES` • `COUNT`
`dynamodb:Attributes`	Represents a list of the attribute names in a request, or the attributes that are returned from a request. `Attributes` values are named the same way and have the same meaning as the parameters for certain DynamoDB API actions, as shown following: • `AttributesToGet` Used by: `BatchGetItem, GetItem, Query, Scan` • `AttributeUpdates` Used by: `UpdateItem` • `Expected`

DynamoDB Condition Key	Description
	Used by: `DeleteItem, PutItem, UpdateItem` • `Item` Used by: `PutItem` • `ScanFilter` Used by: `Scan`
`dynamodb:ReturnValues`	Represents the `ReturnValues` parameter of a request. `ReturnValues` can be any of the following values: • `ALL_OLD` • `UPDATED_OLD` • `ALL_NEW` • `UPDATED_NEW` • `NONE`
`dynamodb:ReturnConsumedCapacity`	Represents the `ReturnConsumedCapacity` parameter of a request. `ReturnConsumedCapacity` can be one of the following values: • `TOTAL` • `NONE`

Limiting user access

Many IAM permissions policies allow users to access only those items in a table where the partition key value matches the user identifier. For example, the game app preceding limits access in this way so that users can only access game data that is associated with their user ID. The IAM substitution variables `${www.amazon.com:user_id}`, `${graph.facebook.com:id}`, and `${accounts.google.com:sub}` contain user identifiers for Login with Amazon, Facebook, and Google. To learn how an application logs in to one of these identity providers and obtains these identifiers, see Using web identity federation.

Important

Fine-grained access control isn't supported for restricting global tables replication. Applying policy conditions for fine-grained access control to DynamoDB service principals or service-linked roles used for global tables replication may interrupt replication within a global table.

Note

Each of the examples in the following section sets the `Effect` clause to `Allow` and specifies only the actions, resources, and parameters that are allowed. Access is permitted only to what is explicitly listed in the IAM policy.
In some cases, it is possible to rewrite these policies so that they are deny-based (that is, setting the `Effect` clause to `Deny` and inverting all of the logic in the policy). However, we recommend that you avoid using deny-based policies with DynamoDB because they're difficult to write correctly, compared to allow-based policies. In addition, future changes to the DynamoDB API (or changes to existing API inputs) can render a deny-based policy ineffective.

Example policies: Using conditions for fine-grained access control

This section shows several policies for implementing fine-grained access control on DynamoDB tables and indexes.

Note

All examples use the us-west-2 Region and contain fictitious account IDs.

The video below explains fine-grained access control in DynamoDB using IAM policy conditions.

1: Grant permissions that limit access to items with a specific partition key value

The following permissions policy grants permissions that allow a set of DynamoDB actions on the `GamesScore` table. It uses the `dynamodb:LeadingKeys` condition key to limit user actions only on the items whose `UserID` partition key value matches the Login with Amazon unique user ID for this app.

Important

The list of actions does not include permissions for `Scan` because `Scan` returns all items regardless of the leading keys.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"FullAccessToUserItems",
         "Effect":"Allow",
         "Action":[
            "dynamodb:GetItem",
            "dynamodb:BatchGetItem",
            "dynamodb:Query",
            "dynamodb:PutItem",
            "dynamodb:UpdateItem",
            "dynamodb:DeleteItem",
            "dynamodb:BatchWriteItem"
         ],
         "Resource":[
            "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores"
         ],
         "Condition":{
            "ForAllValues:StringEquals":{
               "dynamodb:LeadingKeys":[
                  "${www.amazon.com:user_id}"
               ]
            }
         }
      }
   ]
}
```

Note

When using policy variables, you must explicitly specify version `2012-10-17` in the policy. The default version of the access policy language, `2008-10-17`, does not support policy variables.

To implement read-only access, you can remove any actions that can modify the data. In the following policy, only those actions that provide read-only access are included in the condition.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"ReadOnlyAccessToUserItems",
         "Effect":"Allow",
         "Action":[
            "dynamodb:GetItem",
            "dynamodb:BatchGetItem",
            "dynamodb:Query"
         ],
         "Resource":[
            "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores"
         ],
         "Condition":{
            "ForAllValues:StringEquals":{
               "dynamodb:LeadingKeys":[
                  "${www.amazon.com:user_id}"
               ]
            }
         }
      }
   ]
}
```

Important

If you use `dynamodb:Attributes`, you must specify the names of all of the primary key and index key attributes, for the table and any secondary indexes that are listed in the policy. Otherwise, DynamoDB can't use these key attributes to perform the requested action.

2: Grant permissions that limit access to specific attributes in a table

The following permissions policy allows access to only two specific attributes in a table by adding the `dynamodb:Attributes` condition key. These attributes can be read, written, or evaluated in a conditional write or scan filter.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"LimitAccessToSpecificAttributes",
         "Effect":"Allow",
         "Action":[
            "dynamodb:UpdateItem",
            "dynamodb:GetItem",
            "dynamodb:Query",
            "dynamodb:BatchGetItem",
            "dynamodb:Scan"
         ],
         "Resource":[
            "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores"
         ],
         "Condition":{
            "ForAllValues:StringEquals":{
               "dynamodb:Attributes":[
                  "UserId",
                  "TopScore"
               ]
            },
            "StringEqualsIfExists":{
               "dynamodb:Select":"SPECIFIC_ATTRIBUTES",
               "dynamodb:ReturnValues":[
                  "NONE",
                  "UPDATED_OLD",
                  "UPDATED_NEW"
               ]
            }
         }
      }
   ]
}
```

Note

The policy takes an *allow list* approach, which allows access to a named set of attributes. You can write an equivalent policy that denies access to other attributes instead. We don't recommend this *deny list* approach. Users can determine the names of these denied attributes by follow the *principle of least privilege*, as explained in Wikipedia at http://

en.wikipedia.org/wiki/Principle_of_least_privilege, and use an *allow list* approach to enumerate all of the allowed values, rather than specifying the denied attributes.

This policy doesn't permit `PutItem`, `DeleteItem`, or `BatchWriteItem`. These actions always replace the entire previous item, which would allow users to delete the previous values for attributes that they are not allowed to access.

The `StringEqualsIfExists` clause in the permissions policy ensures the following:

- If the user specifies the `Select` parameter, then its value must be `SPECIFIC_ATTRIBUTES`. This requirement prevents the API action from returning any attributes that aren't allowed, such as from an index projection.
- If the user specifies the `ReturnValues` parameter, then its value must be `NONE`, `UPDATED_OLD`, or `UPDATED_NEW`. This is required because the `UpdateItem` action also performs implicit read operations to check whether an item exists before replacing it, and so that previous attribute values can be returned if requested. Restricting `ReturnValues` in this way ensures that users can only read or write the allowed attributes.
- The `StringEqualsIfExists` clause assures that only one of these parameters — `Select` or `ReturnValues` — can be used per request, in the context of the allowed actions.

The following are some variations on this policy:

- To allow only read actions, you can remove `UpdateItem` from the list of allowed actions. Because none of the remaining actions accept `ReturnValues`, you can remove `ReturnValues` from the condition. You can also change `StringEqualsIfExists` to `StringEquals` because the `Select` parameter always has a value (`ALL_ATTRIBUTES`, unless otherwise specified).
- To allow only write actions, you can remove everything except `UpdateItem` from the list of allowed actions. Because `UpdateItem` does not use the `Select` parameter, you can remove `Select` from the condition. You must also change `StringEqualsIfExists` to `StringEquals` because the `ReturnValues` parameter always has a value (`NONE` unless otherwise specified).
- To allow all attributes whose name matches a pattern, use `StringLike` instead of `StringEquals`, and use a multi-character pattern match wildcard character (*).

3: Grant permissions to prevent updates on certain attributes

The following permissions policy limits user access to updating only the specific attributes identified by the dynamodb:Attributes condition key. The StringNotLike condition prevents an application from updating the attributes specified using the dynamodb:Attributes condition key.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"PreventUpdatesOnCertainAttributes",
         "Effect":"Allow",
         "Action":[
            "dynamodb:UpdateItem"
         ],
         "Resource":"arn:aws:dynamodb:us-west-2:123456789012:table/GameScores",
         "Condition":{
            "ForAllValues:StringNotLike":{
               "dynamodb:Attributes":[
                  "FreeGamesAvailable",
                  "BossLevelUnlocked"
               ]
            },
            "StringEquals":{
               "dynamodb:ReturnValues":[
                  "NONE",
                  "UPDATED_OLD",
                  "UPDATED_NEW"
               ]
            }
         }
      }
   ]
}
```

Note the following:

- The UpdateItem action, like other write actions, requires read access to the items so that it can return values before and after the update. In the policy, you limit the action to accessing only the attributes that are allowed to be updated by specifying the dynamodb:ReturnValues

condition key. The condition key restricts `ReturnValues` in the request to specify only `NONE`, `UPDATED_OLD`, or `UPDATED_NEW` and doesn't include `ALL_OLD` or `ALL_NEW`.

- The `PutItem` and `DeleteItem` actions replace an entire item, and thus allows applications to modify any attributes. So when limiting an application to updating only specific attributes, you should not grant permission for these APIs.

4: Grant permissions to query only projected attributes in an index

The following permissions policy allows queries on a secondary index (`TopScoreDateTimeIndex`) by using the `dynamodb:Attributes` condition key. The policy also limits queries to requesting only specific attributes that have been projected into the index.

To require the application to specify a list of attributes in the query, the policy also specifies the `dynamodb:Select` condition key to require that the `Select` parameter of the DynamoDB `Query` action is `SPECIFIC_ATTRIBUTES`. The list of attributes is limited to a specific list that is provided using the `dynamodb:Attributes` condition key.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"QueryOnlyProjectedIndexAttributes",
         "Effect":"Allow",
         "Action":[
            "dynamodb:Query"
         ],
         "Resource":[
            "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores/index/
TopScoreDateTimeIndex"
         ],
         "Condition":{
            "ForAllValues:StringEquals":{
               "dynamodb:Attributes":[
                  "TopScoreDateTime",
                  "GameTitle",
                  "Wins",
                  "Losses",
                  "Attempts"
               ]
            },
            "StringEquals":{
```

```
               "dynamodb:Select":"SPECIFIC_ATTRIBUTES"
            }
         }
      }
   ]
}
```

The following permissions policy is similar, but the query must request all of the attributes that have been projected into the index.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"QueryAllIndexAttributes",
         "Effect":"Allow",
         "Action":[
            "dynamodb:Query"
         ],
         "Resource":[
            "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores/index/
TopScoreDateTimeIndex"
         ],
         "Condition":{
            "StringEquals":{
               "dynamodb:Select":"ALL_PROJECTED_ATTRIBUTES"
            }
         }
      }
   ]
}
```

5: Grant permissions to limit access to certain attributes and partition key values

The following permissions policy allows specific DynamoDB actions (specified in the `Action` element) on a table and a table index (specified in the `Resource` element). The policy uses the `dynamodb:LeadingKeys` condition key to restrict permissions to only the items whose partition key value matches the user's Facebook ID.

```
{
   "Version":"2012-10-17",
   "Statement":[
```

```
      {
         "Sid":"LimitAccessToCertainAttributesAndKeyValues",
         "Effect":"Allow",
         "Action":[
            "dynamodb:UpdateItem",
            "dynamodb:GetItem",
            "dynamodb:Query",
            "dynamodb:BatchGetItem"
         ],
         "Resource":[
            "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores",
            "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores/index/
TopScoreDateTimeIndex"
         ],
         "Condition":{
            "ForAllValues:StringEquals":{
               "dynamodb:LeadingKeys":[
                  "${graph.facebook.com:id}"
               ],
               "dynamodb:Attributes":[
                  "attribute-A",
                  "attribute-B"
               ]
            },
            "StringEqualsIfExists":{
               "dynamodb:Select":"SPECIFIC_ATTRIBUTES",
               "dynamodb:ReturnValues":[
                  "NONE",
                  "UPDATED_OLD",
                  "UPDATED_NEW"
               ]
            }
         }
      }
   ]
}
```

Note the following:

- Write actions allowed by the policy (`UpdateItem`) can only modify `attribute-A` or `attribute-B`.
- Because the policy allows `UpdateItem`, an application can insert new items, and the hidden attributes will be null in the new items. If these attributes are projected into

`TopScoreDateTimeIndex`, the policy has the added benefit of preventing queries that cause fetches from the table.

- Applications cannot read any attributes other than those listed in `dynamodb:Attributes`. With this policy in place, an application must set the `Select` parameter to `SPECIFIC_ATTRIBUTES` in read requests, and only attributes in the allow list can be requested. For write requests, the application cannot set `ReturnValues` to `ALL_OLD` or `ALL_NEW` and it cannot perform conditional write operations based on any other attributes.

Using web identity federation

If you are writing an application targeted at large numbers of users, you can optionally use *web identity federation* for authentication and authorization. Web identity federation removes the need for creating individual users. Instead, users can sign in to an identity provider and then obtain temporary security credentials from AWS Security Token Service (AWS STS). The app can then use these credentials to access AWS services.

Web identity federation supports the following identity providers:

- Login with Amazon
- Facebook
- Google

Additional resources for web identity federation

The following resources can help you learn more about web identity federation:

- The post Web Identity Federation using the AWS SDK for .NET on the AWS Developer blog walks through how to use web identity federation with Facebook. It includes code snippets in C# that show how to assume an IAM role with web identity and how to use temporary security credentials to access an AWS resource.

- The AWS Mobile SDK for iOS and the AWS Mobile SDK for Android contain sample apps. They include code that shows how to invoke the identity providers, and then how to use the information from these providers to get and use temporary security credentials.
- The article Web Identity Federation with Mobile Applications discusses web identity federation and shows an example of how to use web identity federation to access an AWS resource.

Example policy for web identity federation

To show how you can use web identity federation with DynamoDB, revisit the *GameScores* table that was introduced in Using IAM policy conditions for fine-grained access control. Here is the primary key for *GameScores*.

Table Name	Primary Key Type	Partition Key Name and Type	Sort Key Name and Type
GameScores (UserId, GameTitle, ...)	Composite	Attribute Name: UserId Type: String	Attribute Name: GameTitle Type: String

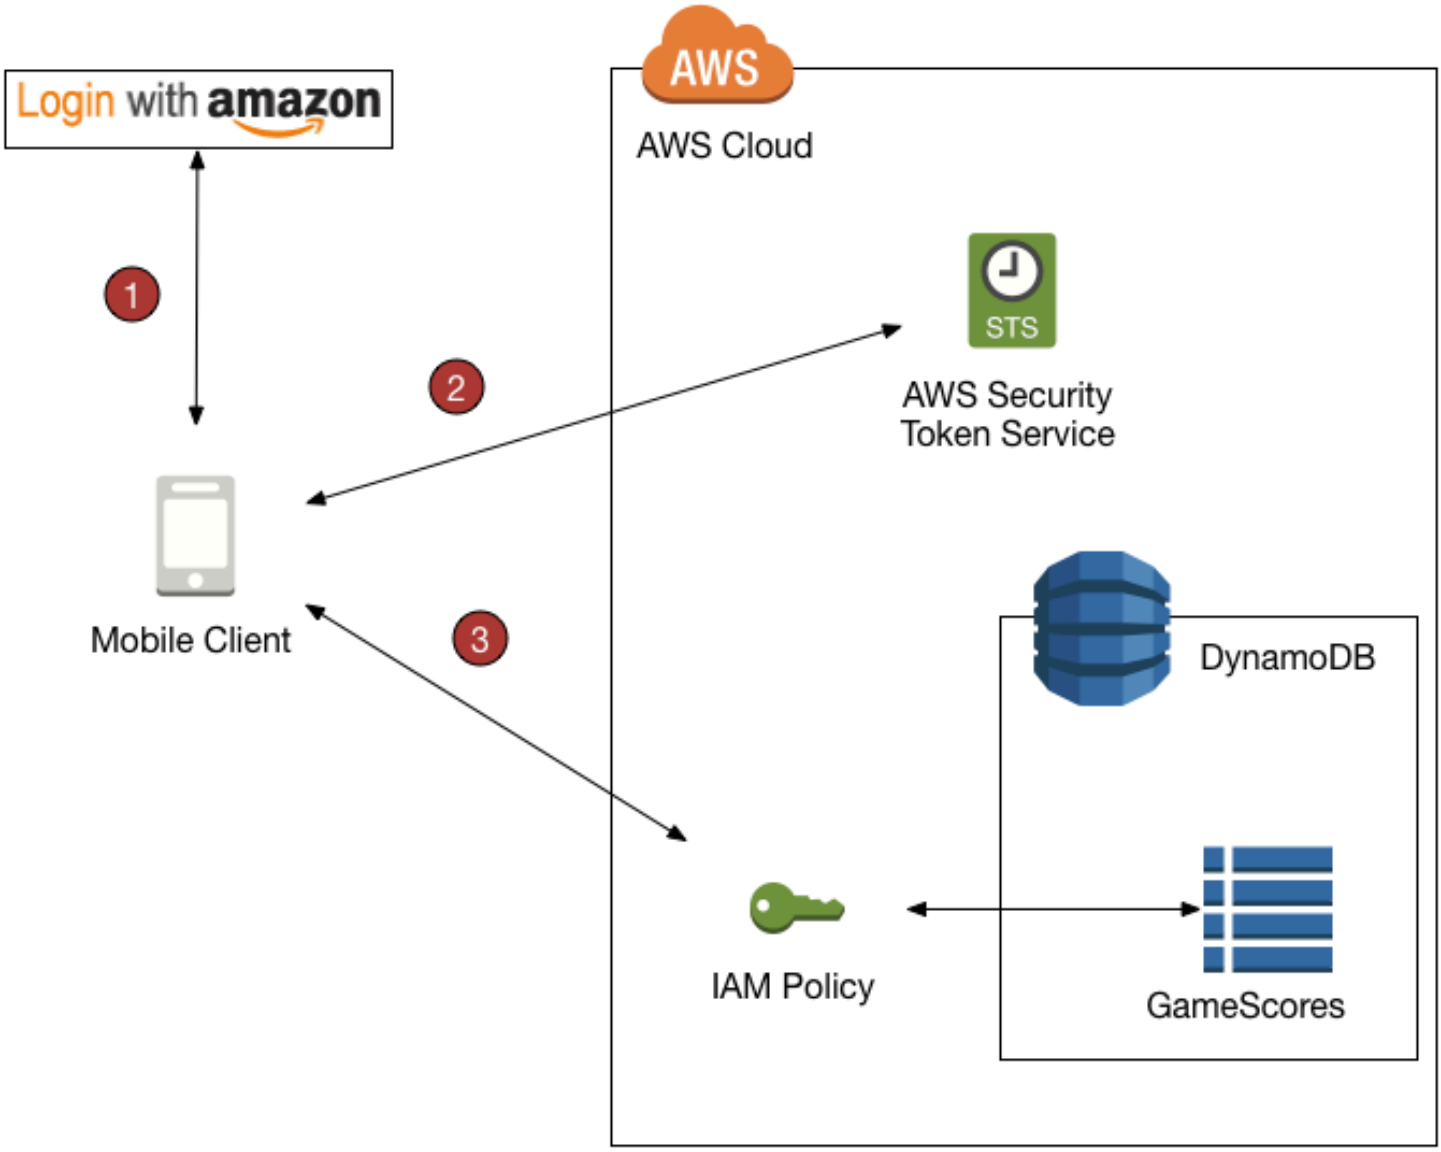
Now suppose that a mobile gaming app uses this table, and that app needs to support thousands, or even millions, of users. At this scale, it becomes very difficult to manage individual app users, and to guarantee that each user can only access their own data in the *GameScores* table. Fortunately, many users already have accounts with a third-party identity provider, such as Facebook, Google, or Login with Amazon. So it makes sense to use one of these providers for authentication tasks.

To do this using web identity federation, the app developer must register the app with an identity provider (such as Login with Amazon) and obtain a unique app ID. Next, the developer needs to create an IAM role. (For this example, this role is named *GameRole*.) The role must have an IAM policy document attached to it, specifying the conditions under which the app can access *GameScores* table.

When a user wants to play a game, they sign in to their Login with Amazon account from within the gaming app. The app then calls AWS Security Token Service (AWS STS), providing the Login with Amazon app ID and requesting membership in *GameRole*. AWS STS returns temporary AWS

credentials to the app and allows it to access the *GameScores* table, subject to the *GameRole* policy document.

The following diagram shows how these pieces fit together.



Web identity federation overview

1. The app calls a third-party identity provider to authenticate the user and the app. The identity provider returns a web identity token to the app.
2. The app calls AWS STS and passes the web identity token as input. AWS STS authorizes the app and gives it temporary AWS access credentials. The app is allowed to assume an IAM role (*GameRole*) and access AWS resources in accordance with the role's security policy.

3. The app calls DynamoDB to access the *GameScores* table. Because it has assumed the *GameRole*, the app is subject to the security policy associated with that role. The policy document prevents the app from accessing data that does not belong to the user.

Once again, here is the security policy for *GameRole* that was shown in Using IAM policy conditions for fine-grained access control:

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowAccessToOnlyItemsMatchingUserID",
         "Effect":"Allow",
         "Action":[
            "dynamodb:GetItem",
            "dynamodb:BatchGetItem",
            "dynamodb:Query",
            "dynamodb:PutItem",
            "dynamodb:UpdateItem",
            "dynamodb:DeleteItem",
            "dynamodb:BatchWriteItem"
         ],
         "Resource":[
            "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores"
         ],
         "Condition":{
            "ForAllValues:StringEquals":{
               "dynamodb:LeadingKeys":[
                  "${www.amazon.com:user_id}"
               ],
               "dynamodb:Attributes":[
                  "UserId",
                  "GameTitle",
                  "Wins",
                  "Losses",
                  "TopScore",
                  "TopScoreDateTime"
               ]
            },
            "StringEqualsIfExists":{
               "dynamodb:Select":"SPECIFIC_ATTRIBUTES"
            }
```

```
            }
        }
    ]
}
```

The `Condition` clause determines which items in *GameScores* are visible to the app. It does this by comparing the Login with Amazon ID to the `UserId` partition key values in `GameScores`. Only the items belonging to the current user can be processed using one of DynamoDB actions that are listed in this policy. Other items in the table cannot be accessed. Furthermore, only the specific attributes listed in the policy can be accessed.

Preparing to use web identity federation

If you are an application developer and want to use web identity federation for your app, follow these steps:

1. **Sign up as a developer with a third-party identity provider.** The following external links provide information about signing up with supported identity providers:
   - Login with Amazon Developer Center
   - Registration on the Facebook site
   - Using OAuth 2.0 to Access Google APIs on the Google site
2. **Register your app with the identity provider.** When you do this, the provider gives you an ID that's unique to your app. If you want your app to work with multiple identity providers, you need to obtain an app ID from each provider.
3. **Create one or more IAM roles.** You need one role for each identity provider for each app. For example, you might create a role that can be assumed by an app where the user signed in using Login with Amazon, a second role for the same app where the user has signed in using Facebook, and a third role for the app where users sign in using Google.

   As part of the role creation process, you need to attach an IAM policy to the role. Your policy document should define the DynamoDB resources required by your app, and the permissions for accessing those resources.

For more information, see About Web Identity Federation in *IAM User Guide*.

> **Note**
>
> As an alternative to AWS Security Token Service, you can use Amazon Cognito. Amazon Cognito is the preferred service for managing temporary credentials for mobile apps. For more information, see Getting credentials in the *Amazon Cognito Developer Guide.*

Generating an IAM policy using the DynamoDB console

The DynamoDB console can help you create an IAM policy for use with web identity federation. To do this, you choose a DynamoDB table and specify the identity provider, actions, and attributes to be included in the policy. The DynamoDB console then generates a policy that you can attach to an IAM role.

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. In the navigation pane, choose **Tables**.
3. In the list of tables, choose the table for which you want to create the IAM policy.
4. Select the **Actions** button, and choose **Create Access Control Policy**.
5. Choose the identity provider, actions, and attributes for the policy.

   When the settings are as you want them, choose **Generate Policy**. The generated policy appears.
6. Choose **See Documentation**, and follow the steps required to attach the generated policy to an IAM role.

Writing your app to use web identity federation

To use web identity federation, your app must assume the IAM role that you created. From that point on, the app honors the access policy that you attached to the role.

At runtime, if your app uses web identity federation, it must follow these steps:

1. **Authenticate with a third-party identity provider.** Your app must call the identity provider using an interface that they provide. The exact way in which you authenticate the user depends on the provider and on what platform your app is running. Typically, if the user is not already signed in, the identity provider takes care of displaying a sign-in page for that provider.

After the identity provider authenticates the user, the provider returns a web identity token to your app. The format of this token depends on the provider, but is typically a very long string of characters.

2. **Obtain temporary AWS security credentials.** To do this, your app sends a `AssumeRoleWithWebIdentity` request to AWS Security Token Service (AWS STS). This request contains the following:
   - The web identity token from the previous step
   - The app ID from the identity provider
   - The Amazon Resource Name (ARN) of the IAM role that you created for this identity provider for this app

   AWS STS returns a set of AWS security credentials that expire after a certain amount of time (3,600 seconds, by default).

   The following is a sample request and response from a `AssumeRoleWithWebIdentity` action in AWS STS. The web identity token was obtained from the Login with Amazon identity provider.

```
GET / HTTP/1.1
Host: sts.amazonaws.com
Content-Type: application/json; charset=utf-8
URL: https://sts.amazonaws.com/?ProviderId=www.amazon.com
&DurationSeconds=900&Action=AssumeRoleWithWebIdentity
&Version=2011-06-15&RoleSessionName=web-identity-federation
&RoleArn=arn:aws:iam::123456789012:role/GameRole
&WebIdentityToken=Atza|IQEBLjAsAhQluyKqyBiYZ8-kclvGTYM81e...(remaining characters
 omitted)
```

```
<AssumeRoleWithWebIdentityResponse
  xmlns="https://sts.amazonaws.com/doc/2011-06-15/">
  <AssumeRoleWithWebIdentityResult>
    <SubjectFromWebIdentityToken>amzn1.account.AGJZDKHJKAUUSW6C44CHPEXAMPLE</
SubjectFromWebIdentityToken>
    <Credentials>
      <SessionToken>AQoDYXdzEMf//////////wEa8AP6nNDwcSLnf+cHupC...(remaining
 characters omitted)</SessionToken>
      <SecretAccessKey>8Jhi60+EWUUbbUShTEsjTxqQtM8UKvsM6XAjdA==</SecretAccessKey>
      <Expiration>2013-10-01T22:14:35Z</Expiration>
      <AccessKeyId>06198791C436IEXAMPLE</AccessKeyId>
```

```
    </Credentials>
    <AssumedRoleUser>
      <Arn>arn:aws:sts::123456789012:assumed-role/GameRole/web-identity-federation</
Arn>
      <AssumedRoleId>AROAJU4SA2VW5SZRF2YMG:web-identity-federation</AssumedRoleId>
    </AssumedRoleUser>
  </AssumeRoleWithWebIdentityResult>
  <ResponseMetadata>
    <RequestId>c265ac8e-2ae4-11e3-8775-6969323a932d</RequestId>
  </ResponseMetadata>
</AssumeRoleWithWebIdentityResponse>
```

3. **Access AWS resources.** The response from AWS STS contains information that your app requires in order to access DynamoDB resources:

   - The `AccessKeyID`, `SecretAccessKey`, and `SessionToken` fields contain security credentials that are valid for this user and this app only.
   - The `Expiration` field signifies the time limit for these credentials, after which they are no longer valid.
   - The `AssumedRoleId` field contains the name of a session-specific IAM role that has been assumed by the app. The app honors the access controls in the IAM policy document for the duration of this session.
   - The `SubjectFromWebIdentityToken` field contains the unique ID that appears in an IAM policy variable for this particular identity provider. The following are the IAM policy variables for supported providers, and some example values for them:

Policy Variable	Example Value
`${www.amazon.com:user_id}`	`amzn1.account.AGJZDKHJKAUUSW6C44CHPEXAMPLE`
`${graph.facebook.com:id}`	`123456789`
`${accounts.google.com:sub}`	`123456789012345678901`

For example IAM policies where these policy variables are used, see Example policies: Using conditions for fine-grained access control.

For more information about how AWS STS generates temporary access credentials, see Requesting Temporary Security Credentials in *IAM User Guide*.

DynamoDB API permissions: Actions, resources, and conditions reference

When you are setting up Identity and Access Management for Amazon DynamoDB and writing a permissions policy that you can attach to an IAM identity (identity-based policies), you can use the list of Actions, resources, and condition keys for Amazon DynamoDB in the *IAM User Guide* as a reference. The page lists each DynamoDB API operation, the corresponding actions for which you can grant permissions to perform the action, and the AWS resource for which you can grant the permissions. You specify the actions in the policy's `Action` field, and you specify the resource value in the policy's `Resource` field.

You can use AWS-wide condition keys in your DynamoDB policies to express conditions. For a complete list of AWS-wide keys, see the IAM JSON policy elements reference in the *IAM User Guide*.

In addition to the AWS-wide condition keys, DynamoDB has its own specific keys that you can use in conditions. For more information, see Using IAM policy conditions for fine-grained access control.

Compliance validation by industry for DynamoDB

To learn whether an AWS service is within the scope of specific compliance programs, see AWS services in Scope by Compliance Program and choose the compliance program that you are interested in. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- Security Compliance & Governance – These solution implementation guides discuss architectural considerations and provide steps for deploying security and compliance features.

- HIPAA Eligible Services Reference – Lists HIPAA eligible services. Not all AWS services are HIPAA eligible.
- AWS Compliance Resources – This collection of workbooks and guides might apply to your industry and location.
- AWS Customer Compliance Guides – Understand the shared responsibility model through the lens of compliance. The guides summarize the best practices for securing AWS services and map the guidance to security controls across multiple frameworks (including National Institute of Standards and Technology (NIST), Payment Card Industry Security Standards Council (PCI), and International Organization for Standardization (ISO)).
- Evaluating Resources with Rules in the *AWS Config Developer Guide* – The AWS Config service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- AWS Security Hub – This AWS service provides a comprehensive view of your security state within AWS. Security Hub uses security controls to evaluate your AWS resources and to check your compliance against security industry standards and best practices. For a list of supported services and controls, see Security Hub controls reference.
- Amazon GuardDuty – This AWS service detects potential threats to your AWS accounts, workloads, containers, and data by monitoring your environment for suspicious and malicious activities. GuardDuty can help you address various compliance requirements, like PCI DSS, by meeting intrusion detection requirements mandated by certain compliance frameworks.
- AWS Audit Manager – This AWS service helps you continuously audit your AWS usage to simplify how you manage risk and compliance with regulations and industry standards.

Resilience and disaster recovery in Amazon DynamoDB

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

If you need to replicate your data or applications over greater geographic distances, use AWS Local Regions. An AWS Local Region is a single data center designed to complement an existing AWS Region. Like all AWS Regions, AWS Local Regions are completely isolated from other AWS Regions.

For more information about AWS Regions and Availability Zones, see AWS global infrastructure.

In addition to the AWS global infrastructure, Amazon DynamoDB offers several features to help support your data resiliency and backup needs.

On-demand backup and restore

DynamoDB provides on-demand backup capability. It allows you to create full backups of your tables for long-term retention and archival. For more information, see On-Demand backup and restore for DynamoDB.

Point-in-time recovery

Point-in-time recovery helps protect your DynamoDB tables from accidental write or delete operations. With point in time recovery, you don't have to worry about creating, maintaining, or scheduling on-demand backups. For more information, see Point-in-time recovery for DynamoDB.

Global tables that sync across AWS regions

DynamoDB automatically spreads the data and traffic for your tables over a sufficient number of servers to handle your throughput and storage requirements, while maintaining consistent and fast performance. All of your data is stored on solid-state disks (SSDs) and is automatically replicated across multiple Availability Zones in an AWS Region, providing built-in high availability and data durability. You can use global tables to keep DynamoDB tables in sync across AWS Regions.

Infrastructure security in Amazon DynamoDB

As a managed service, Amazon DynamoDB is protected by the AWS global network security procedures that are described in Infrastructure protection located in the AWS Well-Architected Framework.

You use AWS published API calls to access DynamoDB through the network. Clients can use TLS (Transport Layer Security) version 1.2 or 1.3. Clients must also support cipher suites with perfect forward secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Diffie-Hellman Ephemeral (ECDHE). Most modern systems such as Java 7 and later support these modes. Additionally, requests must be signed using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

You can also use a virtual private cloud (VPC) endpoint for DynamoDB to enable Amazon EC2 instances in your VPC to use their private IP addresses to access DynamoDB with no exposure to the public internet. For more information, see Using Amazon VPC endpoints to access DynamoDB.

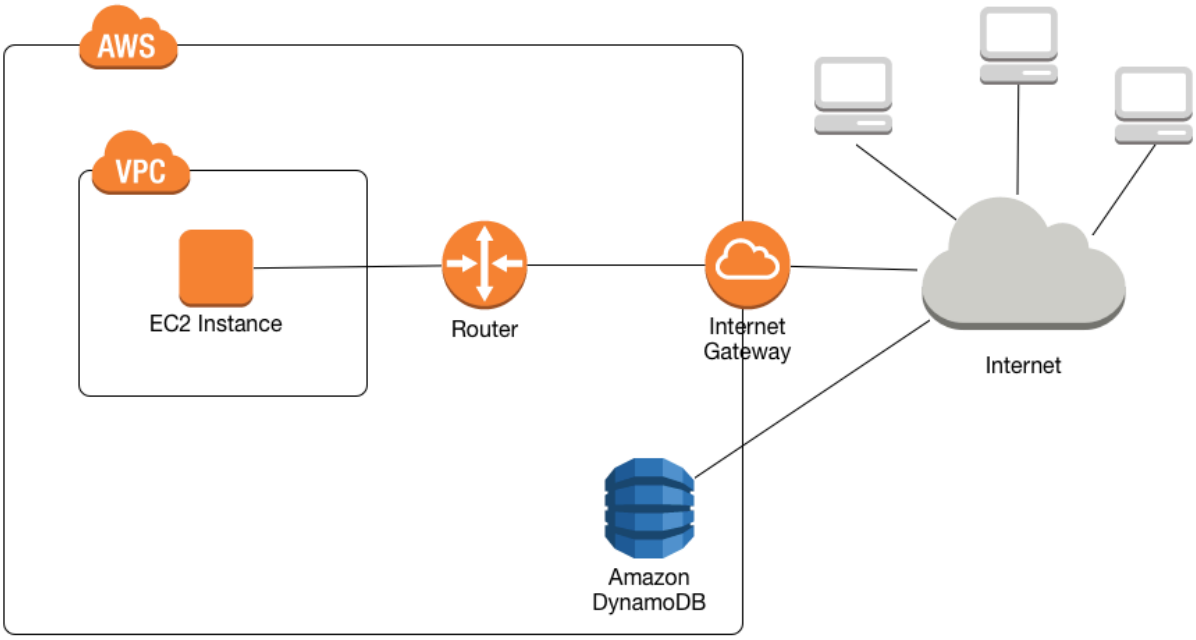
Using Amazon VPC endpoints to access DynamoDB

For security reasons, many AWS customers run their applications within an Amazon Virtual Private Cloud environment (Amazon VPC). With Amazon VPC, you can launch Amazon EC2 instances into a virtual private cloud, which is logically isolated from other networks—including the public internet. With an Amazon VPC, you have control over its IP address range, subnets, routing tables, network gateways, and security settings.

> **Note**
>
> If you created your AWS account after December 4, 2013, then you already have a default VPC in each AWS Region. A default VPC is ready for you to use—you can immediately start using it without having to perform any additional configuration steps.
> For more information, see Default VPC and Default Subnets in the *Amazon VPC User Guide*.

To access the public internet, your VPC must have an internet gateway—a virtual router that connects your VPC to the internet. This allows applications running on Amazon EC2 in your VPC to access internet resources, such as Amazon DynamoDB.

By default, communications to and from DynamoDB use the HTTPS protocol, which protects network traffic by using SSL/TLS encryption. The following diagram shows an Amazon EC2 instance in a VPC accessing DynamoDB, by having DynamoDB use an internet gateway rather than VPC endpoints.



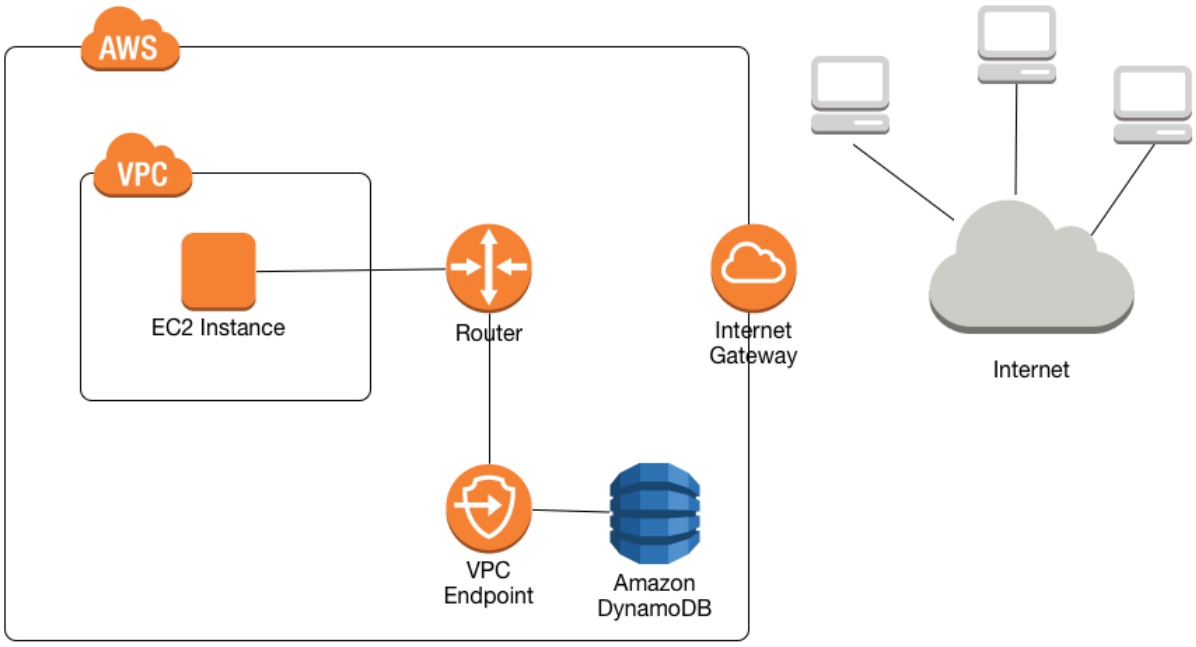
Many customers have legitimate privacy and security concerns about sending and receiving data across the public internet. You can address these concerns by using a virtual private network (VPN) to route all DynamoDB network traffic through your own corporate network infrastructure. However, this approach can introduce bandwidth and availability challenges.

VPC endpoints for DynamoDB can alleviate these challenges. A *VPC endpoint* for DynamoDB enables Amazon EC2 instances in your VPC to use their private IP addresses to access DynamoDB with no exposure to the public internet. Your EC2 instances do not require public IP addresses, and you don't need an internet gateway, a NAT device, or a virtual private gateway in your VPC. You use endpoint policies to control access to DynamoDB. Traffic between your VPC and the AWS service does not leave the Amazon network.

> **Note**
>
> Even when you use public IP addresses, all VPC communication between instances and services hosted in AWS is kept private within the AWS network. Packets that originate from the AWS network with a destination on the AWS network stay on the AWS global network, except traffic to or from AWS China Regions.

When you create a VPC endpoint for DynamoDB, any requests to a DynamoDB endpoint within the Region (for example, *dynamodb.us-west-2.amazonaws.com*) are routed to a private DynamoDB endpoint within the Amazon network. You don't need to modify your applications running on EC2 instances in your VPC. The endpoint name remains the same, but the route to DynamoDB stays entirely within the Amazon network, and does not access the public internet.

The following diagram shows how an EC2 instance in a VPC can use a VPC endpoint to access DynamoDB.



For more information, see the section called “Tutorial: Using a VPC endpoint for DynamoDB”.

Sharing Amazon VPC endpoints and DynamoDB

In order to enable access to the DynamoDB service through a VPC subnet's gateway endpoint, you must have owner account permissions for that VPC subnet.

Once the VPC subnet’s gateway endpoint has been granted access to DynamoDB, any AWS account with access to that subnet can use DynamoDB. This means all account users within the VPC subnet can use any DynamoDB tables which they have access to. This includes DynamoDB tables associated with a different account than the VPC subnet. The VPC subnet owner can still restrict any particular user within the subnet from using the DynamoDB service through the gateway endpoint, at their discretion.

Tutorial: Using a VPC endpoint for DynamoDB

This section walks you through setting up and using a VPC endpoint for DynamoDB.

Topics

- Step 1: Launch an Amazon EC2 instance
- Step 2: Configure your Amazon EC2 instance
- Step 3: Create a VPC endpoint for DynamoDB
- Step 4: (Optional) Clean up

Step 1: Launch an Amazon EC2 instance

In this step, you launch an Amazon EC2 instance in your default Amazon VPC. You can then create and use a VPC endpoint for DynamoDB.

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose **Launch Instance** and do the following:

   Step 1: Choose an Amazon Machine Image (AMI)

   - At the top of the list of AMIs, go to **Amazon Linux AMI** and choose **Select**.

   Step 2: Choose an Instance Type

   - At the top of the list of instance types, choose **t2.micro**.
   - Choose **Next: Configure Instance Details**.

   Step 3: Configure Instance Details

   - Go to **Network** and choose your default VPC.

     Choose **Next: Add Storage**.

   Step 4: Add Storage

   - Skip this step by choosing **Next: Tag Instance**.

Step 5: Tag Instance

- Skip this step by choosing **Next: Configure Security Group**.

Step 6: Configure Security Group

- Choose **Select an existing security group**.
- In the list of security groups, choose **default**. This is the default security group for your VPC.
- Choose **Next: Review and Launch**.

Step 7: Review Instance Launch

- Choose **Launch**.

3. In the **Select an existing key pair or create a new key pair** window, do one of the following:

   - If you do not have an Amazon EC2 key pair, choose **Create a new key pair** and follow the instructions. You will be asked to download a private key file (*.pem* file); you will need this file later when you log in to your Amazon EC2 instance.
   - If you already have an existing Amazon EC2 key pair, go to **Select a key pair** and choose your key pair from the list. You must already have the private key file (*.pem* file) available in order to log in to your Amazon EC2 instance.

4. When you have configured your key pair, choose **Launch Instances**.
5. Return to the Amazon EC2 console home page and choose the instance that you launched. In the lower pane, on the **Description** tab, find the **Public DNS** for your instance. For example: `ec2-00-00-00-00.us-east-1.compute.amazonaws.com`.

   Make a note of this public DNS name, because you will need it in the next step in this tutorial (Step 2: Configure your Amazon EC2 instance).

> **Note**
>
> It will take a few minutes for your Amazon EC2 instance to become available. Before you go on to the next step, ensure that the **Instance State** is `running` and that all of its **Status Checks** have passed.

Step 2: Configure your Amazon EC2 instance

When your Amazon EC2 instance is available, you will be able to log into it and prepare it for first use.

> **Note**
>
> The following steps assume that you are connecting to your Amazon EC2 instance from a computer running Linux. For other ways to connect, see Connect to Your Linux Instance in the Amazon EC2 User Guide.

1. You will need to authorize inbound SSH traffic to your Amazon EC2 instance. To do this, you will create a new EC2 security group, and then assign the security group to your EC2 instance.

   a. In the navigation pane, choose **Security Groups**.

   b. Choose **Create Security Group**. In the **Create Security Group** window, do the following:

      - **Security group name**—type a name for your security group. For example: `my-ssh-access`
      - **Description**—type a short description for the security group.
      - **VPC**—choose your default VPC.
      - In the **Security group rules** section, choose **Add Rule** and do the following:
        - **Type**—choose SSH.
        - **Source**—choose My IP.

      When the settings are as you want them, choose **Create**.

   c. In the navigation pane, choose **Instances**.

   d. Choose the Amazon EC2 instance that you launched in Step 1: Launch an Amazon EC2 instance.

   e. Choose **Actions** --> **Networking** --> **Change Security Groups**.

   f. In the **Change Security Groups**, select the security group that you created earlier in this procedure (for example: `my-ssh-access`). The existing `default` security group should also be selected. When the settings are as you want them, choose **Assign Security Groups**.

2. Use the `ssh` command to log in to your Amazon EC2 instance, as in the following example.

```
ssh -i my-keypair.pem ec2-user@public-dns-name
```

You will need to specify your private key file (*.pem* file) and the public DNS name of your instance. (See Step 1: Launch an Amazon EC2 instance).

The login ID is `ec2-user`. No password is required.

3. Configure your AWS credentials as shown in the following example. Enter your AWS access key ID, secret key, and default Region name when prompted.

```
aws configure
```

```
AWS Access Key ID [None]: AKIAIOSFODNN7EXAMPLE
AWS Secret Access Key [None]: wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
Default region name [None]: us-east-1
Default output format [None]:
```

You are now ready to create a VPC endpoint for DynamoDB.

Step 3: Create a VPC endpoint for DynamoDB

In this step, you will create a VPC endpoint for DynamoDB and test it to make sure that it works.

1. Before you begin, verify that you can communicate with DynamoDB using its public endpoint.

```
aws dynamodb list-tables
```

The output will show a list of DynamoDB tables that you currently own. (If you don't have any tables, the list will be empty.).

2. Verify that DynamoDB is an available service for creating VPC endpoints in the current AWS Region. (The command is shown in bold text, followed by example output.)

```
aws ec2 describe-vpc-endpoint-services
```

```
{
    "ServiceNames": [
        "com.amazonaws.us-east-1.s3",
        "com.amazonaws.us-east-1.dynamodb"
```

```
    ]
}
```

In the example output, DynamoDB is one of the services available, so you can proceed with creating a VPC endpoint for it.

3. Determine your VPC identifier.

```
aws ec2 describe-vpcs
```

```
{
    "Vpcs": [
        {
            "VpcId": "vpc-0bbc736e",
            "InstanceTenancy": "default",
            "State": "available",
            "DhcpOptionsId": "dopt-8454b7e1",
            "CidrBlock": "172.31.0.0/16",
            "IsDefault": true
        }
    ]
}
```

In the example output, the VPC ID is `vpc-0bbc736e`.

4. Create the VPC endpoint. For the `--vpc-id` parameter, specify the VPC ID from the previous step. Use the `--route-table-ids` parameter to associate the endpoint with your route tables.

```
aws ec2 create-vpc-endpoint --vpc-id vpc-0bbc736e --service-name com.amazonaws.us-
east-1.dynamodb --route-table-ids rtb-11aa22bb
```

```
{
    "VpcEndpoint": {
        "PolicyDocument": "{\"Version\":\"2008-10-17\",\"Statement\":[{\"Effect\":
\"Allow\",\"Principal\":\"*\",\"Action\":\"*\",\"Resource\":\"*\"}]}",
        "VpcId": "vpc-0bbc736e",
        "State": "available",
        "ServiceName": "com.amazonaws.us-east-1.dynamodb",
        "RouteTableIds": [
            "rtb-11aa22bb"
```

```
        ],
        "VpcEndpointId": "vpce-9b15e2f2",
        "CreationTimestamp": "2017-07-26T22:00:14Z"
    }
}
```

5. Verify that you can access DynamoDB through the VPC endpoint.

```
aws dynamodb list-tables
```

If you want, you can try some other AWS CLI commands for DynamoDB. For more information, see the AWS CLI Command Reference.

Step 4: (Optional) Clean up

If you want to delete the resources you have created in this tutorial, follow these procedures:

To remove your VPC endpoint for DynamoDB

1. Log in to your Amazon EC2 instance.
2. Determine the VPC endpoint ID.

```
aws ec2 describe-vpc-endpoints
```

```
{
    "VpcEndpoint": {
        "PolicyDocument": "{\"Version\":\"2008-10-17\",\"Statement\":[{\"Effect\":
\"Allow\",\"Principal\":\"*\",\"Action\":\"*\",\"Resource\":\"*\"}]}",
        "VpcId": "vpc-0bbc736e",
        "State": "available",
        "ServiceName": "com.amazonaws.us-east-1.dynamodb",
        "RouteTableIds": [],
        "VpcEndpointId": "vpce-9b15e2f2",
        "CreationTimestamp": "2017-07-26T22:00:14Z"
    }
}
```

In the example output, the VPC endpoint ID is `vpce-9b15e2f2`.

3. Delete the VPC endpoint.

```
aws ec2 delete-vpc-endpoints --vpc-endpoint-ids vpce-9b15e2f2
```

```
{
    "Unsuccessful": []
}
```

The empty array `[]` indicates success (there were no unsuccessful requests).

To terminate your Amazon EC2 instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Choose your Amazon EC2 instance.
4. Choose **Actions**, **Instance State**, **Terminate**.
5. In the confirmation window, choose **Yes, Terminate**.

AWS PrivateLink for DynamoDB

With AWS PrivateLink for DynamoDB, you can provision *interface Amazon VPC endpoints* (interface endpoints) in your virtual private cloud (Amazon VPC). These endpoints are directly accessible from applications that are on premises over VPN and AWS Direct Connect, or in a different AWS Region over Amazon VPC peering. Using AWS PrivateLink and interface endpoints, you can simplify private network connectivity from your applications to DynamoDB.

Applications in your VPC do not need public IP addresses to communicate with DynamoDB using VPC interface endpoints for DynamoDB operations. Interface endpoints are represented by one or more elastic network interfaces (ENIs) that are assigned private IP addresses from subnets in your Amazon VPC. Requests to DynamoDB over interface endpoints stay on the Amazon network. You can also access interface endpoints in your Amazon VPC from on-premises applications through AWS Direct Connect or AWS Virtual Private Network (AWS VPN). For more information about how to connect your Amazon VPC with your on-premises network, see the AWS Direct Connect User Guide and the AWS Site-to-Site VPN User Guide.

For general information about interface endpoints, see Interface Amazon VPC endpoints (AWS PrivateLink) in the *AWS PrivateLink Guide*. AWS PrivateLink is also supported for Amazon

DynamoDB Streams endpoints. For more information, see the section called "AWS PrivateLink for DynamoDB Streams".

Topics

- Types of Amazon VPC endpoints for Amazon DynamoDB
- Considerations when using AWS PrivateLink for Amazon DynamoDB
- Creating an Amazon VPC endpoint
- Accessing Amazon DynamoDB interface endpoints
- Accessing DynamoDB tables and control API operations from DynamoDB interface endpoints
- Updating an on-premises DNS configuration
- Creating an Amazon VPC endpoint policy for DynamoDB
- AWS PrivateLink for DynamoDB Streams

Types of Amazon VPC endpoints for Amazon DynamoDB

You can use two types of Amazon VPC endpoints to access Amazon DynamoDB: *gateway endpoints* and *interface endpoints* (by using AWS PrivateLink). A *gateway endpoint* is a gateway that you specify in your route table to access DynamoDB from your Amazon VPC over the AWS network. *Interface endpoints* extend the functionality of gateway endpoints by using private IP addresses to route requests to DynamoDB from within your Amazon VPC, on premises, or from an Amazon VPC in another AWS Region by using Amazon VPC peering or AWS Transit Gateway. For more information, see What is Amazon VPC peering? and Transit Gateway vs Amazon VPC peering.

Interface endpoints are compatible with gateway endpoints. If you have an existing gateway endpoint in the Amazon VPC, you can use both types of endpoints in the same Amazon VPC.

Gateway endpoints for DynamoDB	Interface endpoints for DynamoDB
In both cases, your network traffic remains on the AWS network.	
Use Amazon DynamoDB public IP addresses	Use private IP addresses from your Amazon VPC to access Amazon DynamoDB
Do not allow access from on premises	Allow access from on premises

Gateway endpoints for DynamoDB	Interface endpoints for DynamoDB
Do not allow access from another AWS Region	Allow access from an Amazon VPC endpoint in another AWS Region by using Amazon VPC peering or AWS Transit Gateway
Not billed	Billed

For more information about gateway endpoints, see Gateway Amazon VPC endpoints in the *AWS PrivateLink Guide*.

Considerations when using AWS PrivateLink for Amazon DynamoDB

Amazon VPC considerations apply to AWS PrivateLink for Amazon DynamoDB. For more information, see Interface endpoint considerations and AWS PrivateLink quotas in the *AWS PrivateLink Guide*. In addition, the following restrictions apply.

AWS PrivateLink for Amazon DynamoDB does not support the following:

- Transport Layer Security (TLS) 1.1
- Private and Hybrid Domain Name System (DNS) services

You can submit up to 50,000 requests per second for each AWS PrivateLink endpoint that you enable.

> **Note**
>
> Network connectivity timeouts to AWS PrivateLink endpoints are not within the scope of DynamoDB error responses and need to be appropriately handled by your applications connecting to the PrivateLink endpoints.

Creating an Amazon VPC endpoint

To create an Amazon VPC interface endpoint, see Create an Amazon VPC endpoint in the *AWS PrivateLink Guide*.

Accessing Amazon DynamoDB interface endpoints

When you create an interface endpoint, DynamoDB generates two types of endpoint-specific, DynamoDB DNS names: *Regional* and *Zonal*.

- A *Regional* DNS name includes a unique Amazon VPC endpoint ID, a service identifier, the AWS Region, and `vpce.amazonaws.com` in its name. For example, for Amazon VPC endpoint ID *`vpce-1a2b3c4d`*, the DNS name generated might be similar to *`vpce-1a2b3c4d-5e6f`*`.dynamodb.us-east-1.vpce.amazonaws.com`.
- A *Zonal* DNS name includes the Availability Zone—for example, *`vpce-1a2b3c4d-5e6f`*`-us-east-1a.dynamodb.us-east-1.vpce.amazonaws.com`. You might use this option if your architecture isolates Availability Zones. For example, you could use it for fault containment or to reduce Regional data transfer costs.

> **Note**
>
> To achieve optimal reliability, we recommend deploying your service across a minimum of three availability zones.

Accessing DynamoDB tables and control API operations from DynamoDB interface endpoints

You can use the AWS CLI or AWS SDKs to access DynamoDB tables and control API operations through DynamoDB interface endpoints.

AWS CLI examples

To access DynamoDB tables or DynamoDB control API operations through DynamoDB interface endpoints in AWS CLI commands, use the `--region` and `--endpoint-url` parameters.

Example: Create a VPC endpoint

```
aws ec2 create-vpc-endpoint \
--region us-east-1 \
--service-name com.amazonaws.us-east-1.dynamodb \
--vpc-id client-vpc-id \
```

```
--subnet-ids client-subnet-id \
--vpc-endpoint-type Interface \
--security-group-ids client-sg-id
```

Example: Modify a VPC endpoint

```
aws ec2 modify-vpc-endpoint \
--region us-east-1 \
--vpc-endpoint-id client-vpc-endpoint-id \
--policy-document policy-document \ #example optional parameter
--add-security-group-ids security-group-ids \ #example optional parameter
# any additional parameters needed, see Privatelink documentation for more details
```

Example: List tables using an endpoint URL

In the following example, replace the Region `us-east-1` and the DNS name of the VPC endpoint ID `vpce-1a2b3c4d-5e6f.dynamodb.us-east-1.vpce.amazonaws.com` with your own information.

```
aws dynamodb --region us-east-1 --endpoint https://vpce-1a2b3c4d-5e6f.dynamodb.us-
east-1.vpce.amazonaws.com list-tables
```

AWS SDK examples

To access DynamoDB tables or DynamoDB control API operations through DynamoDB interface endpoints when using the AWS SDKs, update your SDKs to the latest version. Then, configure your clients to use an endpoint URL for accessing a table or DynamoDB control API operation through DynamoDB interface endpoints.

SDK for Python (Boto3)

Example: Use an endpoint URL to access a DynamoDB table

In the following example, replace the Region `us-east-1` and VPC endpoint ID `https://vpce-1a2b3c4d-5e6f.dynamodb.us-east-1.vpce.amazonaws.com` with your own information.

```
ddb_client = session.client(
service_name='dynamodb',
region_name='us-east-1',
```

```
endpoint_url='https://vpce-1a2b3c4d-5e6f.dynamodb.us-east-1.vpce.amazonaws.com'
)
```

SDK for Java 1.x

Example: Use an endpoint URL to access a DynamoDB table

In the following example, replace the Region `us-east-1` and VPC endpoint ID `https://vpce-1a2b3c4d-5e6f.dynamodb.us-east-1.vpce.amazonaws.com` with your own information.

```
//client build with endpoint config
final AmazonDynamoDB dynamodb =
 AmazonDynamoDBClientBuilder.standard().withEndpointConfiguration(
        new AwsClientBuilder.EndpointConfiguration(
                "https://vpce-1a2b3c4d-5e6f.dynamodb.us-east-1.vpce.amazonaws.com",
                Regions.DEFAULT_REGION.getName()
        )
).build();
```

SDK for Java 2.x

Example: Use an endpoint URL to access DynamoDB table

In the following example, replace the Region us-east-1 and VPC endpoint ID https://vpce-1a2b3c4d-5e6f.dynamodb.us-east-1.vpce.amazonaws.com with your own information.

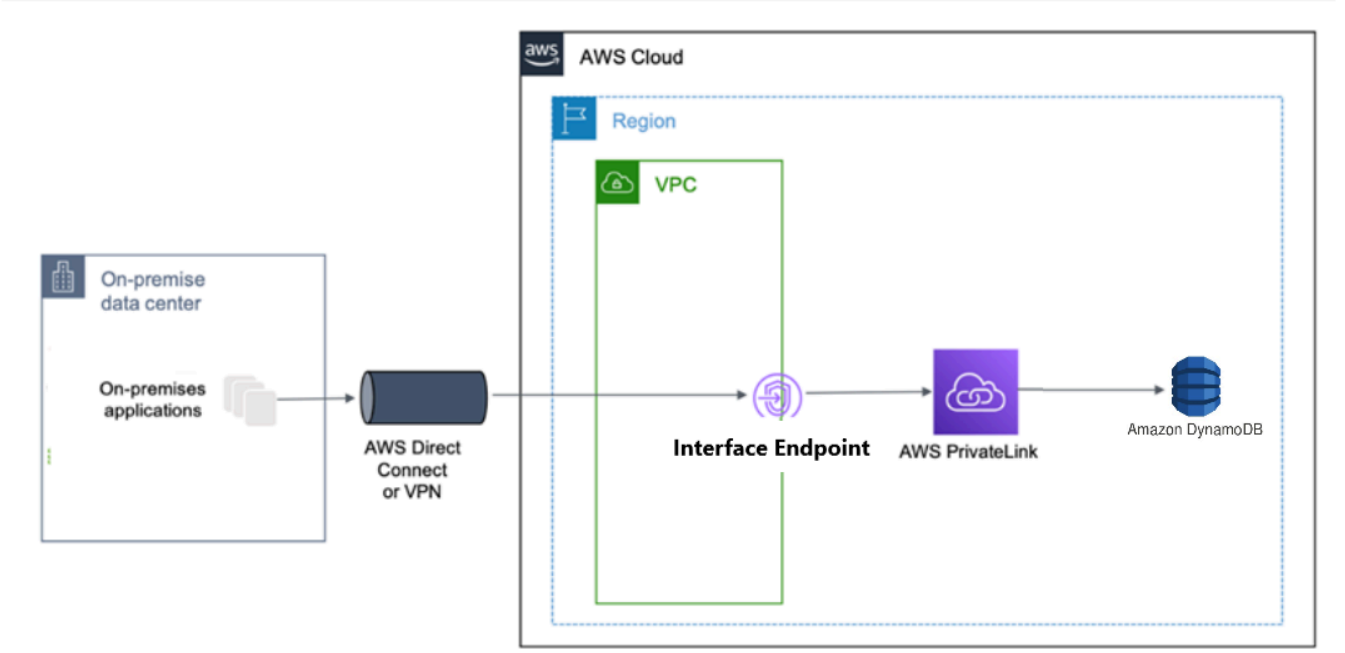
```
Region region = Region.US_EAST_1;
dynamoDbClient = DynamoDbClient.builder().region(region)
.endpointOverride(URI.create("https://vpce-1a2b3c4d-5e6f.dynamodb.us-
east-1.vpce.amazonaws.com"))
.build()
```

Updating an on-premises DNS configuration

When using endpoint-specific DNS names to access the interface endpoints for DynamoDB, you don't have to update your on-premises DNS resolver. You can resolve the endpoint-specific DNS name with the private IP address of the interface endpoint from the public DynamoDB DNS domain.

Using interface endpoints to access DynamoDB without a gateway endpoint or an internet gateway in the Amazon VPC

Interface endpoints in your Amazon VPC can route both in-Amazon VPC applications and on-premises applications to DynamoDB over the Amazon network, as illustrated in the following diagram.

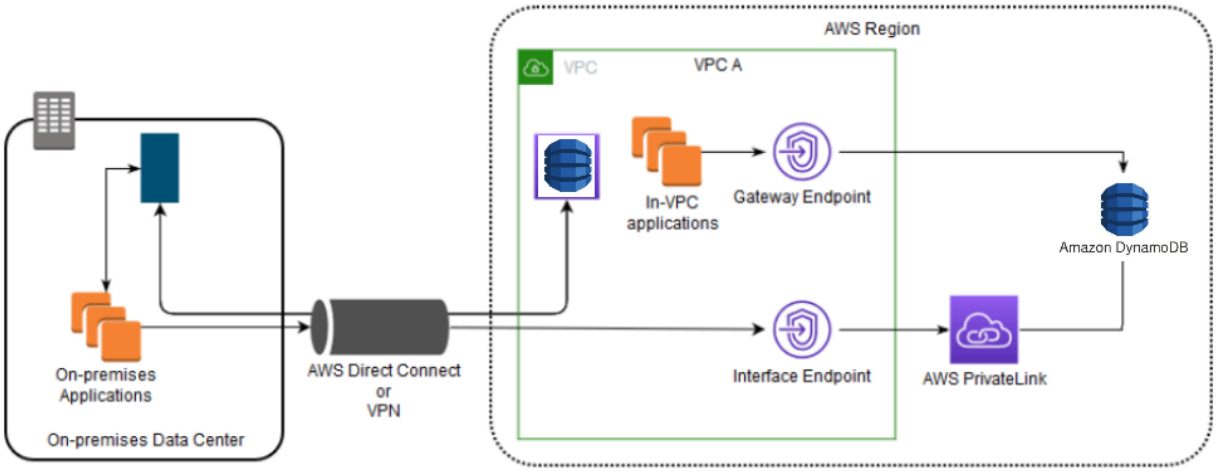


The diagram illustrates the following:

- Your on-premises network uses AWS Direct Connect or AWS VPN to connect to Amazon VPC A.
- Your applications on-premises and in Amazon VPC A use endpoint-specific DNS names to access DynamoDB through the DynamoDB interface endpoint.
- On-premises applications send data to the interface endpoint in the Amazon VPC through AWS Direct Connect (or AWS VPN). AWS PrivateLink moves the data from the interface endpoint to DynamoDB over the AWS network.
- In-Amazon VPC applications also send traffic to the interface endpoint. AWS PrivateLink moves the data from the interface endpoint to DynamoDB over the AWS network.

Using gateway endpoints and interface endpoints together in the same Amazon VPC to access DynamoDB

You can create interface endpoints and retain the existing gateway endpoint in the same Amazon VPC, as the following diagram shows. By taking this approach, you allow in-Amazon VPC applications to continue accessing DynamoDB through the gateway endpoint, which is not billed. Then, only your on-premises applications would use interface endpoints to access DynamoDB. To access DynamoDB this way, you must update your on-premises applications to use endpoint-specific DNS names for DynamoDB.



The diagram illustrates the following:

- On-premises applications use endpoint-specific DNS names to send data to the interface endpoint within the Amazon VPC through AWS Direct Connect (or AWS VPN). AWS PrivateLink moves the data from the interface endpoint to DynamoDB over the AWS network.
- Using default Regional DynamoDB names, in-Amazon VPC applications send data to the gateway endpoint that connects to DynamoDB over the AWS network.

For more information about gateway endpoints, see Gateway Amazon VPC endpoints in the *Amazon VPC User Guide*.

Creating an Amazon VPC endpoint policy for DynamoDB

You can attach an endpoint policy to your Amazon VPC endpoint that controls access to DynamoDB. The policy specifies the following information:

- The AWS Identity and Access Management (IAM) principal that can perform actions
- The actions that can be performed
- The resources on which actions can be performed

Topics

- Example: Restricting access to a specific table from an Amazon VPC endpoint

Example: Restricting access to a specific table from an Amazon VPC endpoint

You can create an endpoint policy that restricts access to only specific DynamoDB tables. This type of policy is useful if you have other AWS services in your Amazon VPC that use tables. The following table policy restricts access to only the *DOC-EXAMPLE-TABLE*. To use this endpoint policy, replace *DOC-EXAMPLE-TABLE* with the name of your table.

```
{
"Version": "2012-10-17",
  "Id": "Policy1216114807515",
  "Statement": [
    { "Sid": "Access-to-specific-table-only",
      "Principal": "*",
      "Action": [
        "dynamodb:GetItem",
        "dynamodb:PutItem"
      ],
      "Effect": "Allow",
      "Resource": ["arn:aws:dynamodb:::DOC-EXAMPLE-TABLE",
                   "arn:aws:dynamodb:::DOC-EXAMPLE-TABLE/*"]
    }
  ]
}
```

AWS PrivateLink for DynamoDB Streams

With AWS PrivateLink for Amazon DynamoDB Streams, you can provision interface Amazon VPC endpoints (interface endpoints) in your virtual private cloud (Amazon VPC). These endpoints are directly accessible from applications that are on premises over VPN and AWS Direct Connect, or in a different AWS Region over Amazon VPC peering. Using AWS PrivateLink and interface endpoints, you can simplify private network connectivity from your applications to DynamoDB Streams.

Applications in your Amazon VPC do not need public IP addresses to communicate with DynamoDB Streams using Amazon VPC interface endpoints for DynamoDB Streams operations. Interface endpoints are represented by one or more elastic network interfaces (ENIs) that are assigned private IP addresses from subnets in your Amazon VPC. Requests to DynamoDB Streams over interface endpoints stay on the Amazon network. You can also access interface endpoints in your Amazon VPC from on-premises applications through AWS Direct Connect or AWS Virtual Private Network (AWS VPN). For more information about how to connect your AWS Virtual Private Network with your on-premises network, see the *AWS Direct Connect User Guide* and the *AWS Site-to-Site VPN User Guide*.

For general information about interface endpoints, see Interface Amazon VPC endpoints (AWS PrivateLink).

> **Note**
>
> Only interface endpoints are supported for DynamoDB Streams. Gateway endpoints aren't supported.

Topics

- Considerations when using AWS PrivateLink for Amazon DynamoDB Streams
- Creating an Amazon VPC endpoint
- Accessing Amazon DynamoDB Streams interface endpoints
- Accessing DynamoDB Streams API operations from DynamoDB Streams interface endpoints
- AWS SDK examples
- Creating an Amazon VPC endpoint policy for DynamoDB Streams

Considerations when using AWS PrivateLink for Amazon DynamoDB Streams

Amazon VPC considerations apply to AWS PrivateLink for Amazon DynamoDB Streams. For more information, see interface endpoint considerations and AWS PrivateLink quotas. The following restrictions apply.

AWS PrivateLink for Amazon DynamoDB Streams doesn't support the following:

- Transport Layer Security (TLS) 1.1
- Private and Hybrid Domain Name System (DNS) services

> **Note**
>
> Network connectivity timeouts to AWS PrivateLink endpoints are not within the scope of DynamoDB Streams error responses and need to be appropriately handled by your applications connecting to the AWS PrivateLink endpoints.

Creating an Amazon VPC endpoint

To create an Amazon VPC interface endpoint, see Create an Amazon VPC endpoint in the *AWS PrivateLink Guide*.

Accessing Amazon DynamoDB Streams interface endpoints

When you create an interface endpoint, DynamoDB generates two types of endpoint-specific, DynamoDB Streams DNS names: *Regional* and *Zonal*.

- A *Regional* DNS name includes a unique Amazon VPC endpoint ID, a service identifier, the AWS Region, and `vpce.amazonaws.com` in its name. For example, for Amazon VPC endpoint ID *`vpce-1a2b3c4d`*, the DNS name generated might be similar to *`vpce-1a2b3c4d-5e6f`*`.streams.dynamodb.us-east-1.vpce.amazonaws.com`.
- A *Zonal* DNS name includes the Availability Zone—for example, *`vpce-1a2b3c4d-5e6f`*`-us-east-1a.streams.dynamodb.us-east-1.vpce.amazonaws.com`. You might use this option if your architecture isolates Availability Zones. For example, you could use it for fault containment or to reduce Regional data transfer costs.

Accessing DynamoDB Streams API operations from DynamoDB Streams interface endpoints

You can use the AWS CLI or AWS SDKs to access DynamoDB Streams API operations through DynamoDB Streams interface endpoints.

AWS CLI examples

To access DynamoDB Streams or API operations through DynamoDB Streams interface endpoints in AWS CLI commands, use the `--region` and `--endpoint-url` parameters.

Example: Create a VPC endpoint

```
aws ec2 create-vpc-endpoint \
--region us-east-1 \
--service-name com.amazonaws.us-east-1.dynamodb-streams \
--vpc-id client-vpc-id \
--subnet-ids client-subnet-id \
--vpc-endpoint-type Interface \
--security-group-ids client-sg-id
```

Example: Modify a VPC endpoint

```
aws ec2 modify-vpc-endpoint \
--region us-east-1 \
--vpc-endpoint-id client-vpc-endpoint-id \
--policy-document policy-document \ #example optional parameter
--add-security-group-ids security-group-ids \ #example optional parameter
# any additional parameters needed, see Privatelink documentation for more details
```

Example: List streams using an endpoint URL

In the following example, replace the Region `us-east-1` and the DNS name of the VPC endpoint ID `vpce-1a2b3c4d-5e6f.streams.dynamodb.us-east-1.vpce.amazonaws.com` with your own information.

```
aws dynamodbstreams --region us-east-1 –endpoint https://
vpce-1a2b3c4d-5e6f.streams.dynamodb.us-east-1.vpce.amazonaws.com list-streams
```

AWS SDK examples

To access Amazon DynamoDB Streams API operations through DynamoDB Streams interface endpoints when using the AWS SDKs, update your SDKs to the latest version. Then, configure your clients to use an endpoint URL for DynamoDB Streams API operation through DynamoDB Streams interface endpoints.

SDK for Python (Boto3)

Example: Use an endpoint URL to access a DynamoDB stream

In the following example, replace the Region `us-east-1` and VPC endpoint ID `https://vpce-1a2b3c4d-5e6f.streams.dynamodb.us-east-1.vpce.amazonaws.com` with your own information.

```
ddb_streams_client = session.client(
service_name='dynamodbstreams',
region_name='us-east-1',
endpoint_url='https://vpce-1a2b3c4d-5e6f.streams.dynamodb.us-
east-1.vpce.amazonaws.com'
)
```

SDK for Java 1.x

Example: Use an endpoint URL to access a DynamoDB stream

In the following example, replace the Region `us-east-1` and VPC endpoint ID `https://vpce-1a2b3c4d-5e6f.streams.dynamodb.us-east-1.vpce.amazonaws.com` with your own information.

```
//client build with endpoint config
final AmazonDynamoDBStreams dynamodbstreams =
 AmazonDynamoDBStreamsClientBuilder.standard().withEndpointConfiguration(
        new AwsClientBuilder.EndpointConfiguration(
                "https://vpce-1a2b3c4d-5e6f.streams.dynamodb.us-
east-1.vpce.amazonaws.com",
                Regions.DEFAULT_REGION.getName()
        )
).build();
```

SDK for Java 2.x

Example: Use an endpoint URL to access DynamoDB stream

In the following example, replace the Region `us-east-1` and VPC endpoint ID `https://vpce-1a2b3c4d-5e6f.streams.dynamodb.us-east-1.vpce.amazonaws.com` with your own information.

```
Region region = Region.US_EAST_1;
dynamoDbStreamsClient = DynamoDbStreamsClient.builder().region(region)
.endpointOverride(URI.create("https://vpce-1a2b3c4d-5e6f.streams.dynamodb.us-
east-1.vpce.amazonaws.com"))
.build()
```

Creating an Amazon VPC endpoint policy for DynamoDB Streams

You can attach an endpoint policy to your Amazon VPC endpoint that controls access to DynamoDB Streams. The policy specifies the following information:

- The AWS Identity and Access Management (IAM) principal that can perform actions
- The actions that can be performed
- The resources on which actions can be performed

Topics

- Example: Restricting access to a specific stream from an Amazon VPC endpoint

Example: Restricting access to a specific stream from an Amazon VPC endpoint

You can create an endpoint policy that restricts access to only specific DynamoDB Streams. This type of policy is useful if you have other AWS services in your Amazon VPC that use DynamoDB Streams. The following stream policy restricts access to only the stream *2025-02-20T11:22:33.444* attached to *DOC-EXAMPLE-TABLE*. To use this endpoint policy, replace *DOC-EXAMPLE-TABLE* with the name of your table and *2025-02-20T11:22:33.444* with the stream label.

```
{
"Version": "2012-10-17",
  "Id": "Policy1216114807515",
  "Statement": [
    { "Sid": "Access-to-specific-stream-only",
      "Principal": "*",
      "Action": [
        "dynamodb:DescribeStream",
        "dynamodb:GetRecords"
      ],
      "Effect": "Allow",
      "Resource": ["arn:aws:dynamodb:::DOC-EXAMPLE-TABLE/
stream/2025-02-20T11:22:33.444"]
    }
  ]
}
```

> **Note**
>
> Gateway endpoints aren't supported in DynamoDB Streams.

Configuration and vulnerability analysis in Amazon DynamoDB

AWS handles basic security tasks like guest operating system (OS) and database patching, firewall configuration, and disaster recovery. These procedures have been reviewed and certified by the appropriate third parties. For more details, see the following resources:

- Compliance validation for Amazon DynamoDB
- Shared responsibility model
- Amazon Web Services: Overview of security processes(whitepaper)

The following security best practices also address configuration and vulnerability analysis in Amazon DynamoDB:

- Monitor DynamoDB compliance with AWS Config Rules
- Monitor DynamoDB configuration with AWS Config

Security best practices for Amazon DynamoDB

Amazon DynamoDB provides a number of security features to consider as you develop and implement your own security policies. The following best practices are general guidelines and don't represent a complete security solution. Because these best practices might not be appropriate or sufficient for your environment, treat them as helpful considerations rather than prescriptions.

Topics

- DynamoDB preventative security best practices
- DynamoDB detective security best practices

DynamoDB preventative security best practices

The following best practices can help you anticipate and prevent security incidents in Amazon DynamoDB.

Encryption at rest

DynamoDB encrypts at rest all user data stored in tables, indexes, streams, and backups using encryption keys stored in AWS Key Management Service (AWS KMS). This provides an additional layer of data protection by securing your data from unauthorized access to the underlying storage .

You can specify whether DynamoDB should use an AWS owned key (default encryption type), an AWS managed key, or a customer managed key to encrypt user data. For more information, see Amazon DynamoDB Encryption at Rest.

Use IAM roles to authenticate access to DynamoDB

For users, applications, and other AWS services to access DynamoDB, they must include valid AWS credentials in their AWS API requests. You should not store AWS credentials directly in the application or EC2 instance. These are long-term credentials that are not automatically rotated, and therefore could have significant business impact if they are compromised. An IAM role enables you to obtain temporary access keys that can be used to access AWS services and resources.

For more information, see Identity and Access Management for Amazon DynamoDB.

Use IAM policies for DynamoDB base authorization

When granting permissions, you decide who is getting them, which DynamoDB APIs they are getting permissions for, and the specific actions you want to allow on those resources. Implementing least privilege is key in reducing security risk and the impact that can result from errors or malicious intent.

Attach permissions policies to IAM identities (that is, users, groups, and roles) and thereby grant permissions to perform operations on DynamoDB resources.

You can do this by using the following:

- AWS Managed (predefined) policies
- Customer managed policies

Use IAM policy conditions for fine-grained access control

When you grant permissions in DynamoDB, you can specify conditions that determine how a permissions policy takes effect. Implementing least privilege is key in reducing security risk and the impact that can result from errors or malicious intent.

You can specify conditions when granting permissions using an IAM policy. For example, you can do the following:

- Grant permissions to allow users read-only access to certain items and attributes in a table or a secondary index.
- Grant permissions to allow users write-only access to certain attributes in a table, based upon the identity of that user.

For more information, see Using IAM Policy Conditions for Fine-Grained Access Control.

Use a VPC endpoint and policies to access DynamoDB

If you only require access to DynamoDB from within a virtual private cloud (VPC), you should use a VPC endpoint to limit access from only the required VPC. Doing this prevents that traffic from traversing the open internet and being subject to that environment.

Using a VPC endpoint for DynamoDB allows you to control and limit access using the following:

- VPC endpoint policies – These policies are applied on the DynamoDB VPC endpoint. They allow you to control and limit API access to the DynamoDB table.
- IAM policies – By using the `aws:sourceVpce` condition on policies attached to users, groups, or roles, you can enforce that all access to the DynamoDB table is via the specified VPC endpoint.

For more information, see Endpoints for Amazon DynamoDB.

Consider client-side encryption

We recommend that you plan your encryption strategy before implementing your table in DynamoDB. If you store sensitive or confidential data in DynamoDB, consider including client-side encryption in your plan. This way you can encrypt data as close as possible to its origin, and ensure its protection throughout its lifecycle. Encrypting your sensitive data in transit and at rest helps ensure that your plaintext data isn't available to any third party.

The AWS Database Encryption SDK for DynamoDB is a software library that helps you protect your table data before you send it to DynamoDB. It encrypts, signs, verifies, and decrypts your DynamoDB table items. You control which attributes are encrypted and signed.

Primary Key considerations

Do not use sensitive names or sensitive plaintext data in your Primary Key for your table and Global Secondary Indexes. Key names will show up in your table definition. For example, the

Primary Key names are accessible to anyone with permissions to call DescribeTable. Key values can show up in your AWS CloudTrail and other logs. Additionally, DynamoDB uses the key values to distribute data and route requests and AWS administrators may observe the values to maintain the health of the service.

If you need to use sensitive data in your table or GSI key values, we recommend using end-to-end client encryption. This allows you to perform key-value references to your data while ensuring that it never appears unencrypted in your DynamoDB related logs. One way to accomplish this is to use the AWS Database Encryption SDK for DynamoDB, but that is not required. If you use your own solution, we should always use a sufficiently secure encryption algorithm. You should not use a non-cryptographic option like a hash, as they are not considered sufficiently secure in most situations.

If your Primary Key key names are sensitive, we recommend using `pk` and `sk` instead. This is a general best practice which leaves your Partition Key design flexible.

Always consult your security experts or AWS account team if you are concerned about what the right choice would be.

DynamoDB detective security best practices

The following best practices for Amazon DynamoDB can help you detect potential security weaknesses and incidents.

Use AWS CloudTrail to monitor AWS managed KMS key usage

If you are using an AWS managed key for encryption at rest, usage of this key is logged into AWS CloudTrail. CloudTrail provides visibility into user activity by recording actions taken on your account. CloudTrail records important information about each action, including who made the request, the services used, the actions performed, parameters for the actions, and the response elements returned by the AWS service. This information helps you track changes made to your AWS resources and troubleshoot operational issues. CloudTrail makes it easier to ensure compliance with internal policies and regulatory standards.

You can use CloudTrail to audit key usage. CloudTrail creates log files that contain a history of AWS API calls and related events for your account. These log files include all AWS KMS API requests made using the AWS Management Console, AWS SDKs, and command line tools, in addition to those made through integrated AWS services. You can use these log files to get information about when the KMS key was used, the operation that was requested, the identity

of the requester, the IP address that the request came from, and so on. For more information, see Logging AWS KMS API Calls with AWS CloudTrail and the AWS CloudTrail User Guide.

Monitor DynamoDB operations using CloudTrail

CloudTrail can monitor both control plane events and data plane events. Control plane operations let you create and manage DynamoDB tables. They also let you work with indexes, streams, and other objects that are dependent on tables. Data plane operations let you perform create, read, update, and delete (also called *CRUD*) actions on data in a table. Some data plane operations also let you read data from a secondary index. To enable logging of data plane events in CloudTrail, you'll need to enable logging of data plane API activity in CloudTrail. See Logging data events for trails for more information.

When activity occurs in DynamoDB, that activity is recorded in a CloudTrail event along with other AWS service events in the event history. For more information, see Logging DynamoDB Operations by Using AWS CloudTrail. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History in the *AWS CloudTrail User Guide*.

For an ongoing record of events in your AWS account, including events for DynamoDB, create a trail. A trail enables CloudTrail to deliver log files to an Amazon Simple Storage Service (Amazon S3) bucket. By default, when you create a trail on the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs.

Use DynamoDB Streams to monitor data plane operations

DynamoDB is integrated with AWS Lambda so that you can create triggers—pieces of code that automatically respond to events in DynamoDB Streams. With triggers, you can build applications that react to data modifications in DynamoDB tables.

If you enable DynamoDB Streams on a table, you can associate the stream Amazon Resource Name (ARN) with a Lambda function that you write. Immediately after an item in the table is modified, a new record appears in the table's stream. AWS Lambda polls the stream and invokes your Lambda function synchronously when it detects new stream records. The Lambda function can perform any actions that you specify, such as sending a notification or initiating a workflow.

For an example, see Tutorial: Using AWS Lambda with Amazon DynamoDB Streams. This example receives a DynamoDB event input, processes the messages that it contains, and writes some of the incoming event data to Amazon CloudWatch Logs.

Monitor DynamoDB configuration with AWS Config

Using AWS Config, you can continuously monitor and record configuration changes of your AWS resources. You can also use AWS Config to inventory your AWS resources. When a change from a previous state is detected, an Amazon Simple Notification Service (Amazon SNS) notification can be delivered for you to review and take action. Follow the guidance in Setting Up AWS Config with the Console, ensuring that DynamoDB resource types are included.

You can configure AWS Config to stream configuration changes and notifications to an Amazon SNS topic. For example, when a resource is updated, you can get a notification sent to your email, so that you can view the changes. You can also be notified when AWS Config evaluates your custom or managed rules against your resources.

For an example, see Notifications that AWS Config Sends to an Amazon SNS topic in the *AWS Config Developer Guide*.

Monitor DynamoDB compliance with AWS Config rules

AWS Config continuously tracks the configuration changes that occur among your resources. It checks whether these changes violate any of the conditions in your rules. If a resource violates a rule, AWS Config flags the resource and the rule as noncompliant.

By using AWS Config to evaluate your resource configurations, you can assess how well your resource configurations comply with internal practices, industry guidelines, and regulations. AWS Config provides AWS managed rules, which are predefined, customizable rules that AWS Config uses to evaluate whether your AWS resources comply with common best practices.

Tag your DynamoDB resources for identification and automation

You can assign metadata to your AWS resources in the form of tags. Each tag is a simple label consisting of a customer-defined key and an optional value that can make it easier to manage, search for, and filter resources.

Tagging allows for grouped controls to be implemented. Although there are no inherent types of tags, they enable you to categorize resources by purpose, owner, environment, or other criteria. The following are some examples:

- Security – Used to determine requirements such as encryption.
- Confidentiality – An identifier for the specific data-confidentiality level a resource supports.
- Environment – Used to distinguish between development, test, and production infrastructure.

For more information, see AWS Tagging Strategies and Tagging for DynamoDB.

Monitor your usage of Amazon DynamoDB as it relates to security best practices by using AWS Security Hub.

Security Hub uses security controls to evaluate resource configurations and security standards to help you comply with various compliance frameworks.

For more information about using Security Hub to evaluate DynamoDB resources, see Amazon DynamoDB controls in the *AWS Security Hub User Guide*.

Monitoring and logging in DynamoDB

Monitoring is an important part of maintaining the reliability, availability, and performance of DynamoDB and your AWS solutions. You should collect monitoring data from all parts of your AWS solutions so you can easily debug a multi-point failure.

Topics

- Monitoring plan
- Performance baseline
- Integrated services
- Automated monitoring tools
- Monitoring metrics in DynamoDB with Amazon CloudWatch
- Logging DynamoDB operations by using AWS CloudTrail
- Analyzing data access using CloudWatch contributor insights for DynamoDB

Monitoring plan

Before you start monitoring DynamoDB, create a monitoring plan that includes answers to the following questions:

- What are your monitoring goals?
- What resources will you monitor?
- How often will you monitor these resources?
- What monitoring tools will you use?
- Who will perform the monitoring tasks?
- Who should be notified when something goes wrong?

Performance baseline

Establish a baseline for normal DynamoDB performance in your environment, by measuring performance at various times and under different load conditions. As you monitor DynamoDB, you should consider storing historical monitoring data. This stored data will give you a baseline from which to compare current performance data, identify normal performance patterns and

performance anomalies, and devise methods to address issues. To establish a baseline you should, at a minimum, monitor the following items:

- The number of read or write capacity units consumed over the specified time period, so you can track how much of your provisioned throughput is used.
- Requests that exceeded a table's provisioned write or read capacity during the specified time period, so you can determine which requests exceed the provisioned throughput quotas of a table.
- System errors, so you can determine if any requests resulted in an error.

Integrated services

DynamoDB automatically monitors your tables on your behalf and reports metrics through Amazon CloudWatch. Additionally, DynamoDB integrates with the following AWS services to help you monitor and troubleshoot your DynamoDB resources.

- AWS CloudTrail captures API calls and related events made by or on behalf of your AWS account and delivers the log files to an Amazon S3 bucket that you specify. For more information, see Logging DynamoDB operations by using AWS CloudTrail.
- Contributor Insights is a diagnostic tool for identifying the most frequently accessed and throttled keys in your table or index at a glance. For more information, see Analyzing data access using CloudWatch contributor insights for DynamoDB.

Automated monitoring tools

AWS provides various tools that you can use to monitor DynamoDB. We recommend that you automate monitoring tasks as much as possible. You can use the following automated monitoring tools to watch DynamoDB and report when something is wrong:

- **Amazon CloudWatch alarms** – Watch a single metric over a time period that you specify, and perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods.

  The action is a notification sent to an Amazon Simple Notification Service (Amazon SNS) topic or Amazon EC2 Auto Scaling policy. Amazon CloudWatch alarms do not invoke actions simply because they are in a particular state; the state must have changed and been maintained for a

specified number of periods. For more information, see Monitoring metrics in DynamoDB with Amazon CloudWatch.

- **AWS CloudTrail log monitoring** – Share log files between accounts, monitor AWS CloudTrail log files in real time by sending them to AWS CloudTrail Logs, write log processing applications in Java, and validate that your log files haven't changed after delivery by AWS CloudTrail. For more information, see What is Amazon CloudWatch Logs in the *AWS CloudTrail User Guide*.

Monitoring metrics in DynamoDB with Amazon CloudWatch

You can monitor DynamoDB using CloudWatch, which collects and processes raw data from DynamoDB into readable, near real-time metrics. These statistics are retained for a period of time, so you can access historical information for a better perspective on how your web application or service is performing. By default, DynamoDB metric data is sent to CloudWatch automatically. For more information, see What is Amazon CloudWatch? and Metrics retention in the *Amazon CloudWatch User Guide*.

Topics

- How do I use DynamoDB metrics?
- Viewing metrics in the CloudWatch console
- Viewing metrics in the AWS CLI
- DynamoDB Metrics and dimensions
- Creating CloudWatch alarms in DynamoDB

How do I use DynamoDB metrics?

The metrics reported by DynamoDB provide information that you can analyze in different ways. The following list shows some common uses for the metrics. These are suggestions to get you started, not a comprehensive list.

How do I use DynamoDB metrics?

How can I?	Relevant metrics
How can I monitor the rate of TTL deletions on my table?	You can monitor `TimeToLiveDeletedItemCount` over the specified time period, to track the rate of TTL deletions on your table. For an example of a server-less application using the

How can I?	Relevant metrics
	`TimeToLiveDeletedItemCount` metric, see Automatically archive items to S3 using DynamoDB time to live (TTL) with AWS Lambda and Amazon Data Firehose.
How can I determine how much of my provisioned throughput is being used?	You can monitor `ConsumedReadCapacityUnits` or `ConsumedWriteCapacityUnits` over the specified time period, to track how much of your provisioned throughput is being used.
How can I determine which requests exceed the provisioned throughput quotas of a table?	`ThrottledRequests` is incremented by one if any event within a request exceeds a provisioned throughput quota. Then, to gain insight into which event is throttling a request, compare `ThrottledRequests` with the `ReadThrottleEvents` and `WriteThrottleEvents` metrics for the table and its indexes.
How can I determine if any system errors occurred?	You can monitor `SystemErrors` to determine if any requests resulted in an HTTP 500 (server error) code. Typically, this metric should be equal to zero. If it isn't, then you might want to investigate.
How can I monitor the latency value for my table operations?	You can monitor `SuccessfulRequestLatency` by tracking the average latency and median latency through percentile metrics (p50). Occasional spikes in latency aren't a cause for concern. However, if average latency or p50 (median) is high, there could be an underlying issue that you must resolve. See Troubleshooting latency issues in Amazon DynamoDB for more information.

Viewing metrics in the CloudWatch console

Metrics are grouped by the service namespace first and then by the various dimension combinations within each namespace.

To view metrics in the CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Metrics, All metrics**.
3. Select the **DynamoDB** namespace. You can also select **Usage** namespace to view DynamoDB usage metrics. For more information about usage metrics, see AWS usage metrics.
4. The **Browse** tab displays all metrics in the namespace.
5. (Optional) To add the metric graph to a CloudWatch dashboard, choose **Actions, Add to dashboard**.

Viewing metrics in the AWS CLI

To obtain metric information using the AWS CLI, use the CloudWatch command `list-metrics`. In the following example, you list all metrics in the `AWS/DynamoDB` namespace.

```
aws cloudwatch list-metrics --namespace "AWS/DynamoDB"
```

To obtain metric statistics, use the command `get-metric-statistics`. The following command gets `ConsumedReadCapacityUnits` statistics for the table `ProductCatalog` over the specific 24-hour period, with a 5-minute granularity.

```
aws cloudwatch get-metric-statistics –namespace AWS/DynamoDB \
     –metric-name ConsumedReadCapacityUnits \
     –start-time 2023-11-01T00:00:00Z \
     –end-time 2023-11-02T00:00:00Z \
     –period 360 \
     –statistics Average \
     –dimensions Name=TableName,Value=ProductCatalog
```

Sample output appears as follows:

```
{
    "Datapoints": [
        {
            "Timestamp": "2023-11-01T 09:18:00+00:00",
```

```
            "Average": 20,
            "Unit": "Count"
        },
        {
            "Timestamp": "2023-11-01T 04:36:00+00:00",
            "Average": 22.5,
            "Unit": "Count"
        },
        {
            "Timestamp": "2023-11-01T 15:12:00+00:00",
            "Average": 20,
            "Unit": "Count"
        }, ...
        {
            "Timestamp": "2023-11-01T 17:30:00+00:00",
            "Average": 25,
            "Unit": "Count"
        }
    ],
    "Label": " ConsumedReadCapacityUnits "
}
```

DynamoDB Metrics and dimensions

When you interact with DynamoDB, it sends metrics and dimensions to CloudWatch.

DynamoDB outputs consumed provisioned throughput for one-minute periods. Auto scaling triggers when your consumed capacity breaches the configured target utilization for two consecutive minutes. CloudWatch alarms might have a short delay of up to a few minutes before triggering auto scaling. This delay ensures accurate CloudWatch metric evaluation. If the consumed throughput spikes are more than a minute apart, auto scaling might not trigger. Similarly, a scale down event can occur when 15 consecutive data points are lower than the target utilization. In either case, after auto scaling triggers, the UpdateTable API is invoked. It then takes several minutes to update the provisioned capacity for the table or index. During this period, any requests that exceed the previous provisioned capacity of the tables are throttled.

Viewing metrics and dimensions

CloudWatch displays the following metrics for DynamoDB:

DynamoDB metrics

> **Note**
>
> Amazon CloudWatch aggregates these metrics at one-minute intervals:
>
> - `ConditionalCheckFailedRequests`
> - `ConsumedReadCapacityUnits`
> - `ConsumedWriteCapacityUnits`
> - `ReadThrottleEvents`
> - `ReturnedBytes`
> - `ReturnedItemCount`
> - `ReturnedRecordsCount`
> - `SuccessfulRequestLatency`
> - `SystemErrors`
> - `TimeToLiveDeletedItemCount`
> - `ThrottledRequests`
> - `TransactionConflict`
> - `UserErrors`
> - `WriteThrottleEvents`
>
> For all other DynamoDB metrics, the aggregation granularity is five minutes.

Not all statistics, such as *Average* or *Sum*, are applicable for every metric. However, all of these values are available through the Amazon DynamoDB console, or by using the CloudWatch console, AWS CLI, or AWS SDKs for all metrics.

In the following list, each metric has a set of valid statistics that are applicable to that metric.

List of Available Metrics

- AccountMaxReads
- AccountMaxTableLevelReads
- AccountMaxTableLevelWrites

- AccountMaxWrites
- AccountProvisionedReadCapacityUtilization
- AccountProvisionedWriteCapacityUtilization
- AgeOfOldestUnreplicatedRecord
- ConditionalCheckFailedRequests
- ConsumedChangeDataCaptureUnits
- ConsumedReadCapacityUnits
- ConsumedWriteCapacityUnits
- FailedToReplicateRecordCount
- MaxProvisionedTableReadCapacityUtilization
- MaxProvisionedTableWriteCapacityUtilization
- OnDemandMaxReadRequestUnits
- OnDemandMaxWriteRequestUnits
- OnlineIndexConsumedWriteCapacity
- OnlineIndexPercentageProgress
- OnlineIndexThrottleEvents
- PendingReplicationCount
- ProvisionedReadCapacityUnits
- ProvisionedWriteCapacityUnits
- ReadThrottleEvents
- ReplicationLatency
- ReturnedBytes
- ReturnedItemCount
- ReturnedRecordsCount
- SuccessfulRequestLatency
- SystemErrors
- TimeToLiveDeletedItemCount
- ThrottledPutRecordCount

- ThrottledRequests
- TransactionConflict
- UserErrors
- WriteThrottleEvents

AccountMaxReads

The maximum number of read capacity units that can be used by an account. This limit doesn't apply to on-demand tables or global secondary indexes.

Units: `Count`

Valid Statistics:

- `Maximum` – The maximum number of read capacity units that can be used by an account.

AccountMaxTableLevelReads

The maximum number of read capacity units that can be used by a table or global secondary index of an account. For on-demand tables, this limit caps the maximum read request units a table or a global secondary index can use.

Units: `Count`

Valid Statistics:

- `Maximum` – The maximum number of read capacity units that can be used by a table or global secondary index of the account.

AccountMaxTableLevelWrites

The maximum number of write capacity units that can be used by a table or global secondary index of an account. For on-demand tables, this limit caps the maximum write request units a table or a global secondary index can use.

Units: `Count`

Valid Statistics:

- `Maximum` – The maximum number of write capacity units that can be used by a table or global secondary index of the account.

AccountMaxWrites

The maximum number of write capacity units that can be used by an account. This limit doesn't apply to on-demand tables or global secondary indexes.

Units: `Count`

Valid Statistics:

- `Maximum` – The maximum number of write capacity units that can be used by an account.

AccountProvisionedReadCapacityUtilization

The percentage of provisioned read capacity units utilized by an account.

Units: `Percent`

Valid Statistics:

- `Maximum` – The maximum percentage of provisioned read capacity units utilized by the account.
- `Minimum` – The minimum percentage of provisioned read capacity units utilized by the account.
- `Average` – The average percentage of provisioned read capacity units utilized by the account. The metric is published for five-minute intervals. Therefore, if you rapidly adjust the provisioned read capacity units, this statistic might not reflect the true average.

AccountProvisionedWriteCapacityUtilization

The percentage of provisioned write capacity units utilized by an account.

Units: `Percent`

Valid Statistics:

- `Maximum` – The maximum percentage of provisioned write capacity units utilized by the account.
- `Minimum` – The minimum percentage of provisioned write capacity units utilized by the account.

- `Average` – The average percentage of provisioned write capacity units utilized by the account. The metric is published for five-minute intervals. Therefore, if you rapidly adjust the provisioned write capacity units, this statistic might not reflect the true average.

AgeOfOldestUnreplicatedRecord

The elapsed time since a record yet to be replicated to the Kinesis data stream first appeared in the DynamoDB table.

Units: `Milliseconds`

Dimensions: `TableName, DelegatedOperation`

Valid Statistics:

- `Maximum`.
- `Minimum`.
- `Average`.

ConditionalCheckFailedRequests

The number of failed attempts to perform conditional writes. The `PutItem`, `UpdateItem`, and `DeleteItem` operations let you provide a logical condition that must evaluate to true before the operation can proceed. If this condition evaluates to false, `ConditionalCheckFailedRequests` is incremented by one. `ConditionalCheckFailedRequests` is also incremented by one for PartiQL Update and Delete statements where a logical condition is provided and that condition evaluates to false.

> **Note**
>
> A failed conditional write will result in an HTTP 400 error (Bad Request). These events are reflected in the `ConditionalCheckFailedRequests` metric, but not in the `UserErrors` metric.

Units: `Count`

Dimensions: `TableName`

Valid Statistics:

- `Minimum`
- `Maximum`
- `Average`
- `SampleCount`
- `Sum`

ConsumedChangeDataCaptureUnits

The number of consumed change data capture units.

Units: `Count`

Dimensions: `TableName, DelegatedOperation`

Valid Statistics:

- `Minimum`
- `Maximum`
- `Average`

ConsumedReadCapacityUnits

The number of read capacity units consumed over the specified time period for both provisioned and on-demand capacity, so you can track how much of your throughput is used. You can retrieve the total consumed read capacity for a table and all of its global secondary indexes, or for a particular global secondary index. For more information, see Read/Write Capacity Mode.

The `TableName` dimension returns the `ConsumedReadCapacityUnits` for the table, but not for any global secondary indexes. To view `ConsumedReadCapacityUnits` for a global secondary index, you must specify both `TableName` and `GlobalSecondaryIndexName`.

> **Note**
>
> This means that short, intense spikes in capacity consumption lasting just a second may not be accurately reflected in the CloudWatch graph, potentially leading to a lower apparent consumption rate for that minute.

Use the Sum statistic to calculate the consumed throughput. For example, get the Sum value over a span of one minute, and divide it by the number of seconds in a minute (60) to calculate the average ConsumedReadCapacityUnits per second. You can compare the calculated value to the provisioned throughput value that you provide DynamoDB.

Units: Count

Dimensions: TableName, GlobalSecondaryIndexName

Valid Statistics:

- Minimum – The minimum number of read capacity units consumed by any individual request to the table or index.
- Maximum – The maximum number of read capacity units consumed by any individual request to the table or index.
- Average – The average per-request read capacity consumed.

> **Note**
>
> The Average value is influenced by periods of inactivity where the sample value will be zero.

- Sum – The total read capacity units consumed. This is the most useful statistic for the ConsumedReadCapacityUnits metric.
- SampleCount – represents the frequency at which the metric is emitted. Even tables with zero traffic will have the SampleCount emitted regularly, but the sample values will always be zero.

> **Note**
>
> The SampleCount value is influenced by periods of inactivity where the sample value will be zero.

ConsumedWriteCapacityUnits

The number of write capacity units consumed over the specified time period for both provisioned and on-demand capacity, so you can track how much of your throughput is used. You can retrieve

the total consumed write capacity for a table and all of its global secondary indexes, or for a particular global secondary index. For more information, see Read/Write Capacity Mode.

The `TableName` dimension returns the `ConsumedWriteCapacityUnits` for the table, but not for any global secondary indexes. To view `ConsumedWriteCapacityUnits` for a global secondary index, you must specify both `TableName` and `GlobalSecondaryIndexName`.

> **Note**
>
> Use the `Sum` statistic to calculate the consumed throughput. For example, get the `Sum` value over a span of one minute, and divide it by the number of seconds in a minute (60) to calculate the average `ConsumedWriteCapacityUnits` per second (recognizing that this average doesn't highlight any large but brief spikes in write activity that occurred during that minute). You can compare the calculated value to the provisioned throughput value that you provide DynamoDB.

Units: `Count`

Dimensions: `TableName, GlobalSecondaryIndexName`

Valid Statistics:

- `Minimum` – The minimum number of write capacity units consumed by any individual request to the table or index.
- `Maximum` – The maximum number of write capacity units consumed by any individual request to the table or index.
- `Average` – The average per-request write capacity consumed.

  > **Note**
  >
  > The `Average` value is influenced by periods of inactivity where the sample value will be zero.

- `Sum` – The total write capacity units consumed. This is the most useful statistic for the `ConsumedWriteCapacityUnits` metric.
- `SampleCount` – represents the frequency at which the metric is emitted. Even tables with zero traffic will have the `SampleCount` emitted regularly, but the sample values will always be zero.

> **Note**
>
> The `SampleCount` value is influenced by periods of inactivity where the sample value will be zero.

FailedToReplicateRecordCount

The number of records that DynamoDB failed to replicate to your Kinesis data stream.

Units: `Count`

Dimensions: `TableName`, `DelegatedOperation`

Valid Statistics:

- Sum

MaxProvisionedTableReadCapacityUtilization

The percentage of provisioned read capacity utilized by the highest provisioned read table or global secondary index of an account.

Units: `Percent`

Valid Statistics:

- `Maximum` – The maximum percentage of provisioned read capacity units utilized by the highest provisioned read table or global secondary index of an account.
- `Minimum` – The minimum percentage of provisioned read capacity units utilized by the highest provisioned read table or global secondary index of an account.
- `Average` – The average percentage of provisioned read capacity units utilized by the highest provisioned read table or global secondary index of the account. The metric is published for five-minute intervals. Therefore, if you rapidly adjust the provisioned read capacity units, this statistic might not reflect the true average.

MaxProvisionedTableWriteCapacityUtilization

The percentage of provisioned write capacity utilized by the highest provisioned write table or global secondary index of an account.

Units: `Percent`

Valid Statistics:

- `Maximum` – The maximum percentage of provisioned write capacity units utilized by the highest provisioned write table or global secondary index of an account.
- `Minimum` – The minimum percentage of provisioned write capacity units utilized by the highest provisioned write table or global secondary index of an account.
- `Average` – The average percentage of provisioned write capacity units utilized by the highest provisioned write table or global secondary index of the account. The metric is published for five-minute intervals. Therefore, if you rapidly adjust the provisioned write capacity units, this statistic might not reflect the true average.

OnDemandMaxReadRequestUnits

The number of specified on-demand read request units for a table or a global secondary index.

To view `OnDemandMaxReadRequestUnits` for a table, you must specify `TableName`. To view `OnDemandMaxReadRequestUnits` for a global secondary index, you must specify both `TableName` and `GlobalSecondaryIndexName`.

Units: Count

Dimensions: `TableName`, `GlobalSecondaryIndexName`

Valid Statistics:

- `Minimum` – The lowest setting for on-demand read request units. If you use `UpdateTable` to increase read request units, this metric shows the lowest value of on-demand `ReadRequestUnits` during this time period.
- `Maximum` – The highest setting for on-demand read request units. If you use `UpdateTable` to decrease read request units, this metric shows the highest value of on-demand `ReadRequestUnits` during this time period.

- `Average` – The average on-demand read request units. The `OnDemandMaxReadRequestUnits` metric is published at five-minute intervals. Therefore, if you rapidly adjust the on-demand read request units, this statistic might not reflect the true average.

OnDemandMaxWriteRequestUnits

The number of specified on-demand write request units for a table or a global secondary index.

To view `OnDemandMaxWriteRequestUnits` for a table, you must specify `TableName`. To view `OnDemandMaxWriteRequestUnits` for a global secondary index, you must specify both `TableName` and `GlobalSecondaryIndexName`.

Units: `Count`

Dimensions: `TableName`, `GlobalSecondaryIndexName`

Valid Statistics:

- `Minimum` – The lowest setting for on-demand write request units. If you use `UpdateTable` to increase write request units, this metric shows the lowest value of on-demand `WriteRequestUnits` during this time period.
- `Maximum` – The highest setting for on-demand write request units. If you use `UpdateTable` to decrease write request units, this metric shows the highest value of on-demand `WriteRequestUnits` during this time period.
- `Average` – The average on-demand write request units. The `OnDemandMaxWriteRequestUnits` metric is published at five-minute intervals. Therefore, if you rapidly adjust the on-demand write request units, this statistic might not reflect the true average.

OnlineIndexConsumedWriteCapacity

The number of write capacity units consumed when adding a new global secondary index to a table. If the write capacity of the index is too low, incoming write activity during the backfill phase might be throttled. This can increase the time it takes to create the index. You should monitor this statistic while the index is being built to determine whether the write capacity of the index is underprovisioned.

You can adjust the write capacity of the index using the `UpdateTable` operation, even while the index is still being built.

The `ConsumedWriteCapacityUnits` metric for the index doesn't include the write throughput consumed during index creation.

> **Note**
>
> This metric may not be emitted if the new global secondary index's backfill phase completes quickly (less than a few minutes), which may occur if the base table has few or no items to backfill in the index.

Units: `Count`

Dimensions: `TableName, GlobalSecondaryIndexName`

Valid Statistics:

- `Minimum`
- `Maximum`
- `Average`
- `SampleCount`
- `Sum`

OnlineIndexPercentageProgress

The percentage of completion when a new global secondary index is being added to a table. DynamoDB must first allocate resources for the new index, and then backfill attributes from the table into the index. For large tables, this process might take a long time. You should monitor this statistic to view the relative progress as DynamoDB builds the index.

Units: `Count`

Dimensions: `TableName, GlobalSecondaryIndexName`

Valid Statistics:

- `Minimum`
- `Maximum`
- `Average`

- SampleCount
- Sum

OnlineIndexThrottleEvents

The number of write throttle events that occur when adding a new global secondary index to a table. These events indicate that the index creation will take longer to complete, because incoming write activity is exceeding the provisioned write throughput of the index.

You can adjust the write capacity of the index using the UpdateTable operation, even while the index is still being built.

The WriteThrottleEvents metric for the index doesn't include any throttle events that occur during index creation.

Units: Count

Dimensions: TableName, GlobalSecondaryIndexName

Valid Statistics:

- Minimum
- Maximum
- Average
- SampleCount
- Sum

PendingReplicationCount

Metric for Global tables version 2017.11.29 (Legacy) (global tables only). The number of item updates that are written to one replica table, but that have not yet been written to another replica in the global table.

Units: Count

Dimensions: TableName, ReceivingRegion

Valid Statistics:

- Average

- Sample Count
- Sum

ProvisionedReadCapacityUnits

The number of provisioned read capacity units for a table or a global secondary index. The TableName dimension returns the ProvisionedReadCapacityUnits for the table, but not for any global secondary indexes. To view ProvisionedReadCapacityUnits for a global secondary index, you must specify both TableName and GlobalSecondaryIndexName.

Units:Count

Dimensions: TableName, GlobalSecondaryIndexName

Valid Statistics:

- Minimum – The lowest setting for provisioned read capacity. If you use UpdateTable to increase read capacity, this metric shows the lowest value of provisioned ReadCapacityUnits during this time period.
- Maximum – The highest setting for provisioned read capacity. If you use UpdateTable to decrease read capacity, this metric shows the highest value of provisioned ReadCapacityUnits during this time period.
- Average – The average provisioned read capacity. The ProvisionedReadCapacityUnits metric is published at five-minute intervals. Therefore, if you rapidly adjust the provisioned read capacity units, this statistic might not reflect the true average.

ProvisionedWriteCapacityUnits

The number of provisioned write capacity units for a table or a global secondary index.

The TableName dimension returns the ProvisionedWriteCapacityUnits for the table, but not for any global secondary indexes. To view ProvisionedWriteCapacityUnits for a global secondary index, you must specify both TableName and GlobalSecondaryIndexName.

Units: Count

Dimensions: TableName, GlobalSecondaryIndexName

Valid Statistics:

- `Minimum` – The lowest setting for provisioned write capacity. If you use `UpdateTable` to increase write capacity, this metric shows the lowest value of provisioned `WriteCapacityUnits` during this time period.
- `Maximum` – The highest setting for provisioned write capacity. If you use `UpdateTable` to decrease write capacity, this metric shows the highest value of provisioned `WriteCapacityUnits` during this time period.
- `Average` – The average provisioned write capacity. The `ProvisionedWriteCapacityUnits` metric is published at five-minute intervals. Therefore, if you rapidly adjust the provisioned write capacity units, this statistic might not reflect the true average.

ReadThrottleEvents

Requests to DynamoDB that exceed the provisioned read capacity units for a table or a global secondary index.

A single request can result in multiple events. For example, a `BatchGetItem` that reads 10 items is processed as 10 `GetItem` events. For each event, `ReadThrottleEvents` is incremented by one if that event is throttled. The `ThrottledRequests` metric for the entire `BatchGetItem` is not incremented unless *all 10* of the `GetItem` events are throttled.

The `TableName` dimension returns the `ReadThrottleEvents` for the table, but not for any global secondary indexes. To view `ReadThrottleEvents` for a global secondary index, you must specify both `TableName` and `GlobalSecondaryIndexName`.

Units: `Count`

Dimensions: `TableName, GlobalSecondaryIndexName`

Valid Statistics:

- `SampleCount`
- `Sum`

ReplicationLatency

(This metric is for DynamoDB global tables.) The elapsed time between an updated item appearing in the DynamoDB stream for one replica table, and that item appearing in another replica in the global table.

Units: Milliseconds

Dimensions: TableName, ReceivingRegion

Valid Statistics:

- Average
- Minimum
- Maximum

ReturnedBytes

The number of bytes returned by GetRecords operations (Amazon DynamoDB Streams) during the specified time period.

Units: Bytes

Dimensions: Operation, StreamLabel, TableName

Valid Statistics:

- Minimum
- Maximum
- Average
- SampleCount
- Sum

ReturnedItemCount

The number of items returned by Query, Scan or ExecuteStatement (select) operations during the specified time period.

The number of items *returned* is not necessarily the same as the number of items that were evaluated. For example, suppose that you requested a Scan on a table or an index that had 100 items, but specified a FilterExpression that narrowed the results so that only 15 items were returned. In this case, the response from Scan would contain a ScanCount of 100 and a Count of 15 returned items.

Units: Count

Dimensions: TableName, Operation

Valid Statistics:

- Minimum
- Maximum
- Average
- SampleCount
- Sum

ReturnedRecordsCount

The number of stream records returned by GetRecords operations (Amazon DynamoDB Streams) during the specified time period.

Units: Count

Dimensions: Operation, StreamLabel, TableName

Valid Statistics:

- Minimum
- Maximum
- Average
- SampleCount
- Sum

SuccessfulRequestLatency

The latency of successful requests to DynamoDB or Amazon DynamoDB Streams during the specified time period. SuccessfulRequestLatency can provide two different kinds of information:

- The elapsed time for successful requests (Minimum, Maximum, Sum, Average, or Percentile).

- The number of successful requests (`SampleCount`).

`SuccessfulRequestLatency` reflects activity only within DynamoDB or Amazon DynamoDB Streams, and doesn't consider network latency or client-side activity.

> **Note**
>
> To analyze custom percentile values (such as p99.9), you can manually enter the desired percentile (e.g., p99.9) in the CloudWatch metric statistic field. This allows you to evaluate latency distributions beyond the default percentiles listed in the dropdown.

Units: `Milliseconds`

Dimensions: `TableName, Operation, StreamLabel`

Valid Statistics:

- `Minimum`
- `Maximum`
- `Sum`
- `Average`
- `Percentile`
- `SampleCount`

SystemErrors

The requests to DynamoDB or Amazon DynamoDB Streams that generate an HTTP 500 status code during the specified time period. An HTTP 500 usually indicates an internal service error.

Units: `Count`

Dimensions: `TableName, Operation`

Valid Statistics:

- Sum

- SampleCount

TimeToLiveDeletedItemCount

The number of items deleted by Time to Live (TTL) during the specified time period. This metric helps you monitor the rate of TTL deletions on your table.

Units: Count

Dimensions: TableName

Valid Statistics:

- Sum

ThrottledPutRecordCount

The number of records that were throttled by your Kinesis data stream due to insufficient Kinesis Data Streams capacity.

Units: Count

Dimensions: TableName, DelegatedOperation

Valid Statistics:

- Minimum
- Maximum
- Average
- SampleCount

ThrottledRequests

Requests to DynamoDB that exceed the provisioned throughput limits on a resource (such as a table or an index).

ThrottledRequests is incremented by one if any event within a request exceeds a provisioned throughput limit. For example, if you update an item in a table with global secondary indexes,

there are multiple events—a write to the table, and a write to each index. If one or more of these events are throttled, then `ThrottledRequests` is incremented by one.

> **Note**
>
> In a batch request (`BatchGetItem` or `BatchWriteItem`), `ThrottledRequests` is incremented only if *every* request in the batch is throttled.
> If any individual request within the batch is throttled, one of the following metrics is incremented:
>
> - `ReadThrottleEvents` – For a throttled `GetItem` event within `BatchGetItem`.
> - `WriteThrottleEvents` – For a throttled `PutItem` or `DeleteItem` event within `BatchWriteItem`.

To gain insight into which event is throttling a request, compare `ThrottledRequests` with the `ReadThrottleEvents` and `WriteThrottleEvents` for the table and its indexes.

> **Note**
>
> A throttled request will result in an HTTP 400 status code. All such events are reflected in the `ThrottledRequests` metric, but not in the `UserErrors` metric.

Units: `Count`

Dimensions: `TableName, Operation`

Valid Statistics:

- `Sum`
- `SampleCount`

TransactionConflict

Rejected item-level requests due to transactional conflicts between concurrent requests on the same items. For more information, see Transaction Conflict Handling in DynamoDB.

Units: `Count`

Dimensions: `TableName`

Valid Statistics:

- `Sum` – The number of rejected item-level requests due to transaction conflicts.

  > **Note**
  >
  > If multiple item-level requests within a call to `TransactWriteItems` or `TransactGetItems` were rejected, `Sum` is incremented by one for each item-level `Put`, `Update`, `Delete`, or `Get` request.

- `SampleCount` – The number of rejected requests due to transaction conflicts.

  > **Note**
  >
  > If multiple item-level requests within a call to `TransactWriteItems` or `TransactGetItems` are rejected, `SampleCount` is only incremented by one.

- `Min` – The minimum number of rejected item-level requests within a call to `TransactWriteItems`, `TransactGetItems`, `PutItem`, `UpdateItem`, or `DeleteItem`.
- `Max` – The maximum number of rejected item-level requests within a call to `TransactWriteItems`, `TransactGetItems`, `PutItem`, `UpdateItem`, or `DeleteItem`.
- `Average` – The average number of rejected item-level requests within a call to `TransactWriteItems`, `TransactGetItems`, `PutItem`, `UpdateItem`, or `DeleteItem`.

UserErrors

Requests to DynamoDB or Amazon DynamoDB Streams that generate an HTTP 400 status code during the specified time period. An HTTP 400 usually indicates a client-side error, such as an invalid combination of parameters, an attempt to update a nonexistent table, or an incorrect request signature.

Some examples of exceptions that will log metrics related to `UserErrors` would be:

- `ResourceNotFoundException`
- `ValidationException`
- `TransactionConflict`

All such events are reflected in the UserErrors metric, except for the following:

- *ProvisionedThroughputExceededException* – See the ThrottledRequests metric in this section.
- *ConditionalCheckFailedException* – See the ConditionalCheckFailedRequests metric in this section.

UserErrors represents the aggregate of HTTP 400 errors for DynamoDB or Amazon DynamoDB Streams requests for the current AWS Region and the current AWS account.

Units: Count

Valid Statistics:

- Sum
- SampleCount

WriteThrottleEvents

Requests to DynamoDB that exceed the provisioned write capacity units for a table or a global secondary index.

A single request can result in multiple events. For example, a PutItem request on a table with three global secondary indexes would result in four events—the table write, and each of the three index writes. For each event, the WriteThrottleEvents metric is incremented by one if that event is throttled. For single PutItem requests, if any of the events are throttled, ThrottledRequests is also incremented by one. For BatchWriteItem, the ThrottledRequests metric for the entire BatchWriteItem is not incremented unless all of the individual PutItem or DeleteItem events are throttled.

The TableName dimension returns the WriteThrottleEvents for the table, but not for any global secondary indexes. To view WriteThrottleEvents for a global secondary index, you must specify both TableName and GlobalSecondaryIndexName.

Units: Count

Dimensions: TableName, GlobalSecondaryIndexName

Valid Statistics:

- Sum

- `SampleCount`

Usage metrics

Usage metrics in CloudWatch allow you to proactively manage usage by visualizing metrics in the CloudWatch console, creating custom dashboards, detecting changes in activity with CloudWatch anomaly detection, and configuring alarms that alert you when usage approaches a threshold.

DynamoDB also integrates these usage metrics with Service Quotas. You can use CloudWatch to manage your account's use of your service quotas. For more information, see Visualizing your service quotas and setting alarms

List of Available Usage Metrics

- AccountProvisionedWriteCapacityUnits
- AccountProvisionedReadCapacityUnits
- TableCount

AccountProvisionedWriteCapacityUnits

The sum of write capacity units provisioned for all tables and global secondary indexes of an account.

Units: `Count`

Valid Statistics:

- `Minimum` – The lowest number of provisioned write capacity units during a time period.
- `Maximum` – The highest number of provisioned write capacity units during a time period.
- `Average` - The average number provisioned write capacity units account during a time period.

This metric is published at five-minute intervals. Therefore, if you rapidly adjust the provisioned write capacity units, this statistic might not reflect the true average.

AccountProvisionedReadCapacityUnits

The sum of read capacity units provisioned for all tables and global secondary indexes of an account.

Units: Count

Valid Statistics:

- Minimum – The lowest number of provisioned read capacity units during a time period.
- Maximum – The highest number of provisioned read capacity units during a time period.
- Average - The average number provisioned read capacity units account during a time period.

This metric is published at five-minute intervals. Therefore, if you rapidly adjust the provisioned read capacity units, this statistic might not reflect the true average.

TableCount

The number of active tables of an account.

Units: Count

Valid Statistics:

- Minimum – The lowest number of tables during a time period.
- Maximum – The highest number of tables during a time period.
- Average - The average number tables during a time period.

Understanding metrics and dimensions for DynamoDB

The metrics for DynamoDB are qualified by the values for the account, table name, global secondary index name, or operation. You can use the CloudWatch console to retrieve DynamoDB data along any of the dimensions in the table below.

List of Available Dimensions

- DelegatedOperation
- GlobalSecondaryIndexName
- Operation
- OperationType
- Verb
- ReceivingRegion
- StreamLabel

- TableName

DelegatedOperation

This dimension limits the data to operations DynamoDB performs on your behalf. The following operations are captured:

- Change data capture for Kinesis Data Streams.

GlobalSecondaryIndexName

This dimension limits the data to a global secondary index on a table. If you specify `GlobalSecondaryIndexName`, you must also specify `TableName`.

Operation

This dimension limits the data to one of the following DynamoDB operations:

- `PutItem`
- `DeleteItem`
- `UpdateItem`
- `GetItem`
- `BatchGetItem`
- `Scan`
- `Query`
- `BatchWriteItem`
- `TransactWriteItems`
- `TransactGetItems`
- `ExecuteTransaction`
- `BatchExecuteStatement`
- `ExecuteStatement`

In addition, you can limit the data to the following Amazon DynamoDB Streams operation:

- `GetRecords`

OperationType

This dimension limits the data to one of the following operation types:

- `Read`
- `Write`

This dimension is emitted for `ExecuteTransaction` and `BatchExecuteStatement` requests.

Verb

This dimension limits the data to one of the following DynamoDB PartiQL verbs:

- Insert: `PartiQLInsert`
- Select: `PartiQLSelect`
- Update: `PartiQLUpdate`
- Delete: `PartiQLDelete`

This dimension is emitted for the `ExecuteStatement` operation.

ReceivingRegion

This dimension limits the data to a particular AWS region. It is used with metrics originating from replica tables within a DynamoDB global table.

StreamLabel

This dimension limits the data to a specific stream label. It is used with metrics originating from Amazon DynamoDB Streams `GetRecords` operations.

TableName

This dimension limits the data to a specific table. This value can be any table name in the current region and the current AWS account.

Creating CloudWatch alarms in DynamoDB

A CloudWatch alarm watches a single metric over a specified time period, and performs one or more specified actions, based on the value of the metric relative to a threshold over time. The action is a notification sent to an Amazon SNS topic or Auto Scaling policy. You can also add alarms

to dashboards so you can monitor and receive alerts about your AWS resources and applications across multiple regions. There is no limit to the number of alarms you can create. CloudWatch alarms do not invoke actions simply because they are in a particular state; the state must have changed and been maintained for a specified number of periods. For a list of recommended DynamoDB alarms, see Recommended alarms.

> **Note**
>
> You must specify all the required dimensions when creating your CloudWatch alarm, since CloudWatch will not aggregate metrics for a missing dimension. Creating a CloudWatch alarm with a missing dimension will not result in an error, when creating the alarm.

Assume you have a provisioned table with five read capacity units. You want to be notified before you consume the entire provisioned read capacity, so you decide to create a CloudWatch alarm to get notified when the consumed capacity reaches 80% of what you have provisioned for the table. You can create alarms in the CloudWatch console or using the AWS CLI.

Creating an alarm in the CloudWatch console

To create an alarm in the CloudWatch console

1. Sign in to the AWS Management Console and open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All alarms**.
3. Choose **Create alarm**.
4. Find the row with the table that you want to monitor and **`ConsumeReadCapacityUnits`** in the **Metric Name** column. Select the check box next to this row and choose **Select metric**.
5. Under **Specify metric and conditions**, for **Statistic** choose **Sum**. Choose a **Period** of **1 minute**.
6. Under **Conditions**, specify the following:
   a. For **Threshold type**, choose **Static**.
   b. For **Whenever `ConsumedReadCapacityUnits` is**, choose **Greater/Equal** and specify the threshold as 240.
7. Choose **Next**.
8. Under **Notification**, choose **`In alarm`** and select an SNS topic to notify when the alarm is in ALARM state.

9. When finished, choose **Next**.
10. Enter a name and description for the alarm and choose **Next**.
11. Under **Preview and create**, confirm that the information and conditions are what you want, then choose **Create alarm**.

Creating an alarm in the AWS CLI

```
aws cloudwatch put-metric-alarm \
    -\-alarm-name ReadCapacityUnitsLimitAlarm \
    -\-alarm-description "Alarm when read capacity reaches 80% of my provisioned read
 capacity" \
    -\-namespace AWS/DynamoDB \
    -\-metric-name ConsumedReadCapacityUnits \
    -\-dimensions Name=TableName,Value=myTable \
    -\-statistic Sum \
    -\-threshold 240 \
    -\-comparison-operator GreaterThanOrEqualToThreshold \
    -\-period 60 \
    -\-evaluation-periods 1 \
    -\-alarm-actions arn:aws:sns:us-east-1:123456789012:capacity-alarm
```

Test the alarm.

```
aws cloudwatch set-alarm-state -\-alarm-name ReadCapacityUnitsLimitAlarm -\-state-
reason "initializing" -\-state-value OK
```

```
aws cloudwatch set-alarm-state -\-alarm-name ReadCapacityUnitsLimitAlarm -\-state-
reason "initializing" -\-state-value ALARM
```

More AWS CLI examples

The following procedure describes how you're notified if you have requests that exceed the provisioned througput quotas of a table.

1. Create an Amazon SNS topic `arn:aws:sns:us-east-1:123456789012:requests-exceeding-throughput`. For more information, see Set up Amazon Simple Notification Service.
2. Create the alarm.

```
aws cloudwatch put-metric-alarm \
        -\-alarm-name ReadCapacityUnitsLimitAlarm \
        -\-alarm-description "Alarm when read capacity reaches 80% of my
 provisioned read capacity" \
        -\-namespace AWS/DynamoDB \
        -\-metric-name ConsumedReadCapacityUnits \
        -\-dimensions Name=TableName,Value=myTable \
        -\-statistic Sum \
        -\-threshold 240 \
        -\-comparison-operator GreaterThanOrEqualToThreshold \
        -\-period 60 \
        -\-evaluation-periods 1 \
        -\-alarm-actions arn:aws:sns:us-east-1:123456789012:capacity-alarm
```

3. Test the alarm.

```
aws cloudwatch set-alarm-state --alarm-name RequestsExceedingThroughputAlarm --
state-reason "initializing" --state-value OK
```

```
aws cloudwatch set-alarm-state --alarm-name RequestsExceedingThroughputAlarm --
state-reason "initializing" --state-value ALARM
```

The following procedure describes how you're notified if you get system errors.

1. Create an Amazon SNS topic `arn:aws:sns:us-east-1:123456789012:notify-on-system-errors`. For more information, see Set up Amazon Simple Notification Service.
2. Create the alarm.

```
aws cloudwatch put-metric-alarm \
    --alarm-name SystemErrorsAlarm \
    --alarm-description "Alarm when system errors occur" \
    --namespace AWS/DynamoDB \
    --metric-name SystemErrors \
    --dimensions Name=TableName,Value=myTable
 Name=Operation,Value=aDynamoDBOperation \
    --statistic Sum \
    --threshold 0 \
    --comparison-operator GreaterThanThreshold \
    --period 60 \
```

```
    --unit Count \
    --evaluation-periods 1 \
    --treat-missing-data breaching \
    --alarm-actions arn:aws:sns:us-east-1:123456789012:notify-on-system-errors
```

3. Test the alarm.

```
aws cloudwatch set-alarm-state --alarm-name SystemErrorsAlarm --state-reason
 "initializing" --state-value OK
```

```
aws cloudwatch set-alarm-state --alarm-name SystemErrorsAlarm --state-reason
 "initializing" --state-value ALARM
```

Logging DynamoDB operations by using AWS CloudTrail

DynamoDB is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in DynamoDB. CloudTrail captures all API calls for DynamoDB as events. The calls captured include calls from the DynamoDB console and code calls to the DynamoDB API operations, using both PartiQL and the classic API. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for DynamoDB. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**. Using the information collected by CloudTrail, you can determine the request that was made to DynamoDB, the IP address from which the request was made, who made the request, when it was made, and additional details.

For robust monitoring and alerting, you can also integrate CloudTrail events with Amazon CloudWatch Logs. To enhance your analysis of DynamoDB service activity and identify changes in activities for an AWS account, you can query AWS CloudTrail logs using Amazon Athena. For example, you can use queries to identify trends and further isolate activity by attributes such as source IP address or user.

To learn more about CloudTrail, including how to configure and enable it, see the AWS CloudTrail User Guide.

Topics

- DynamoDB information in CloudTrail
- Understanding DynamoDB log file entries

DynamoDB information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When supported event activity occurs in DynamoDB, that activity is recorded in a CloudTrail event along with other AWS service events in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see Working with CloudTrail Event history.

For an ongoing record of events in your AWS account, including events for DynamoDB, create a trail. A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- Overview for creating a trail
- CloudTrail supported services and integrations
- Configuring Amazon SNS notifications for CloudTrail
- Receiving CloudTrail log files from multiple regions and Receiving CloudTrail log files from multiple accounts

Control plane events in CloudTrail

The following API actions are logged by default as events in CloudTrail files:

Amazon DynamoDB

- CreateBackup
- CreateGlobalTable
- CreateTable
- DeleteBackup
- DeleteTable
- DescribeBackup
- DescribeContinuousBackups
- DescribeGlobalTable
- DescribeLimits
- DescribeTable

- DescribeTimeToLive
- ListBackups
- ListTables
- ListTagsOfResource
- ListGlobalTables
- RestoreTableFromBackup
- RestoreTableToPointInTime
- TagResource
- UntagResource
- UpdateGlobalTable
- UpdateTable
- UpdateTimeToLive
- DescribeReservedCapacity
- DescribeReservedCapacityOfferings
- PurchaseReservedCapacityOfferings
- DescribeScalableTargets
- RegisterScalableTarget

DynamoDB Streams

- DescribeStream
- ListStreams

DynamoDB Accelerator (DAX)

- CreateCluster
- CreateParameterGroup
- CreateSubnetGroup
- DecreaseReplicationFactor
- DeleteCluster
- DeleteParameterGroup
- DeleteSubnetGroup

- DescribeClusters
- DescribeDefaultParameters
- DescribeEvents
- DescribeParameterGroups
- DescribeParameters
- DescribeSubnetGroups
- IncreaseReplicationFactor
- ListTags
- RebootNode
- TagResource
- UntagResource
- UpdateCluster
- UpdateParameterGroup
- UpdateSubnetGroup

DynamoDB data plane events in CloudTrail

To enable logging of the following API actions in CloudTrail files, you'll need to enable logging of data plane API activity in CloudTrail. See Logging data events for trails for more information.

Data plane events can be filtered by resource type, for granular control over which DynamoDB API calls you want to selectively log and pay for in CloudTrail. For example, by specifying `AWS::DynamoDB::Stream` as a resource type, you can log only calls to the DynamoDB streams APIs. For tables with streams enabled, the resource field in the data plane event contains both `AWS::DynamoDB::Stream` and `AWS::DynamoDB::Table`. If you specify `AWS::DynamoDB::Table` as a resource type, it will log both DynamoDB table and DynamoDB streams events by default. You can add an additional filter to exclude the streams events, if you don't want the streams events to be logged. For more information, see DataResource in the *AWS CloudTrail API Reference*.

Amazon DynamoDB

- BatchExecuteStatement
- BatchGetItem
- BatchWriteItem

- DeleteItem
- ExecuteStatement
- ExecuteTransaction
- GetItem
- PutItem
- Query
- Scan
- TransactGetItems
- TransactWriteItems
- UpdateItem

> **Note**
>
> DynamoDB Time to Live data plane actions are not logged by CloudTrail

DynamoDB Streams

- GetRecords
- GetShardIterator

Understanding DynamoDB log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

> **Note**
>
> Non key attribute values will be redacted in the CloudTrail logs of actions using the PartiQL API, and will not appear in logs of actions using the classic API.

For more information, see the CloudTrail userIdentity element.

The following examples demonstrate CloudTrail logs of these event types:

Amazon DynamoDB

- `UpdateTable`
- `DeleteTable`
- `CreateCluster`
- `PutItem` (Successful)
- `UpdateItem` (Unsuccessful)
- `TransactWriteItems` (Successful)
- `TransactWriteItems` (With `TransactionCanceledException`)
- `ExecuteStatement`
- `BatchExecuteStatement`

DynamoDB Streams

- `GetRecords`

Analyzing data access using CloudWatch contributor insights for DynamoDB

Amazon CloudWatch Contributor Insights for Amazon DynamoDB is a diagnostic tool for identifying the most frequently accessed and throttled keys in your table or index at a glance. This tool uses CloudWatch contributor insights.

By enabling CloudWatch Contributor Insights for DynamoDB on a table or global secondary index, you can view the most accessed and throttled items in those resources.

> **Note**
>
> CloudWatch charges apply for Contributor Insights for DynamoDB. For more information about pricing, see Amazon CloudWatch pricing.

- Using IAM with CloudWatch contributor insights for DynamoDB

CloudWatch contributor insights for DynamoDB: How it works

Amazon DynamoDB integrates with CloudWatch Contributor Insights to provide information about the most accessed and throttled items in a table or global secondary index. DynamoDB delivers this information to you via CloudWatch Contributor Insights rules, reports, and graphs of report data.

CloudWatch Contributor Insights for DynamoDB is designed to have no performance impact on your DynamoDB table.

For more information about CloudWatch Contributor Insights, see Using Contributor Insights to analyze high-cardinality data in the *Amazon CloudWatch User Guide*.

The following sections describe the core concepts and behavior of CloudWatch Contributor Insights for DynamoDB.

Topics

- CloudWatch contributor insights for DynamoDB rules
- Understanding CloudWatch contributor insights for DynamoDB graphs
- Interactions with other DynamoDB features
- CloudWatch contributor insights for DynamoDB billing

CloudWatch contributor insights for DynamoDB rules

When you enable CloudWatch Contributor Insights for DynamoDB on a table or global secondary index, DynamoDB creates the following rules on your behalf:

- **Most accessed items (partition key)** — Identifies the partition keys of the most accessed items in your table or global secondary index.

  CloudWatch rule name format: `DynamoDBContributorInsights-PKC-[resource_name]-[creationtimestamp]`
- **Most throttled keys (partition key)** — Identifies the partition keys of the most throttled items in your table or global secondary index.

  CloudWatch rule name format: `DynamoDBContributorInsights-PKT-[resource_name]-[creationtimestamp]`

> **Note**
>
> When you enable Contributor Insights on your DynamoDB table, you're still subject to Contributor Insights rules limits. For more information, see CloudWatch service quotas.

If your table or global secondary index has a sort key, DynamoDB also creates the following rules specific to sort keys:

- **Most accessed keys (partition and sort keys)** — Identifies the partition and sort keys of the most accessed items in your table or global secondary index.

  CloudWatch rule name format: `DynamoDBContributorInsights-SKC-[resource_name]-[creationtimestamp]`
- **Most throttled keys (partition and sort keys)** — Identifies the partition and sort keys of the most throttled items in your table or global secondary index.

  CloudWatch rule name format: `DynamoDBContributorInsights-SKT-[resource_name]-[creationtimestamp]`

> **Note**
>
> - You can't use the CloudWatch console or APIs to directly modify or delete the rules created by CloudWatch Contributor Insights for DynamoDB. Disabling CloudWatch Contributor Insights for DynamoDB on a table or global secondary index automatically deletes the rules created for that table or global secondary index.

- When you use the GetInsightRuleReport operation with CloudWatch Contributor Insights rules that are created by DynamoDB, only `MaxContributorValue` and `Maximum` return useful statistics. The other statistics in this list don't return meaningful values.
- CloudWatch Contributor Insights for DynamoDB has a limit of 25 contributors. Requesting more than 25 contributors will return an error.

You can create CloudWatch Alarms using the CloudWatch Contributor Insights for DynamoDB rules. This allows you to be notified when any item exceed or meets a specific threshold for `ConsumedThroughputUnits` or `ThrottleCount`. For more information, see Setting an alarm on Contributor Insights metric data.

Understanding CloudWatch contributor insights for DynamoDB graphs

CloudWatch Contributor Insights for DynamoDB displays two types of graphs on both the DynamoDB and CloudWatch consoles: *Most Accessed Items* and *Most Throttled Items*.

Most accessed items

Use this graph to identify the most accessed items in the table or global secondary index. The graph displays `ConsumedThroughputUnits` on the y-axis and time on the x-axis. Each of the top N keys is displayed in its own color, with a legend displayed below the x-axis.

DynamoDB measures key access frequency by using `ConsumedThroughputUnits`, which measures combined read and write traffic. `ConsumedThroughputUnits` is defined as the following:

- Provisioned — *(3 x consumed write capacity units) + consumed read capacity units*
- On-demand — *(3 x write request units) + read request units*

On the DynamoDB console, each data point in the graph represents the maximum of `ConsumedThroughputUnits` over a 1-minute period. For example, a graph value of 180,000 `ConsumedThroughputUnits` indicates that the item was accessed continuously at the per-item maximum throughput of 1,000 write request units or 3,000 read request units for a 60-second span within that 1-minute period (3,000 x 60 seconds). In other words, the graphed values represent the highest-traffic minute within each 1-minute period. You can change the time granularity of the `ConsumedThroughputUnits` metric (for example, to view 5-minute metrics instead of 1-minute) on the CloudWatch console.

If you see several closely clustered lines without any obvious outliers, it indicates that your workload is relatively balanced across items over the given time window. If you see isolated points in the graph instead of connected lines, it indicates an item that was frequently accessed only for a brief period.

If your table or global secondary index has a sort key, DynamoDB creates two graphs: one for the most accessed partition keys and one for the most accessed partition + sort key pairs. You can see traffic at the partition key level in the partition key–only graph. You can see traffic at the item level in the partition + sort key graphs.

Most throttled items

Use this graph to identify the most throttled items in the table or global secondary index. The graph displays `ThrottleCount` on the y-axis and time on the x-axis. Each of the top *N* keys is displayed in its own color, with a legend displayed below the x-axis.

DynamoDB measures throttle frequency using `ThrottleCount`, which is the count of `ProvisionedThroughputExceededException`, `ThrottlingException`, and `RequestLimitExceeded` errors.

Write throttling caused by insufficient write capacity for a global secondary index is not measured. You can use the *Most Accessed Items* graph of the global secondary index to identify imbalanced access patterns that may cause write throttling. For more information, see Provisioned throughput Considerations for Global Secondary Indexes.

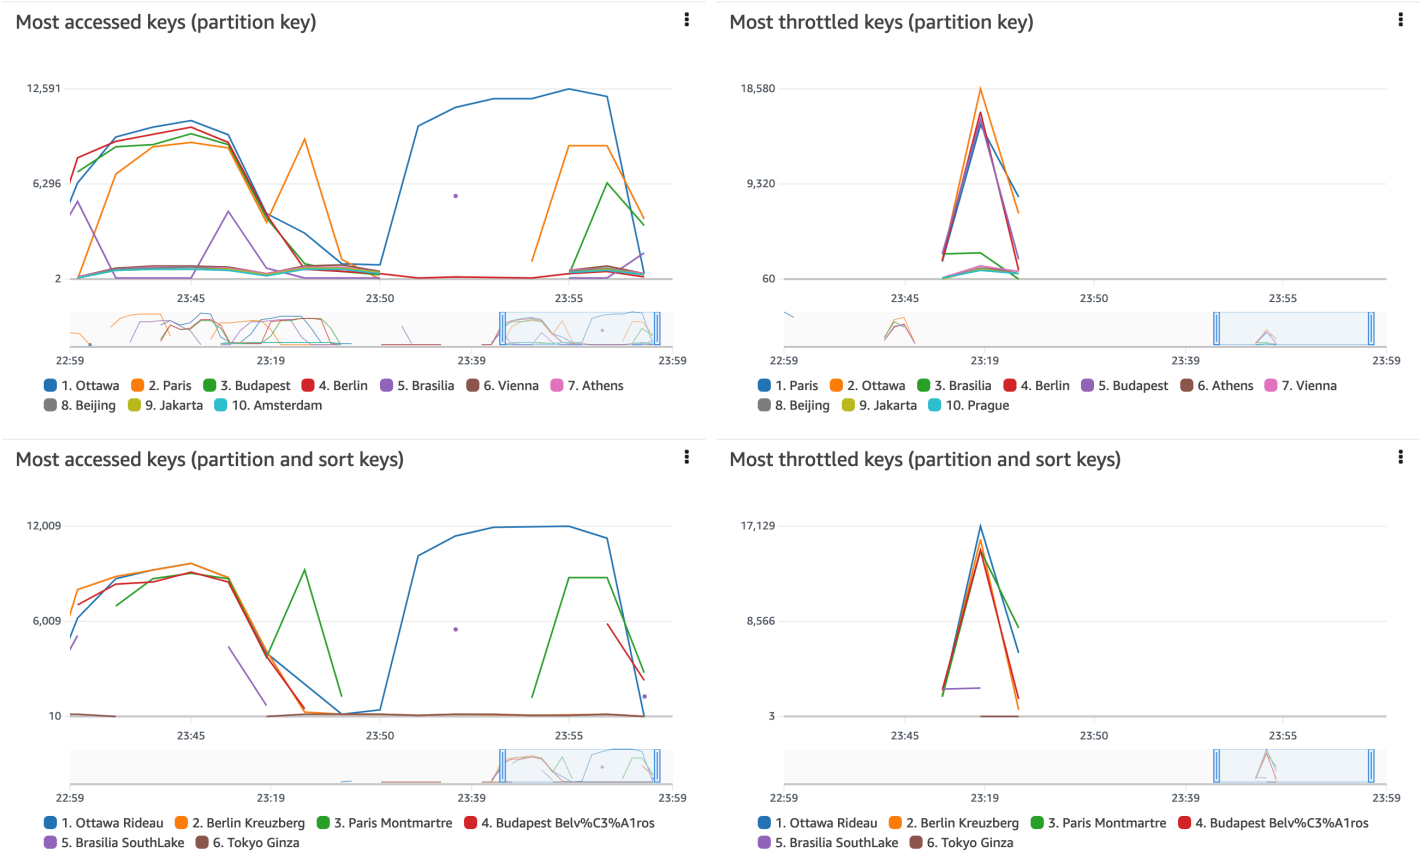
On the DynamoDB console, each data point in the graph represents the count of throttle events over a 1-minute period.

If you see no data in this graph, it indicates that your requests are not being throttled. If you see isolated points in the graph instead of connected lines, it indicates that an item was frequently throttled for a brief period.

If your table or global secondary index has a sort key, DynamoDB creates two graphs: one for most throttled partition keys and one for most throttled partition + sort key pairs. You can see throttle count at the partition key level in the partition key-only graph, and throttle count at the item-level in the partition + sort key graphs.

Report examples

The following are examples of the reports generated for a table with both a partition key and sort key.



Interactions with other DynamoDB features

The following sections describe how CloudWatch Contributor Insights for DynamoDB behaves and interacts with several other features in DynamoDB.

Global tables

CloudWatch Contributor Insights for DynamoDB monitors global table replicas as distinct tables. The Contributor Insights graphs for a replica in one AWS Region might not show the same patterns as another Region. This is because write data is replicated across all replicas in a global table, but each replica can serve Region-bound read traffic.

DynamoDB Accelerator (DAX)

CloudWatch Contributor Insights for DynamoDB doesn't show DAX cache responses. It only shows responses to accessing a table or a global secondary index.

> **Note**
>
> DynamoDB CloudWatch Contributor Insights does not support PartiQL requests.

Encryption at rest

CloudWatch Contributor Insights for DynamoDB doesn't affect how encryption works in DynamoDB. The primary key data that is published in CloudWatch is encrypted with the AWS owned key. However, DynamoDB also supports the AWS managed key and a customer managed key.

CloudWatch Contributor Insights for DynamoDB displays partition keys and sort keys (if applicable) of frequently accessed and throttled items. While CloudWatch Contributor Insights works with encrypted DynamoDB tables, it's important to note that it uses its own Amazon-owned encryption context, which is separate from the table's configured encryption.

If your DynamoDB table's primary key contains sensitive information and your organization's security policies require full control over encryption processes, enabling CloudWatch Contributor Insights may not be suitable.

Fine-grained access control

CloudWatch Contributor Insights for DynamoDB doesn't function differently for tables with fine-grained access control (FGAC). In other words, any user who has the appropriate CloudWatch permissions can view FGAC-protected primary keys in CloudWatch Contributor Insights graphs.

If the table's primary key contains FGAC-protected data that you don't want published to CloudWatch, you should not enable CloudWatch Contributor Insights for DynamoDB for that table.

Access control

You control access to CloudWatch Contributor Insights for DynamoDB using AWS Identity and Access Management (IAM) by limiting DynamoDB control plane permissions and CloudWatch data plane permissions. For more information see, Using IAM with CloudWatch Contributor Insights for DynamoDB.

CloudWatch contributor insights for DynamoDB billing

Charges for CloudWatch Contributor Insights for DynamoDB appear in the CloudWatch section of your monthly bill. These charges are calculated based on the number of DynamoDB events that

are processed. For tables and global secondary indexes with CloudWatch Contributor Insights for DynamoDB enabled, each item that is written or read via a data plane operation represents one event.

If a table or global secondary index includes a sort key, each item that is read or written represents two events. This is because DynamoDB is identifying top contributors from separate time series: one for partitions keys only, and one for partition and sort key pairs.

For example, assume that your application performs the following DynamoDB operations: a `GetItem`, a `PutItem`, and a `BatchWriteItem` that puts five items

- If your table or global secondary index has only a partition key, it results in 7 events (1 for the `GetItem`, 1 for the `PutItem`, and 5 for the `BatchWriteItem`).
- If your table or global secondary index has a partition key and sort key, it results in 14 events (2 for the `GetItem`, 2 for the `PutItem`, and 10 for the `BatchWriteItem`).
- A `Query` operation always results in 1 event, regardless of the number of items returned.

Unlike other DynamoDB features, CloudWatch Contributor Insights for DynamoDB billing *does not* vary based on the following:

- The capacity mode (provisioned vs. on-demand)
- Whether you perform read or write requests
- The size (KB) of the items read or written

Getting started with CloudWatch Contributor Insights for DynamoDB

This section describes how to use Amazon CloudWatch Contributor Insights with the Amazon DynamoDB console or the AWS Command Line Interface (AWS CLI).

In the following examples, you use the DynamoDB table that is defined in the Getting started with DynamoDB tutorial.

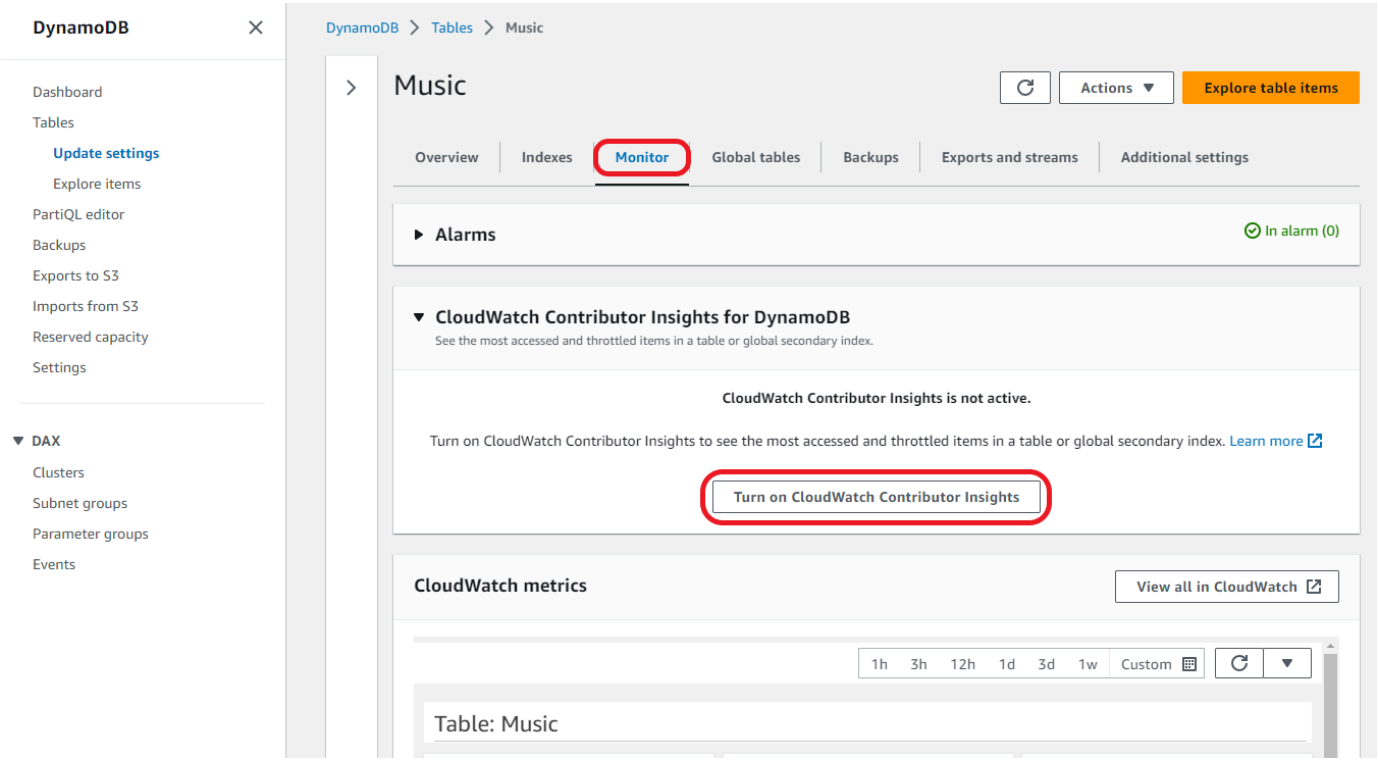
Topics

- Using Contributor Insights (console)
- Using Contributor Insights (AWS CLI)

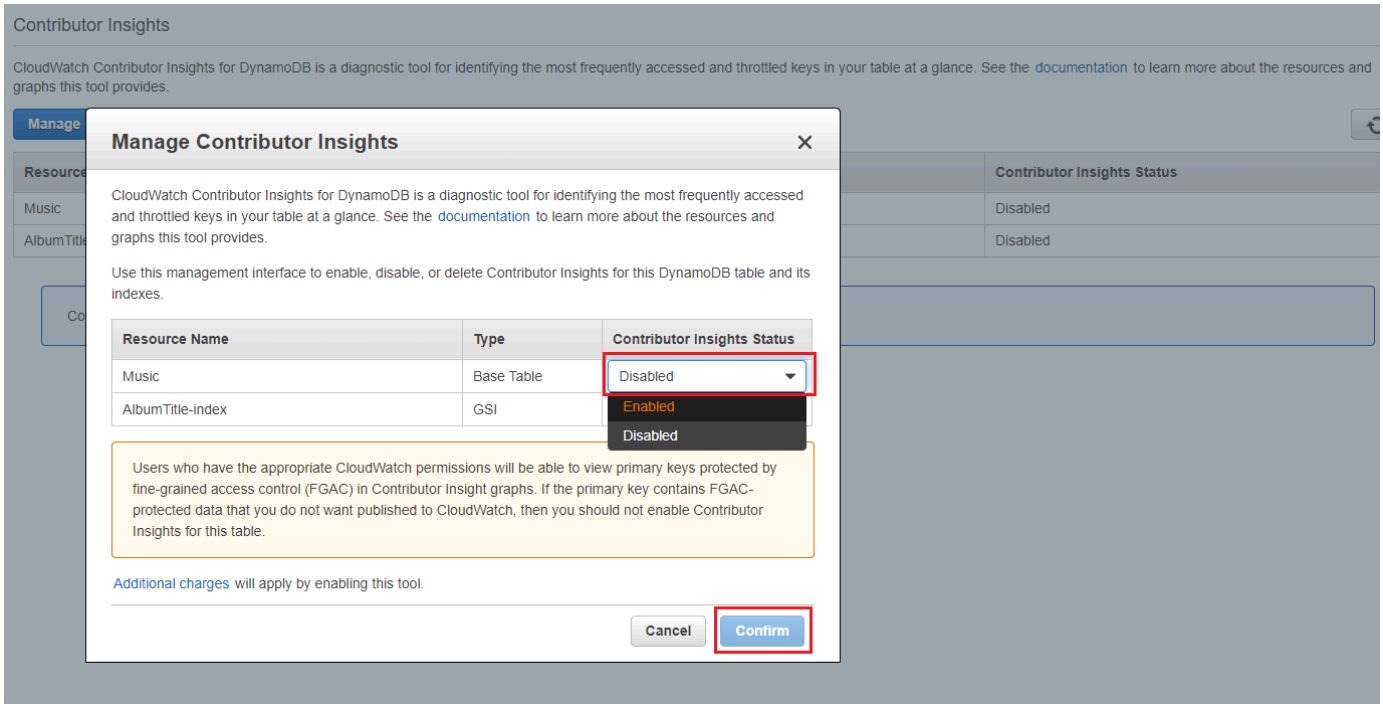
Using Contributor Insights (console)

To use Contributor Insights in the console

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. In the navigation pane on the left side of the console, choose **Tables**.
3. Choose the `Music` table.
4. Choose the **Monitor** tab.
5. Choose **Turn on CloudWatch Contributor Insights**.

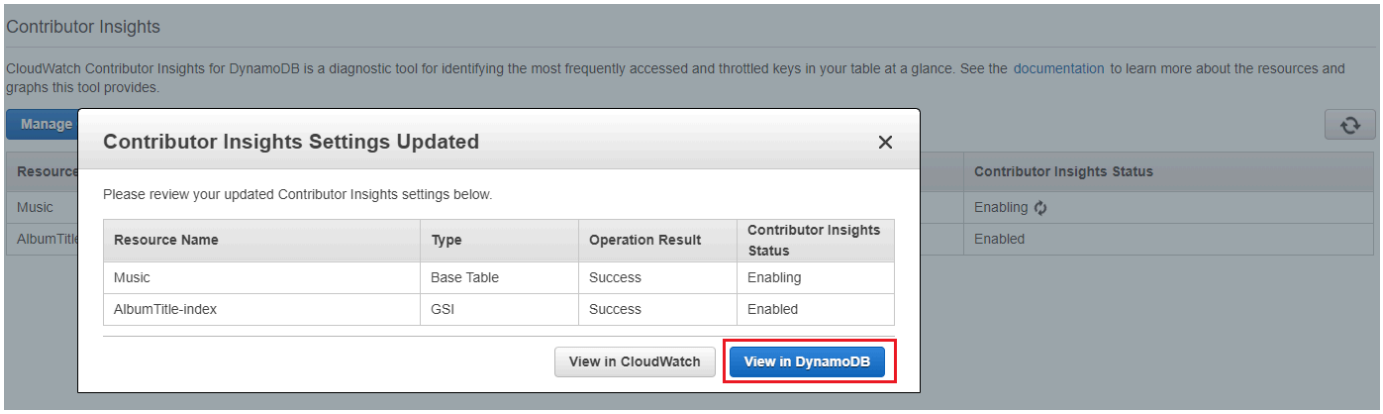


6. In the **Manage Contributor Insights** dialog box, under **Contributor Insights Status**, choose **Enabled** for both the `Music` base table and the `AlbumTitle-index` global secondary index. Then choose **Confirm**.

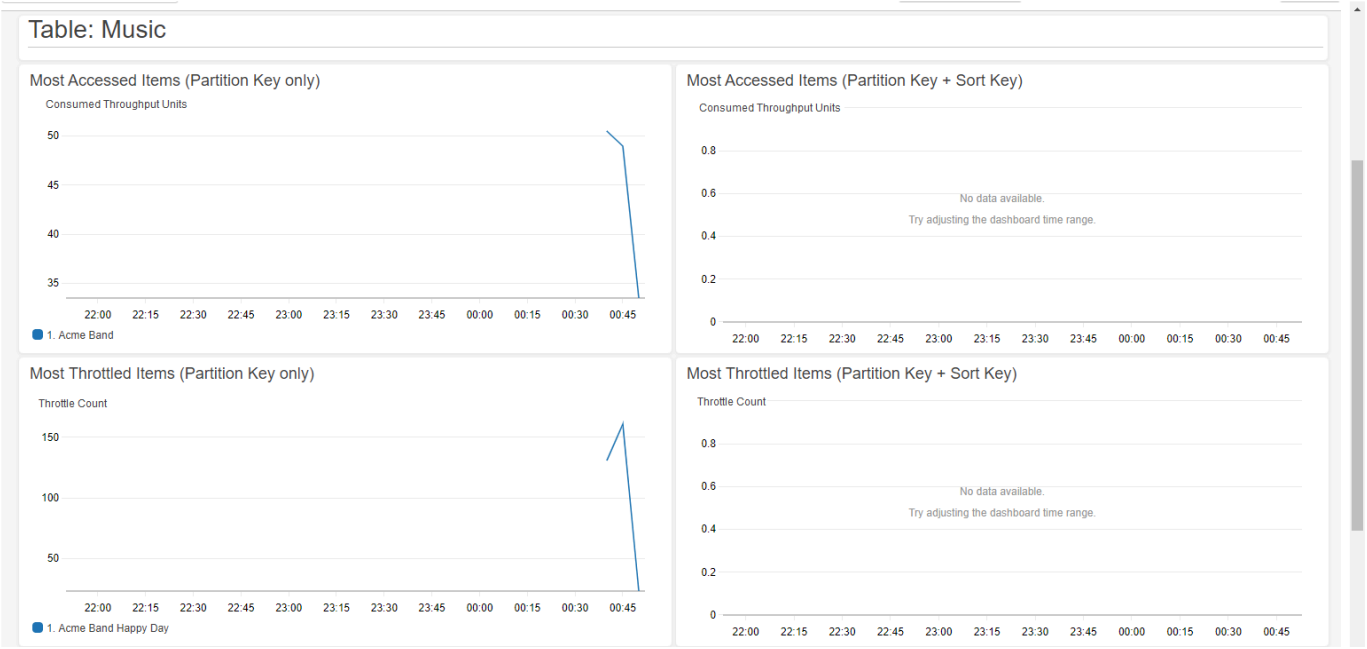


If the operation fails, see [DescribeContributorInsights FailureException] in the *Amazon DynamoDB API Reference* for possible reasons.

7. Choose **View in DynamoDB**.



8. The Contributor Insights graphs are now visible on the **Contributor Insights** tab for the `Music` table.

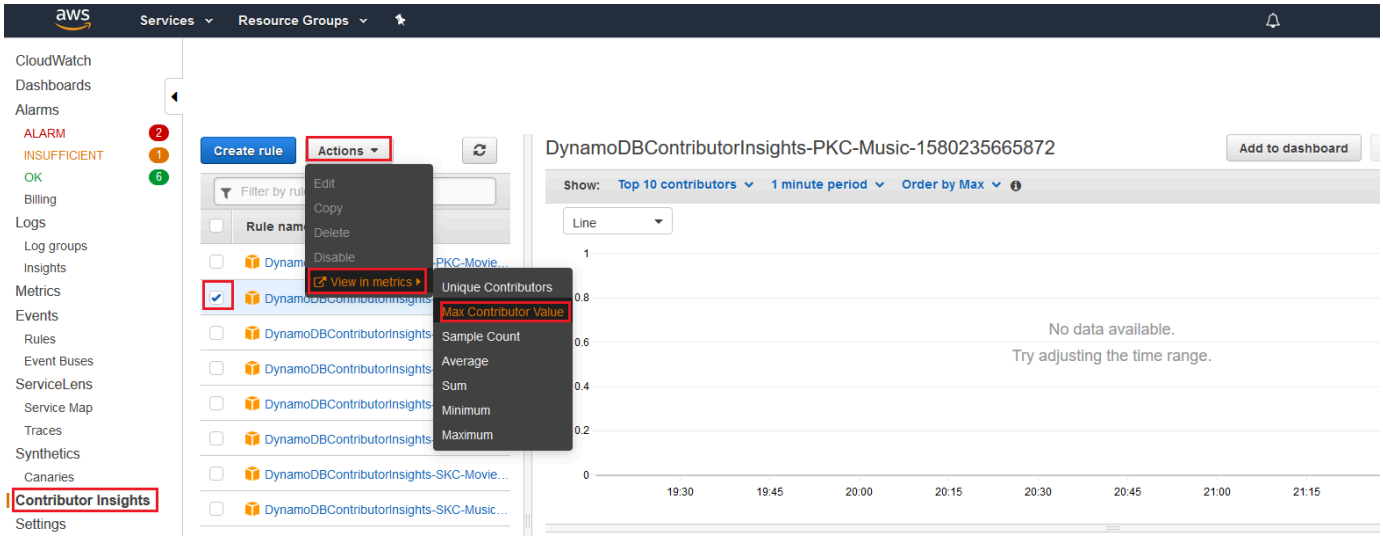


Creating CloudWatch alarms

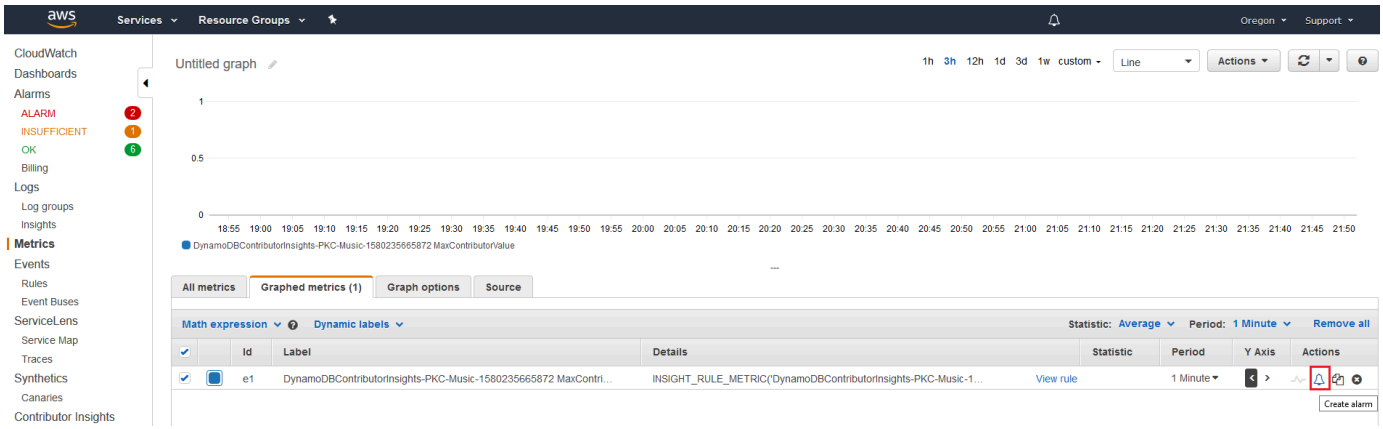
Follow these steps to create a CloudWatch alarm and be notified when any partition key consumes more than 50,000 ConsumedThroughputUnits.

1. Sign in to the AWS Management Console and open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/
2. In the navigation pane on the left side of the console, choose **Contributor Insights**.
3. Choose the **DynamoDBContributorInsights-PKC-Music** rule.
4. Choose the **Actions** drop down.
5. Choose **View in metrics**.
6. Choose **Max Contributor Value**.

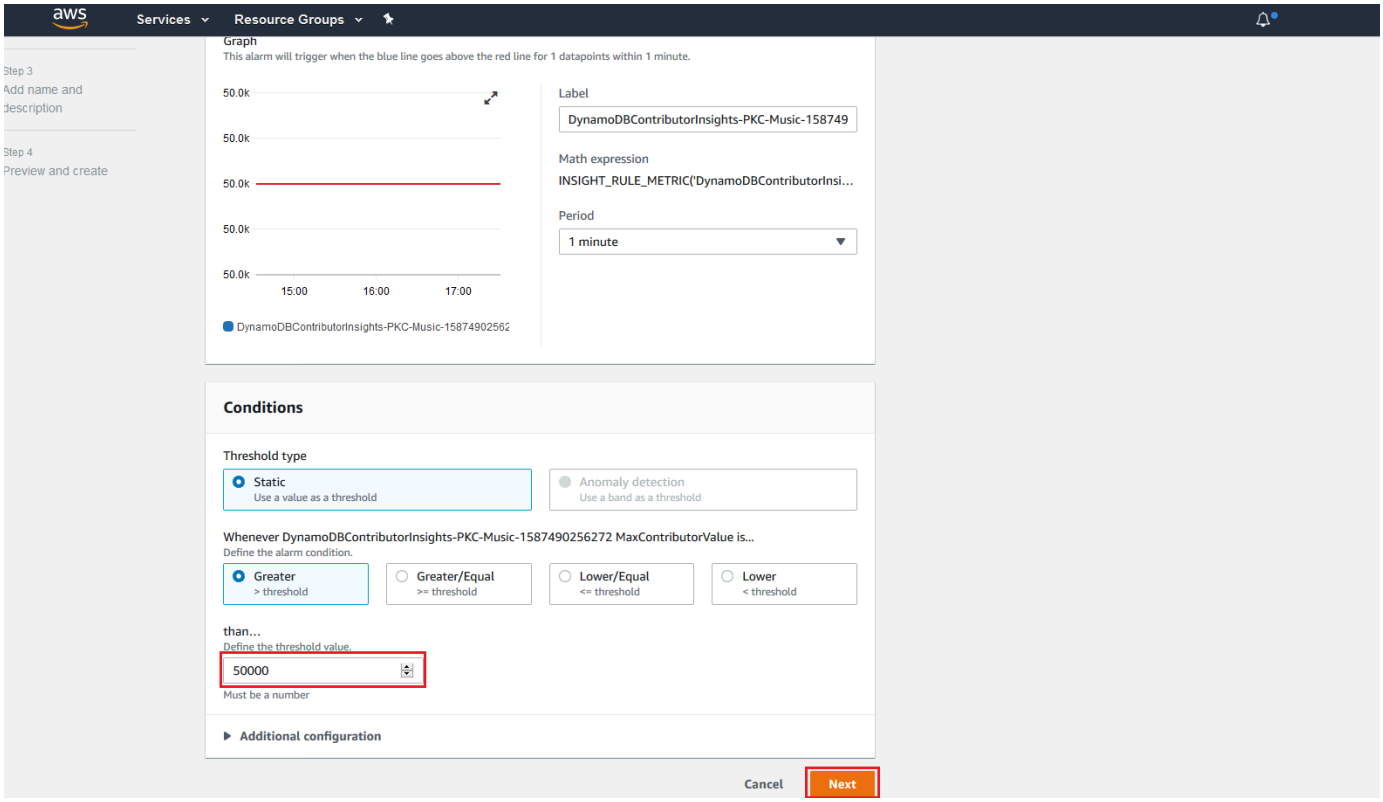
> **Note**
>
> Only `Max Contributor Value` and `Maximum` return useful statistics. The other statistics in this list don't return meaningful values.



7. On the **Actions** column, Choose **Create Alarm**.



8. Enter a value of 50000 for **threshold** and choose **Next**.



9. See Using Amazon CloudWatch alarms for details on how to configure the notification for the alarm.

Using Contributor Insights (AWS CLI)

To use Contributor Insights in the AWS CLI

1. Enable CloudWatch Contributor Insights for DynamoDB on the `Music` base table.

```
aws dynamodb update-contributor-insights --table-name Music --contributor-insights-action=ENABLE
```

2. Enable Contributor Insights for DynamoDB on the `AlbumTitle-index` global secondary index.

```
aws dynamodb update-contributor-insights --table-name Music --index-name
 AlbumTitle-index --contributor-insights-action=ENABLE
```

3. Get the status and rules for the `Music` table and all its indexes.

```
aws dynamodb describe-contributor-insights --table-name Music
```

4. Disable CloudWatch Contributor Insights for DynamoDB on the `AlbumTitle-index` global secondary index.

```
aws dynamodb update-contributor-insights --table-name Music --index-name
 AlbumTitle-index --contributor-insights-action=DISABLE
```

5. Get the status of the `Music` table and all its indexes.

```
aws dynamodb list-contributor-insights --table-name Music
```

Using IAM with CloudWatch contributor insights for DynamoDB

The first time that you enable Amazon CloudWatch Contributor Insights for Amazon DynamoDB, DynamoDB automatically creates an AWS Identity and Access Management (IAM) service-linked role for you. This role, `AWSServiceRoleForDynamoDBCloudWatchContributorInsights`, allows DynamoDB to manage CloudWatch Contributor Insights rules on your behalf. Don't delete this service-linked role. If you delete it, all your managed rules will no longer be cleaned up when you delete your table or global secondary index.

For more information about service-linked roles, see Using service-linked roles in the *IAM User Guide*.

The following permissions are required:

- To enable or disable CloudWatch Contributor Insights for DynamoDB, you must have `dynamodb:UpdateContributorInsights` permission on the table or index.
- To view CloudWatch Contributor Insights for DynamoDB graphs, you must have `cloudwatch:GetInsightRuleReport` permission.
- To describe CloudWatch Contributor Insights for DynamoDB for a given DynamoDB table or index, you must have `dynamodb:DescribeContributorInsights` permission.
- To list CloudWatch Contributor Insights for DynamoDB statuses for each table and global secondary index, you must have `dynamodb:ListContributorInsights` permission.

Example: Enable or disable CloudWatch contributor insights for DynamoDB

The following IAM policy grants permissions to enable or disable CloudWatch Contributor Insights for DynamoDB.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "iam:CreateServiceLinkedRole",
            "Resource": "arn:aws:iam::*:role/aws-service-role/
contributorinsights.dynamodb.amazonaws.com/
AWSServiceRoleForDynamoDBCloudWatchContributorInsights",
            "Condition": {"StringLike": {"iam:AWSServiceName":
 "contributorinsights.dynamodb.amazonaws.com"}}
        },
        {
            "Effect": "Allow",
            "Action": [
                "dynamodb:UpdateContributorInsights"
            ],
            "Resource": "arn:aws:dynamodb:*:*:table/*"
        }
    ]
}
```

For tables encryped by KMS key, the user needs to have kms:Decrypt permissions in order to update Contributor Insights.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "iam:CreateServiceLinkedRole",
            "Resource": "arn:aws:iam::*:role/aws-service-role/
contributorinsights.dynamodb.amazonaws.com/
AWSServiceRoleForDynamoDBCloudWatchContributorInsights",
            "Condition": {"StringLike": {"iam:AWSServiceName":
 "contributorinsights.dynamodb.amazonaws.com"}}
        },
        {
```

```
            "Effect": "Allow",
            "Action": [
                "dynamodb:UpdateContributorInsights"
            ],
            "Resource": "arn:aws:dynamodb:*:*:table/*"
        },
        {
            "Effect": "Allow",
            "Resource": "arn:aws:kms:*:*:key/*",
            "Action": [
                "kms:Decrypt"
            ],
        }
    ]
}
```

Example: Retrieve CloudWatch contributor insights rule report

The following IAM policy grants permissions to retrieve CloudWatch Contributor Insights rule report.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "cloudwatch:GetInsightRuleReport"
            ],
            "Resource": "arn:aws:cloudwatch:*:*:insight-rule/
DynamoDBContributorInsights*"
        }
    ]
}
```

Example: Selectively apply CloudWatch contributor insights for DynamoDB permissions based on resource

The following IAM policy grants permissions to allow the `ListContributorInsights` and `DescribeContributorInsights` actions and denies the `UpdateContributorInsights` action for a specific global secondary index.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "dynamodb:ListContributorInsights",
                "dynamodb:DescribeContributorInsights"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Deny",
            "Action": [
                "dynamodb:UpdateContributorInsights"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books/index/
Author-index"
        }
    ]
}
```

Using service-linked roles for CloudWatch Contributor Insights for DynamoDB

CloudWatch Contributor Insights for DynamoDB uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to CloudWatch Contributor Insights for DynamoDB. Service-linked roles are predefined by CloudWatch Contributor Insights for DynamoDB and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up CloudWatch Contributor Insights for DynamoDB easier because you don't have to manually add the necessary permissions. CloudWatch Contributor Insights for DynamoDB defines the permissions of its service-linked roles, and unless defined otherwise, only CloudWatch Contributor Insights for DynamoDB can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

For information about other services that support service-linked roles, see AWS Services That Work with IAM and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for CloudWatch Contributor Insights for DynamoDB

CloudWatch Contributor Insights for DynamoDB uses the service-linked role named **AWSServiceRoleForDynamoDBCloudWatchContributorInsights**. The purpose of the service-linked role is to allow Amazon DynamoDB to manage Amazon CloudWatch Contributor Insights rules created for DynamoDB tables and global secondary indexes, on your behalf.

The `AWSServiceRoleForDynamoDBCloudWatchContributorInsights` service-linked role trusts the following services to assume the role:

- `contributorinsights.dynamodb.amazonaws.com`

The role permissions policy allows CloudWatch Contributor Insights for DynamoDB to complete the following actions on the specified resources:

- Action: `Create and manage Insight Rules` on `DynamoDBContributorInsights`

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-Linked Role Permissions in the *IAM User Guide*.

Creating a service-linked role for CloudWatch Contributor Insights for DynamoDB

You don't need to manually create a service-linked role. When you enable Contributor Insights in the AWS Management Console, the AWS CLI, or the AWS API, CloudWatch Contributor Insights for DynamoDB creates the service-linked role for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you enable Contributor Insights, CloudWatch Contributor Insights for DynamoDB creates the service-linked role for you again.

Editing a service-linked role for CloudWatch Contributor Insights for DynamoDB

CloudWatch Contributor Insights for DynamoDB does not allow you to edit the `AWSServiceRoleForDynamoDBCloudWatchContributorInsights` service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the *IAM User Guide*.

Deleting a service-linked role for CloudWatch Contributor Insights for DynamoDB

You don't need to manually delete the `AWSServiceRoleForDynamoDBCloudWatchContributorInsights` role. When you disable Contributor Insights in the AWS Management Console, the AWS CLI, or the AWS API, CloudWatch Contributor Insights for DynamoDB cleans up the resources.

You can also use the IAM console, the AWS CLI or the AWS API to manually delete the service-linked role. To do this, you must first manually clean up the resources for your service-linked role and then you can manually delete it.

> **Note**
>
> If the CloudWatch Contributor Insights for DynamoDB service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To manually delete the service-linked role using IAM

Use the IAM console, the AWS CLI, or the AWS API to delete the `AWSServiceRoleForDynamoDBCloudWatchContributorInsights` service-linked role. For more information, see Deleting a service-linked role in the *IAM User Guide*.

Best practices for designing and architecting with DynamoDB

NoSQL design for DynamoDB

NoSQL database systems like Amazon DynamoDB use alternative models for data management, such as key-value pairs or document storage. When you switch from a relational database

management system to a NoSQL database system like DynamoDB, it's important to understand the key differences and specific design approaches.

Topics

- Differences between relational data design and NoSQL
- Two key concepts for NoSQL design
- Approaching NoSQL design
- NoSQL Workbench for DynamoDB

Differences between relational data design and NoSQL

Relational database systems (RDBMS) and NoSQL databases have different strengths and weaknesses:

- In RDBMS, data can be queried flexibly, but queries are relatively expensive and don't scale well in high-traffic situations (see First steps for modeling relational data in DynamoDB).
- In a NoSQL database such as DynamoDB, data can be queried efficiently in a limited number of ways, outside of which queries can be expensive and slow.

These differences make database design different between the two systems:

- In RDBMS, you design for flexibility without worrying about implementation details or performance. Query optimization generally doesn't affect schema design, but normalization is important.
- In DynamoDB, you design your schema specifically to make the most common and important queries as fast and as inexpensive as possible. Your data structures are tailored to the specific requirements of your business use cases.

Two key concepts for NoSQL design

NoSQL design requires a different mindset than RDBMS design. For an RDBMS, you can go ahead and create a normalized data model without thinking about access patterns. You can then extend it later when new questions and query requirements arise. You can organize each type of data into its own table.

How NoSQL design is different

- By contrast, you shouldn't start designing your schema for DynamoDB until you know the questions it will need to answer. Understanding the business problems and the application use cases up front is essential.
- You should maintain as few tables as possible in a DynamoDB application. Having fewer tables keeps things more scalable, requires less permissions management, and reduces overhead for your DynamoDB application. It can also help keep backup costs lower overall.

Approaching NoSQL design

The first step in designing your DynamoDB application is to identify the specific query patterns that the system must satisfy.

In particular, it is important to understand three fundamental properties of your application's access patterns before you begin:

- **Data size**: Knowing how much data will be stored and requested at one time will help determine the most effective way to partition the data.
- **Data shape**: Instead of reshaping data when a query is processed (as an RDBMS system does), a NoSQL database organizes data so that its shape in the database corresponds with what will be queried. This is a key factor in increasing speed and scalability.
- **Data velocity**: DynamoDB scales by increasing the number of physical partitions that are available to process queries, and by efficiently distributing data across those partitions. Knowing in advance what the peak query loads will be might help determine how to partition data to best use I/O capacity.

After you identify specific query requirements, you can organize data according to general principles that govern performance:

- **Keep related data together.** Research has shown that the principle of 'locality of reference', keeping related data together in one place, is a key factor in improving performance and response times in NoSQL systems, just as it was found to be important for optimizing routing tables many years ago.

  As a general rule, you should maintain as few tables as possible in a DynamoDB application.

Exceptions are cases where high-volume time series data are involved, or datasets that have very different access patterns. A single table with inverted indexes can usually enable simple queries to create and retrieve the complex hierarchical data structures required by your application.

- **Use sort order.** Related items can be grouped together and queried efficiently if their key design causes them to sort together. This is an important NoSQL design strategy.
- **Distribute queries.** It's also important that a high volume of queries not be focused on one part of the database, where they can exceed I/O capacity. Instead, you should design data keys to distribute traffic evenly across partitions as much as possible, avoiding hot spots.
- **Use global secondary indexes.** By creating specific global secondary indexes, you can enable different queries than your main table can support, and that are still fast and relatively inexpensive.

These general principles translate into some common design patterns that you can use to model data efficiently in DynamoDB.

NoSQL Workbench for DynamoDB

NoSQL Workbench for DynamoDB is a cross-platform, client-side GUI application that you can use for modern database development and operations. It's available for Windows, macOS, and Linux. NoSQL Workbench is a visual development tool that provides data modeling, data visualization, sample data generation, and query development features to help you design, create, query, and manage DynamoDB tables. With NoSQL Workbench for DynamoDB, you can build new data models from, or design models based on, existing data models that satisfy your application's data access patterns. You can also import and export the designed data model at the end of the process. For more information, see Building data models with NoSQL Workbench.

Using the DynamoDB Well-Architected Lens to optimize your DynamoDB workload

This section describes the Amazon DynamoDB Well-Architected Lens, a collection of design principles and guidance for designing well-architected DynamoDB workloads.

Optimizing costs on DynamoDB tables

This section covers best practices on how to optimize costs for your existing DynamoDB tables. You should look at the following strategies to see which cost optimization strategy best suits your

needs and approach them iteratively. Each strategy will provide an overview of what might be impacting your costs, what signs to look for, and prescriptive guidance on how to reduce them.

Topics

- Evaluate your costs at the table level
- Evaluate your DynamoDB table's capacity mode
- Evaluate your DynamoDB table's auto scaling settings
- Evaluate your DynamoDB table class selection
- Identify your unused resources in DynamoDB
- Evaluate your DynamoDB table usage patterns
- Evaluate your DynamoDB streams usage
- Evaluate your provisioned capacity for right-sized provisioning in your DynamoDB table

Evaluate your costs at the table level

The Cost Explorer tool found within the AWS Management Console allows you to see costs broken down by type, such as read, write, storage and backup charges. You can also see these costs summarized by period such as month or day.

One challenge administrators can face is when the costs of only one particular table need to be reviewed. Some of this data is available via the DynamoDB console or via calls to the `DescribeTable` API, however Cost Explorer does not, by default, allow you to filter or group by costs associated with a specific table. This section will show you how to use tagging to perform individual table cost analysis in Cost Explorer.

Topics

- How to view the costs of a single DynamoDB table
- Cost Explorer's default view
- How to use and apply table tags in Cost Explorer

How to view the costs of a single DynamoDB table

Both the Amazon DynamoDB AWS Management Console and the `DescribeTable` API will show you information about a single table, including the primary key schema, any indexes on the table,

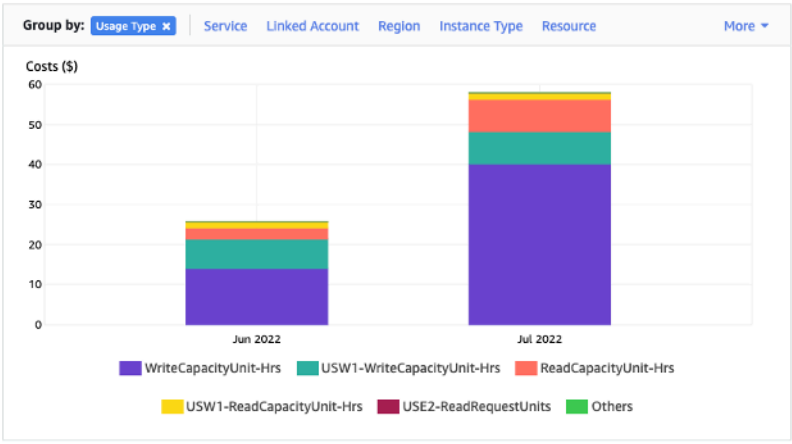
and the size and item count of the table and any indexes. The size of the table, plus the size of the indexes, can be used to calculate the monthly storage cost for your table. For example, $0.25 per GB in the us-east-1 region.

If the table is in provisioned capacity mode, the current RCU and WCU settings are returned as well. These could be used to calculate the current read and write costs for the table, but these costs could change, especially if the table has been configured with Auto Scaling.

> **Note**
>
> If the table is in on-demand capacity mode, then `DescribeTable` will not help estimate throughput costs, as these are billed based on actual, not provisioned usage in any one period.

Cost Explorer's default view

Cost Explorer's default view provides charts showing the cost of consumed resources such as throughput and storage. You can choose to group costs by period, such as totals by month or by day. The costs of storage, reads, writes, and other features can be broken out and compared as well.



How to use and apply table tags in Cost Explorer

By default, Cost Explorer does not provide a summary of the costs for any one specific table, as it will combine the costs of multiple tables into a total. However, you can use AWS resource tagging to identify each table by a metadata tag. Tags are key-value pairs you can use for a variety of purposes, such as to identify all resources belonging to a project or department. For this example, we'll assume you have a table named **MyTable**.

1. Set a tag with the key of **table_name** and the value of **MyTable**.
2. Activate the tag within Cost Explorer and then filter on the tag value to gain more visibility into each table's costs.

> **Note**
>
> It may take one or two days for the tag to start appearing in Cost Explorer

You can set metadata tags yourself in the console, or via automation such as the AWS CLI or AWS SDK. Consider requiring a **table_name** tag to be set as part of your organization's new table creation process. For existing tables, there is a Python utility available that will find and apply these tags to all existing tables in a certain region in your account. See Eponymous Table Tagger on GitHub for more details.

Evaluate your DynamoDB table's capacity mode

This section provides an overview of how to select the appropriate capacity mode for your DynamoDB table. Each mode is tuned to meet the needs of a different workload in terms of responsiveness to change in throughput, as well as how that usage is billed. You must balance these factors when making your decision.

Topics

- What table capacity modes are available
- When to select on-demand capacity mode
- When to select provisioned capacity mode
- Additional factors to consider when choosing a table capacity mode

What table capacity modes are available

When you create a DynamoDB table, you must select either on-demand or provisioned capacity mode. You can switch between capacity modes once every 24 hours. The only exception to this is if you switch a provisioned mode table to on-demand mode, you can switch back to provisioned mode in the same 24-hour period.

On-demand capacity mode

The on-demand capacity mode is designed to eliminate the need to plan or provision the capacity of your DynamoDB table. In this mode, your table will instantly accommodate requests to your table without the need to scale any resources up or down (up to twice the previous peak throughput of the table).

DynamoDB on-demand offers pay-per-request pricing for read and write requests so that you only pay for what you use.

Provisioned capacity mode

The provisioned capacity mode is a more traditional model where you must define how much capacity the table has available for requests either directly or with the assistance of auto scaling. Because a specific capacity is provisioned for the table at any given time, billing is based off of the total capacity provisioned rather than the number of requests consumed. Going over the allocated capacity can also cause the table to reject requests and reduce the experience of your applications users.

Provisioned capacity mode requires constant monitoring to find a balance between not over-provisioning or under-provisioning the table to keep both throttling low and costs tuned.

When to select on-demand capacity mode

When optimizing for cost, on-demand mode is your best choice when you have a workload similar to the following graphs.

The following factors contribute to this type of workload:

- Traffic pattern that evolves over time
- Variable volume of requests (resulting from batch workloads)
- Unpredictable request timing (resulting in traffic spikes)
- Drops to zero or below 30% of the peak for a given hour

For workloads with the above factors, using auto scaling to maintain enough capacity on the table to respond to spikes in traffic will likely lead to the table being overprovisioned and costing more than necessary or the table being under provisioned and requests being unnecessarily throttled. On-demand capacity mode is the better choice because it can handle fluctuating traffic without requiring you to predict or adjust capacity.

With on-demand mode's pay-per-request pricing model, you don't have to worry about idle capacity because you only pay for the throughput you actually use. You are billed per read or write request consumed, so your costs directly reflect your actual usage, making it easy to balance costs and performance. Optionally, you can also configure maximum read or write (or both) throughput per second for individual on-demand tables and global secondary indexes to help keep costs and usage bounded. For more information, see maximum throughput for on-demand tables .

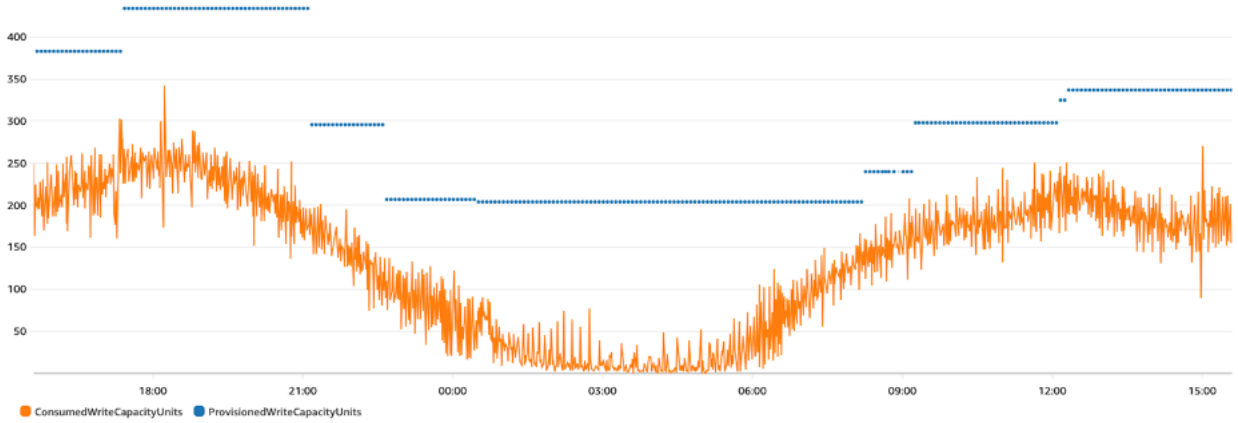
When to select provisioned capacity mode

An ideal workload for provisioned capacity mode is one with a more steady and predictable usage pattern like the graph below.

> **Note**
>
> We recommend reviewing metrics at a fine-grained period, such as 14 days, before taking action on your provisioned capacity.

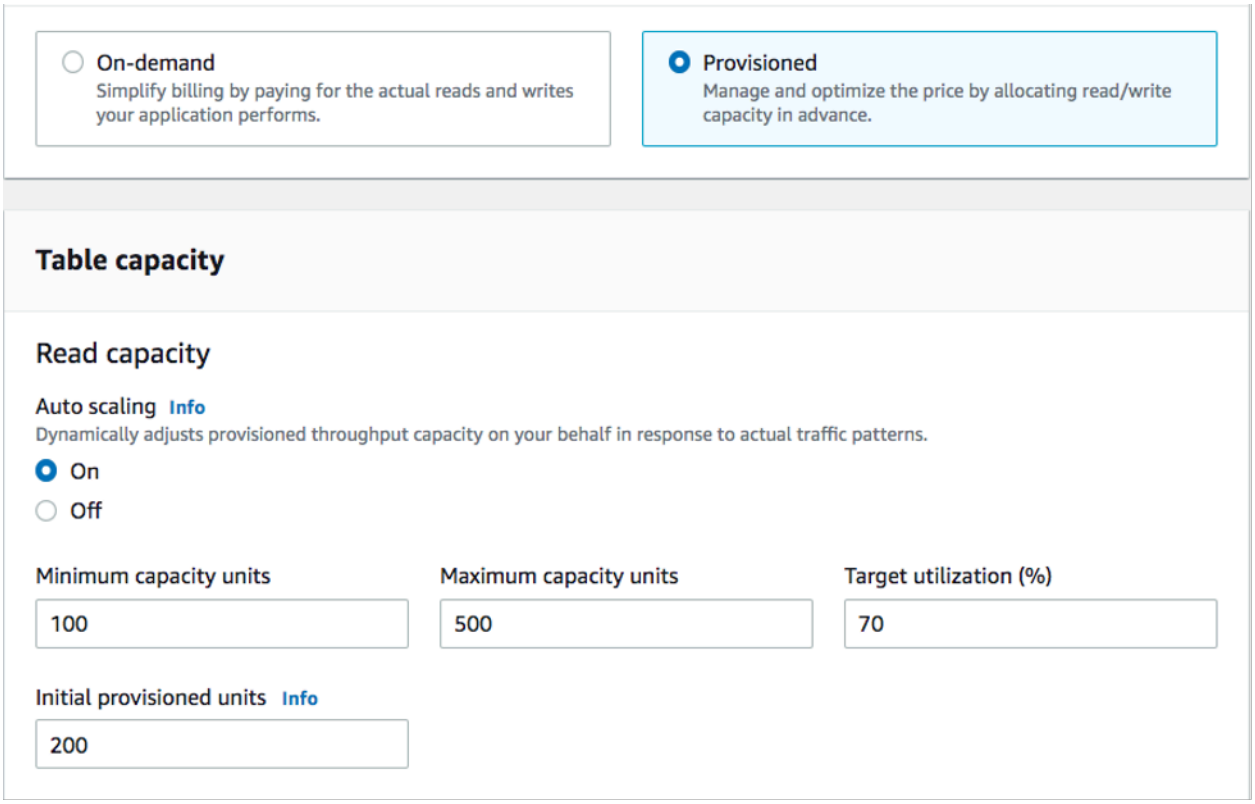
The following factors contribute to this type of workload:

- Steady, predictable and cyclical traffic for a given hour or day
- Limited short-term bursts of traffic



Since the traffic volumes within a given hour or day are more stable, you can set the provisioned capacity of the table relatively close to the actual consumed capacity of the table. Cost optimizing a provisioned capacity table is ultimately an exercise in getting the provisioned capacity (blue line) as close to the consumed capacity (orange line) as possible without increasing `ThrottledRequests` on the table. The space between the two lines is both wasted capacity as well as insurance against a bad user experience due to throttling. If you can predict your application's throughput requirements and you prefer the cost predictability of controlling read and write capacity, then you may want to continue using provisioned tables.

DynamoDB provides auto scaling for provisioned capacity tables which will automatically balance this on your behalf. This lets you track your consumed capacity throughout the day and set the capacity of the table based on a handful of variables. When using auto scaling, your table will be over-provisioned and you need to fine tune the ratio between number of throttles versus over-provisioned capacity units to match your workload needs.



Minimum capacity units

You can set the minimum capacity of a table to limit throttling, but it will not reduce the cost of the table. If your table has periods of low usage follow by a sudden burst of high usage, setting the minimum can prevent auto scaling from setting the table capacity too low.

Maximum capacity units

You can set the maximum capacity of a table to limit a table scaling higher than intended. Consider applying a maximum for Dev or Test tables where large-scale load testing is not desired. You can set a maximum for any table, but be sure to regularly evaluate this setting against the table baseline when using it in Production to prevent accidental throttling.

Target utilization

Setting the target utilization of the table is the primary means of cost optimization for a provisioned capacity table. Setting a lower percent value here will increase how much the table is overprovisioned, increasing cost, but reducing the risk of throttling. Setting a higher percent value will decrease how much the table is overprovisioned, but increase the risk of throttling.

Additional factors to consider when choosing a table capacity mode

When deciding between the two modes, there are some additional factors worth considering.

Provisioned capacity utilization

To determine when on-demand mode would cost less than provisioned capacity, it's helpful to look at your provisioned capacity utilization, which refers to how efficiently the allocated (or “provisioned) resources are being used. On-demand mode costs less for workloads with average provisioned capacity utilization below 35%. In many cases, even for workloads with provisioned capacity utilization higher than 35%, it can be more cost-effective to use on-demand mode especially if the workload has periods of low activity mixed with occasional peaks.

Reserved capacity

For provisioned capacity tables, DynamoDB offers the ability to purchase reserved capacity for your read and write capacity (replicated write capacity units (rWCU) and Standard-IA tables are currently not eligible). Reserved capacity offers significant discounts over standard provisioned capacity pricing.

When deciding between the two table modes, consider how much this additional discount will affect the cost of the table. In some cases, it may cost less to run a relatively unpredictable workload can be cheaper to run on an overprovisioned provisioned capacity table with reserved capacity.

Improving predictability of your workload

In some situations, a workload may seemingly have both a predictable and unpredictable pattern. While this can be easily supported with an on-demand table, costs will likely be better if the unpredictable patterns in the workload can be improved.

One of the most common causes of these patterns is batch imports. This type of traffic can often exceed the baseline capacity of the table to such a degree that throttling would occur if it were to run. To keep a workload like this running on a provisioned capacity table, consider the following options:

- If the batch occurs at scheduled times, you can schedule an increase to your auto- scaling capacity before it runs
- If the batch occurs randomly, consider trying to extend the time it runs rather than executing as fast as possible

- Add a ramp up period to the import where the velocity of the import starts small but is slowly increased over a few minutes until auto scaling has had the opportunity to start adjusting table capacity

Evaluate your DynamoDB table's auto scaling settings

This section provides an overview of how to evaluate the auto scaling settings on your DynamoDB tables. Amazon DynamoDB auto scaling is a feature that manages table and global secondary index (GSI) throughput based on your application traffic and your target utilization metric. This ensures your tables or GSIs will have the required capacity required for your application patterns.

The AWS auto scaling service will monitor your current table utilization and compare it to the target utilization value: `TargetValue`. It will notify you if it is time to increase or decrease the capacity allocated.

Topics

- Understanding your auto scaling settings
- How to identify tables with low target utilization (<=50%)
- How to address workloads with seasonal variance
- How to address spiky workloads with unknown patterns
- How to address workloads with linked applications

Understanding your auto scaling settings

Defining the correct value for the target utilization, initial step, and final values is an activity that requires involvement from your operations team. This allows you to properly define the values based on historical application usage, which will be used to trigger the AWS auto scaling policies. The utilization target is the percentage of your total capacity that needs to be hit during a period of time before the auto scaling rules apply.

When you set a **high utilization target (a target around 90%)** it means your traffic needs to be higher than 90% for a period of time before the auto scaling kicks in. You should not use a high utilization target unless your application is very constant and doesn't receive spikes in traffic.

When you set a very **low utilization (a target less than 50%)** it means your application would need to reach 50% of the provisioned capacity before it triggers an auto scaling policy. Unless your

application traffic grows at a very aggressive rate, this usually translates into unused capacity and wasted resources.

How to identify tables with low target utilization (<=50%)

You can use either the AWS CLI or AWS Management Console to monitor and identify the `TargetValues` for your auto scaling policies in your DynamoDB resources:

AWS CLI

1. Return the entire list of resources by running the following command:

   ```
   aws application-autoscaling describe-scaling-policies --service-namespace
    dynamodb
   ```

   This command will return the entire list of auto scaling policies that are issued to any DynamoDB resource. If you only want to retrieve the resources from a particular table, you can add the `–resource-id parameter`. For example:

   ```
   aws application-autoscaling describe-scaling-policies --service-namespace
    dynamodb --resource-id "table/<table-name>”
   ```

2. Return only the auto scaling policies for a particular GSI by running the following command

   ```
   aws application-autoscaling describe-scaling-policies --service-namespace
    dynamodb --resource-id "table/<table-name>/index/<gsi-name>”
   ```

   The values we're interested in for the auto scaling policies are highlighted below. We want to ensure that the target value is greater than 50% to avoid over-provisioning. You should obtain a result similar to the following:

   ```
   {
       "ScalingPolicies": [
           {
               "PolicyARN": "arn:aws:autoscaling:<region>:<account-
   id>:scalingPolicy:<uuid>:resource/dynamodb/table/<table-name>/index/<index-
   name>:policyName/$<full-gsi-name>-scaling-policy",
               "PolicyName": $<full-gsi-name>”,
               "ServiceNamespace": "dynamodb",
               "ResourceId": "table/<table-name>/index/<index-name>",
               "ScalableDimension": "dynamodb:index:WriteCapacityUnits",
   ```

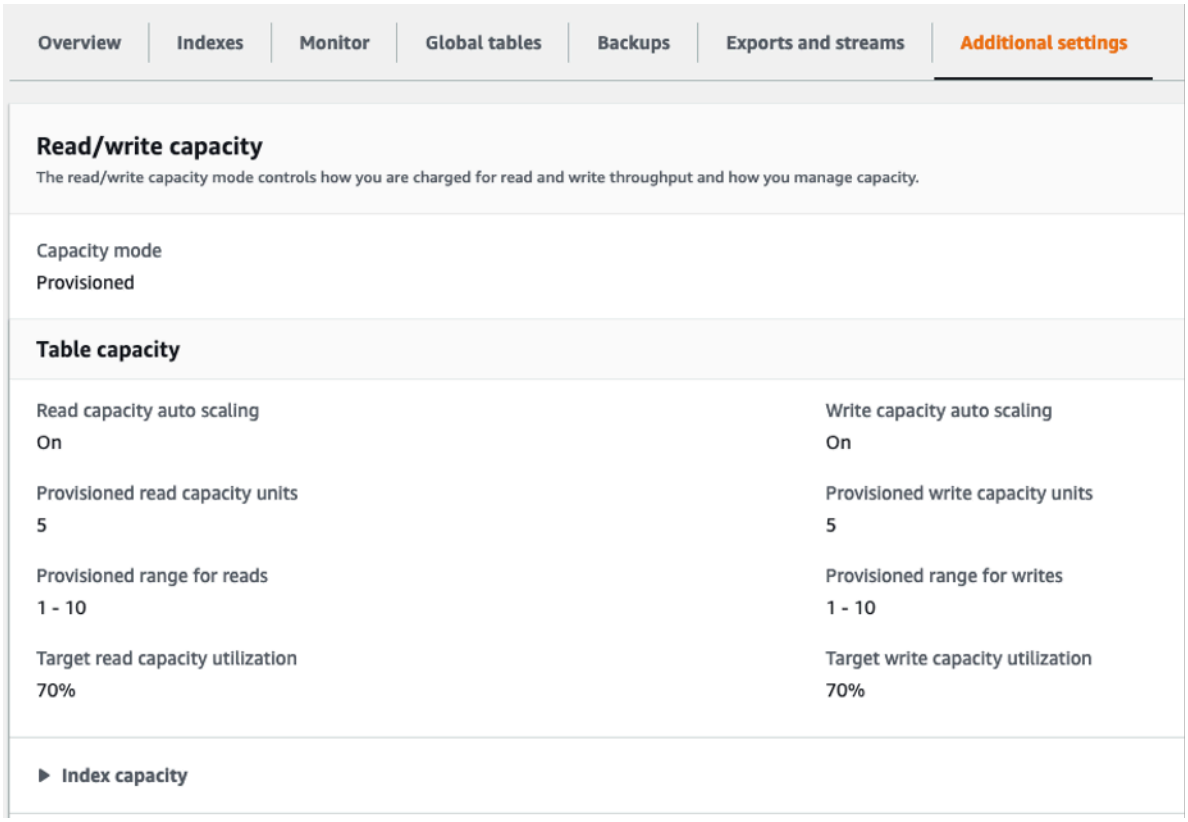
```
            "PolicyType": "TargetTrackingScaling",
            "TargetTrackingScalingPolicyConfiguration": {
                "TargetValue": 70.0,
                "PredefinedMetricSpecification": {
                    "PredefinedMetricType": "DynamoDBWriteCapacityUtilization"
                }
            },
            "Alarms": [
                ...
            ],
            "CreationTime": "2022-03-04T16:23:48.641000+10:00"
        },
        {
            "PolicyARN": "arn:aws:autoscaling:<region>:<account-
id>:scalingPolicy:<uuid>:resource/dynamodb/table/<table-name>/index/<index-
name>:policyName/$<full-gsi-name>-scaling-policy",
            "PolicyName":$<full-gsi-name>”,
            "ServiceNamespace": "dynamodb",
            "ResourceId": "table/<table-name>/index/<index-name>",
            "ScalableDimension": "dynamodb:index:ReadCapacityUnits",
            "PolicyType": "TargetTrackingScaling",
            "TargetTrackingScalingPolicyConfiguration": {
                "TargetValue": 70.0,
                "PredefinedMetricSpecification": {
                    "PredefinedMetricType": "DynamoDBReadCapacityUtilization"
                }
            },
            "Alarms": [
                ...
            ],
            "CreationTime": "2022-03-04T16:23:47.820000+10:00"
        }
    ]
}
```

AWS Management Console

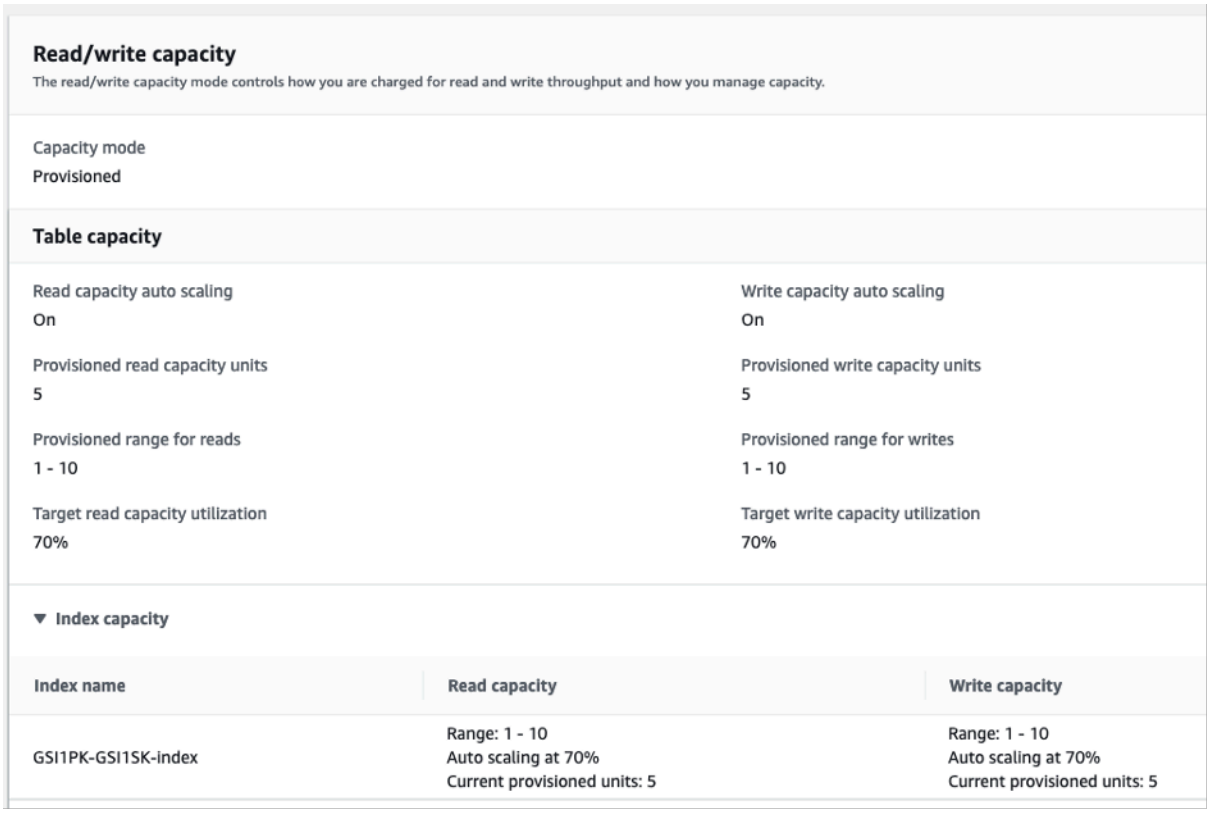
1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.

   Select an appropriate AWS Region if necessary.

2. On the left navigation bar, select **Tables**. On the **Tables** page, select the table's **Name**.
3. On the *Table details* page, choose **Additional settings**, and then review your table's auto scaling settings.



For indexes, expand the **Index capacity** section to review the index's auto scaling settings.



If your target utilization values are less than or equal to 50%, you should explore your table utilization metrics to see if they are under-provisioned or over-provisioned.

How to address workloads with seasonal variance

Consider the following scenario: your application is operating under a minimum average value most of the time, but the utilization target is low so your application can react quickly to events that happen at certain hours in the day and you have enough capacity and avoid getting throttled. This scenario is common when you have an application that is very busy during normal office hours (9 AM to 5 PM) but then it works at a base level during after hours. Since some users will start to connect before 9 am, the application uses this low threshold to ramp up quickly to get to the *required* capacity during peak hours.

This scenario could look like this:

- Between 5 PM and 9 AM the `ConsumedWriteCapacity` units stay between 90 and 100
- Users start to connect to the application before 9 AM and the capacity units increases considerably (the maximum value you've seen is 1500 WCU)
- On average, your application usage varies between 800 to 1200 during working hours

If the previous scenario applies to you, consider using scheduled auto scaling, where your table could still have an application auto scaling rule configured, but with a less aggressive target utilization that only provisions the extra capacity at the specific intervals you require.

You can use AWS CLI to execute the following steps to create a scheduled auto scaling rule that will execute based on the time of day and the day of the week.

1. Register your DynamoDB table or GSI as scalable target with Application Auto Scaling. A scalable target is a resource that Application Auto Scaling can scale out or in.

```
aws application-autoscaling register-scalable-target \
    --service-namespace dynamodb \
    --scalable-dimension dynamodb:table:WriteCapacityUnits \
    --resource-id table/<table-name> \
    --min-capacity 90 \
    --max-capacity 1500
```

2. Set up scheduled actions according to your requirements.

   We'll need two rules to cover the scenario: one to scale up and another to scale down. The first rule to scale up the scheduled action:

```
aws application-autoscaling put-scheduled-action \
    --service-namespace dynamodb \
    --scalable-dimension dynamodb:table:WriteCapacityUnits \
    --resource-id table/<table-name> \
    --scheduled-action-name my-8-5-scheduled-action \
    --scalable-target-action MinCapacity=800,MaxCapacity=1500 \
    --schedule "cron(45 8 ? * MON-FRI *)" \
    --timezone "Australia/Brisbane"
```

   The second rule to scale down the scheduled action:

```
aws application-autoscaling put-scheduled-action \
    --service-namespace dynamodb \
    --scalable-dimension dynamodb:table:WriteCapacityUnits \
    --resource-id table/<table-name> \
    --scheduled-action-name my-5-8-scheduled-down-action \
    --scalable-target-action MinCapacity=90,MaxCapacity=1500 \
    --schedule "cron(15 17 ? * MON-FRI *)" \
    --timezone "Australia/Brisbane"
```

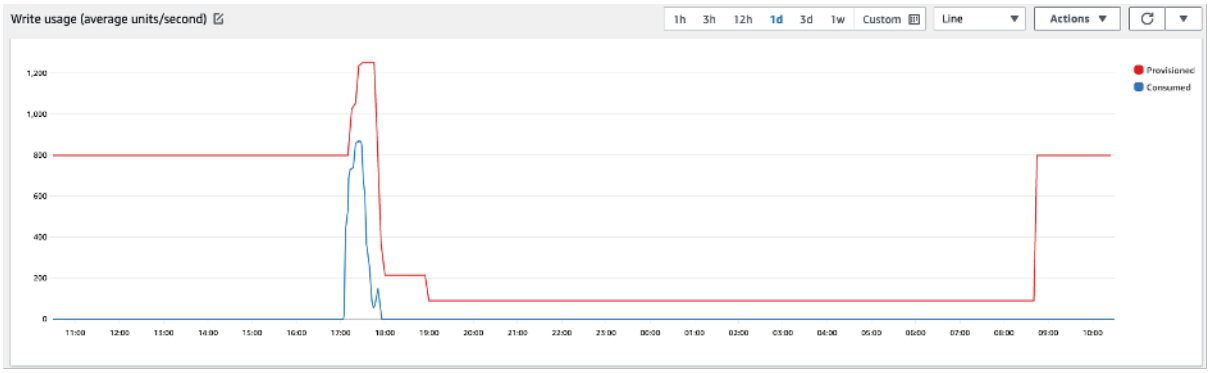
3. Run the following command to validate both rules have been activated:

```
aws application-autoscaling describe-scheduled-actions --service-namespace dynamodb
```

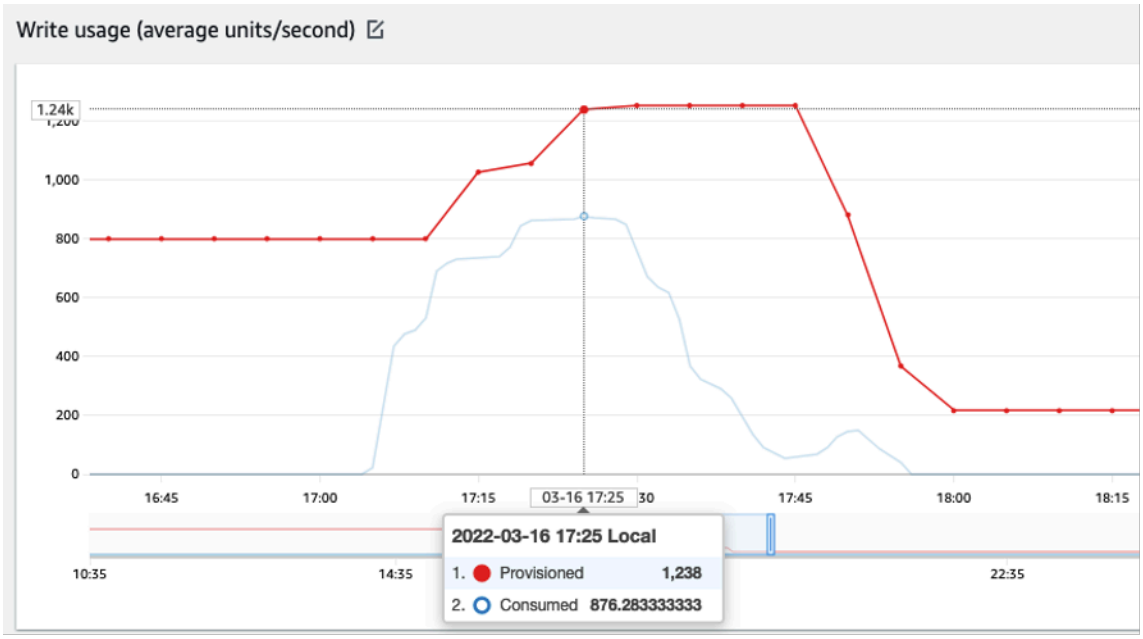
You should get a result like this:

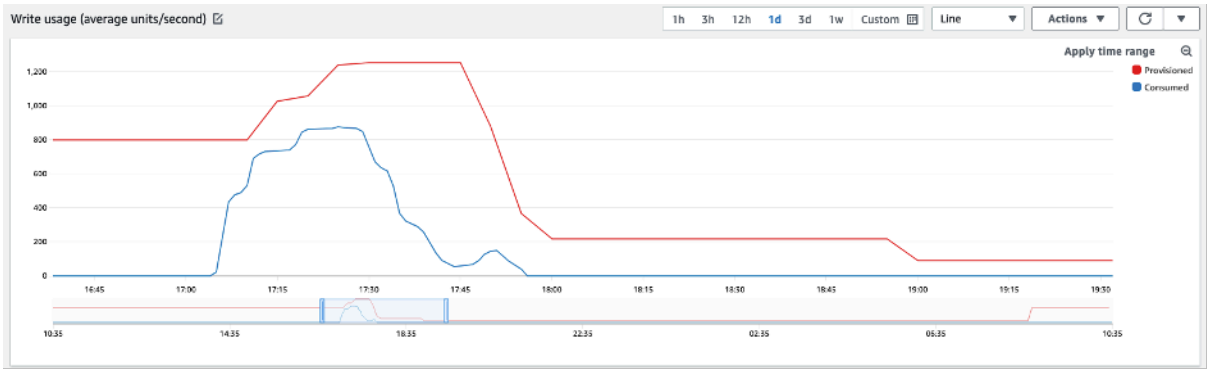
```
{
    "ScheduledActions": [
        {
            "ScheduledActionName": "my-5-8-scheduled-down-action",
            "ScheduledActionARN":
 "arn:aws:autoscaling:<region>:<account>:scheduledAction:<uuid>:resource/dynamodb/
table/<table-name>:scheduledActionName/my-5-8-scheduled-down-action",
            "ServiceNamespace": "dynamodb",
            "Schedule": "cron(15 17 ? * MON-FRI *)",
            "Timezone": "Australia/Brisbane",
            "ResourceId": "table/<table-name>",
            "ScalableDimension": "dynamodb:table:WriteCapacityUnits",
            "ScalableTargetAction": {
                "MinCapacity": 90,
                "MaxCapacity": 1500
            },
            "CreationTime": "2022-03-15T17:30:25.100000+10:00"
        },
        {
            "ScheduledActionName": "my-8-5-scheduled-action",
            "ScheduledActionARN":
 "arn:aws:autoscaling:<region>:<account>:scheduledAction:<uuid>:resource/dynamodb/
table/<table-name>:scheduledActionName/my-8-5-scheduled-action",
            "ServiceNamespace": "dynamodb",
            "Schedule": "cron(45 8 ? * MON-FRI *)",
            "Timezone": "Australia/Brisbane",
            "ResourceId": "table/<table-name>",
            "ScalableDimension": "dynamodb:table:WriteCapacityUnits",
            "ScalableTargetAction": {
                "MinCapacity": 800,
                "MaxCapacity": 1500
            },
            "CreationTime": "2022-03-15T17:28:57.816000+10:00"
        }
    ]
}
```

The following picture shows a sample workload that always keeps the 70% target utilization. Notice how the auto scaling rules are still applying and the throughput will not be reduced.



Zooming in, we can see there was a spike in the application that triggered the 70% auto scaling threshold, forcing the auto scaling to kick in and provide the extra capacity required for the table. The scheduled auto scaling action will affect maximum and minimum values, and it is your responsibility to set them up.





How to address spiky workloads with unknown patterns

In this scenario, the application uses a very low utilization target because you don't know the application patterns yet, and you want to ensure your workload is not throttled.

Consider using on-demand capacity mode instead. On-demand tables are perfect for spiky workloads where you don't know the traffic patterns. With on-demand capacity mode, you pay per request for the data reads and writes your application performs on your tables. You do not need to specify how much read and write throughput you expect your application to perform, as DynamoDB instantly accommodates your workloads as they ramp up or down.

How to address workloads with linked applications

In this scenario, the application depends on other systems, like batch processing scenarios where you can have big spikes in traffic according to events in the application logic.

Consider developing custom auto scaling logic that reacts to those events where you can increase table capacity and `TargetValues` depending on your specific needs. You could benefit from Amazon EventBridge and use a combination of AWS services like Lambda and Step Functions to react to your specific application needs.

Evaluate your DynamoDB table class selection

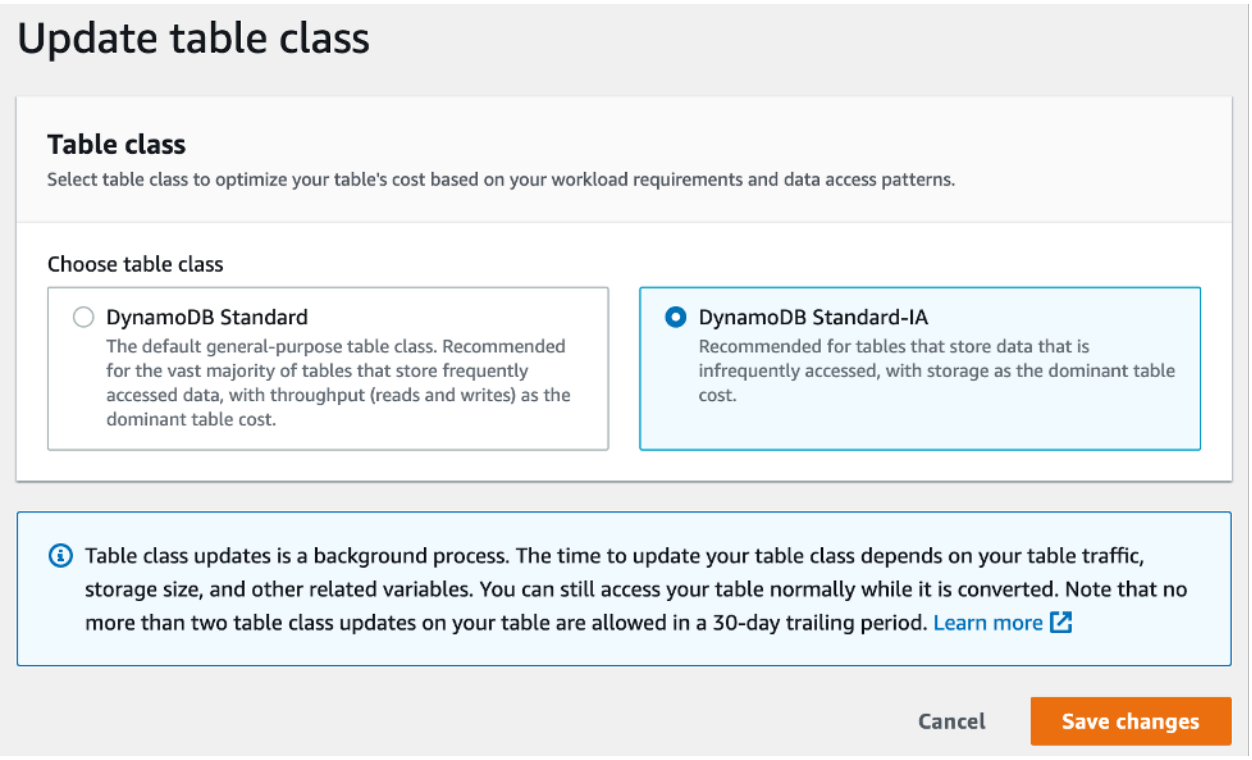
This section provides an overview of how to select the appropriate table class for your DynamoDB table. With the launch of the Standard Infrequent-Access (Standard-IA) table class, you now have the ability to optimize a table for either lower storage cost or lower throughput cost.

Topics

- What table classes are available
- When to select the DynamoDB Standard table class
- When to select DynamoDB Standard-IA table class
- Additional factors to consider when choosing a table class

What table classes are available

When you create a DynamoDB Table, you must select either DynamoDB Standard or DynamoDB Standard-IA for the table class. The table class can be changed twice in a 30-day period, so you can always change it in the future. Selecting either table class has no effect on table performance, availability, reliability, or durability.



Standard table class

The Standard table class is the default option for new tables. This option maintains the original billing balance of DynamoDB which offers a balance of throughput and storage costs for tables with frequently accessed data.

Standard-IA table class

The Standard-IA table class offers a lower storage cost (~60% lower) for workloads that require long-term storage of data with infrequent updates or reads. Since the class is optimized for infrequent access, reads and writes will be billed at a slightly higher cost (~25% higher) than the Standard table class.

When to select the DynamoDB Standard table class

DynamoDB Standard table class is best suited for tables whose storage cost is approximately 50% or less of the overall monthly cost of the table. This cost balance is indicative of a workload that regularly accesses or updates items already stored within DynamoDB.

When to select DynamoDB Standard-IA table class

DynamoDB Standard-IA table class is best suited for tables whose storage cost is approximately 50% or more of the overall monthly cost of the table. This cost balance is indicative of a workload that creates or reads fewer items per month than it keeps in storage.

A common use for the Standard-IA table class is moving less frequently accessed data to individual Standard-IA tables. For further information, see Optimizing the storage costs of your workloads with Amazon DynamoDB Standard-IA table class.

Additional factors to consider when choosing a table class

When deciding between the two table classes, there are some additional factors worth considering as part of your decision.

Reserved capacity

Purchasing reserved capacity for tables using the Standard-IA table class is currently not supported. When transitioning from a Standard table with reserved capacity to a Standard-IA table without reserved capacity, you may not see a cost benefit.

Identify your unused resources in DynamoDB

This section provides an overview of how to evaluate your unused resources regularly. As your application requirements evolve you should ensure no resources are unused and contributing to unnecessary Amazon DynamoDB costs. The procedures described below will use Amazon CloudWatch metrics to identify unused resources and will help you identify and take action on those resources to reduce costs.

You can monitor DynamoDB using CloudWatch, which collects and processes raw data from DynamoDB into readable, near real-time metrics. These statistics are retained for a period of time, so that you can access historical information to better understand your utilization. By default, DynamoDB metric data is sent to CloudWatch automatically. For more information, see What is Amazon CloudWatch? and Metrics retention in the *Amazon CloudWatch User Guide*.

Topics

- How to identify unused resources
- Identifying unused table resources
- Cleaning up unused table resources

- Identifying unused GSI resources
- Cleaning up unused GSI resources
- Cleaning up unused global tables
- Cleaning up unused backups or point-in-time recovery (PITR)

How to identify unused resources

To identify unused tables or indexes, we'll look at the following CloudWatch metrics over a period of 30 days to understand if there are any active reads or writes on the table or any reads on the global secondary indexes (GSIs):

ConsumedReadCapacityUnits

The number of read capacity units consumed over the specified time period, so you can track how much consumed capacity you have used. You can retrieve the total consumed read capacity for a table and all of its global secondary indexes, or for a particular global secondary index.

ConsumedWriteCapacityUnits

The number of write capacity units consumed over the specified time period, so you can track how much consumed capacity you have used. You can retrieve the total consumed write capacity for a table and all of its global secondary indexes, or for a particular global secondary index.

Identifying unused table resources

Amazon CloudWatch is a monitoring and observability service which provides the DynamoDB table metrics you'll use to identify unused resources. CloudWatch metrics can be viewed through the AWS Management Console as well as through the AWS Command Line Interface.

AWS Command Line Interface

To view your tables metrics through the AWS Command Line Interface, you can use the following commands.

1. First, evaluate your table's reads:

```
aws cloudwatch get-metric-statistics --metric-name
ConsumedReadCapacityUnits --start-time <start-time> --end-time <end-
time> --period <period> --namespace AWS/DynamoDB --statistics Sum --
```

```
dimensions Name=TableName,Value=<table-name>
```

To avoid falsely identifying a table as unused, evaluate metrics over a longer period. Choose an appropriate start-time and end-time range, such as **30 days**, and an appropriate period, such as **86400**.

In the returned data, any **Sum** above **0** indicates that the table you are evaluating received read traffic during that period.

The following result shows a table receiving read traffic in the evaluated period:

```
        {
            "Timestamp": "2022-08-25T19:40:00Z",
            "Sum": 36023355.0,
            "Unit": "Count"
        },
        {
            "Timestamp": "2022-08-12T19:40:00Z",
            "Sum": 38025777.5,
            "Unit": "Count"
        },
```

The following result shows a table not receiving read traffic in the evaluated period:

```
        {
            "Timestamp": "2022-08-01T19:50:00Z",
            "Sum": 0.0,
            "Unit": "Count"
        },
        {
            "Timestamp": "2022-08-20T19:50:00Z",
            "Sum": 0.0,
            "Unit": "Count"
        },
```

2. Next, evaluate your table's writes:

```
aws cloudwatch get-metric-statistics --metric-name
ConsumedWriteCapacityUnits --start-time <start-time> --end-time <end-
time> --period <period> --namespace AWS/DynamoDB --statistics Sum --
dimensions Name=TableName,Value=<table-name>
```

To avoid falsely identifying a table as unused, you will want to evaluate metrics over a longer period. Choose an appropriate start-time and end-time range, such as **30 days**, and an appropriate period, such as **86400**.

In the returned data, any **Sum** above **0** indicates that the table you are evaluating received read traffic during that period.

The following result shows a table receiving write traffic in the evaluated period:

```
{
    "Timestamp": "2022-08-19T20:15:00Z",
    "Sum": 41014457.0,
    "Unit": "Count"
},
{
    "Timestamp": "2022-08-18T20:15:00Z",
    "Sum": 40048531.0,
    "Unit": "Count"
},
```

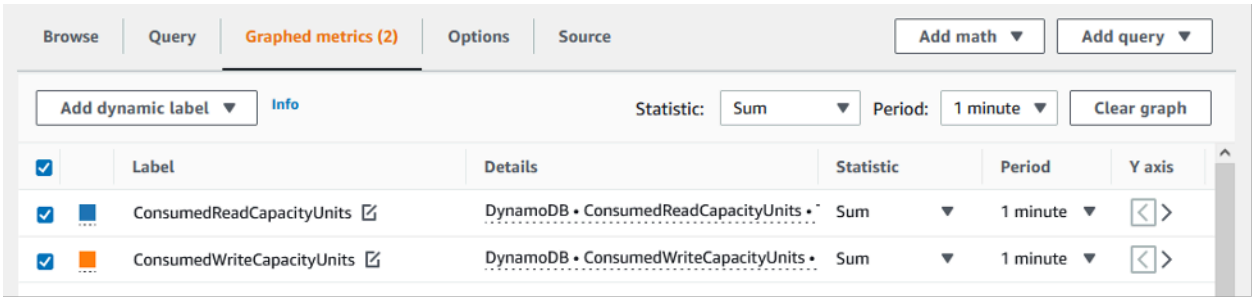
The following result shows a table not receiving write traffic in the evaluated period:

```
{
    "Timestamp": "2022-07-31T20:15:00Z",
    "Sum": 0.0,
    "Unit": "Count"
},
{
    "Timestamp": "2022-08-19T20:15:00Z",
    "Sum": 0.0,
    "Unit": "Count"
},
```

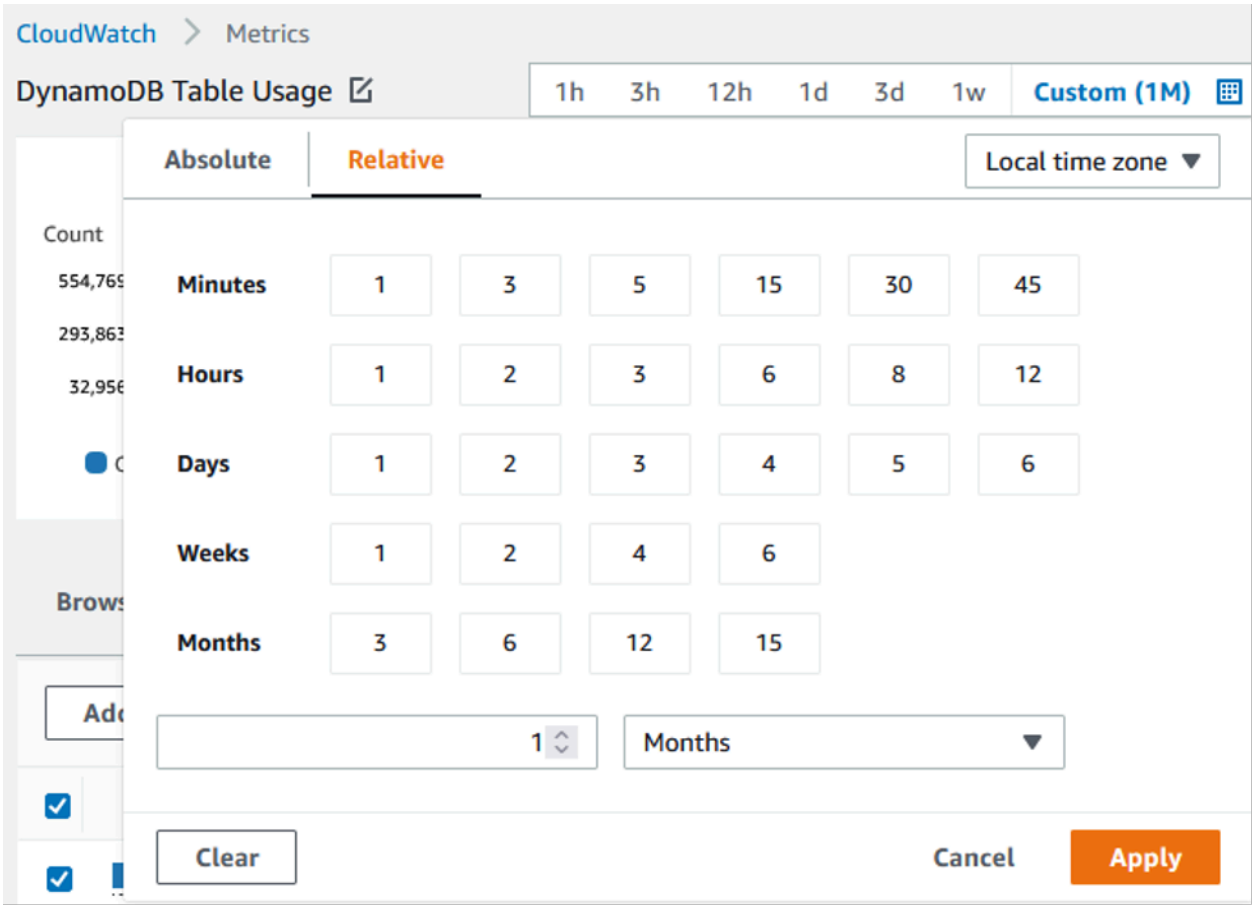
AWS Management Console

The following steps will allow you to evaluate your resources utilization through the AWS Management Console.

1. Log into the AWS console and navigate to the CloudWatch service page at https://console.aws.amazon.com/cloudwatch/. Select the appropriate AWS region in the top right of the console, if necessary.
2. On the left navigation bar, locate the Metrics section and select **All metrics**.
3. The action above will open a dashboard with two panels. In the top panel you will see currently graphed metrics. In the bottom you will select the metrics available to graph. Select DynamoDB in the bottom panel.
4. In the DynamoDB metrics selection panel select the **Table Metrics** category to show the metrics for your tables in the current region.
5. Identify your table name by scrolling down the menu, then select the metrics `ConsumedReadCapacityUnits` and `ConsumedWriteCapacityUnits` for your table.
6. Select the **Graphed metrics (2)** tab and adjust the **Statistic** column to **Sum**.



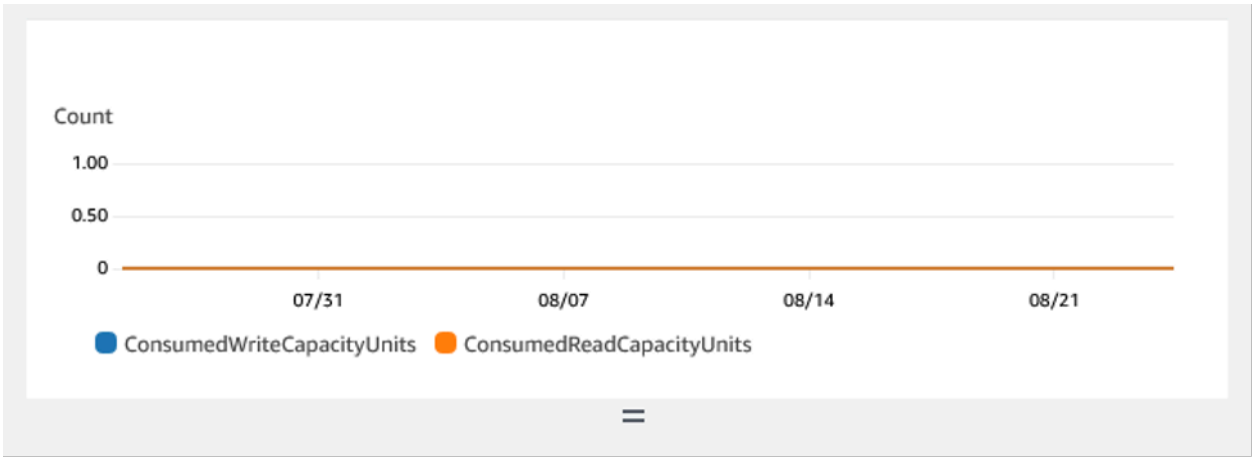
7. To avoid falsely identifying a table as unused, you'll want to evaluate metrics over a longer period. At the top of the graph panel choose an appropriate time frame, such as 1 month, to evaluate your table. Select **Custom**, select **1 Months** in the dropdowns, and choose **Apply**.



8. Evaluate the graphed metrics for your table to determine if it is being used. Metrics that have gone above **0** indicate that a table has been used during the evaluated time period. A flat graph at **0** for both read and write indicates a table that is unused.

   The following image shows a table with read traffic:

   The following image shows a table without read traffic:



Cleaning up unused table resources

If you have identified unused table resources, you can reduce their ongoing costs in the following ways.

> **Note**
>
> If you have identified an unused table but would still like to keep it available in case it needs to be accessed in the future, consider switching it to on-demand mode. Otherwise, you can consider backing up and deleting the table entirely.

Capacity modes

DynamoDB charges for reading, writing, and storing data in your DynamoDB tables.

DynamoDB has two capacity modes, which come with specific billing options for processing reads and writes on your tables: on-demand and provisioned. The read/write capacity mode controls how you are charged for read and write throughput and how you manage capacity.

For on-demand mode tables, you don't need to specify how much read and write throughput you expect your application to perform. DynamoDB charges you for the reads and writes that your application performs on your tables in terms of read request units and write request units. If there is no activity on your table/index you do not pay for throughput but you'll still incur a storage charge.

Table class

DynamoDB also offers two table classes designed to help you optimize for cost. The DynamoDB Standard table class is the default and is recommended for most workloads. The DynamoDB Standard-Infrequent Access (DynamoDB Standard-IA) table class is optimized for tables where storage is the dominant cost.

If there is no activity on your table or index, storage is likely to be the dominant cost and changing table class will offer a significant savings.

Deleting tables

If you've discovered an unused table and would like to delete it, you may wish to make a backup or export of the data first.

Backups taken through AWS Backup can leverage cold storage tiering, further reducing costs. Refer to the Using AWS Backup with DynamoDB documentation for information on how enable backups through AWS Backup as well as the Managing backup plans documentation for information on how to use lifecycle to move your backup to cold storage.

Alternatively, you may choose to export your table's data to S3. To do so, refer to the Export to Amazon S3 documentation. Once your data is exported, if you wish to leverage S3 Glacier Instant Retrieval, S3 Glacier Flexile Retrieval, or S3 Glacier Deep Archive to further reduce costs, see Managing your storage lifecycle.

After your table has been backed up, you may choose to delete it either through the AWS Management Console or through the AWS Command Line Interface.

Identifying unused GSI resources

The steps for identifying an unused global secondary are similar to those for identifying an unused table. Since DynamoDB replicates items written to your base table into your GSI if they contain the attribute used as the GSI's partition key, an unused GSI is still likely to have `ConsumedWriteCapacityUnits` above 0 if its base table is in use. As a result, you'll be evaluating only the `ConsumedReadCapacityUnits` metric to determine if your GSI is unused.

To view your GSI metrics through the AWS AWS CLI, you can use the following commands to evaluate your tables reads:

```
aws cloudwatch get-metric-statistics --metric-name
ConsumedReadCapacityUnits --start-time <start-time> --end-time <end-
time> --period <period> --namespace AWS/DynamoDB --statistics Sum --
dimensions Name=TableName,Value=<table-name>
```

```
Name=GlobalSecondaryIndexName,Value=<index-name>
```

To avoid falsely identifying a table as unused, you will want to evaluate metrics over a longer period. Choose an appropriate start-time and end-time range, such as 30 days, and an appropriate period, such as 86400.

In the returned data, any Sum above 0 indicates that the table you are evaluating received read traffic during that period.

The following result shows a GSI receiving read traffic in the evaluated period:

```
        {
          "Timestamp": "2022-08-17T21:20:00Z",
          "Sum": 36319167.0,
          "Unit": "Count"
        },
        {
          "Timestamp": "2022-08-11T21:20:00Z",
          "Sum": 1869136.0,
          "Unit": "Count"
        },
```

The following result shows a GSI receiving minimal read traffic in the evaluated period:

```
        {
          "Timestamp": "2022-08-28T21:20:00Z",
          "Sum": 0.0,
          "Unit": "Count"
        },
        {
          "Timestamp": "2022-08-15T21:20:00Z",
          "Sum": 2.0,
          "Unit": "Count"
        },
```

The following result shows a GSI receiving no read traffic in the evaluated period:

```
        {
          "Timestamp": "2022-08-17T21:20:00Z",
          "Sum": 0.0,
          "Unit": "Count"
        },
```

```
        {
          "Timestamp": "2022-08-11T21:20:00Z",
          "Sum": 0.0,
          "Unit": "Count"
        },
```

Cleaning up unused GSI resources

If you've identified an unused GSI, you can choose to delete it. Since all data present in a GSI is also present in the base table, additional backup is not necessary before deleting a GSI. If in the future the GSI is once again needed, it may be added back to the table.

If you have identified an infrequently used GSI, you should consider design changes in your application that would allow you to delete it or reduce its cost. For example, while DynamoDB scans should be used sparingly because they can consume large amounts of system resources, they may be more cost effective than a GSI if the access pattern it supports is used very infrequently.

Additionally, if a GSI is required to support an infrequent access pattern consider projecting a more limited set of attributes. While this may require subsequent queries against the base table to support your infrequent access patterns, it can potentially offer a significant reduction in storage and write costs.

Cleaning up unused global tables

Amazon DynamoDB global tables provide a fully managed solution for deploying a multi-Region, multi-active database, without having to build and maintain your own replication solution.

Global tables are ideal for providing low-latency access to data close to users and as well as a secondary region for disaster recovery.

If the global tables option is enabled for a resource in an effort to provide low-latency access to data but is not part of your disaster recovery strategy, validate that both replicas are actively serving read traffic by evaluating their CloudWatch metrics. If one replica does not serve read traffic, it may be an unused resource.

If global tables are part of your disaster recovery strategy, one replica not receiving read traffic may be expected under an active/standby pattern.

Cleaning up unused backups or point-in-time recovery (PITR)

DynamoDB offers two styles of backup. Point-in-time recovery provides continuous backups for up to 35 days to help you protect against accidental writes or deletes while on-demand backup allows

for snapshot creation which can be saved long term. You can set the recovery period to any value between 1 and 35 days. Both types of backups have costs associated with them.

Refer to the documentation for Backup and restore for DynamoDB and Point-in-time backups for DynamoDB to determine if your tables have backups enabled that may no longer be needed.

Evaluate your DynamoDB table usage patterns

This section provides an overview of how to evaluate if you are efficiently using your DynamoDB tables. There are certain usage patterns which are not optimal for DynamoDB, and they allow room for optimization from both a performance and cost perspective.

Topics

- Perform fewer strongly-consistent read operations
- Perform fewer transactions for read operations
- Perform fewer scans
- Shorten attribute names
- Enable Time to Live (TTL)
- Replace global tables with cross-Region backups

Perform fewer strongly-consistent read operations

DynamoDB allows you to configure read consistency on a per-request basis. Read requests are eventually consistent by default. Eventually consistent reads are charged at 0.5 RCU for upto 4 KB of data.

Most parts of distributed workloads are flexible and can tolerate eventual consistency. However, there can be access patterns requiring strongly consistent reads. Strongly consistent reads are charged at 1 RCU for upto 4 KB of data, essentially doubling your read costs. DynamoDB provides you with the flexibility to use both consistency models on the same table.

You can evaluate your workload and application code to confirm if strongly consistent reads are used only where required.

Perform fewer transactions for read operations

DynamoDB allows you to group certain actions in an all-or-nothing manner, which means you have the ability to execute ACID transactions with DynamoDB. However, as is the case with relational databases, it is not necessary to follow this approach for every action.

A transactional read operation of up to 4 KB consumes 2 RCUs as opposed to the default 0.5 RCUs for reading the same amount of data in an eventually consistent manner. The costs are doubled in write operations which means, a transactional write of up to 1 KB equates to 2 WCUs.

To determine if all operations on your tables are transactions, CloudWatch metrics for the table can be filtered down to the transaction APIs. If transaction APIs are the only graphs available under the `SuccessfulRequestLatency` metrics for the table, this would confirm that every operation is a transaction for this table. Alternatively, if the overall capacity utilization trend matches the transaction API trend, consider revisiting the application design as it seems dominated by transactional APIs.

Perform fewer scans

The extensive use of `Scan` operations generally stems from the need to run analytical queries on the DynamoDB data. Running frequent `Scan` operations on large table can be inefficient and expensive.

A better alternative is to use the Export to S3 feature and choosing a point in time to export the table state to S3. AWS offers services like Athena which can then be used to run analytical queries on the data without consuming any capacity from the table.

The frequency for `Scan` operations can be determined using the `SampleCount` statistic under the `SuccessfulRequestLatency` metric for `Scan`. If `Scan` operations are indeed very frequent, the access patterns and data model should be re-evaluated.

Shorten attribute names

The total size of an item in DynamoDB is the sum of its attribute name lengths and values. Having long attribute names not only contributes towards storage costs, but it might also lead to higher RCU/WCU consumption. We recommend that you choose shorter attribute names rather than long ones. Having shorter attribute names can help limit the item size within the next 4KB/1KB boundary after which you would consume additional RCU/WCU to access data.

Enable Time to Live (TTL)

Time to Live (TTL) can identify items older than the expiry time that you have set on an item and remove them from the table. If your data grows over time and older data becomes irrelevant, enabling TTL on the table can help trim your data down and save on storage costs.

Another useful aspect of TTL is that the expired items occur on your DynamoDB streams, so rather than just removing the data from your data, it is possible to consume those items from the stream

and archive them to a lower cost storage tier. Additionally, deleting items via TTL comes at no additional cost — it does not consume capacity, and there's no overhead of designing a clean up application.

Replace global tables with cross-Region backups

Global tables allow you to maintain multiple active replica tables in different Regions — they can all accept write operations and replicate data across each other. It is easy to set up replicas and the synchronization is managed for you. The replicas converge to a consistent state using a last writer wins strategy.

If you are using Global tables purely as a part of failover or disaster recovery (DR) strategy, you can replace them with a cross-Region backup copy for relatively lenient recovery point objectives and recovery time objective requirements. If you do not require fast local access and the high availability of five nines, maintaining a global table replica might not be the best approach for failover.

As an alternative, consider using AWS Backup to manage DynamoDB backups. You can schedule regular backups and copy them across Regions to meet DR requirements in a more cost-effective approach compared to using Global tables.

Evaluate your DynamoDB streams usage

This section provides an overview of how to evaluate your DynamoDB Streams usage. There are certain usage patterns which are not optimal for DynamoDB, and they allow room for optimization from both a performance and cost perspective.

You have two native streaming integrations for streaming and event-driven use cases:

- Amazon DynamoDB Streams
- Amazon Kinesis Data Streams

This page will just focus on cost optimization strategies for these options. If you'd like to instead find out how to choose between the two options, see Streaming options for change data capture.

Topics

- Optimizing costs for DynamoDB Streams
- Optimizing costs for Kinesis Data Streams

- Cost optimization strategies for both types of Streams usage

Optimizing costs for DynamoDB Streams

As mentioned in the pricing page for DynamoDB Streams, regardless of the table's throughput capacity mode, DynamoDB charges on the number of read requests made towards the table's DynamoDB Stream. Read requests made towards a DynamoDB Stream are different from the read requests made towards a DynamoDB table.

Each read request in terms of the stream is in the form of a `GetRecords` API call that can return up to 1000 records or 1 MB worth of records in the response, whichever is reached first. None of the other DynamoDB Stream APIs are charged and DynamoDB Streams are not charged for being idle. In other words, if no read requests are made to a DynamoDB Stream, no charges will be incurred for having a DynamoDB Stream enabled on a table.

Here are a few consumer applications for DynamoDB Streams:

- AWS Lambda function(s)
- Amazon Kinesis Data Streams-based applications
- Customer consumer applications built using an AWS SDK

Read requests made by AWS Lambda-based consumers of DynamoDB Streams are free, whereas calls made by consumers of any other kind are charged. Every month, the first 2,500,000 read requests made by non-Lambda consumers are also free of cost. This applies to all read requests made to any DynamoDB Streams in an AWS Account for each AWS Region.

Monitoring your DynamoDB Streams usage

DynamoDB Streams charges on the billing console are grouped together for all DynamoDB Streams across the AWS Region in an AWS Account. Currently, tagging DynamoDB Streams is not supported, so cost allocation tags cannot be used to identify granular costs for DynamoDB Streams. The volume of `GetRecords` calls can be obtained at the DynamoDB Stream level to compute the charges per stream. The volume is represented by the DynamoDB Stream's CloudWatch metric `SuccessfulRequestLatency` and its `SampleCount` statistic. This metric will also include `GetRecords` calls made by global tables to perform on-going replication as well as calls made by AWS Lambda consumers, both of which are not charged. For information on other CloudWatch metrics published by DynamoDB Streams, see DynamoDB Metrics and dimensions.

Using AWS Lambda as the consumer

Evaluate if using AWS Lambda functions as the consumers for DynamoDB Streams is feasible because that can eliminate costs associated with reading from the DynamoDB Stream. On the other hand, DynamoDB Streams Kinesis Adapter or SDK based consumer applications will be charged on the number of `GetRecords` calls they make towards the DynamoDB Stream.

Lambda function invocations will be charged based on standard Lambda pricing, however no charges will be incurred by DynamoDB Streams. Lambda will poll shards in your DynamoDB Stream for records at a base rate of 4 times per second. When records are available, Lambda invokes your function and waits for the result. If processing succeeds, Lambda resumes polling until it receives more records.

Tuning DynamoDB Streams Kinesis Adapter-based consumer applications

Since read requests made by non-Lambda based consumers are charged for DynamoDB Streams, it is important to find a balance between the near real-time requirement and the number of times the consumer application must poll the DynamoDB Stream.

The frequency of polling DynamoDB Streams using a DynamoDB Streams Kinesis Adapter based application is determined by the configured `idleTimeBetweenReadsInMillis` value. This parameter determines the amount of time in milliseconds that the consumer should wait before processing a shard in case the previous `GetRecords` call made to the same shard did not return any records. By default, this value for this parameter is 1000 ms. If near real-time processing is not required, this parameter could be increased to have the consumer application make fewer `GetRecords` calls and optimize on DynamoDB Streams calls.

Optimizing costs for Kinesis Data Streams

When a Kinesis Data Stream is set as the destination to deliver change data capture events for a DynamoDB table, the Kinesis Data Stream may need separate sizing management which will affect the overall costs. DynamoDB charges in terms of Change Data capture Units (CDUs) where each unit is a made of up a 1 KB DynamoDB item size attempted by the DynamoDB service to the destination Kinesis Data Stream.

In addition to charges by the DynamoDB service, standard Kinesis Data Stream charges will be incurred. As mentioned in the pricing page, the service pricing differs based on the capacity mode - provisioned and on-demand, which are distinct from DynamoDB table capacity modes and are user-defined. At a high level, Kinesis Data Streams charges an hourly rate based on the capacity mode, as well as on data ingested into the stream by DynamoDB service. There may be additional

charges like data retrieval (for on-demand mode), extended data retention (beyond default 24 hours), and enhanced fan-out consumer retrievals depending on the user configuration for the Kinesis Data Stream.

Monitoring your Kinesis Data Streams usage

Kinesis Data Streams for DynamoDB publishes metrics from DynamoDB in addition to standard Kinesis Data Stream CloudWatch Metrics. It may be possible that a `Put` attempt by the DynamoDB service is throttled by the Kinesis service because of insufficient Kinesis Data Streams capacity, or by dependent components like a AWS KMS service that may be configured to encrypt the Kinesis Data Stream data at rest.

To learn more about CloudWatch metrics published by DynamoDB service for the Kinesis Data Stream, see Monitoring change data capture with Kinesis Data Streams. In order to avoid additional costs of service retries due to throttles, it is important to right size the Kinesis Data Stream in case of Provisioned Mode.

Choosing the right capacity mode for Kinesis Data Streams

Kinesis Data Streams are supported in two capacity modes – provisioned mode and on-demand mode.

- If the workload involving Kinesis Data Stream has predictable application traffic, traffic that is consistent or ramps gradually, or traffic that can be forecasted accurately, then Kinesis Data Streams' **provisioned mode** is suitable and will be more cost efficient
- If the workload is new, has unpredictable application traffic, or you prefer not to manage capacity, then Kinesis Data Streams' **on-demand mode** is suitable and will be more cost efficient

A best practice to optimize costs would be to evaluate if the DynamoDB table associated with the Kinesis Data Stream has a predictable traffic pattern that can leverage provisioned mode of Kinesis Data Streams. If the workload is new, you could use on-demand mode for the Kinesis Data Streams for a few initial weeks, review the CloudWatch metrics to understand traffic patterns, and then switch the same Stream to provisioned mode based on the nature of the workload. In the case of provisioned mode, estimation on number shards can be made by following shard management considerations for Kinesis Data Streams.

Evaluate your consumer applications using Kinesis Data Streams for DynamoDB

Since Kinesis Data Streams don't charge on the number of `GetRecords` calls like DynamoDB Streams, consumer applications could make as many number of calls as possible, provided the

frequency is under the throttling limits for `GetRecords`. In terms of on-demand mode for Kinesis Data Streams, data reads are charged on a per GB basis. For provisioned mode Kinesis Data Streams, reads are not charged if the data is less than 7 days old. In the case of Lambda functions as Kinesis Data Streams consumers, Lambda polls each shard in your Kinesis Stream for records at a base rate of once per second.

Cost optimization strategies for both types of Streams usage

Event filtering for AWS Lambda consumers

Lambda event filtering allows you to discard events based on a filter criteria from being available in the Lambda function invocation batch. This optimizes Lambda costs for processing or discarding unwanted stream records within the consumer function logic. To learn more about configuring event filtering and writing your filtering criteria, see Lambda event filtering.

Tuning AWS Lambda consumers

Costs could be further be optimized by tuning Lambda configuration parameters like increasing the `BatchSize` to process more per invocation, enabling `BisectBatchOnFunctionError` to prevent processing duplicates (which incurs additional costs), and setting `MaximumRetryAttempts` to not run into too many retries. By default, failed consumer Lambda invocations are retried infinitely until the record expires from the stream, which is around 24 hours for DynamoDB Streams and configurable from 24 hours to up to 1 year for Kinesis Data Streams. Additional Lambda configuration options available including the ones mentioned above for DynamoDB Stream consumers are in the AWS Lambda developer guide.

Evaluate your provisioned capacity for right-sized provisioning in your DynamoDB table

This section provides an overview of how to evaluate if you have right-sized provisioning on your DynamoDB tables. As your workload evolves, you should modify your operational procedures appropriately, especially when your DynamoDB table is configured in provisioned mode and you have the risk to over-provision or under-provision your tables.

The procedures described below require statistical information that should be captured from the DynamoDB tables that are supporting your production application. To understand your application behavior, you should define a period of time that is significant enough to capture the data seasonality from your application. For example, if your application shows weekly patterns, using a three week period should give you enough room for analysing application throughput needs.

If you don't know where to start, use at least one month's worth of data usage for the calculations below.

While evaluating capacity, DynamoDB tables can configure **Read Capacity Units (RCUs)** and **Write Capacity Units (WCU)** independently. If your tables have any Global Secondary Indexes (GSI) configured, you will need to specify the throughput that it will consume, which will be also independent from the RCUs and WCUs from the base table.

> **Note**
>
> Local Secondary Indexes (LSI) consume capacity from the base table.

Topics

- How to retrieve consumption metrics on your DynamoDB tables
- How to identify under-provisioned DynamoDB tables
- How to identify over-provisioned DynamoDB tables

How to retrieve consumption metrics on your DynamoDB tables

To evaluate the table and GSI capacity, monitor the following CloudWatch metrics and select the appropriate dimension to retrieve either table or GSI information:

Read Capacity Units	Write Capacity Units
`ConsumedReadCapacityUnits`	`ConsumedWriteCapacityUnits`
`ProvisionedReadCapacityUnits`	`ProvisionedWriteCapacityUnits`
`ReadThrottleEvents`	`WriteThrottleEvents`

You can do this either through the AWS CLI or the AWS Management Console.

AWS CLI

Before we retrieve the table consumption metrics, we'll need to start by capturing some historical data points using the CloudWatch API.

Start by creating two files: `write-calc.json` and `read-calc.json`. These files will represent the calculations for a table or GSI. You'll need to update some of the fields, as indicated in the table below, to match your environment.

Field Name	Definition	Example
`<table-name>`	The name of the table that you will be analysing	SampleTable
`<period>`	The period of time that you will be using to evaluate the utilization target, based in seconds	For a 1-hour period you should specify: 3600
`<start-time>`	The beginning of your evaluation interval, specified in ISO8601 format	2022-02-21T23:00:00
`<end-time>`	The end of your evaluatio n interval, specified in ISO8601 format	2022-02-22T06:00:00

The write calculations file will retrieve the number of WCU provisioned and consumed in the time period for the date range specified. It will also generate a utilization percentage that will be used for analysis. The full content of the `write-calc.json` file should look like this:

```
{
  "MetricDataQueries": [
    {
      "Id": "provisionedWCU",
      "MetricStat": {
        "Metric": {
          "Namespace": "AWS/DynamoDB",
          "MetricName": "ProvisionedWriteCapacityUnits",
          "Dimensions": [
            {
              "Name": "TableName",
              "Value": "<table-name>"
            }
```

```
          ]
        },
        "Period": <period>,
        "Stat": "Average"
      },
      "Label": "Provisioned",
      "ReturnData": false
    },
    {
      "Id": "consumedWCU",
      "MetricStat": {
        "Metric": {
          "Namespace": "AWS/DynamoDB",
          "MetricName": "ConsumedWriteCapacityUnits",
          "Dimensions": [
            {
              "Name": "TableName",
              "Value": "<table-name>""
            }
          ]
        },
        "Period": <period>,
        "Stat": "Sum"
      },
      "Label": "",
      "ReturnData": false
    },
    {
      "Id": "m1",
      "Expression": "consumedWCU/PERIOD(consumedWCU)",
      "Label": "Consumed WCUs",
      "ReturnData": false
    },
    {
      "Id": "utilizationPercentage",
      "Expression": "100*(m1/provisionedWCU)",
      "Label": "Utilization Percentage",
      "ReturnData": true
    }
  ],
  "StartTime": "<start-time>",
  "EndTime": "<ent-time>",
  "ScanBy": "TimestampDescending",
  "MaxDatapoints": 24
```

```
}
```

The read calculations file uses a similar file. This file will retrieve how many RCUs were provisioned and consumed during the time period for the date range specified. The contents of the `read-calc.json` file should look like this:

```
{
  "MetricDataQueries": [
    {
      "Id": "provisionedRCU",
      "MetricStat": {
        "Metric": {
          "Namespace": "AWS/DynamoDB",
          "MetricName": "ProvisionedReadCapacityUnits",
          "Dimensions": [
            {
              "Name": "TableName",
              "Value": "<table-name>"
            }
          ]
        },
        "Period": <period>,
        "Stat": "Average"
      },
      "Label": "Provisioned",
      "ReturnData": false
    },
    {
      "Id": "consumedRCU",
      "MetricStat": {
        "Metric": {
          "Namespace": "AWS/DynamoDB",
          "MetricName": "ConsumedReadCapacityUnits",
          "Dimensions": [
            {
              "Name": "TableName",
              "Value": "<table-name>"
            }
          ]
        },
        "Period": <period>,
        "Stat": "Sum"
      },
```

```
      "Label": "",
      "ReturnData": false
    },
    {
      "Id": "m1",
      "Expression": "consumedRCU/PERIOD(consumedRCU)",
      "Label": "Consumed RCUs",
      "ReturnData": false
    },
    {
      "Id": "utilizationPercentage",
      "Expression": "100*(m1/provisionedRCU)",
      "Label": "Utilization Percentage",
      "ReturnData": true
    }
  ],
  "StartTime": "<start-time>",
  "EndTime": "<end-time>",
  "ScanBy": "TimestampDescending",
  "MaxDatapoints": 24
}
```

One you've created the files, you can start retrieving utilization data.

1. To retreive the write utilization data, issue the following command:

   ```
   aws cloudwatch get-metric-data --cli-input-json file://write-calc.json
   ```

2. To retreive the read utilization data, issue the following command:

   ```
   aws cloudwatch get-metric-data --cli-input-json file://read-calc.json
   ```

The result for both queries will be a series of data points in JSON format that will be used for analysis. Your result will depend on the number of data points you specified, the period, and your own specific workload data. It could look something like this:

```
{
    "MetricDataResults": [
        {
            "Id": "utilizationPercentage",
            "Label": "Utilization Percentage",
```

```
            "Timestamps": [
                "2022-02-22T05:00:00+00:00",
                "2022-02-22T04:00:00+00:00",
                "2022-02-22T03:00:00+00:00",
                "2022-02-22T02:00:00+00:00",
                "2022-02-22T01:00:00+00:00",
                "2022-02-22T00:00:00+00:00",
                "2022-02-21T23:00:00+00:00"
            ],
            "Values": [
                91.55364583333333,
                55.066631944444445,
                2.6114930555555556,
                24.9496875,
                40.94725694444445,
                25.61819444444444,
                0.0
            ],
            "StatusCode": "Complete"
        }
    ],
    "Messages": []
}
```

> **Note**
>
> If you specify a short period and a long time range, you might need to modify the `MaxDatapoints` which is by default set to 24 in the script. This represents one data point per hour and 24 per day.

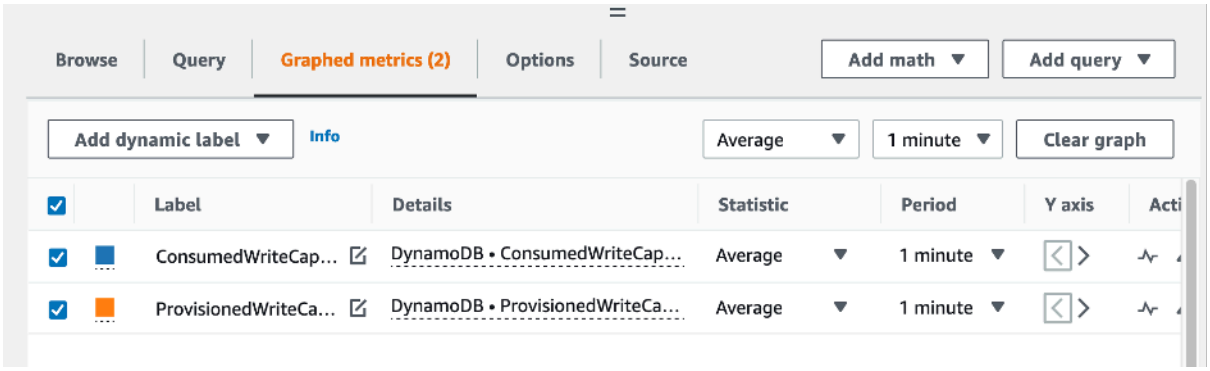
AWS Management Console

1. Log into the AWS Management Console and navigate to the CloudWatch service page. Select an appropriate AWS Region if necessary.
2. Locate the **Metrics** section on the left navigation bar and select **All metrics**.
3. This will open a dashboard with two panels. The top panel will show you the graphic, and the bottom panel will show the metrics you want to graph. Choose **DynamoDB**.
4. Choose **Table Metrics**. This will show you the tables in your current Region.

5. Use the Search box to search for your table name and choose the write operation metrics: `ConsumedWriteCapacityUnits` and `ProvisionedWriteCapacityUnits`

> **Note**
>
> This example talks about write operation metrics, but you can also use these steps to graph the read operation metrics.

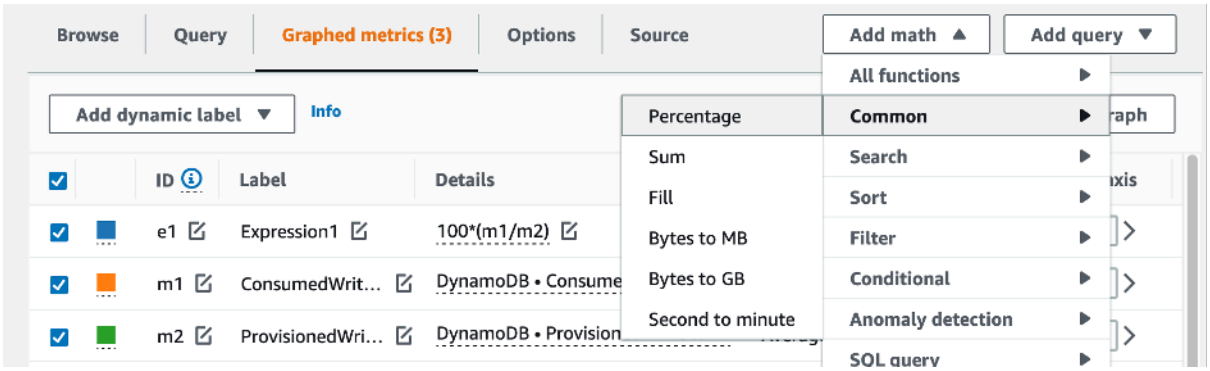
6. Choose the **Graphed metrics (2)** tab to modify the formulas. By default, CloudWatch selects the statistical function **Average** for the graphs.



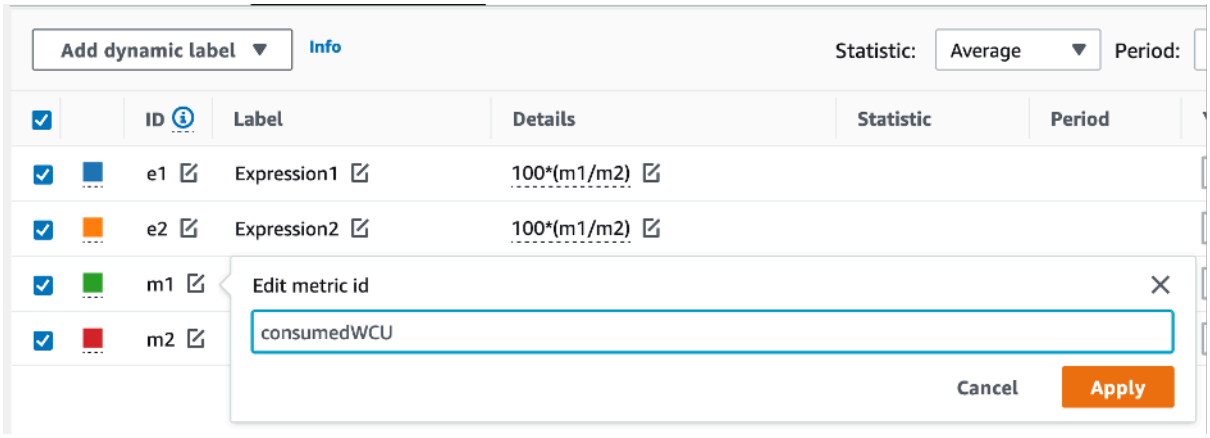
7. While having both graphed metrics selected (the checkbox on the left) select the menu **Add math**, followed by **Common**, and then select the **Percentage** function. Repeat the procedure twice.

   First time selecting the **Percentage** function:

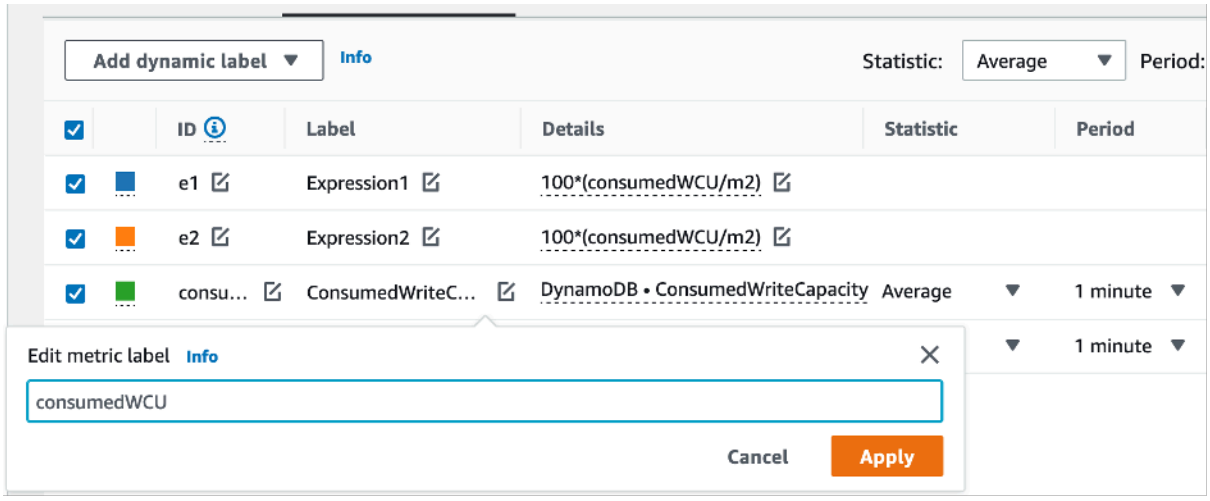
   Second time selecting the **Percentage** function:



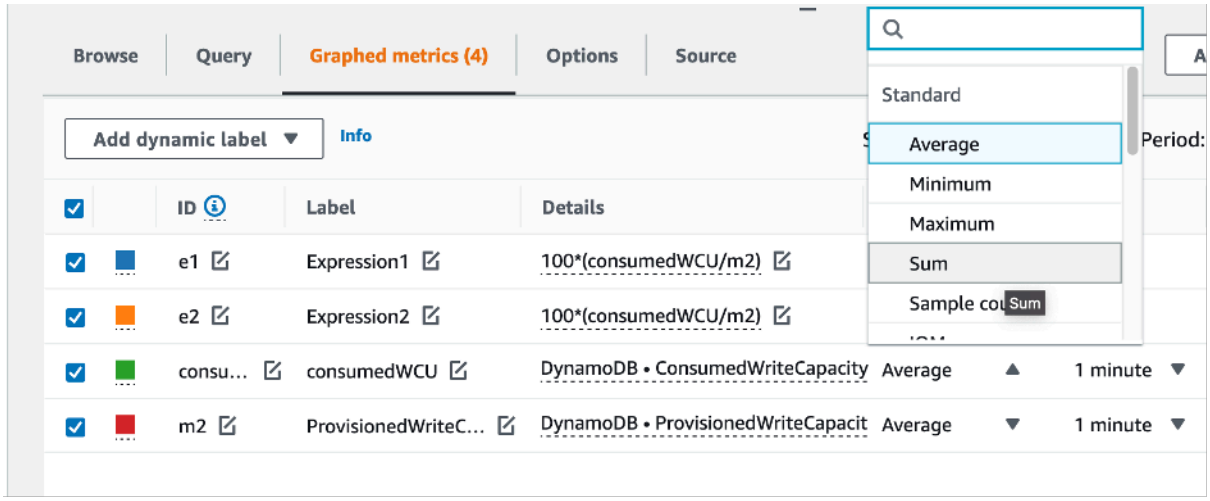
8. At this point you should have four metrics in the bottom menu. Let's work on the `ConsumedWriteCapacityUnits` calculation. To be consistent, we need to match the names for the ones we used in the AWS CLI section. Click on the **m1 ID** and change this value to **consumedWCU**.

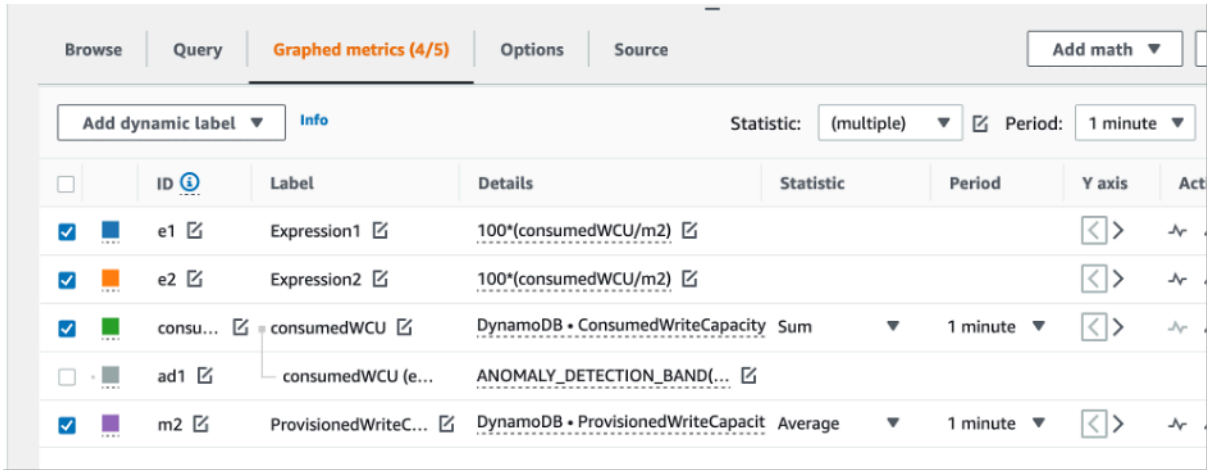


Rename the **ConsumedWriteCapacityUnit** label as **consumedWCU**.

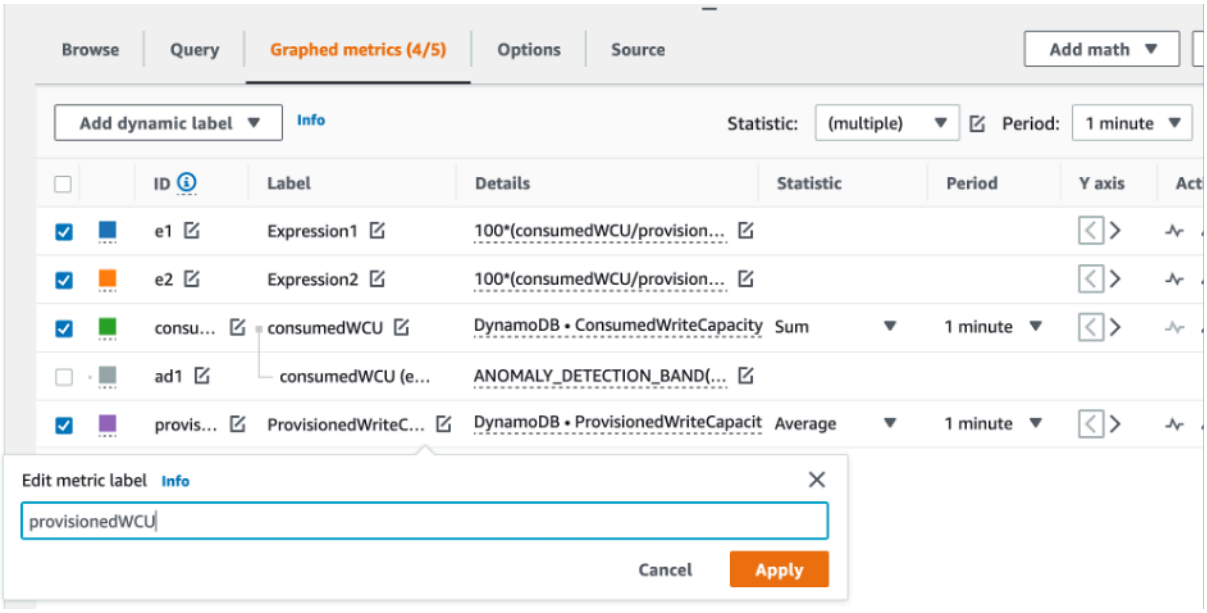


9. Change the statistic from **Average** to **Sum**. This action will automatically create another metric called **ANOMALY_DETECTION_BAND**. For the scope of this procedure, let's ignore it by removing the checkbox on the newly generated **ad1 metric**.





10. Repeat step 8 to rename the **m2 ID** to **provisionedWCU**. Leave the statistic set to **Average**.



11. Select the **Expression1** label and update the value to **m1** and the label to **Consumed WCUs**.

> **Note**
>
> Make sure you have only selected **m1** (checkbox on the left) and **provisionedWCU** to properly visualize the data. Update the formula by clicking in **Details** and changing the formula to **consumedWCU/PERIOD(consumedWCU)**. This step might also generate another **ANOMALY_DETECTION_BAND** metric, but for the scope of this procedure we can ignore it.
>
> >

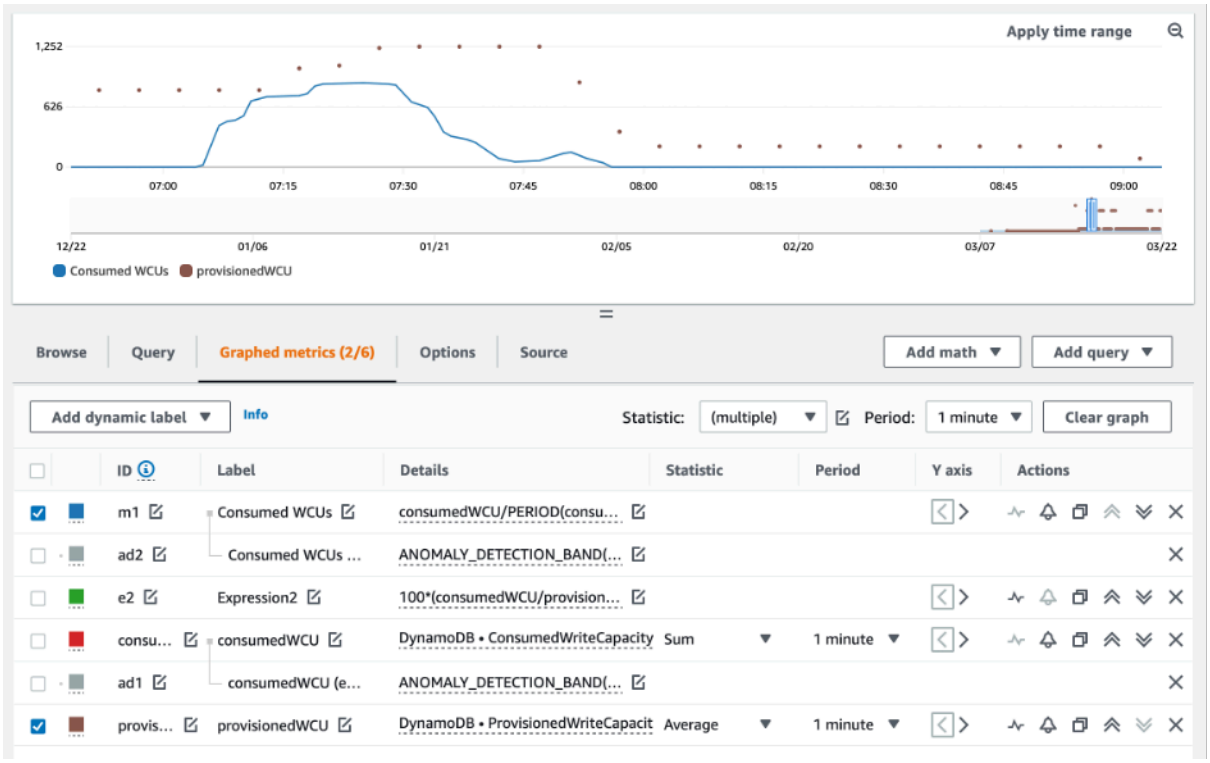
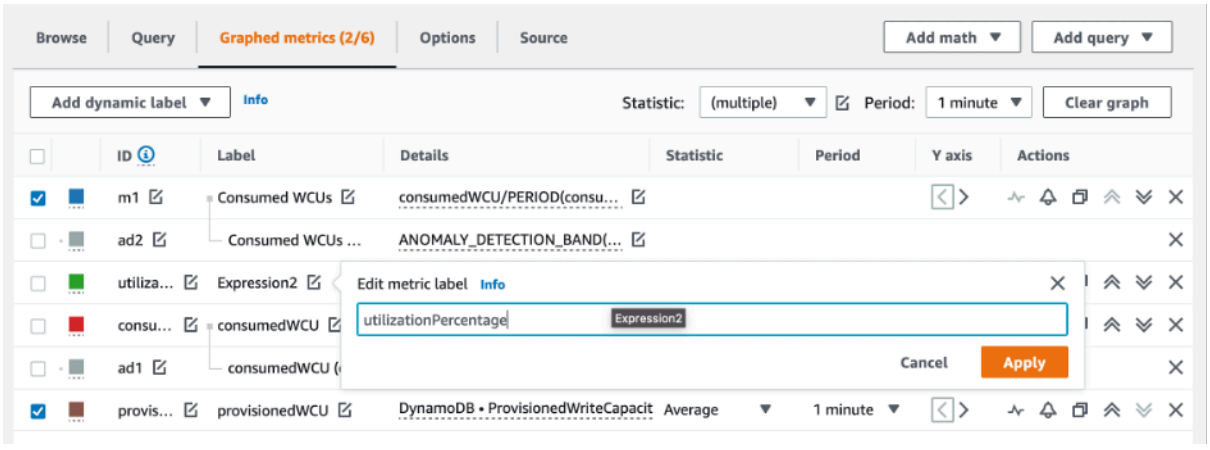
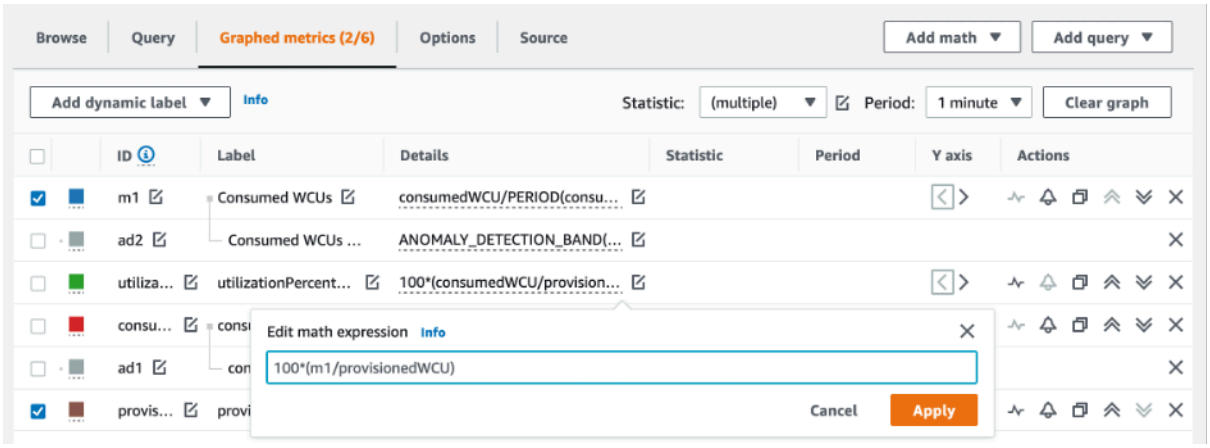
12. You should have now have two graphics: one that indicates your provisioned WCUs on the table and another that indicates the consumed WCUs. The shape of the graphic might be different from the one below, but you can use it as reference:



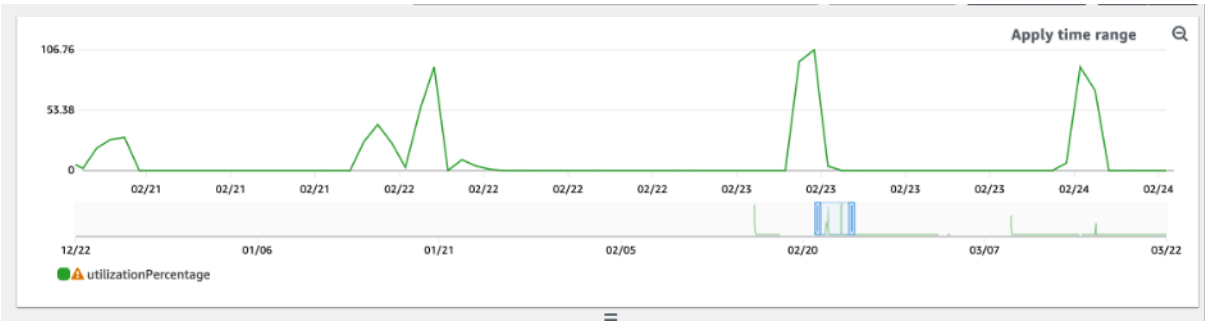
13. Update the percentage formula by selecting the Expression2 graphic (**e2**). Rename the labels and IDs to **utilizationPercentage**. Rename the formula to match **100*(m1/provisionedWCU)**.





14. Remove the checkbox from all the metrics but **utilizationPercentage** to visualize your utilization patterns. The default interval is set to 1 minute, but feel free to modify it as you need.

Here is view of a longer period of time as well as a bigger period of 1 hour. You can see there are some intervals where the utilization was higher than 100%, but this particular workload has longer intervals with zero utilization.



At this point, you might have different results from the pictures in this example. It all depends on the data from your workload. Intervals with more than 100% utilization are prone to throttling events. DynamoDB offers burst capacity, but as soon as the burst capacity is done anything above 100% will be throttled.

How to identify under-provisioned DynamoDB tables

For most workloads, a table is considered under-provisioned when it constantly consumes more than 80% of their provisioned capacity.

Burst capacity is a DynamoDB feature that allow customers to temporarily consume more RCUs/WCUs than originally provisioned (more than the per-second provisioned throughput that was defined in the table). The burst capacity was created to absorb sudden increases in traffic due to special events or usage spikes. This burst capacity doesn't last forever. As soon as the unused RCUs and WCUs are depleted, you will get throttled if you try to consume more capacity than provisioned. When your application traffic is getting close to the 80% utilization rate, your risk of throttling is significantly higher.

The 80% utilization rate rule varies from the seasonality of your data and your traffic growth. Consider the following scenarios:

- If your traffic has been **stable** at ~90% utilization rate for the last 12 months, your table has just the right capacity
- If your application traffic is **growing** at a rate of 8% monthly in less than 3 months, you will arrive at 100%
- If your application traffic is **growing** at a rate of 5% in a little more than 4 months, you will still arrive at 100%

The results from the queries above provide a picture of your utilization rate. Use them as a guide to further evaluate other metrics that can help you choose to increase your table capacity as required (for example: a monthly or weekly growth rate). Work with your operations team to define what is a good percentage for your workload and your tables.

There are special scenarios where the data is skewed when we analyse it on a daily or weekly basis. For example, with seasonal applications that have spikes in usage during working hours (but then drops to almost zero outside of working hours), you could benefit by scheduling auto scaling where you specify the hours of the day (and the days of the week) to increase the provisioned capacity and when to reduce it. Instead of aiming for higher capacity so you can cover the busy hours, you can also benefit from DynamoDB table auto scaling configurations if your seasonality is less pronounced.

> **Note**
>
> When you create a DynamoDB auto scaling configuration for your base table, remember to include another configuration for any GSI that is associated with the table.

How to identify over-provisioned DynamoDB tables

The query results obtained from the scripts above provide the data points required to perform some initial analysis. If your data set presents values lower than 20% utilization for several intervals, your table might be over-provisioned. To further define if you need to reduce the number of WCUs and RCUS, you should revisit the other readings in the intervals.

When your tables contain several low usage intervals, you can really benefit from using auto scaling policies, either by scheduling auto scaling or just configuring the default auto scaling policies for the table that are based on utilization.

If you have a workload with low utilization to high throttle ratio (**Max(ThrottleEvents)/ Min(ThrottleEvents)** in the interval), this could happen when you have a very spiky workload where traffic increases a lot during some days (or hours), but in general the traffic is consistently low. In these scenarios it might be beneficial to use scheduled auto scaling.

The AWS Well-Architected Framework helps cloud architects build secure, high-performing, resilient, and efficient infrastructure for a variety of applications and workloads. Built around six pillars—operational excellence, security, reliability, performance efficiency, cost optimization, and sustainability—AWS Well-Architected provides a consistent approach for customers and partners to evaluate architectures and implement scalable designs.

The AWS Well-Architected Lenses extend the guidance offered by AWS Well-Architected to specific industry and technology domains. The Amazon DynamoDB Well-Architected Lens focuses on DynamoDB workloads. It provides best practices, design principles and questions to assess and review a DynamoDB workload. Completing an Amazon DynamoDB Well-Architected Lens review will provide you with education and guidance around recommended design principles as it relates to each of the AWS Well-Architected pillars. This guidance is based on our experience working with customers across various industries, segments, sizes and geographies.

As a direct outcome of the Well-Architected Lens review, you will receive a summary of actionable recommendations to optimize and improve your DynamoDB workload.

Conducting the Amazon DynamoDB Well-Architected Lens review

The DynamoDB Well-Architected Lens review is usually performed by an AWS Solutions Architect together with the customer, but can also be performed by the customer as a self-service. While we recommend reviewing all six of the Well-Architected Pillars as part of the Amazon DynamoDB Well-Architected Lens, you can also decide to prioritize your focus on one or more pillars first.

Additional information and instructions for conducting an Amazon DynamoDB Well-Architected Lens review are available in this video and the DynamoDB Well-Architected Lens GitHub page.

The pillars of the Amazon DynamoDB Well-Architected Lens

The Amazon DynamoDB Well-Architected Lens is built around six pillars:

Performance efficiency pillar

The performance efficiency pillar includes the ability to use computing resources efficiently to meet system requirements, and to maintain that efficiency as demand changes and technologies evolve.

The primary DynamoDB design principles for this pillar revolve around modeling the data, choosing partition keys and sort keys, and defining secondary indexes based on the application access patterns. Additional considerations include choosing the optimal throughput mode for the workload, AWS SDK tuning and, when appropriate, using an optimal caching strategy. To learn more about these design principles, watch this deep dive video about the performance efficiency pillar of the DynamoDB Well-Architected Lens.

Cost optimization pillar

The cost optimization pillar focuses on avoiding unnecessary costs.

Key topics include understanding and controlling where money is being spent, selecting the most appropriate and right number of resource types, analyzing spend over time, designing your data models to optimize the cost for application-specific access patterns, and scaling to meet business needs without overspending.

The key cost optimization design principles for DynamoDB revolve around choosing the most appropriate capacity mode and table class for your tables and avoiding over-provisioning capacity by either using the on-demand capacity mode, or provisioned capacity mode with autoscaling. Additional considerations include efficient data modeling and querying to reduce the amount of

consumed capacity, reserving portions of the consumed capacity at discounted price, minimizing item size, identifying and removing unused resources and using TTL to automatically delete aged-out data at no cost. To learn more about these design principles, watch this deep dive video about the cost optimization pillar of the DynamoDB Well-Architected Lens.

See Cost optimization for additional information on cost optimization best practices for DynamoDB.

Operational excellence pillar

The operational excellence pillar focuses on running and monitoring systems to deliver business value, and continually improving processes and procedures. Key topics include automating changes, responding to events, and defining standards to manage daily operations.

The main operational excellence design principles for DynamoDB include monitoring DynamoDB metrics through Amazon CloudWatch and AWS Config and automatically alert and remediate when predefined thresholds are breached, or non compliant rules are detected. Additional considerations are defining DynamoDB resources via infrastructure as a code and leveraging tags for better organization, identification and cost accounting of your DynamoDB resources. To learn more about these design principles, watch this deep dive video about the operational excellence pillar of the DynamoDB Well-Architected Lens.

Reliability pillar

The reliability pillar focuses on ensuring a workload performs its intended function correctly and consistently when it's expected to. A resilient workload quickly recovers from failures to meet business and customer demand. Key topics include distributed system design, recovery planning, and how to handle change.

The essential reliability design principles for DynamoDB revolve around choosing the backup strategy and retention based on your RPO and RTO requirements, using DynamoDB global tables for multi-regional workloads, or cross-region disaster recovery scenarios with low RTO, implementing retry logic with exponential backoff in the application by configuring and using these capabilities in the AWS SDK, and monitoring DynamoDB metrics through Amazon CloudWatch and automatically alerting and remediating when predefined thresholds are breached. To learn more about these design principles, watch this deep dive video about the reliability pillar of the DynamoDB Well-Architected Lens.

Security pillar

The security pillar focuses on protecting information and systems. Key topics include confidentiality and integrity of data, identifying and managing who can do what with privilege management, protecting systems, and establishing controls to detect security events.

The main security design principles for DynamoDB are encrypting data in transit with HTTPS, choosing the type of keys for data at rest encryption and defining the IAM roles and policies to authenticate, authorize and provide fine grain access to DynamoDB resources. Additional considerations include auditing DynamoDB control plane and data plane operations through AWS CloudTrail. To learn more about these design principles, watch this deep dive video about the security pillar of the DynamoDB Well-Architected Lens.

See Security for additional information on security for DynamoDB.

Sustainability pillar

The sustainability pillar focuses on minimizing the environmental impacts of running cloud workloads. Key topics include a shared responsibility model for sustainability, understanding impact, and maximizing utilization to minimize required resources and reduce downstream impacts.

The main sustainability design principles for DynamoDB include identifying and removing unused DynamoDB resources, avoiding over-provisioning though the usage of on-demand capacity mode or provisioned capacity-mode with autoscaling, efficient querying to reduce the amount of capacity being consumed and reduction of the storage footprint by compressing data and by deleting aged-out data through the use of TTL. To learn more about these design principles, watch this deep dive video about the sustainability pillar of the DynamoDB Well-Architected Lens.

Best practices for designing and using partition keys effectively in DynamoDB

The primary key that uniquely identifies each item in an Amazon DynamoDB table can be simple (a partition key only) or composite (a partition key combined with a sort key).

You should design your application for uniform activity across all partition keys in the table and its secondary indexes. You can determine the access patterns that your application requires, and read and write units that each table and secondary index requires.

> **Note**
>
> Adaptive capacity applies to on-demand mode and provisioned capacity.

By default, every partition in a DynamoDB table is designed to deliver a maximum capacity of 3,000 read units per second and 1,000 write units per second. One read unit represents one strongly consistent read operation per second, or two eventually consistent read operations per second, for an item up to 4 KB in size. One write unit represents one write operation per second for an item up to 1 KB in size.

You must factor in the item size when evaluating the partition throughput limits for your table. For example, if the table has an item size of 20 KB, a single consistent read operation will consume 5 read units. This means you can concurrently drive 600 consistent read operations per second on that single item before reaching the partition limits. The total throughput across all partitions in the table can be constrained by the provisioned throughput in provisioned mode, or by the table level throughput limit in on-demand mode. See Service Quotas for more information.

Topics

- Designing partition keys to distribute your workload in DynamoDB
- Using write sharding to distribute workloads evenly in your DynamoDB table
- Distributing write activity efficiently during data upload in DynamoDB

Designing partition keys to distribute your workload in DynamoDB

The partition key portion of a table's primary key determines the logical partitions in which a table's data is stored. This in turn affects the underlying physical partitions. A partition key design that doesn't distribute I/O requests effectively can create "hot" partitions that result in throttling and use your provisioned I/O capacity inefficiently.

The optimal usage of a table's provisioned throughput depends not only on the workload patterns of individual items, but also on the partition key design. This doesn't mean that you must access all partition key values to achieve an efficient throughput level, or even that the percentage of accessed partition key values must be high. It does mean that the more distinct partition key values that your workload accesses, the more those requests will be spread across the partitioned space. In general, you'll use your provisioned throughput more efficiently as the ratio of partition key values accessed to the total number of partition key values increases.

The following is a comparison of the provisioned throughput efficiency of some common partition key schemas.

Partition key value	Uniformity
User ID, where the application has many users.	Good
Status code, where there are only a few possible status codes.	Bad
Item creation date, rounded to the nearest time period (for example, day, hour, or minute).	Bad
Device ID, where each device accesses data at relatively similar intervals.	Good
Device ID, where even if there are many devices being tracked, one is by far more popular than all the others.	Bad

If a single table has only a small number of partition key values, consider distributing your write operations across more distinct partition key values. In other words, structure the primary key elements to avoid one "hot" (heavily requested) partition key value that slows overall performance.

For example, consider a table with a composite primary key. The partition key represents the item's creation date, rounded to the nearest day. The sort key is an item identifier. On a given day, say `2014-07-09`, **all** of the new items are written to that single partition key value (and corresponding physical partition).

If the table fits entirely into a single partition (considering growth of your data over time), and if your application's read and write throughput requirements don't exceed the read and write capabilities of a single partition, your application won't encounter any unexpected throttling as a result of partitioning.

To use NoSQL Workbench for DynamoDB to help visualize your partition key design, see Building data models with NoSQL Workbench.

Using write sharding to distribute workloads evenly in your DynamoDB table

One way to better distribute writes across a partition key space in Amazon DynamoDB is to expand the space. You can do this in several different ways. You can add a random number to the partition key values to distribute the items among partitions. Or you can use a number that is calculated based on something that you're querying on.

Sharding using random suffixes

One strategy for distributing loads more evenly across a partition key space is to add a random number to the end of the partition key values. Then you randomize the writes across the larger space.

For example, for a partition key that represents today's date, you might choose a random number between 1 and 200 and concatenate it as a suffix to the date. This yields partition key values like 2014-07-09.1, 2014-07-09.2, and so on, through 2014-07-09.200. Because you are randomizing the partition key, the writes to the table on each day are spread evenly across multiple partitions. This results in better parallelism and higher overall throughput.

However, to read all the items for a given day, you would have to query the items for all the suffixes and then merge the results. For example, you would first issue a Query request for the partition key value 2014-07-09.1. Then issue another Query for 2014-07-09.2, and so on, through 2014-07-09.200. Finally, your application would have to merge the results from all those Query requests.

Sharding using calculated suffixes

A randomizing strategy can greatly improve write throughput. But it's difficult to read a specific item because you don't know which suffix value was used when writing the item. To make it easier to read individual items, you can use a different strategy. Instead of using a random number to distribute the items among partitions, use a number that you can calculate based upon something that you want to query on.

Consider the previous example, in which a table uses today's date in the partition key. Now suppose that each item has an accessible OrderId attribute, and that you most often need to find items by order ID in addition to date. Before your application writes the item to the table, it could calculate a hash suffix based on the order ID and append it to the partition key date. The calculation might

generate a number between 1 and 200 that is fairly evenly distributed, similar to what the random strategy produces.

A simple calculation would likely suffice, such as the product of the UTF-8 code point values for the characters in the order ID, modulo 200, + 1. The partition key value would then be the date concatenated with the calculation result.

With this strategy, the writes are spread evenly across the partition key values, and thus across the physical partitions. You can easily perform a `GetItem` operation for a particular item and date because you can calculate the partition key value for a specific `OrderId` value.

To read all the items for a given day, you still must `Query` each of the `2014-07-09.N` keys (where `N` is 1–200), and your application then has to merge all the results. The benefit is that you avoid having a single "hot" partition key value taking all of the workload.

> **Note**
>
> For a more efficient strategy specifically designed to handle high-volume time series data, see Time series data.

Distributing write activity efficiently during data upload in DynamoDB

Typically, when you load data from other data sources, Amazon DynamoDB partitions your table data on multiple servers. You get better performance if you upload data to all the allocated servers simultaneously.

For example, suppose that you want to upload user messages to a DynamoDB table that uses a composite primary key with `UserID` as the partition key and `MessageID` as the sort key.

When you upload the data, one approach you can take is to upload all message items for each user, one user after another:

UserID	MessageID
U1	1
U1	2

UserID	MessageID
U1	...
U1	... up to 100
U2	1
U2	2
U2	...
U2	... up to 200

The problem in this case is that you are not distributing your write requests to DynamoDB across your partition key values. You are taking one partition key value at a time and uploading all of its items before going to the next partition key value and doing the same.

Behind the scenes, DynamoDB is partitioning the data in your table across multiple servers. To fully use all the throughput capacity that is provisioned for the table, you must distribute your workload across your partition key values. By directing an uneven amount of upload work toward items that all have the same partition key value, you are not fully using all the resources that DynamoDB has provisioned for your table.

You can distribute your upload work by using the sort key to load one item from each partition key value, then another item from each partition key value, and so on:

UserID	MessageID
U1	1
U2	1
U3	1
...	...
U1	2
U2	2

UserID	MessageID
U3	2
...	...

Every upload in this sequence uses a different partition key value, keeping more DynamoDB servers busy simultaneously and improving your throughput performance.

Best practices for using sort keys to organize data in DynamoDB

In an Amazon DynamoDB table, the primary key that uniquely identifies each item in the table can be composed of a partition key and a sort key.

Well-designed sort keys have two key benefits:

- They gather related information together in one place where it can be queried efficiently. Careful design of the sort key lets you retrieve commonly needed groups of related items using range queries with operators such as `begins_with`, `between`, >, <, and so on.
- Composite sort keys let you define hierarchical (one-to-many) relationships in your data that you can query at any level of the hierarchy.

  For example, in a table listing geographical locations, you might structure the sort key as follows.

  ```
  [country]#[region]#[state]#[county]#[city]#[neighborhood]
  ```

  This would let you make efficient range queries for a list of locations at any one of these levels of aggregation, from `country`, to a `neighborhood`, and everything in between.

Using sort keys for version control

Many applications need to maintain a history of item-level revisions for audit or compliance purposes and to be able to retrieve the most recent version easily. There is an effective design pattern that accomplishes this using sort key prefixes:

- For each new item, create two copies of the item: One copy should have a version-number prefix of zero (such as `v0_`) at the beginning of the sort key, and one should have a version-number prefix of one (such as `v1_`).
- Every time the item is updated, use the next higher version-prefix in the sort key of the updated version, and copy the updated contents into the item with version-prefix zero. This means that the latest version of any item can be located easily using the zero prefix.

For example, a parts manufacturer might use a schema like the one illustrated below.

Primary Key		Data-Item Attributes...				
Partition Key *Equipment_ID*	Sort Key *(varies)*	Attribute 1	Attribute 2	Attribute 3	Attribute 4	...
Equipment_1	Details	Name: Biphasic Cardiometer *(equipment name)*	Factory_ID: S14_Tukwilla *(factory where manufactured)*	Line_ID R_7 *(assembly-line ID)*		
	v0_Audit	Auditor: Padma *(name of the auditor)*	Latest: 3 *(most recent audit version)*	Time: 2018-04-15T11:00 *(audit date and time)*	Result Passed *(audit result)*	...etc.
	v1_Audit	Auditor: Rick *(name of the auditor)*	Time: 2018-03-14T11:00 *(audit date and time)*	Result Open *(audit result)*	Report: 0943922EKG14 *(detailed problem report in S3)*	...etc.
	v2_Audit	Auditor: George *(name of the auditor)*	Time: 2018-03-18T11:00 *(audit date and time)*	Result Open *(audit result)*	Report: 0943923EKG15 *(detailed problem report in S3)*	...etc.
	v3_Audit	Auditor: Padma *(name of the auditor)*	Time: 2018-04-15T11:00 *(audit date and time)*	Result Passed *(audit result)*	Report: x792 *(pass confirmation report)*	...etc.

The `Equipment_1` item goes through a sequence of audits by various auditors. The results of each new audit are captured in a new item in the table, starting with version number one, and then incrementing the number for each successive revision.

When each new revision is added, the application layer replaces the contents of the zero-version item (having sort key equal to `v0_Audit`) with the contents of the new revision.

Whenever the application needs to retrieve for the most recent audit status, it can query for the sort key prefix of `v0_`.

If the application needs to retrieve the entire revision history, it can query all the items under the item's partition key and filter out the `v0_` item.

This design also works for audits across multiple parts of a piece of equipment, if you include the individual part-IDs in the sort key after the sort key prefix.

Best practices for using secondary indexes in DynamoDB

Secondary indexes are often essential to support the query patterns that your application requires. At the same time, overusing secondary indexes or using them inefficiently can add cost and reduce performance unnecessarily.

General guidelines for secondary indexes in DynamoDB

Amazon DynamoDB supports two types of secondary indexes:

- **Global secondary index (GSI)—** An index with a partition key and a sort key that can be different from those on the base table. A global secondary index is considered "global" because queries on the index can span all of the data in the base table, across all partitions. A global secondary index has no size limitations and has its own provisioned throughput settings for read and write activity that are separate from those of the table.

- **Local secondary index (LSI)—**An index that has the same partition key as the base table, but a different sort key. A local secondary index is "local" in the sense that every partition of a local secondary index is scoped to a base table partition that has the same partition key value. As a result, the total size of indexed items for any one partition key value can't exceed 10 GB. Also, a local secondary index shares provisioned throughput settings for read and write activity with the table it is indexing.

Each table in DynamoDB can have up to 20 global secondary indexes (default quota) and 5 local secondary indexes.

Global secondary indexes are often more useful than local secondary indexes. Determining which type of index to use will also depend on your application's requirements. For a comparison of global secondary indexes and local secondary indexes, and more information on how to choose between them, see the section called “Working with indexes”.

The following are some general principles and design patterns to keep in mind when creating indexes in DynamoDB:

Topics

- Use indexes efficiently
- Choose projections carefully
- Optimize frequent queries to avoid fetches
- Be aware of item-collection size limits when creating local secondary indexes

Use indexes efficiently

Keep the number of indexes to a minimum. Don't create secondary indexes on attributes that you don't query often. Indexes that are seldom used contribute to increased storage and I/O costs without improving application performance.

Choose projections carefully

Because secondary indexes consume storage and provisioned throughput, you should keep the size of the index as small as possible. Also, the smaller the index, the greater the performance advantage compared to querying the full table. If your queries usually return only a small subset of attributes, and the total size of those attributes is much smaller than the whole item, project only the attributes that you regularly request.

If you expect a lot of write activity on a table compared to reads, follow these best practices:

- Consider projecting fewer attributes to minimize the size of items written to the index. However, this only applies if the size of projected attributes would otherwise be larger than a single write capacity unit (1 KB). For example, if the size of an index entry is only 200 bytes, DynamoDB rounds this up to 1 KB. In other words, as long as the index items are small, you can project more attributes at no extra cost.
- Avoid projecting attributes that you know will rarely be needed in queries. Every time you update an attribute that is projected in an index, you incur the extra cost of updating the index as well. You can still retrieve non-projected attributes in a `Query` at a higher provisioned throughput cost, but the query cost may be significantly lower than the cost of updating the index frequently.
- Specify `ALL` only if you want your queries to return the entire table item sorted by a different sort key. Projecting all attributes eliminates the need for table fetches, but in most cases, it doubles your costs for storage and write activity.

Balance the need to keep your indexes as small as possible against the need to keep fetches to a minimum, as explained in the next section.

Optimize frequent queries to avoid fetches

To get the fastest queries with the lowest possible latency, project all the attributes that you expect those queries to return. In particular, if you query a local secondary index for attributes that are not projected, DynamoDB automatically fetches those attributes from the table, which requires reading the entire item from the table. This introduces latency and additional I/O operations that you can avoid.

Keep in mind that "occasional" queries can often turn into "essential" queries. If there are attributes that you don't intend to project because you anticipate querying them only occasionally, consider whether circumstances might change and you might regret not projecting those attributes after all.

For more information about table fetches, see Provisioned throughput considerations for Local Secondary Indexes.

Be aware of item-collection size limits when creating local secondary indexes

An *item collection* is all the items in a table and its local secondary indexes that have the same partition key. No item collection can exceed 10 GB, so it's possible to run out of space for a particular partition key value.

When you add or update a table item, DynamoDB updates all local secondary indexes that are affected. If the indexed attributes are defined in the table, the local secondary indexes grow too.

When you create a local secondary index, think about how much data will be written to it, and how many of those data items will have the same partition key value. If you expect that the sum of table and index items for a particular partition key value might exceed 10 GB, consider whether you should avoid creating the index.

If you can't avoid creating the local secondary index, you must anticipate the item collection size limit and take action before you exceed it. As a best practice, you should utilize the `ReturnItemCollectionMetrics` parameter when writing items to monitor and alert on item collection sizes that approach the 10GB size limit. Exceeding the maximum item collection size will result in failed write attempts. You can mitigate the item collection size issues by monitoring and alerting on item collection sizes before they impact your application.

> **Note**
>
> Once created, you cannot delete a local secondary index.

For strategies on working within the limit and taking corrective action, see Item collection size limit.

Take advantage of sparse indexes

For any item in a table, DynamoDB writes a corresponding index entry **only if the index sort key value is present in the item**. If the sort key doesn't appear in every table item, or if the index partition key is not present in the item, the index is said to be *sparse*.

Sparse indexes are useful for queries over a small subsection of a table. For example, suppose that you have a table where you store all your customer orders, with the following key attributes:

- Partition key: `CustomerId`
- Sort key: `OrderId`

To track open orders, you can insert an attribute named `isOpen` in order items that have not already shipped. Then when the order ships, you can delete the attribute. If you then create an index on `CustomerId` (partition key) and `isOpen` (sort key), only those orders with `isOpen`

defined appear in it. When you have thousands of orders of which only a small number are open, it's faster and less expensive to query that index for open orders than to scan the entire table.

Instead of using a type of attribute like `isOpen`, you could use an attribute with a value that results in a useful sort order in the index. For example, you could use an `OrderOpenDate` attribute set to the date on which each order was placed, and then delete it after the order is fulfilled. That way, when you query the sparse index, the items are returned sorted by the date on which each order was placed.

Examples of sparse indexes in DynamoDB

Global secondary indexes are sparse by default. When you create a global secondary index, you specify a partition key and optionally a sort key. Only items in the base table that contain those attributes appear in the index.

By designing a global secondary index to be sparse, you can provision it with lower write throughput than that of the base table, while still achieving excellent performance.

For example, a gaming application might track all scores of every user, but generally only needs to query a few high scores. The following design handles this scenario efficiently:

Table

Primary Key		Data Attributes...		
Partition Key	*Sort Key*			
Player_ID	Game_ID	Attribute 1	Attribute 2	Attribute 3
Rick	Game_1	Score: 36,750 *(game score)*	Date: 2017-11-14 *(date of game)*	
	Game_2	Score: 69,450 *(game score)*	Date: 2017-12-31 *(date of game)*	
	Game_3	Score: 135,900 *(game score)*	Date: 2018-01-19 *(date of game)*	Award: Champ *(type of award)*
Padma	Game_4	Score: 25,350 *(game score)*	Date: 2018-01-27 *(date of game)*	
	Game_5	Score: 69,450 *(game score)*	Date: 2028-01-19 *(date of game)*	
	Game_6	Score: 147,300 *(game score)*	Date: 2018-02-02 *(date of game)*	Award: Champ *(type of award)*
	Game_7	Score: 169,100 *(game score)*	Date: 2018-03-10 *(date of game)*	Award: Champ *(type of award)*

Here, Rick has played three games and achieved `Champ` status in one of them. Padma has played four games and achieved `Champ` status in two of them. Notice that the `Award` attribute is present only in items where the user achieved an award. The associated global secondary index looks like the following:

GSI	Primary Key	Projected Attributes...			
	Partition Key				
	Award	Player_ID	Game_ID	Score	Date
	Champ	Rick	Game_3	135,900	2018-01-19
		Padma	Game_6	147,300	2018-02-02
		Padma	Game_7	169,100	2018-03-10

The global secondary index contains only the high scores that are frequently queried, which are a small subset of the items in the base table.

Using Global Secondary Indexes for materialized aggregation queries in DynamoDB

Maintaining near real-time aggregations and key metrics on top of rapidly changing data is becoming increasingly valuable to businesses for making rapid decisions. For example, a music library might want to showcase its most downloaded songs in near-real time.

Consider the following music library table layout:

Music Library Table

Primary Key		Data-Item Attributes...			
Partition Key	Sort Key	Attribute 1	Attribute 2	Attribute 3	
Song-129 *(song ID)*	Details	Title: Wild Love *(song title)*	Artist: Argyboots *(artist or band name)*	Downloads: 15,314,822 *(lifetime total downloads)*	...etc.
	Month-2018-01	GSI Primary Key Month: 2018-01 *(download month)*	GSI Secondary Key MonthTotal: 1,746,992 *(month total downloads)*		
	Dld-9349823681	Time: 2018-01-01T00:00:07 *(download timestamp)*			
	Dld-9349823682	Time: 2018-01-01T00:00:07 *(download timestamp)*			
	Dld-9349823683	Time: 2018-01-01T00:00:07 *(download timestamp)*			

The table in this example stores songs with the `songID` as the partition key. You can enable Amazon DynamoDB Streams on this table and attach a Lambda function to the streams so that as each song is downloaded, an entry is added to the table with `Partition-Key=SongID` and `Sort-Key=DownloadID`. As these updates are made, they trigger a Lambda function in DynamoDB Streams. The Lambda function can aggregate and group the downloads by `songID` and update the top-level item, `Partition-Key=songID`, and `Sort-Key=Month`. Keep in mind that if a lambda execution fails just after writing the new aggregated value, it may be retried and aggregate the value more than once, leaving you with an approximate value.

To read the updates in near-real time, with single-digit millisecond latency, use the global secondary index with query conditions `Month=2018-01`, `ScanIndexForward=False`, `Limit=1`.

Another key optimization used here is that the global secondary index is a sparse index and is available only on the items that need to be queried to retrieve the data in real time. The global secondary index can serve additional workflows that need information on the top 10 songs that were popular, or any song downloaded in that month.

Overloading Global Secondary Indexes in DynamoDB

Although Amazon DynamoDB has a default quota of 20 global secondary indexes per table, in practice, you can index across far more than 20 data fields. As opposed to a table in a relational database management system (RDBMS), in which the schema is uniform, a table in DynamoDB can hold many different kinds of data items at one time. In addition, the same attribute in different items can contain entirely different kinds of information.

Consider the following example of a DynamoDB table layout that saves a variety of different kinds of data.

Primary Key		Data-Item Attributes...		
Partition Key	Sort Key	Attribute 1	Attribute 2	...
HR-974 *(employee ID)*	Employee_Name	Data: Murphy, John *(employee name)*	Start: 2008-11-08 *(start date)*	...etc.
	YYYY-Q1	Data: $5,477 *(order totals in USD)*	Name: Murphy, John *(employee name)*	
	HR_confidential	Data: 2008-11-08 *(hire date)*	Name: Murphy, John *(employee name)*	...etc.
	Warehouse_01	Data: Murphy, John *(employee name)*		
	v0_Job_title	Data: Operator-1 *(job title)*	Start: 2008-11-08 *(start date)*	...etc.
	v1_Job_title	Data: Operator-2 *(job title)*	Start: 2016-11-04 *(start date)*	...etc.
	v2_Job_title	Data: Supervisor-1 *(job title)*	Start: 2017-11-01 *(start date)*	...etc.

The `Data` attribute, which is common to all the items, has different content depending on its parent item. If you create a global secondary index for the table that uses the table's sort key as its partition key and the `Data` attribute as its sort key, you can make a variety of different queries using that single global secondary index. These queries might include the following:

- Look up an employee by name in the global secondary index, using `Employee_Name` as the partition key value and the employee's name (for example `Murphy, John`) as the sort key value.
- Use the global secondary index to find all employees working in a particular warehouse by searching on a warehouse ID (such as `Warehouse_01`).
- Get a list of recent hires, querying the global secondary index on `HR_confidential` as a partition key value and using a range of dates in the sort key value.

Using Global Secondary Index write sharding for selective table queries in DynamoDB

When you need to query recent data within a specific time window, DynamoDB's requirement of providing a partition key for most read operations can present a challenge. To address this scenario, you can implement an effective query pattern using a combination of write sharding and a Global Secondary Index (GSI).

This approach allows you to efficiently retrieve and analyze time-sensitive data without performing full table scans, which can be resource-intensive and costly. By strategically designing your table structure and indexing, you can create a flexible solution that supports time-based data retrieval while maintaining optimal performance.

Topics

- Pattern design
- Sharding strategy
- Querying the sharded GSI
- Parallel query execution considerations
- Code example

Pattern design

When working with DynamoDB, you can overcome time-based data retrieval challenges by implementing a sophisticated pattern that combines write sharding and Global Secondary Indexes to enable flexible, efficient querying across recent data windows.

Structure of the table

- Partition Key (PK): "Username"

Structure of the GSI

- GSI Partition Key (PK_GSI): "ShardNumber#"
- GSI Sort Key (SK_GSI): ISO 8601 timestamp (e.g., "2030-04-01T12:00:00Z")

[TABLE] - TimeBounded Metadata Actions

PK	SK_GSI	Address	PK_GSI
Trenton69	2023-12-05T06:40:31.312Z	117 Hudson Divide	ShardNumber#0
Scot_Langworth-Prosacco	2024-10-09T14:44:45.819Z	84021 Herzog Skyway	ShardNumber#6
Juliet.Morissette	2025-03-28T07:20:56.538Z	4871 N Broadway	ShardNumber#4
Kay.Von71	2024-11-23T16:19:26.763Z	14554 Odell Throughway	ShardNumber#2
Kiarra43	2023-11-15T16:21:57.078Z	8471 London Road	ShardNumber#1
Marcella91	2024-12-17T09:02:31.623Z	10271 Nick Crescent	ShardNumber#6
Bernard.Lemke36	2025-09-09T00:18:34.482Z	5438 Douglas Groves	ShardNumber#2
Daisha83	2024-01-24T06:38:08.482Z	8786 Armstrong Radial	ShardNumber#3

Jeremie_VonRueden-Mills	2025-04-06T04:24:23.701Z	157 Koch Drives	ShardNumber#1
Verna28	2025-10-10T18:42:21.059Z	70040 Baylee Trafficway	ShardNumber#1
Trycia.Doyle	2024-01-10T17:00:08.360Z	9511 Tillman Extensions	ShardNumber#2

Sharding strategy

Assuming you decide to use 10 shards, your shard numbers could range from 0 to 9. When logging an activity, you would calculate the shard number (for example, by using a hash function on the user ID and then taking the modulus of the number of shards) and prepend it to the GSI partition key. This method distributes the entries across different shards, mitigating the risk of hot partitions.

Querying the sharded GSI

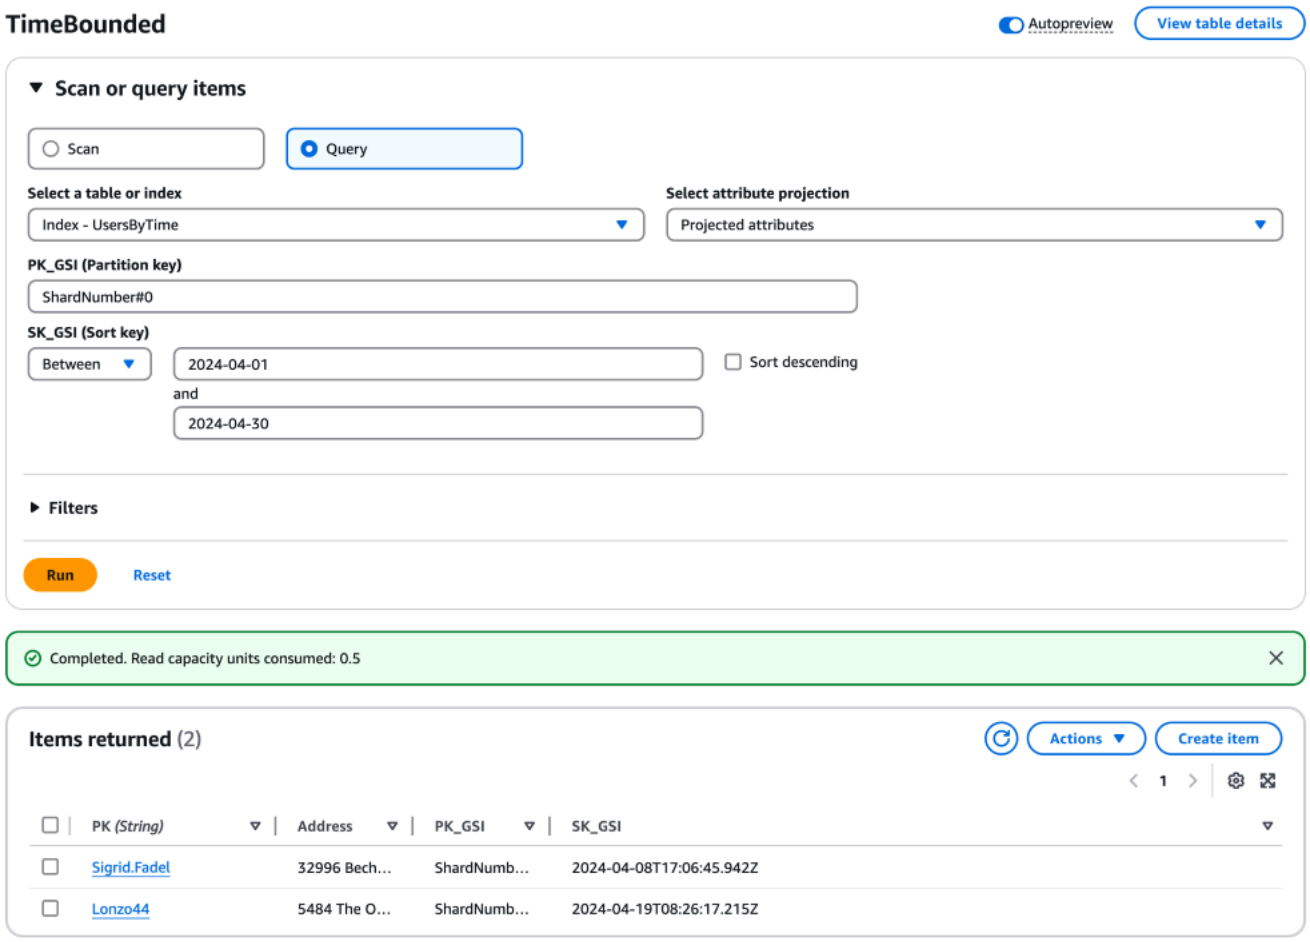
Querying across all shards for items within a particular time range in a DynamoDB table, where data is sharded across multiple partition keys, requires a different approach than querying a single partition. Since DynamoDB queries are limited to a single partition key at a time, you can't directly query across multiple shards with a single query operation. However, you can achieve the desired result through application-level logic by performing multiple queries, each targeting a specific shard, and then aggregating the results. The procedure below explains how to do this.

To query and aggregate shards

1. Identify the range of shard numbers used in your sharding strategy. For instance, if you have 10 shards, your shard numbers would range from 0-9.

2. For each shard, construct and execute a query to fetch items within the desired time range. These queries can be executed in parallel to improve efficiency. Use the partition key with the shard number and the sort key with your time range for these queries. Here's an example query for a single shard:

```
aws dynamodb query \
    --table-name "YourTableName" \
    --index-name "YourIndexName" \
    --key-condition-expression "PK_GSI = :pk_val AND SK_GSI BETWEEN :start_date
 AND :end_date" \
    --expression-attribute-values '{
        ":pk_val": {"S": "ShardNumber#0"},
        ":start_date": {"S": "2024-04-01"},
        ":end_date": {"S": "2024-04-30"}
    }'
```



You would replicate this query for each shard, adjusting the partition key accordingly (e.g., "ShardNumber#1", "ShardNumber#2", ..., "ShardNumber#9").

3. Aggregate the results from each query after all queries are complete. Perform this aggregation in your application code, combining the results into a single dataset that represents the items from all shards within your specified time range.

Parallel query execution considerations

Each query consumes read capacity from your table or index. If you're using provisioned throughput, ensure that your table is provisioned with enough capacity to handle the burst of parallel queries. If you're using on-demand capacity, be mindful of the potential cost implications.

Code example

To execute parallel queries across shards in DynamoDB using Python, you can use the boto3 library, which is the Amazon Web Services SDK for Python. This example assumes you have boto3 installed and configured with appropriate AWS credentials.

The following Python code demonstrates how to perform parallel queries across multiple shards for a given time range. It uses concurrent futures to execute queries in parallel, reducing the overall execution time compared to sequential execution.

```
import boto3
from concurrent.futures import ThreadPoolExecutor, as_completed

# Initialize a DynamoDB client
dynamodb = boto3.client('dynamodb')

# Define your table name and the total number of shards
table_name = 'YourTableName'
total_shards = 10  # Example: 10 shards numbered 0 to 9
time_start = "2030-03-15T09:00:00Z"
time_end = "2030-03-15T10:00:00Z"

def query_shard(shard_number):
    """
    Query items in a specific shard for the given time range.
    """
    response = dynamodb.query(
```

```
        TableName=table_name,
        IndexName='YourGSIName',  # Replace with your GSI name
        KeyConditionExpression="PK_GSI = :pk_val AND SK_GSI BETWEEN :date_start
 AND :date_end",
        ExpressionAttributeValues={
            ":pk_val": {"S": f"ShardNumber#{shard_number}"},
            ":date_start": {"S": time_start},
            ":date_end": {"S": time_end},
        }
    )
    return response['Items']

# Use ThreadPoolExecutor to query across shards in parallel
with ThreadPoolExecutor(max_workers=total_shards) as executor:
    # Submit a future for each shard query
    futures = {executor.submit(query_shard, shard_number): shard_number for
 shard_number in range(total_shards)}

    # Collect and aggregate results from all shards
    all_items = []
    for future in as_completed(futures):
        shard_number = futures[future]
        try:
            shard_items = future.result()
            all_items.extend(shard_items)
            print(f"Shard {shard_number} returned {len(shard_items)} items")
        except Exception as exc:
            print(f"Shard {shard_number} generated an exception: {exc}")

# Process the aggregated results (e.g., sorting, filtering) as needed
# For example, simply printing the count of all retrieved items
print(f"Total items retrieved from all shards: {len(all_items)}")
```

Before running this code, make sure to replace `YourTableName` and `YourGSIName` with the actual table and GSI names from your DynamoDB setup. Also, adjust `total_shards`, `time_start`, and `time_end` variables according to your specific requirements.

This script queries each shard for items within the specified time range and aggregates the results.

Using Global Secondary Indexes to create an eventually consistent replica in DynamoDB

You can use a global secondary index to create an eventually consistent replica of a table. Creating a replica can allow you to do the following:

- **Set different provisioned read capacity for different readers.** For example, suppose that you have two applications: One application handles high-priority queries and needs the highest levels of read performance, whereas the other handles low-priority queries that can tolerate throttling of read activity.

  If both of these applications read from the same table, a heavy read load from the low-priority application could consume all the available read capacity for the table. This would throttle the high-priority application's read activity.

  Instead, you can create a replica through a global secondary index whose read capacity you can set separate from that of the table itself. You can then have your low-priority app query the replica instead of the table.
- **Eliminate reads from a table entirely.** For example, you might have an application that captures a high volume of clickstream activity from a website, and you don't want to risk having reads interfere with that. You can isolate this table and prevent reads by other applications (see Using IAM policy conditions for fine-grained access control), while letting other applications read a replica created using a global secondary index.

To create a replica, set up a global secondary index that has the same key schema as the parent table, with some or all of the non-key attributes projected into it. In applications, you can direct some or all read activity to this global secondary index rather than to the parent table. You can then adjust the provisioned read capacity of the global secondary index to handle those reads without changing the parent table's provisioned read capacity.

There is always a short propagation delay between a write to the parent table and the time when the written data appears in the index. In other words, your applications should take into account that the global secondary index replica is only *eventually consistent* with the parent table.

You can create multiple global secondary index replicas to support different read patterns. When you create the replicas, project only the attributes that each read pattern actually requires. An application can then consume less provisioned read capacity to obtain only the data it needs rather

than having to read the item from the parent table. This optimization can result in significant cost savings over time.

Best practices for storing large items and attributes in DynamoDB

Amazon DynamoDB limits the size of each item that you store in a table to 400 KB (see Quotas in Amazon DynamoDB). If your application needs to store more data in an item than the DynamoDB size limit permits, you can try compressing one or more large attributes or breaking the item into multiple items (efficiently indexed by sort keys). You can also store the item as an object in Amazon Simple Storage Service (Amazon S3) and store the Amazon S3 object identifier in your DynamoDB item.

As a best practice, you should utilize the `ReturnConsumedCapacity` parameter when writing items to monitor and alert on items sizes that approach the 400 KB maximum item size. Exceeding the maximum item size will result in failed write attempts. DynamoDB will return a ValidationException error. Monitoring and alerting on item sizes will enable you to mitigate the items size issues before they impact your application.

Compressing large attribute values

Compressing large attribute values can let them fit within item limits in DynamoDB and reduce your storage costs. Compression algorithms such as GZIP or LZO produce binary output that you can then store in a `Binary` attribute type within the item.

As an example, consider a table that stores messages written by forum users. Such messages often contain long strings of text, which are candidates for compression. While compression can reduce item sizes, the downside is that the compressed attribute values are not useful for filtering.

For sample code that demonstrates how to compress such messages in DynamoDB, see the following:

- Example: Handling binary type attributes using the AWS SDK for Java document API
- Example: Handling binary type attributes using the AWS SDK for .NET low-level API

Vertical partitioning

An alternative solution to dealing with large items is to break them down into smaller chunks of data and associating all relevant items by the partition key value. You can then use a sort key string to identify the associated information stored alongside it. By doing this, and having multiple items grouped by the same partition key value, you are creating an *item collection*.

For more information on this approach, see:

- Use vertical partitioning to scale data efficiently in Amazon DynamoDB
- Implement vertical partitioning in Amazon DynamoDB using AWS Glue

Storing large attribute values in Amazon S3

As mentioned previously, you can also use Amazon S3 to store large attribute values that cannot fit in a DynamoDB item. You can store them as an object in Amazon S3 and then store the object identifier in your DynamoDB item.

You can also use the object metadata support in Amazon S3 to provide a link back to the parent item in DynamoDB. Store the primary key value of the item as Amazon S3 metadata of the object in Amazon S3. Doing this often helps with maintenance of the Amazon S3 objects.

For example, consider the `ProductCatalog` table. Items in this table store information about item price, description, book authors, and dimensions for other products. If you wanted to store an image of each product that was too large to fit in an item, you could store the images in Amazon S3 instead of in DynamoDB.

When implementing this strategy, keep the following in mind:

- DynamoDB doesn't support transactions that cross Amazon S3 and DynamoDB. Therefore, your application must deal with any failures, which could include cleaning up orphaned Amazon S3 objects.
- Amazon S3 limits the length of object identifiers. So you must organize your data in a way that doesn't generate excessively long object identifiers or violate other Amazon S3 constraints.

For more information about how to use Amazon S3, see the Amazon Simple Storage Service User Guide.

Best practices for handling time series data in DynamoDB

General design principles in Amazon DynamoDB recommend that you keep the number of tables you use to a minimum. For most applications, a single table is all you need. However, for time series data, you can often best handle it by using one table per application per period.

Design pattern for time series data

Consider a typical time series scenario, where you want to track a high volume of events. Your write access pattern is that all the events being recorded have today's date. Your read access pattern might be to read today's events most frequently, yesterday's events much less frequently, and then older events very little at all. One way to handle this is by building the current date and time into the primary key.

The following design pattern often handles this kind of scenario effectively:

- Create one table per period, provisioned with the required read and write capacity and the required indexes.
- Before the end of each period, prebuild the table for the next period. Just as the current period ends, direct event traffic to the new table. You can assign names to these tables that specify the periods they have recorded.
- As soon as a table is no longer being written to, reduce its provisioned write capacity to a lower value (for example, 1 WCU), and provision whatever read capacity is appropriate. Reduce the provisioned read capacity of earlier tables as they age. You might choose to archive or delete the tables whose contents are rarely or never needed.

The idea is to allocate the required resources for the current period that will experience the highest volume of traffic and scale down provisioning for older tables that are not used actively, therefore saving costs. Depending on your business needs, you might consider write sharding to distribute traffic evenly to the logical partition key. For more information, see Using write sharding to distribute workloads evenly in your DynamoDB table.

Time series table examples

The following is a time series data example in which the current table is provisioned at a higher read/write capacity and the older tables are scaled down because they are accessed infrequently.

Current table — Provisioned at: WCU=750 and RCU=300

Primary Key		Attributes		
Partition Key	Sort Key	Radiant Intensity	Wavelength	...
2018-03-15	00:00:00.002	17.372 W/Sr	713 nm	...
2018-03-15	00:00:00.004	17.385 W/Sr	712 nm	...
2018-03-15	00:00:00.005	17.478 W/Sr	708 nm	...

Best practices for managing many-to-many relationships in DynamoDB tables

Adjacency lists are a design pattern that is useful for modeling many-to-many relationships in Amazon DynamoDB. More generally, they provide a way to represent graph data (nodes and edges) in DynamoDB.

Adjacency list design pattern

When different entities of an application have a many-to-many relationship between them, the relationship can be modeled as an adjacency list. In this pattern, all top-level entities (synonymous to nodes in the graph model) are represented using the partition key. Any relationships with other entities (edges in a graph) are represented as an item within the partition by setting the value of the sort key to the target entity ID (target node).

The advantages of this pattern include minimal data duplication and simplified query patterns to find all entities (nodes) related to a target entity (having an edge to a target node).

A real-world example where this pattern has been useful is an invoicing system where invoices contain multiple bills. One bill can belong in multiple invoices. The partition key in this example is either an `InvoiceID` or a `BillID`. `BillID` partitions have all attributes specific to bills. `InvoiceID` partitions have an item storing invoice-specific attributes, and an item for each `BillID` that rolls up to the invoice.

The schema looks like the following.

Table	Primary Key		Data Attributes...	
	Partition Key	*Sort Key (and GSI PK)*		
	`Invoice-92551`	**Inv_ID:** Invoice-92551 *(invoice ID)*	**Dated:** 2018-02-07 *(date created)*	More attributes of this invoice...
		Bill_ID: Bill-4224663 *(bill ID)*	**Dated:** 2017-12-03 *(date created)*	Attributes of this bill *in this invoice*..
		Bill_ID: Bill-4224687 *(bill ID)*	**Dated:** 2018-01-09 *(date created)*	Attributes of this bill *in this invoice*..
	`Invoice-92552`	**Inv_ID:** Invoice-92552 *(invoice ID)*	**Dated:** 2018-03-04 *(date created)*	More attributes of this invoice...
		Bill_ID: Bill-4224687 *(bill ID)*	**Dated:** 2018-01-09 *(date created)*	Attributes of this bill *in this invoice*..
	`Bill-4224663`	**Bill_ID:** Bill-4224663 *(bill ID)*	**Dated:** 2017-12-03 *(date created)*	More attributes of this bill...
	`Bill-4224687`	**Bill_ID:** Bill-4224687 *(bill ID)*	**Dated:** 2018-01-09 *(date created)*	More attributes of this bill...

Using the preceding schema, you can see that all bills for an invoice can be queried using the primary key on the table. To look up all invoices that contain a part of a bill, create a global secondary index on the table's sort key.

The projections for the global secondary index look like the following.

GSI	Primary Key *Partition Key*	Projected Attributes...	
	Bill-4224663	Bill_ID: Bill-4224663 *(table primary key)*	Attributes of this bill...
		Inv_ID: Invoice-92551 *(table primary key)*	Attributes of this bill *in this invoice*..
	Bill-4224687	Bill_ID: Bill-4224687 *(table primary key)*	Attributes of this bill...
		Inv_ID: Invoice-92551 *(table primary key)*	Attributes of this bill *in this invoice*..
		Inv_ID: Invoice-92552 *(table primary key)*	Attributes of this bill *in this invoice*..
	Invoice-92551	Inv_ID: Invoice-92551 *(table primary key)*	Attributes of this invoice...
	Invoice-92552	Inv_ID: Invoice-92552 *(table primary key)*	Attributes of this invoice...

Materialized graph pattern

Many applications are built around understanding rankings across peers, common relationships between entities, neighbor entity state, and other types of graph style workflows. For these types of applications, consider the following schema design pattern.

TABLE	Primary Key		Attributes		
	PK (NodeId)	SK (TypeTarget, GSI 2 SK)	Data	GSI PK	Graph Projections
	1	DATE|2|BIRTH	1980-12-19	Hash(Person.Data)	
		PERSON|1	Data (GSI1 SK)	GSI PK	
			John Doe	Hash(Person.Data)	
		PERSON|5|FRIEND	Data	GSI PK	
			Jane Smith	Hash(Person.Data)	
		PLACE|4|BIRTH	Data	GSI PK	
			USA|Texas|Austin	Hash(Person.Data)	
		SKILL|6	Data	GSI PK	
			Java Developer|Senior	Hash(Person.Data)	
	2	DATE|2	Data	GSI PK

		SKILL|7	NodeID	Data	
			7	Guitar	
			NodeID	Data	
			5	Guitar|Advanced	

The preceding schema shows a graph data structure that is defined by a set of data partitions containing the items that define the edges and nodes of the graph. Edge items contain a `Target` and a `Type` attribute. These attributes are used as part of a composite key name "TypeTarget" to identify the item in a partition in the primary table or in a second global secondary index.

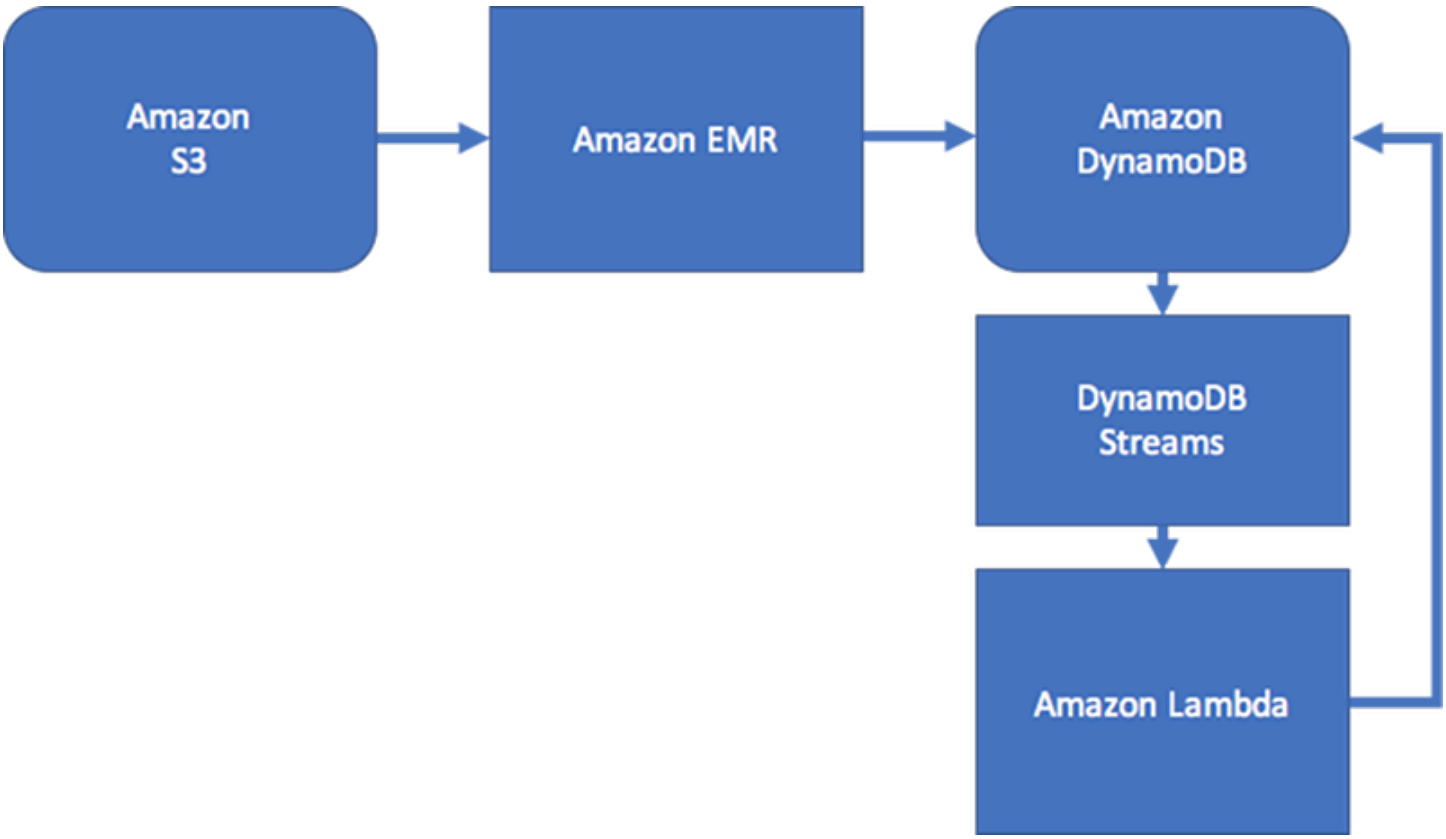
The first global secondary index is built on the `Data` attribute. This attribute uses global secondary index-overloading as described earlier to index several different attribute types, namely `Dates`, `Names`, `Places`, and `Skills`. Here, one global secondary index is effectively indexing four different attributes.

As you insert items into the table, you can use an intelligent sharding strategy to distribute item sets with large aggregations (birthdate, skill) across as many logical partitions on the global secondary indexes as are needed to avoid hot read/write problems.

The result of this combination of design patterns is a solid datastore for highly efficient real-time graph workflows. These workflows can provide high-performance neighbor entity state and edge aggregation queries for recommendation engines, social-networking applications, node rankings, subtree aggregations, and other common graph use cases.

If your use case isn't sensitive to real-time data consistency, you can use a scheduled Amazon EMR process to populate edges with relevant graph summary aggregations for your workflows. If your application doesn't need to know immediately when an edge is added to the graph, you can use a scheduled process to aggregate results.

To maintain some level of consistency, the design could include Amazon DynamoDB Streams and AWS Lambda to process edge updates. It could also use an Amazon EMR job to validate results on a regular interval. This approach is illustrated by the following diagram. It is commonly used in social networking applications, where the cost of a real-time query is high and the need to immediately know individual user updates is low.



IT service-management (ITSM) and security applications generally need to respond in real time to entity state changes composed of complex edge aggregations. Such applications need a system that can support real-time multiple node aggregations of second- and third-level relationships, or complex edge traversals. If your use case requires these types of real-time graph query workflows, we recommend that you consider using Amazon Neptune to manage these workflows.

> **Note**
>
> If you need to query highly connected datasets or execute queries that need to traverse multiple nodes (also known as multi-hop queries) with millisecond latency, you should consider using Amazon Neptune. Amazon Neptune is a purpose-built, high-performance graph database engine optimized for storing billions of relationships and querying the graph with millisecond latency.

Best practices for querying and scanning data in DynamoDB

This section covers some best practices for using `Query` and `Scan` operations in Amazon DynamoDB.

Performance considerations for scans

In general, `Scan` operations are less efficient than other operations in DynamoDB. A `Scan` operation always scans the entire table or secondary index. It then filters out values to provide the result you want, essentially adding the extra step of removing data from the result set.

If possible, you should avoid using a `Scan` operation on a large table or index with a filter that removes many results. Also, as a table or index grows, the `Scan` operation slows. The `Scan` operation examines every item for the requested values and can use up the provisioned throughput for a large table or index in a single operation. For faster response times, design your tables and indexes so that your applications can use `Query` instead of `Scan`. (For tables, you can also consider using the `GetItem` and `BatchGetItem` APIs.)

Alternatively, you can design your application to use `Scan` operations in a way that minimizes the impact on your request rate. This can include modeling when it might be more efficient to use a global secondary index instead of a `Scan` operation. Further information on this process is in the following video.

Modeling low velocity access patterns

Avoiding sudden spikes in read activity

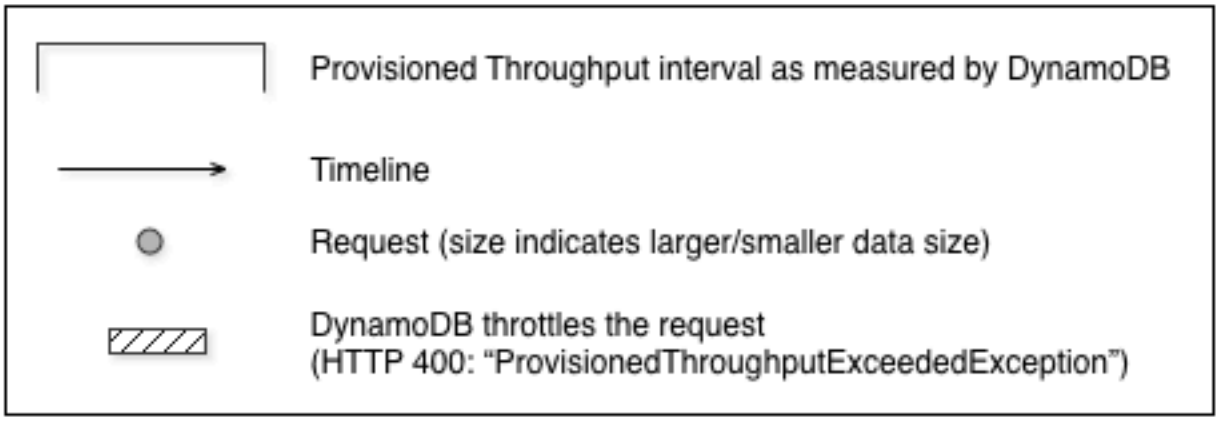
When you create a table, you set its read and write capacity unit requirements. For reads, the capacity units are expressed as the number of strongly consistent 4 KB data read requests per

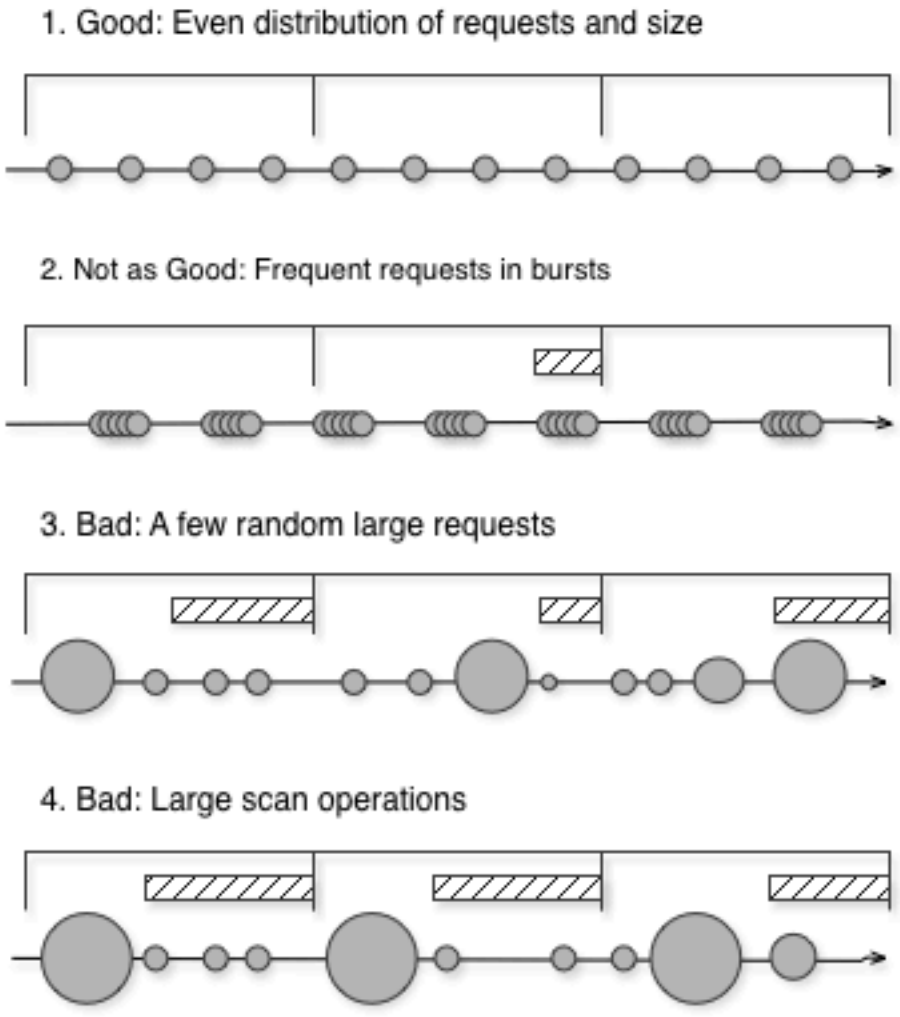
second. For eventually consistent reads, a read capacity unit is two 4 KB read requests per second. A `Scan` operation performs eventually consistent reads by default, and it can return up to 1 MB (one page) of data. Therefore, a single `Scan` request can consume (1 MB page size / 4 KB item size) / 2 (eventually consistent reads) = 128 read operations. If you request strongly consistent reads instead, the `Scan` operation would consume twice as much provisioned throughput—256 read operations.

This represents a sudden spike in usage, compared to the configured read capacity for the table. This usage of capacity units by a scan prevents other potentially more important requests for the same table from using the available capacity units. As a result, you likely get a `ProvisionedThroughputExceeded` exception for those requests.

The problem is not just the sudden increase in capacity units that the `Scan` uses. The scan is also likely to consume all of its capacity units from the same partition because the scan requests read items that are next to each other on the partition. This means that the request is hitting the same partition, causing all of its capacity units to be consumed, and throttling other requests to that partition. If the request to read data is spread across multiple partitions, the operation would not throttle a specific partition.

The following diagram illustrates the impact of a sudden spike of capacity unit usage by `Query` and `Scan` operations, and its impact on your other requests against the same table.





As illustrated here, the usage spike can impact the table's provisioned throughput in several ways:

1. Good: Even distribution of requests and size

2. Not as good: Frequent requests in bursts
3. Bad: A few random large requests
4. Bad: Large scan operations

Instead of using a large `Scan` operation, you can use the following techniques to minimize the impact of a scan on a table's provisioned throughput.

- **Reduce page size**

  Because a Scan operation reads an entire page (by default, 1 MB), you can reduce the impact of the scan operation by setting a smaller page size. The `Scan` operation provides a *Limit* parameter that you can use to set the page size for your request. Each `Query` or `Scan` request that has a smaller page size uses fewer read operations and creates a "pause" between each request. For example, suppose that each item is 4 KB and you set the page size to 40 items. A `Query` request would then consume only 20 eventually consistent read operations or 40 strongly consistent read operations. A larger number of smaller `Query` or `Scan` operations would allow your other critical requests to succeed without throttling.
- **Isolate scan operations**

  DynamoDB is designed for easy scalability. As a result, an application can create tables for distinct purposes, possibly even duplicating content across several tables. You want to perform scans on a table that is not taking "mission-critical" traffic. Some applications handle this load by rotating traffic hourly between two tables—one for critical traffic, and one for bookkeeping. Other applications can do this by performing every write on two tables: a "mission-critical" table, and a "shadow" table.

Configure your application to retry any request that receives a response code that indicates you have exceeded your provisioned throughput. Or, increase the provisioned throughput for your table using the `UpdateTable` operation. If you have temporary spikes in your workload that cause your throughput to exceed, occasionally, beyond the provisioned level, retry the request with exponential backoff. For more information about implementing exponential backoff, see Error retries and exponential backoff.

Taking advantage of parallel scans

Many applications can benefit from using parallel `Scan` operations rather than sequential scans. For example, an application that processes a large table of historical data can perform a parallel

scan much faster than a sequential one. Multiple worker threads in a background "sweeper" process could scan a table at a low priority without affecting production traffic. In each of these examples, a parallel `Scan` is used in such a way that it does not starve other applications of provisioned throughput resources.

Although parallel scans can be beneficial, they can place a heavy demand on provisioned throughput. With a parallel scan, your application has multiple workers that are all running `Scan` operations concurrently. This can quickly consume all of your table's provisioned read capacity. In that case, other applications that need to access the table might be throttled.

A parallel scan can be the right choice if the following conditions are met:

- The table size is 20 GB or larger.
- The table's provisioned read throughput is not being fully used.
- Sequential `Scan` operations are too slow.

Choosing TotalSegments

The best setting for `TotalSegments` depends on your specific data, the table's provisioned throughput settings, and your performance requirements. You might need to experiment to get it right. We recommend that you begin with a simple ratio, such as one segment per 2 GB of data. For example, for a 30 GB table, you could set `TotalSegments` to 15 (30 GB / 2 GB). Your application would then use 15 workers, with each worker scanning a different segment.

You can also choose a value for `TotalSegments` that is based on client resources. You can set `TotalSegments` to any number from 1 to 1000000, and DynamoDB lets you scan that number of segments. For example, if your client limits the number of threads that can run concurrently, you can gradually increase `TotalSegments` until you get the best `Scan` performance with your application.

Monitor your parallel scans to optimize your provisioned throughput use, while also making sure that your other applications aren't starved of resources. Increase the value for `TotalSegments` if you don't consume all of your provisioned throughput but still experience throttling in your `Scan` requests. Reduce the value for `TotalSegments` if the `Scan` requests consume more provisioned throughput than you want to use.

Best practices for DynamoDB table design

General design principles in Amazon DynamoDB recommend that you keep the number of tables you use to a minimum. In the majority of cases, we recommend that you consider using a single table. However if a single or small number of tables are not viable, these guidelines may be of use.

- The per account limit cannot be increased above 10,000 tables per account. If your application requires more tables, plan for distributing the tables across multiple accounts. For more information see service, account, and table quotas in Amazon DynamoDB.
- Consider control plane limits for concurrent control plane operations that might impact your table management.
- Work with AWS solution architects to validate your design patterns for multi-tenant designs.

Best practices for DynamoDB global table design

Global tables build on Amazon DynamoDB's global footprint to provide you with a fully managed, multi-Region, and multi-active database that delivers fast, local, read and write performance for massively scaled, global applications. With global tables your data replicates automatically across your choice of AWS Regions. Because global tables use existing DynamoDB APIs, no changes to your application will be needed. There are no upfront costs or commitments for using global tables, and you pay only for the resources you use.

Prescriptive guidance for DynamoDB global table design

Efficient use of global tables requires careful considerations of factors like your preferred write mode, routing model, and evacuation processes. You must instrument your application across every Region and be ready to adjust your routing or perform an evacuation to maintain global health. The reward is having a globally distributed data set with low-latency reads and writes and a 99.999% service level agreement.

Key facts about DynamoDB global table design

- There are two versions of global tables: the current version Global Tables version 2019.11.21 (Current) (sometimes called "V2"), and Global tables version 2017.11.29 (Legacy) (sometimes called "V1"). This guide focuses exclusively on the current version, V2.
- Without the use of global tables, DynamoDB is a Regional service. It is highly available and intrinsically resilient to failures of infrastructure with a Region, including the failure of an entire availability zone (AZ). A single-Region DynamoDB table has a 99.99% availability https://aws.amazon.com/dynamodb/sla/Service Level Agreement (SLA).
- With the use of global tables, DynamoDB allows a table to replicate its data between two or more Regions. A multi-Region DynamoDB table has a 99.999% availability SLA. With proper planning, global tables can help create an architecture that is resilient and resists Regional failures.
- Global tables employ an active-active replication model. From the perspective of DynamoDB, the table in each Region has equal standing to accept read and write requests. After receiving a write request, the local replica table will replicate the write to other participating Regions in the background.
- Items are replicated individually. Items updated within a single transaction may not be replicated together.
- Each table partition in the source Region replicates its writes in parallel with every other partition. The sequence of writes within the remote Region may not match the sequence of writes that happened within the source Region. For more information about table partitions, see the blog post Scaling DynamoDB: How partitions, hot keys, and split for heat impact performance.
- A newly written item is usually propagated to all replica tables within a second. Nearby Regions tend to propagate faster.
- Amazon CloudWatch provides a `ReplicationLatency` metric for each Region pair. It is calculated based on looking at arriving items and comparing their arrival time with their initial

write time and computing an average. Timings are stored within CloudWatch in the source Region. Viewing the average and maximum timings can help determine the average and worst-case replication lag. There is no SLA on this latency.

- If the same item is updated at about the same time (within this `ReplicationLatency` window) in two different Regions, and the second write happens before the first write was replicated, there's a potential for write conflicts. Global tables resolves such conflicts with a *last writer wins* mechanism, based on the timestamp of the writes. The first write "loses" to the second write. These conflicts are not recorded in CloudWatch or AWS CloudTrail.
- Each item has a last write timestamp held as a private system property. The *last writer wins* approach is implemented by using a conditional write that requires the incoming item's timestamp be greater than the existing item's timestamp.
- A global table will replicate all items to all participating Regions. If you want to have different replication scopes, you can create different tables and give each of the tables different participating Regions.
- Writes will be accepted to the local Region even if the replica Region is offline or the `ReplicationLatency` grows. The local table continues to attempt replicating items to the remote table until each item succeeds.
- In the unlikely event a Region goes fully offline, when it later comes back online all pending outbound and inbound replications will be retried. No special action is required to bring the tables back in sync. The *last writer wins* mechanism ensures the data will eventually become consistent.
- You can add a new Region to a DynamoDB table at any time. DynamoDB will handle the initial sync and ongoing replication. If a Region is removed, even if it's the original Region, that will only delete the table for that Region.
- DynamoDB does not have a global endpoint. All requests are made to a regional endpoint, which then accesses the global table instance that's local to that Region.
- Calls to DynamoDB should not go cross-Region. The best practice is for the compute layer in one Region to directly access only the local DynamoDB endpoint for that Region. If problems are detected within a Region, whether those problems are in the DynamoDB layer or in the surrounding stack, then the end user traffic should be routed to a different compute layer hosted in a different Region. Thanks to global table replication, the different Region will already have a local copy of the same data for it to locally work with. In some circumstances the compute layer in one Region may pass the request onward to another Region's compute layer for processing, but this should not directly access the remote DynamoDB endpoint. For more information on this particular use case see Compute-layer request routing.

DynamoDB global table use cases

Global tables provides these common benefits:

- **Lower-latency reads.** You can place a copy of the data closer to the end user to reduce network latency during reads. The cache is kept as fresh as the `ReplicationLatency` value.
- **Lower-latency writes.** You can write to a nearby region to reduce network latency and the time taken to achieve the write. The write traffic must be carefully routed to ensure no conflicts. Techniques for routing are discussed in more detail in Request routing with DynamoDB global tables.
- **Increased resiliency and disaster recovery.** You can evacuate a Region (move away some or all requests going to that Region) should the Region have degraded performance or a full outage, with a Recovery Point Objective (RPO) and Recovery Time Objective (RTO) measured in seconds. Using global tables also increases the DynamoDB SLA from 99.99% to 99.999%.
- **Seamless Region migration.** You can add a new Region and then delete the old Region to migrate a deployment from one Region to another, all without downtime at the data layer. For example, you can use DynamoDB global tables for an order management system achieve reliably low latency processing at a high scale while also maintaining resilience to AZ and Regional failures.

Write modes with DynamoDB global tables

Global tables are always active-active at the table level. However, you might want to treat them as active-passive by controlling how you route write requests. For example, you might decide to route write requests to a single Region to avoid potential write conflicts.

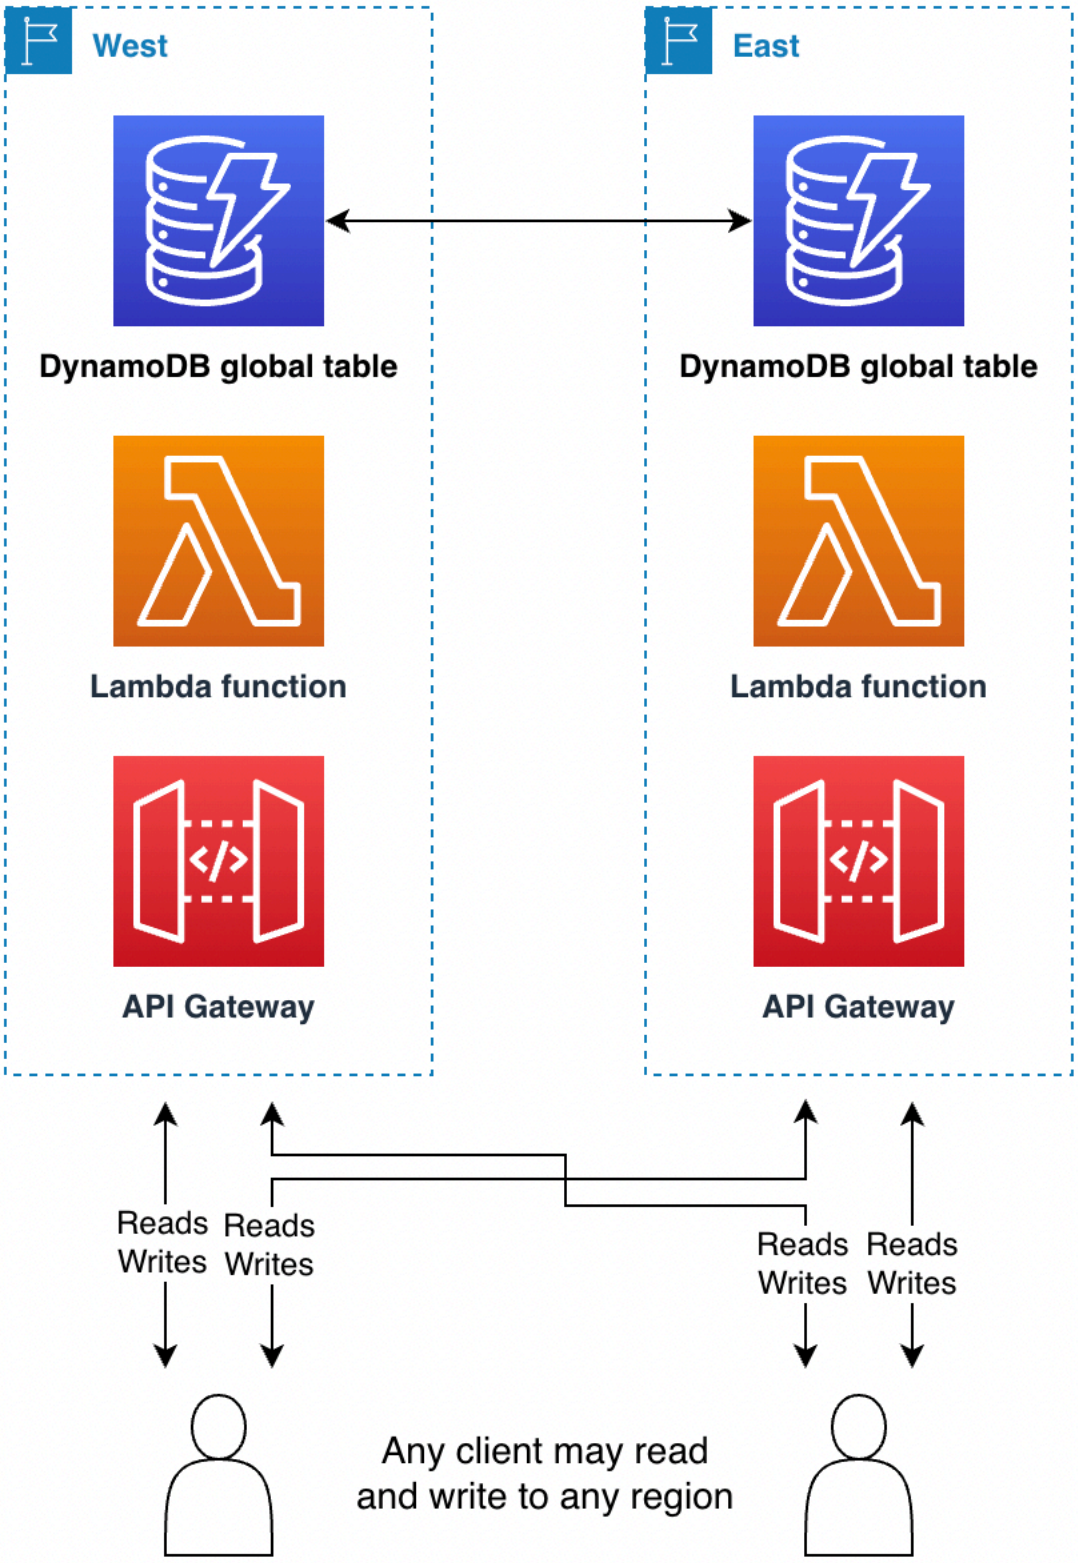
There are three main categorizations of managed write patterns:

- Write to any Region mode (no primary)
- Write to one Region mode (single primary)
- Write to your Region mode (mixed primary)

You should consider which write pattern fits your use case. This choice affects how you route requests, evacuate a Region, and handle disaster recovery. Overall best practices can differ depending on your application's write mode.

Write to any Region mode (no primary)

The *write to any Region* mode is fully active-active and doesn't impose restrictions on where a write may occur. Any Region may accept a write at any time. This is the simplest mode. It can be used only with some type of applications. It's suitable when all writers are idempotent, and therefore safely repeatable so that concurrent or repeated write operations across Regions are not in conflict. For example, when a user updates their contact data. This mode also works well for a special case of being idempotent, an append-only dataset where all writes are unique inserts under a deterministic primary key. Lastly, this mode is suitable where the risk of conflicting writes would be acceptable.



The *write to any Region* mode is the most straightforward architecture to implement. Routing is easier because any Region can be the write target at any time. Failover is easier, because any recent

writes can be replayed any number of times to any secondary Region. Where possible, you should design for this write mode.

For example, video streaming services often use global tables for tracking bookmarks, reviews, watch status flags, and so on. These deployments can use the *write to any Region* mode as long as they ensure that every write is idempotent and the next correct value for an item doesn't depend on its current value. This will be the case for user updates which assign the user's new state directly, such as setting a new latest time code, assigning a new review, or setting a new watch status. If the user's write requests are routed to different Regions, the last write operation will persist and the global state will settle according to the last assignment. Read operations in this mode will eventually become consistent, after being delayed by the latest `ReplicationLatency` value.

In another example, a financial services firm uses global tables as part of a system to maintain a running tally of debit card purchases for each customer, to calculate that customer's cash-back rewards. New transactions stream in from around the world and go to multiple Regions. For their current design that doesn't take advantage of global tables, they use a single Running Balance item per customer. Customer actions update the balance with an ADD expression, which is not idempotent because the new correct value depends on the current value. This means the balance got out of sync if there were two write operations to the same balance at around the same time in different Regions.

This same firm could achieve a *write to any Region* mode through a careful redesign with DynamoDB's global tables. The new design could follow an "event streaming" model - essentially a ledger with an append-only workflow. Each customer action appends a new item to the item collection maintained for that customer. The item collection is the set of items that share a primary key, having different sort keys. Each write action that appends the customer action is an idempotent insert, using the customer ID as the partition key and transaction ID as the sort key. This design makes the calculation of the balance more involved, because it requires a `Query` to pull the items followed by some client-side math. But the advantage is that it makes all writes idempotent, which provides significant routing and failover simplifications. For more information see Request routing with DynamoDB global tables.

For a third example, let's say there's a customer doing online ad placement. They've decided a low risk of data loss would be acceptable to achieve the design simplifications of the *write to any Region* mode. When they serve ads, they have just a few milliseconds to retrieve enough metadata to determine what ad to show, and then to record the ad impression so the same ad won't repeated to that user. With global tables they can get both low-latency reads for end users across the world

and low-latency writes. They can record all ad impressions for a user within a single item, and represent that as a growing List. They can use one item instead of appending to an item collection, because this way they can remove older ad impressions as part of each write without paying for a delete. This write operation is NOT idempotent, so if the same end user sees ads served out of multiple Regions at approximately the same time there's a chance one ad impression write could overwrite the other. For online ad placement, the risk that a user might occasionally see a repeated ad is worth having this simpler and more efficient design.

Single primary ("Write to one Region")

The *write to one Region* mode is active-passive and routes all table writes to a single active region. Note that DynamoDB doesn't have a notion of a single active region; the application routing outside DynamoDB manages this. The *write to one Region* mode avoids write conflicts by ensuring writes only flow to one Region at a time. This write mode is helpful when you want to use conditional expressions or transactions, because they won't work unless you know you're acting against the latest data. So using conditional expressions and transactions requires sending all write requests to the one Region with the latest data.

Eventually consistent reads can go to any replica Regions to achieve lower latencies. Strongly consistent reads must go to the single primary region.

a single region at a time

It's sometimes necessary to change the active Region in response to a Regional failure, to help with data. Evacuating a Region with DynamoDB global tables is one example of this use case. Some customers will change the currently active Region on a regular schedule, such as a "follow- the-sun" deployment. This places the active Region near the geography with the most activity, giving it the lowest latency reads and writes. It also has the side benefit of calling the Region- changing code path on a daily basis, making sure it's well tested before any disaster recovery.

The passive Region(s) may keep a downscaled set of infrastructure surrounding DynamoDB that gets built up only should it become the active region. For a more in-depth discussion of pilot light and warm standby designs see Disaster Recovery (DR) Architecture on AWS, Part III: Pilot Light and Warm Standby.

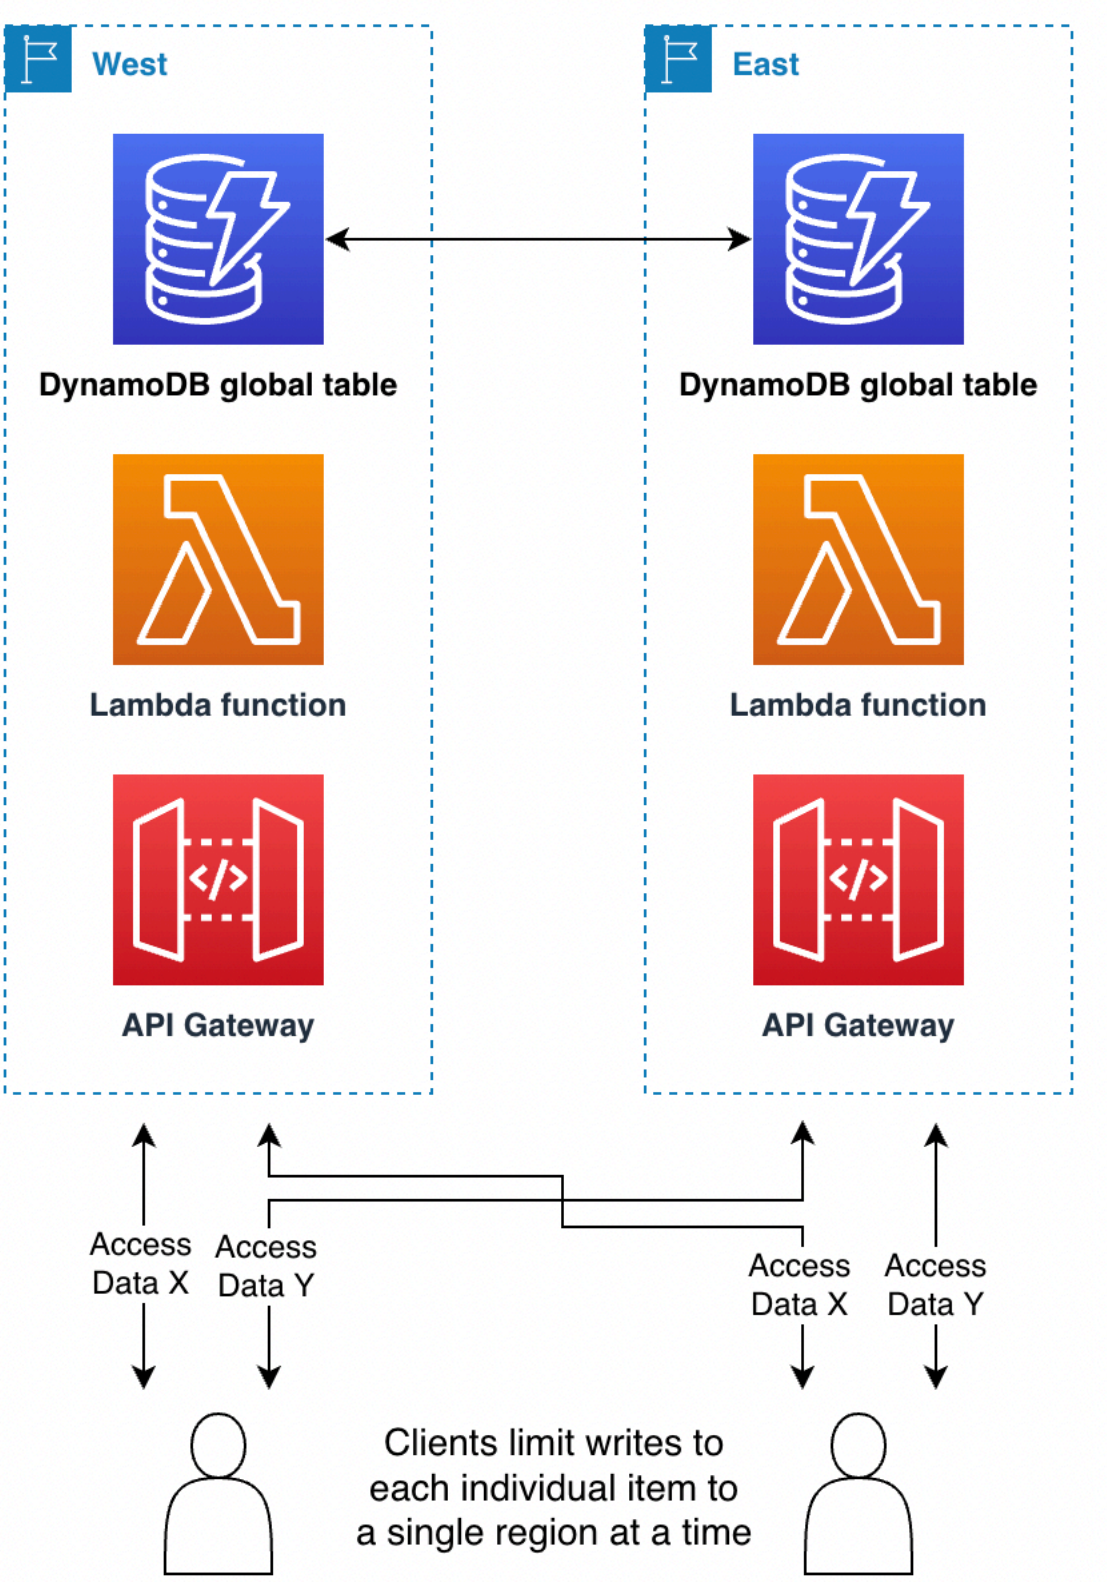
Using the *write to one Region* mode works well when leveraging global tables for low-latency globally distributed reads. For example, a large social media company has millions of users and billions of posts. Each user gets assigned to a Region at time of account creation, placed geographically near to their location. Into that non-global table goes all their data. The company uses a separate global table to hold the mapping of users to their home regions, using a *write to one Region* mode. It keeps read-only copies around the world to help locate each user's data directly with minimum added latency. Updates are rare (only when moving a user's home Region from one to another) and always go through one Region for writing, to avoid any chance of write conflicts.

As another example, consider a financial services customer who implemented a daily cash back calculation. They use *write to any Region* mode for calculating the balance but use *write to one Region* mode for tracking the actual cash back payments. If they want to reward a customer 1 penny for every $10 spent a day, they will need to `Query` for all transactions from the previous day, calculate the total spent, write the cash back decision to a new table, delete the queried set of items to mark them as consumed, and replace them with a singular item storing any remainder amount that should go into the next day's calculations. This work requires transactions, and so will work better with the *write to one Region* mode. An application may mix write modes, even on the same table, as long as the workloads have no chance of overlapping.

Mixed primary ("Write to your Region")

The *write to your Region* mode assigns different data subsets to different Regions and allows write operations only to items through its home region. this mode is active-passive but assigns the active Region based on the item. Every Region is primary for its own non-overlapping data set, and writes must be guarded to ensure proper locality.

This mode is similar to *write to one Region* except that it enables lower latency writes, because the data associated with each end user can be placed in closer network proximity to that user. It also spreads the surrounding infrastructure more evenly between Regions and requires less work to build out infrastructure during a failover scenario, because all regions will have a portion of their infrastructure already active.



Determining the home region for items can be done in a variety of ways:

- **Intrinsic:** Some aspect of the data makes clear to what Region it's homed, like its partition key. For example, a customer and all data about that customer would be marked within the customer data as homed to a certain region. This technique is described in Use Region pinning to set a home Region for items in an Amazon DynamoDB global table
- **Negotiated:** The home region of each data set is negotiated in some external manner, such as with a separate global service that maintains assignments. The assignment may have a finite duration after which it's subject to renegotiation.
- **Table-oriented:** Instead of a single replicating global table, have as many global tables as there are replicating Regions. Each table's name indicates its home Region. In standard operations, all data is written to the home Region while other Regions keep a read-only copy. During a failover, another Region will temporarily adopt write duties for that table.

For example, imagine you're working for a gaming company. You need low latency reads and writes for all gamers around the world. You can home each gamer to the Region closest them. That region takes all their reads and writes, ensuring there's always strong read-after-write consistency. However, if that gamer travels or their home Region suffers an outage, a complete copy of their data will be available in alternative Regions. So the gamer can be assigned to different home Region as is useful.

As another example, imagine you're working at a video conferencing company. Each conference call's metadata gets assigned to a particular Region. Callers can use the Region that's closest to them for lowest latency. If there's a Region outage, using global tables allows quick recovery because the system can move the processing of the call to a different Region where there's already a replicated copy of the data.

Request routing with DynamoDB global tables

Perhaps the most complex piece of a global table deployment is managing request routing. Requests must first go from an end user to a Region that's chosen and routed in some manner. The request encounters some stack of services in that Region, including a compute layer that perhaps consists of a load balancer backed by an AWS Lambdafunction, container, or Amazon Elastic Compute Cloud (Amazon EC2) node, and possibly other services including another database. That compute layer communicates with DynamoDB It should do that by using the local endpoint for that Region. The data in the global table replicates to all other participating Regions, and each Region has a similar stack of services around its DynamoDB table.

The global table provides each stack in the various Regions with a local copy of the same data. You might consider designing for a single stack in a single Region and anticipate making remote calls to a secondary Region's DynamoDB endpoint if there's an issue with the local DynamoDB table. This is not best practice. The latencies associated with going across Regions might be 100 times higher than for local access. A back-and-forth series of 5 requests might take milliseconds when performed locally but seconds when crossing the globe. It's better to route the end user to another Region for processing. To ensure resiliency you need replication across multiple Regions, with replication of the compute layer as well as the data layer.

There are numerous alternative techniques to route an end user request to a Region for processing. The optimum choice depends on your write mode and your failover considerations. This section discusses four options: client-driven, compute-layer, Route 53, and Global Accelerator.

Client-driven request routing

With client-driven request routing, an end user client such as an application, a web page with JavaScript another client will keeps track of the valid application endpoints. In this case that will be application endpoints like an Amazon API Gateway rather than literal DynamoDB endpoints. The end user client uses its own embedded logic to choose which Region to communicate with. It may choose based on random selection, lowest observed latencies, highest observed bandwidth measurements, or locally-performed health checks.

Routing is client's choice

The advantage to client-driven request routing is it can be adaptive to things such as real-world public internet traffic conditions to switch Regions should it notice any degraded performance. The client must be aware of all potential endpoints, but launching a new Regional endpoint is not a frequent occurrence.

With the *write to any Region*mode, a client can unilaterally select its preferred endpoint. If its access to one Region becomes impaired, the client can route to another endpoint.

With the *write to one Region* mode, the client will need a mechanism to route its writes to the currently active region. This could be as basic as empirically testing which region is presently accepting writes (noting any write rejections and falling back to an alternate) or as complex as calling a global coordinator to query for the current application state (perhaps built on the Route 53 Application Recovery Controller (ARC) routing control which provides a 5-region quorum-driven system to maintain global state for needs such as this). The client can decide if reads can go to any Region for eventual consistency or must be routed to the active region for strong consistency. For further information see How Route 53 works.

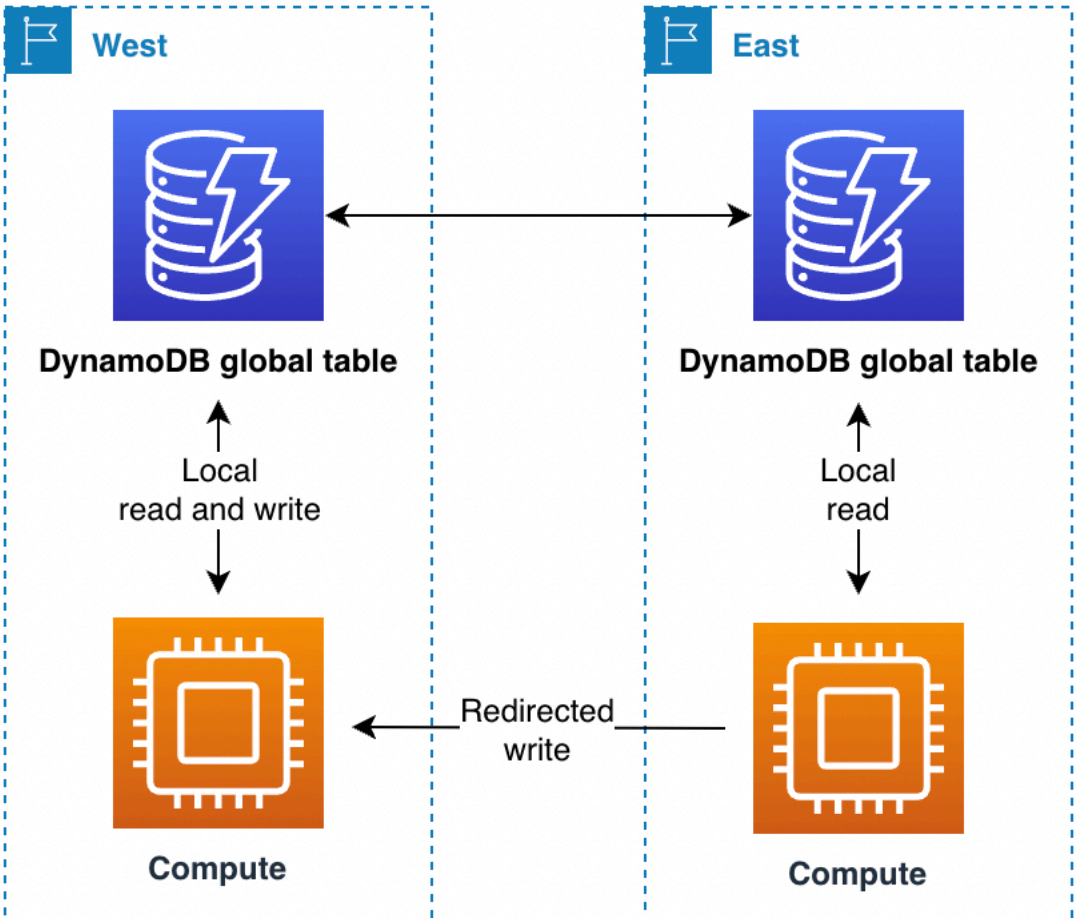
With the *write to your Region* mode, the client needs to determine the home region for the data set it's working against. For example, if the client corresponds to a user account and each user account is homed to a Region, the client can request the appropriate endpoint from a global login system.

For example, a financial services company that helps users manage their business finances via the web could use global tables with a *write to your Region* mode. Each user must login to a central service. That service returns credentials and the endpoint for the Region where those credentials will work. The credentials are valid for a short time. After that the webpage auto-negotiates a new login, which provides an opportunity to potentially redirect the user's activity to a new Region.

Compute-layer request routing

With compute-layer request routing, the code running in the compute layer decides whether it wants to process the request locally, or pass it to a copy of itself that's running in another Region. When you use the *write to one Region* mode, the compute layer may detect that it's not the active region and allow local read operations while forwarding all write operations onto another Region. This compute layer code must be aware of data topology and routing rules, and enforce them reliably based on the latest settings that specify which Regions are active for which data. The outer software stack within the Region doesn't have to be aware of how read and write requests are routed by the microservice. In a robust design, the receiving Region validates whether it is the current primary for the write operation. If it isn't, it generates an error that indicates that the

global state needs to be corrected. The receiving Region might also buffer the write operation for a while if the primary Region is in the process of changing. In all cases, the compute stack in a Region writes only to its local DynamoDB endpoint, but the compute stacks might communicate with one another.



In this scenario, let's say a financial services company uses a follow-the-sun Single Primary model. They use a system and a library for this routing process. Their overall system maintains the global state, similar to AWS's ARC routing control. They use a global table to track which Region is the primary Region, and when the next primary switch is scheduled. All read and write operations go through the library, which coordinates with their system. The library allows read operations to be performed locally, at low latency. For write operations, the application checks if the local Region is the current primary Region. If so, the write operation completes directly. If not, the library forwards the write task to the library that's in the current primary Region. That receiving library confirms that it also considers itself the primary Region and raises an error if it isn't, which indicates a propagation delay with the global state. This approach provides a validation benefit by not writing directly to a remote DynamoDB endpoint.

Route 53 request routing

Amazon Application Recovery Controller (ARC) is a Domain Name Service (DNS) technology. With Route 53, the client requests its endpoint by looking up a well-known DNS domain name, and Route 53 returns the IP address corresponding to the regional endpoint(s) it thinks most appropriate. Route 53 has a list of routing policies it uses to determine the appropriate region. Route 53 also can do failover routing to route traffic away from regions that fail health checks.

Regional endpoints

- With *write to any Region* mode, or if combined with the compute-layer request routing on the backend, Route 53 can be given full access to return the Region based on any complex internal rules such as the Region in closest network proximity, or closest geographic proximity, or any other choice.
- With *write to one Region* mode, Route 53 can be configured to return the currently active region (using Route 53 ARC).

> **Note**
>
> Clients cache the IP addresses in the response from Route 53 for a time indicated by the time to live (TTL) setting on the domain name. A longer TTL extends the recovery time objective (RTO) for all clients to recognize the new endpoint. A value of 60 seconds is typical for failover use. Not all software perfectly adheres to DNS TTL expiration.

- With *write to your Region* mode, it's best to avoid Route 53 unless you're also using compute-layer request routing.

Global Accelerator request routing

A client uses AWS Global Accelerator to looks up the well-known domain name in Route 53. However, instead of getting back an IP address that corresponds to a regional endpoint the client receives an anycast static IP address which routes to the nearest AWS edge location. Starting from that edge location, all traffic gets routed on the private AWS network and to some endpoint (such as a load balancer or API Gateway) in a Region chosen by routing rules that are maintained within Global Accelerator. Compared with routing based on Route 53 rules, Global Accelerator request routing has lower latencies because it reduces the amount of traffic on the public internet. In addition, because Global Accelerator doesn't depend on DNS TTL expiration to change routing rules it can adjust routing more quickly.

- With *write to any Region* mode, or if combined with the compute-layer request routing on the back- end, Global Accelerator works seamlessly. The client connects to the nearest edge location and need not be concerned with which Region receives the request.
- With *write to one Region* Global Accelerator routing rules must send requests to the currently active Region. You can use health checks that artificially report a failure on any Region that's not considered by your global system to be the active Region. As with DNS, it's possible to use an alternative DNS domain name for routing read requests if the requests can be from any Region.
- With *write to your Region* mode, it's best to avoid Global Accelerator unless you're also using compute-layer request routing.

Evacuating a Region with DynamoDB global tables

Evacuating a Region is the process of migrating read and write activity away from that Region. This is most often write activity, and sometimes read activity.

Evacuating a live Region

You might decide to evacuate a live Region for a number of reasons. The evacuation could be part of usual business activity such as if you're using a follow-the-sun write to one Region mode. The evacuation could also be due to a business decision to change the currently active Region, in response to failures in the software stack outside DynamoDB, or because you're encountering general issues such as higher than usual latencies within the Region.

With *write to any Region* mode, evacuating a live Region is straightforward. You can route traffic to the alternative Regions through any routing system, and let the write operations that have already occurred in the evacuated Region replicate as usual.

With *write to one Region* and *write to your Region* modes, you must make sure all writes to the active Region have been fully recorded, stream processed, and globally propagated before starting writes in the new active Region. This is necessary to ensure that future writes are against the latest version of the data.

Let's say that Region A is active and Region B is passive (either for the full table or for items that are homed in Region A). The typical mechanism to perform an evacuation is to pause write operations to A, wait long enough for those operations to have fully propagated to B, update the architecture stack to recognize B as active, and then resume write operations to B. There is

no metric to indicate with absolute certainty that Region A has fully replicated its data to Region B. If Region A is healthy, pausing write operations to Region A and waiting 10 times the recent maximum value of the `ReplicationLatency` metric would typically be sufficient to determine that replication is complete. If Region A is unhealthy and shows other areas of increased latencies, you would choose a larger multiple for the wait time.

Evacuating an offline Region

There's a special case to consider: what if Region A went fully offline without notice? This is extremely unlikely, but is still prudent to consider. If this happens, any write operations in Region A that were not yet propagated are held and propagated after Region A comes back online. The write operations aren't lost, but their propagation is indefinitely delayed.

How to proceed in this event is the application's decision. For business continuity, write operations might need to proceed to the new primary Region B. However, if an item in Region B receives an update while there is a pending propagation of a write operation for that item from Region A, the propagation is suppressed under the *last writer wins* model. Any update in Region B might suppress an incoming write request.

With the *write to any Region* mode, reads and writes can continue in Region B, trusting that the items in Region A will propagate to Region B eventually and recognizing the potential for missing items until Region A comes back online. When possible, you should consider replaying recent write traffic (for example, by using an upstream event source) to fill in the gap of any potentially missing write operations and let the *last writer wins* conflict resolution suppress the eventual propagation of the incoming write operation.

With the other write modes, you have to consider the degree to which work can continue with a slightly out-of-date view of the world. Some small duration of write operations, as tracked by `ReplicationLatency`, will be missing until Region A comes back online. Can business move forward? In some use cases it can, but in others it might not without additional mitigation mechanisms.

For example, imagine you need to maintain an available credit balance without interruption even after Region failure. You could split the balance into two different items, one homed in Region A and one in Region B, each starting with half the available balance. This would use the *write to your Region* mode. Transactional updates processed in each Region would write against the local copy of the balance. If Region A goes fully offline, work could still proceed with transaction processing in Region B, and write operations would be limited to the balance portion held in Region B. Splitting

the balance like this introduces complexities when the balance gets low or the credit has to be rebalanced, but it does provide one example of safe business recovery even with uncertain pending write operations.

As another example, imagine you're capturing web form data. You can use Optimistic Concurrency Control (OCC) to assign versions to data items and embed the latest version into the web form as a hidden field. On each submit, the write operation succeeds only if the version in the database still matches the version that the form was built against. If the versions don't match, the web form can be refreshed (or carefully merged) based on the current version in the database, and the user can proceed again. The OCC model usually protects against another client overwriting and producing a new version of the data, but it can also help during failover where a client might encounter older versions of data.

Let's imagine that you're using the timestamp as the version. Let's say that the form was first built against Region A at 12:00 but (after failover) tries to write to Region B and notices that the latest version in the database is 11:59. In this scenario, the client can either wait for the 12:00 version to propagate to Region B and then write on top of that version, or build on 11:59 and create a new 12:01 version (which, after writing, would suppress the incoming version after Region A recovers).

As a final example, a financial services company holds data about customer accounts and their financial transactions in a DynamoDB database. In the event of a complete Region A outage, they wanted to make sure that any write activity related to their accounts was either fully available in Region B, or wanted to quarantine their accounts as known partial until Region A came back online. Instead of pausing all business, they decided to pause business only to the tiny fraction of accounts that they determined had unpropagated transactions. To achieve this, they used a third Region, which we will call Region C. Before they processed any write operations in Region A, they placed a succinct summary of those pending operations (for example, a new transaction count for an account) in Region C. This summary was sufficient for Region B to determine if its view was fully up to date. This action effectively locked the account from the time of writing in Region C until Region A accepted the write operations and Region B received them. The data in Region C wasn't used except as part of a failover process, after which Region B could cross-check its data with Region C to check if any of its accounts were out of date. Those accounts would be marked as quarantined until the Region A recovery propagated the partial data to Region B.

If Region C were to fail, a new Region D could be spun up for use instead. The data in Region C was very transient, and after a few minutes Region D would have a sufficiently up-to-date record of the in-flight write operations to be fully useful. If Region B were to fail, Region A could continue accepting write requests in cooperation with Region C. This company was willing to accept higher

latency writes (to two Regions: C and then A) and was fortunate to have a data model where the state of an account could be succinctly summarized.

Throughput capacity planning for DynamoDB global tables

Migrating traffic from one Region to another requires careful consideration of DynamoDB table settings regarding capacity.

Some considerations on managing write capacity:

- A global table must be in on-demand mode or provisioned with auto scaling enabled.
- If provisioned with auto scaling, the write settings (minimum, maximum, and target utilization) are replicated across Regions. Although the auto scaling settings are synchronized, the actual provisioned write capacity might float independently between Regions.
- One reason you might see different provisioned write capacity is due to the TTL feature. When you enable TTL in DynamoDB, you can specify an attribute name whose value indicates the time of expiration for the item, in Unix epoch time format in seconds. After that time, DynamoDB can delete the item without incurring write costs. With global tables, you can configure TTL in any Region, and the setting is automatically replicated to other Regions that are associated with the global table. When an item is eligible for deletion through a TTL rule, that work can be done in any Region. The delete operation is performed without consuming write units on the source table, but the replica tables will get a replicated write of that delete operation and will incur replicated write unit costs.
- If you're using auto scaling, make sure that the maximum provisioned write capacity setting is sufficiently high to handle all write operations as well as all potential TTL delete operations. Auto scaling adjusts each Region according to its write consumption. On-demand tables have no maximum provisioned write capacity setting, but the *table-level maximum write throughput limit* specifies the maximum sustained write capacity the on-demand table will allow. The default limit to 40,000, but it is adjustable. We recommend that you set it high enough to handle all write operations (including TTL write operations) that the on-demand table might need. This value must be the same across all participating Regions when you set up global tables.

Some considerations on managing read capacity:

- Read capacity management settings are allowed to differ between Regions because it's assumed that different Regions might have independent read patterns. When you first add a global replica

to a table, the capacity of the source Region is propagated. After creation you can adjust the read capacity settings, which aren't transferred to the other side.

- When you use DynamoDB auto scaling, make sure that the maximum provisioned read capacity settings are sufficiently high to handle all read operations across all Regions. During standard operations the read capacity will perhaps be spread across Regions, but during failover the table should be able to automatically adapt to the increased read workload. On-demand tables have no maximum provisioned read capacity setting, but the *table-level maximum read throughput limit* specifies the maximum sustained read capacity the on-demand table will allow. The default limit is 40,000, but it is adjustable. We recommend that you set it high enough to handle all read operations that the table might need if all read operations were to route to this single Region.
- If a table in one Region doesn't usually receive read traffic but might have to absorb a large amount of read traffic after a failover, you can raise the provisioned read capacity of the table, wait for the table to finish updating, and then provision the table down again. You can either leave the table in provisioned mode or switch it to on-demand mode. This pre-warms the table for accepting a higher level of read traffic.

ARC has readiness checks that can be useful for confirming that DynamoDB Regions have similar table settings and account quotas, whether or not you use Route 53 to route requests. These readiness checks can also help in adjusting account-level quotas to make sure they match.

Preparation checklist for DynamoDB global tables and Frequently Asked Questions

Use the following checklist for decisions and tasks when you deploy global tables.

- Determine how many and which Regions should participate in the global table.
- Determine your application's write mode. For more information, see Write modes with DynamoDB global tables.
- Plan your Request routing with DynamoDB global tables strategy, based on your write mode.
- Define your

  Evacuating a Region is the process of migrating read and write activity away from that Region. This is most often write activity, and sometimes read activity.

Evacuating a live Region

You might decide to evacuate a live Region for a number of reasons. The evacuation could be part of usual business activity such as if you're using a follow-the-sun write to one Region mode. The evacuation could also be due to a business decision to change the currently active Region, in response to failures in the software stack outside DynamoDB, or because you're encountering general issues such as higher than usual latencies within the Region.

With *write to any Region* mode, evacuating a live Region is straightforward. You can route traffic to the alternative Regions through any routing system, and let the write operations that have already occurred in the evacuated Region replicate as usual.

With *write to one Region* and *write to your Region* modes, you must make sure all writes to the active Region have been fully recorded, stream processed, and globally propagated before starting writes in the new active Region. This is necessary to ensure that future writes are against the latest version of the data.

Let's say that Region A is active and Region B is passive (either for the full table or for items that are homed in Region A). The typical mechanism to perform an evacuation is to pause write operations to A, wait long enough for those operations to have fully propagated to B, update the architecture stack to recognize B as active, and then resume write operations to B. There is no metric to indicate with absolute certainty that Region A has fully replicated its data to Region B. If Region A is healthy, pausing write operations to Region A and waiting 10 times the recent maximum value of the `ReplicationLatency` metric would typically be sufficient to determine that replication is complete. If Region A is unhealthy and shows other areas of increased latencies, you would choose a larger multiple for the wait time.

Evacuating an offline Region

There's a special case to consider: what if Region A went fully offline without notice? This is extremely unlikely, but is still prudent to consider. If this happens, any write operations in Region A that were not yet propagated are held and propagated after Region A comes back online. The write operations aren't lost, but their propagation is indefinitely delayed.

How to proceed in this event is the application's decision. For business continuity, write operations might need to proceed to the new primary Region B. However, if an item in Region B receives an update while there is a pending propagation of a write operation for that item

from Region A, the propagation is suppressed under the *last writer wins* model. Any update in Region B might suppress an incoming write request.

With the *write to any Region* mode, reads and writes can continue in Region B, trusting that the items in Region A will propagate to Region B eventually and recognizing the potential for missing items until Region A comes back online. When possible, you should consider replaying recent write traffic (for example, by using an upstream event source) to fill in the gap of any potentially missing write operations and let the *last writer wins* conflict resolution suppress the eventual propagation of the incoming write operation.

With the other write modes, you have to consider the degree to which work can continue with a slightly out-of-date view of the world. Some small duration of write operations, as tracked by `ReplicationLatency`, will be missing until Region A comes back online. Can business move forward? In some use cases it can, but in others it might not without additional mitigation mechanisms.

For example, imagine you need to maintain an available credit balance without interruption even after Region failure. You could split the balance into two different items, one homed in Region A and one in Region B, each starting with half the available balance. This would use the *write to your Region* mode. Transactional updates processed in each Region would write against the local copy of the balance. If Region A goes fully offline, work could still proceed with transaction processing in Region B, and write operations would be limited to the balance portion held in Region B. Splitting the balance like this introduces complexities when the balance gets low or the credit has to be rebalanced, but it does provide one example of safe business recovery even with uncertain pending write operations.

As another example, imagine you're capturing web form data. You can use Optimistic Concurrency Control (OCC) to assign versions to data items and embed the latest version into the web form as a hidden field. On each submit, the write operation succeeds only if the version in the database still matches the version that the form was built against. If the versions don't match, the web form can be refreshed (or carefully merged) based on the current version in the database, and the user can proceed again. The OCC model usually protects against another client overwriting and producing a new version of the data, but it can also help during failover where a client might encounter older versions of data.

Let's imagine that you're using the timestamp as the version. Let's say that the form was first built against Region A at 12:00 but (after failover) tries to write to Region B and notices that the latest version in the database is 11:59. In this scenario, the client can either wait for

> the 12:00 version to propagate to Region B and then write on top of that version, or build on 11:59 and create a new 12:01 version (which, after writing, would suppress the incoming version after Region A recovers).
>
> As a final example, a financial services company holds data about customer accounts and their financial transactions in a DynamoDB database. In the event of a complete Region A outage, they wanted to make sure that any write activity related to their accounts was either fully available in Region B, or wanted to quarantine their accounts as known partial until Region A came back online. Instead of pausing all business, they decided to pause business only to the tiny fraction of accounts that they determined had unpropagated transactions. To achieve this, they used a third Region, which we will call Region C. Before they processed any write operations in Region A, they placed a succinct summary of those pending operations (for example, a new transaction count for an account) in Region C. This summary was sufficient for Region B to determine if its view was fully up to date. This action effectively locked the account from the time of writing in Region C until Region A accepted the write operations and Region B received them. The data in Region C wasn't used except as part of a failover process, after which Region B could cross-check its data with Region C to check if any of its accounts were out of date. Those accounts would be marked as quarantined until the Region A recovery propagated the partial data to Region B.
>
> If Region C were to fail, a new Region D could be spun up for use instead. The data in Region C was very transient, and after a few minutes Region D would have a sufficiently up-to-date record of the in-flight write operations to be fully useful. If Region B were to fail, Region A could continue accepting write requests in cooperation with Region C. This company was willing to accept higher latency writes (to two Regions: C and then A) and was fortunate to have a data model where the state of an account could be succinctly summarized.

evacuation plan, based on your write mode and routing strategy.

- Capture metrics on the health, latency, and errors across each Region. For a list of DynamoDB metrics, see the AWS blog post Monitoring Amazon DynamoDB for Operational Awareness for a list of metrics to observe. You should also use synthetic canaries (artificial requests designed to detect failures, named after the canary in the coal mine), as well as live observation of customer traffic. Not all issues will appear in the DynamoDB metrics.
- Set alarms for any sustained increase in `ReplicationLatency`. An increase might indicate an accidental misconfiguration in which the global table has different write settings in different Regions, which leads to failed replicated requests and increased latencies. It could also indicate that there is a Regional disruption. A good example is to generate an alert if the recent average

exceeds 180,000 milliseconds. You might also watch for `ReplicationLatency` dropping to 0, which indicates stalled replication.

- Assign sufficient maximum read and write settings for each global table.
- Identify the reasons for evacuating a Region in advance. If the decision involves human judgment, document all considerations. This work should be done carefully in advance, not under stress.
- Maintain a runbook for every action that must take place when you evacuate a Region. Usually very little work is involved for the global tables, but moving the rest of the stack might be complex.

> **Note**
>
> It's best practice to rely only on data plane operations and not control plane operations because some control plane operations may be degraded during region failures.

For more information, see the AWS blog post Build resilient applications with Amazon DynamoDB global tables: Part 4.

- Test all aspects of the runbook periodically, including Region evacuations. An untested runbook is an unreliable runbook.
- Consider using Resilience Hub to evaluate the resilience of your entire application (including global tables). It provides a comprehensive view of your overall application portfolio resilience status through its dashboard.
- Consider using ARC readiness checks to evaluate the current configuration of your application and track any deviances from best practices.
- When writing a health check for use with Route 53 or Global Accelerator, it's not sufficient to just ping that the DynamoDB endpoint is up. That doesn't cover the many failure modes such as IAM configuration errors, code deployment problems, failure in the stack outside DynamoDB, higher than average read or write latencies, and so on. It's best to perform a set of calls that exercise a full database flow.

Frequently Asked Questions (FAQ) for deploying global tables

What are some useful principles for overall usage of DynamoDB global tables?

DynamoDB global tables has very few control knobs yet still requires a number of considerations. You must determine your write mode, routing model, and evacuation processes. You must instrument your application across every Region and be ready to adjust your routing or perform an evacuation to maintain global health. The reward is having a globally distributed data set with low-latency reads and writes and a 99.999% service level agreement.

What is the pricing for global tables?

A write to a traditional DynamoDB table is priced in Write Capacity Units (WCUs, for provisioned tables) or Write Request Units (WRUs, for on-demand tables). If you write a 5 KB item it incurs a charge of 5 units. A write to a global table is priced in Replicated Write Capacity Units (rWCUs, for provisioned tables) or Replicated Write Request Units (rWRUs, for on-demand tables).

The rWCUs and rWRUs include the cost of the streaming infrastructure needed to manage the replication.

Replicated Write Unit charges are incurred in every Region where the item is directly written or replicate written.

Writing to a Global Secondary Index (GSI) is considered a local write and uses regular Write Units.

There is no Reserved Capacity available for rWCUs at this time. Purchasing Reserved Capacity may still be beneficial for tables with GSIs consuming write units.

The initial bootstrap when adding a new Region to a global table is charged like a restore per GB of data restored, plus cross-Region data transfer fees.

Which Regions does global tables support?

Global Tables version 2019.11.21 (Current) is available in all Regions.

How are GSIs handled with global tables?

In Global Tables version 2019.11.21 (Current), when you create a GSI in one Region it's automatically created in other participating Regions and automatically backfilled.

How do I stop replication of a global table?

You can delete a replica table the same way you would delete any other table. Deleting the global table stops replication to that Region and deletes the table copy kept in that Region. However, you cannot stop replication while keeping copies of the table as independent entities, nor can you pause replication.

How do DynamoDB Streams interact with global tables?

Each global table produces an independent stream based on all its writes, wherever they started from. You can choose to consume the DynamoDB stream in one Region or in all Regions (independently). If you want to process local but not replicated write operations, you can add your own Region attribute to each item to identify the writing Region. You can then use a Lambda event filter to call the Lambda function only for write operations in the local Region. This helps with insert and update operations, but unfortunately not delete operations.

How do global tables handle transactions?

Transactional operations provide atomicity, consistency, isolation, and durability (ACID) guarantees only within the Region where the write operation originally occurred. Transactions are not supported across Regions in global tables. For example, if you have a global table with replicas in the US East (Ohio) and US West (Oregon) Regions and perform a `TransactWriteItems` operation in the US East (Ohio) Region, you might observe partially completed transactions in the US West (Oregon) Region as changes are replicated. Changes are replicated to other Regions only after they have been committed in the source Region.

How do global tables interact with the DynamoDB Accelerator cache (DAX)?

Global tables bypass DAX by updating DynamoDB directly, so DAX isn't aware that it's holding stale data. The DAX cache is refreshed only when the cache's TTL expires.

Do tags on tables propagate?

No, tags do not automatically propagate.

Should I backup tables in all Regions or just one?

The answer depends on the purpose of the backup. If you want to ensure data durability, DynamoDB already provides that safeguard. The service ensures durability. If you want to keep a snapshot for historical records (for example, to meet regulatory requirements), backing up in one Region should suffice. You can copy the backup to additional Regions by using AWS Backup. If you want to recover erroneously deleted or modified data, use DynamoDB point-in-time recovery (PITR) in one Region.

How do I deploy global tables using AWS CloudFormation?

CloudFormation represents a DynamoDB table and a global table as two separate resources: `AWS::DynamoDB::Table` and `AWS::DynamoDB::GlobalTable`. One approach is to create all

tables that can potentially be global by using the `GlobalTable` construct. You can then keep them as standalone tables initially, and add Regions later if needed.

In CloudFormation, each global table is controlled by a single stack, in a single Region, regardless of the number of replicas. When you deploy your template, CloudFormation creates and updates all replicas as part of a single stack operation. You should not deploy the same AWS::DynamoDB::GlobalTable resource in multiple Regions. This will result in errors and is unsupported. If you deploy your application template in multiple Regions, you can use conditions to create the `AWS::DynamoDB::GlobalTable` resource in a single Region. Alternatively, you can choose to define your `AWS::DynamoDB::GlobalTable` resources in a stack that's separate from your application stack, and make sure that it's deployed to a single Region.

If you have a regular table and you want to convert it to a global table while keeping it managed by CloudFormation then set the deletion policy to Retain, remove the table from the stack, convert the table to a global table in the console, and then import the global table as a new resource to the stack.

Cross-account replication is not supported at this time.

Best practices for managing the control plane in DynamoDB

> **Note**
>
> DynamoDB is introducing a control plane throttle limit of 2,500 requests per second with the option for a retry. See below for additional details.

DynamoDB control plane operations let you manage DynamoDB tables as well as objects that are dependent on tables such as indexes. For more information about these operations, see Control plane.

In some circumstances, you may need to take actions and use data returned by control plane calls as part of your business logic. For example, you might need to know the value of `ProvisionedThroughput` returned by `DescribeTable`. In these circumstances, follow these best practices:

- Do not excessively query the DynamoDB control plane.
- Do not mix control plane calls and data plane calls within the same code.
- Handle throttles on control plane requests and retry with a backoff.

- Invoke and track changes to a particular resource from a single client.
- Instead of retrieving data for the same table multiple times at short intervals, cache the data for processing.

Best practices for using bulk data operations in DynamoDB

DynamoDB supports batch operations such as `BatchWriteItem` using which you can perform up to 25 `PutItem` and `DeleteItem` requests together. However, `BatchWriteItem` doesn't support `UpdateItem` operations. When it comes to bulk updates, the distinction lies in the requirements and the nature of the update. You can use other DynamoDB APIs such as `TransactWriteItems` for batch size up to 100. When more items are involved, you can use services such as AWS Glue, Amazon EMR, AWS Step Functions or use custom scripts and tools like DynamoDB-shell for bulk updates.

Topics

- Conditional batch update
- Efficient bulk operations

Conditional batch update

DynamoDB supports batch operations such as `BatchWriteItem` using which you can perform up to 25 `PutItem` and `DeleteItem` requests in a single batch. However, `BatchWriteItem` doesn't support `UpdateItem` operations and doesn't support condition expressions. As a workaround, you can use other DynamoDB APIs such as `TransactWriteItems` for batch size up to 100.

When more items are involved, and a major chunk of data needs to be changed, you can use services such as AWS Glue, Amazon EMR, AWS Step Functions or use custom scripts and tools like DynamoDB-shell for efficient bulk updates.

When to use this pattern

- DynamoDB-shell is not a supported for production use case.
- `TransactWriteItems` – up to 100 individual updates with or without conditions, executing as an all or nothing ACID bundle. `TransactWriteItems` calls can also be supplied with a `ClientRequestToken` if your application requires idempotency, meaning multiple identical calls have the same effect as one single call. This ensures you don't execute the same transaction multiple times and end up with an incorrect state of data.

Trade-off – Additional throughput is consumed. 2 WCUs per 1KB write instead of the standard 1 WGU per 1 KB write.

- PartiQL `BatchExecuteStatement` – up to 25 updates with or without conditions. `BatchExecuteStatement` always returns a success response to the overall request, and also returns a list of individual operation responses that preserves order.

  Trade-off – For larger batches, additional client-side logic is required to distribute requests in batches of 25. Individual error responses need to be considered to determine retry strategy.

Code examples

These code examples use the boto3 library, which is the AWS SDK for Python. The examples assume you have boto3 installed and configured with appropriate AWS credentials.

Assume an inventory database for an electrical appliance vendor who has multiple warehouses across European cities. Because it is end of summer, the vendor would like to clear out desk fans to make room for other stock. The vendor wants to provide a price discount for all desk fans supplied out of warehouses in Italy but only if they have a reserve stock of 20 desk fans. The DynamoDB table is called **inventory**, it has a key schema of Partition key **sku** which is a unique identifier for each product and a Sort key **warehouse** which is an identifier for a warehouse.

The following Python code demonstrates how to perform this conditional batch update using `BatchExecuteStatement` API call.

```
import boto3

client=boto3.client("dynamodb")

before_image=client.query(TableName='inventory', KeyConditionExpression='sku=:pk_val
 AND begins_with(warehouse, :sk_val)', ExpressionAttributeValues={':pk_val':
{'S':'F123'},':sk_val':{'S':'WIT'}},
 ProjectionExpression='sku,warehouse,quantity,price')
print("Before update: ", before_image['Items'])

response=client.batch_execute_statement(
        Statements=[
            {'Statement': 'UPDATE inventory SET price=price-5 WHERE sku=? AND
 warehouse=? AND quantity > 20', 'Parameters': [{'S':'F123'}, {'S':'WITTUR1'}],
 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'},
```

```
            {'Statement': 'UPDATE inventory SET price=price-5 WHERE sku=? AND
 warehouse=? AND quantity > 20', 'Parameters': [{'S':'F123'}, {'S':'WITROM1'}],
 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'},
            {'Statement': 'UPDATE inventory SET price=price-5 WHERE sku=? AND
 warehouse=? AND quantity > 20', 'Parameters': [{'S':'F123'}, {'S':'WITROM2'}],
 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'},
            {'Statement': 'UPDATE inventory SET price=price-5 WHERE sku=? AND
 warehouse=? AND quantity > 20', 'Parameters': [{'S':'F123'}, {'S':'WITROM5'}],
 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'},
            {'Statement': 'UPDATE inventory SET price=price-5 WHERE sku=? AND
 warehouse=? AND quantity > 20', 'Parameters': [{'S':'F123'}, {'S':'WITVEN1'}],
 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'},
            {'Statement': 'UPDATE inventory SET price=price-5 WHERE sku=? AND
 warehouse=? AND quantity > 20', 'Parameters': [{'S':'F123'}, {'S':'WITVEN2'}],
 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'},
            {'Statement': 'UPDATE inventory SET price=price-5 WHERE sku=? AND
 warehouse=? AND quantity > 20', 'Parameters': [{'S':'F123'}, {'S':'WITVEN3'}],
 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'},
        ],
        ReturnConsumedCapacity='TOTAL'
    )

after_image=client.query(TableName='inventory', KeyConditionExpression='sku=:pk_val
 AND begins_with(warehouse, :sk_val)', ExpressionAttributeValues={':pk_val':
{'S':'F123'},':sk_val':{'S':'WIT'}},
 ProjectionExpression='sku,warehouse,quantity,price')
print("After update: ", after_image['Items'])
```

Execution produces the below output on sample data:

```
Before update:  [{'quantity': {'N': '20'}, 'warehouse': {'S': 'WITROM1'}, 'price':
 {'N': '40'}, 'sku': {'S': 'F123'}}, {'quantity': {'N': '25'}, 'warehouse': {'S':
 'WITROM2'}, 'price': {'N': '40'}, 'sku': {'S': 'F123'}}, {'quantity': {'N':
 '28'}, 'warehouse': {'S': 'WITROM5'}, 'price': {'N': '38'}, 'sku': {'S': 'F123'}},
 {'quantity': {'N': '26'}, 'warehouse': {'S': 'WITTUR1'}, 'price': {'N': '40'}, 'sku':
 {'S': 'F123'}}, {'quantity': {'N': '10'}, 'warehouse': {'S': 'WITVEN1'}, 'price':
 {'N': '38'}, 'sku': {'S': 'F123'}}, {'quantity': {'N': '20'}, 'warehouse': {'S':
 'WITVEN2'}, 'price': {'N': '38'}, 'sku': {'S': 'F123'}}, {'quantity': {'N': '50'},
 'warehouse': {'S': 'WITVEN3'}, 'price': {'N': '35'}, 'sku': {'S': 'F123'}}]
After update:  [{'quantity': {'N': '20'}, 'warehouse': {'S': 'WITROM1'}, 'price': {'N':
 '40'}, 'sku': {'S': 'F123'}}, {'quantity': {'N': '25'}, 'warehouse': {'S': 'WITROM2'},
 'price': {'N': '35'}, 'sku': {'S': 'F123'}}, {'quantity': {'N': '28'}, 'warehouse':
```

```
 {'S': 'WITROM5'}, 'price': {'N': '33'}, 'sku': {'S': 'F123'}}, {'quantity': {'N':
 '26'}, 'warehouse': {'S': 'WITTUR1'}, 'price': {'N': '35'}, 'sku': {'S': 'F123'}},
 {'quantity': {'N': '10'}, 'warehouse': {'S': 'WITVEN1'}, 'price': {'N': '38'}, 'sku':
 {'S': 'F123'}}, {'quantity': {'N': '20'}, 'warehouse': {'S': 'WITVEN2'}, 'price':
 {'N': '38'}, 'sku': {'S': 'F123'}}, {'quantity': {'N': '50'}, 'warehouse': {'S':
 'WITVEN3'}, 'price': {'N': '30'}, 'sku': {'S': 'F123'}}]
```

Since this is a bounded operation for an internal system, idempotency requirements haven't been considered. It's possible to place additional guardrails like price update should go through only if price is greater than 35 and less than 40 to make the updates more robust.

Alternatively, we can perform the same batch update operation using `TransactWriteItems` in case of stricter idempotency and ACID requirements. However, it is important to remember that either all the operations in the transaction bundle go through or the entire bundle fails.

Let's assume a case where there is a heatwave in Italy and the demand for desk fans has increased sharply. The vendor wants to increase their desk fan cost going out of every warehouse in Italy by 20 Euros but the regulatory body only allows this cost increase if the current cost is less than 70 Euros across their entire inventory. It's essential that the price is updated throughout the inventory at once and only once and only if the cost is less than 70 Euros in each of their warehouse.

The following Python code demonstrates how to perform this batch update using `TransactWriteItems` API call.

```
import boto3

client=boto3.client("dynamodb")

before_image=client.query(TableName='inventory', KeyConditionExpression='sku=:pk_val
 AND begins_with(warehouse, :sk_val)', ExpressionAttributeValues={':pk_val':
{'S':'F123'},':sk_val':{'S':'WIT'}},
 ProjectionExpression='sku,warehouse,quantity,price')
print("Before update: ", before_image['Items'])

response=client.transact_write_items(
        ClientRequestToken='UUIDAWS124',
        TransactItems=[
            {'Update': { 'Key': {'sku': {'S':'F123'}, 'warehouse': {'S':'WITTUR1'}},
 'UpdateExpression': 'SET price = price + :inc', 'ConditionExpression': 'price < :cap',
```

```
 'ExpressionAttributeValues': { ':inc': {'N': '20'}, ':cap': {'N': '70'}}, 'TableName':
 'inventory', 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'}},
           {'Update': { 'Key': {'sku': {'S':'F123'}, 'warehouse': {'S':'WITROM1'}},
 'UpdateExpression': 'SET price = price + :inc', 'ConditionExpression': 'price < :cap',
 'ExpressionAttributeValues': { ':inc': {'N': '20'}, ':cap': {'N': '70'}}, 'TableName':
 'inventory', 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'}},
           {'Update': { 'Key': {'sku': {'S':'F123'}, 'warehouse': {'S':'WITROM2'}},
 'UpdateExpression': 'SET price = price + :inc', 'ConditionExpression': 'price < :cap',
 'ExpressionAttributeValues': { ':inc': {'N': '20'}, ':cap': {'N': '70'}}, 'TableName':
 'inventory', 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'}},
           {'Update': { 'Key': {'sku': {'S':'F123'}, 'warehouse': {'S':'WITROM5'}},
 'UpdateExpression': 'SET price = price + :inc', 'ConditionExpression': 'price < :cap',
 'ExpressionAttributeValues': { ':inc': {'N': '20'}, ':cap': {'N': '70'}}, 'TableName':
 'inventory', 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'}},
           {'Update': { 'Key': {'sku': {'S':'F123'}, 'warehouse': {'S':'WITVEN1'}},
 'UpdateExpression': 'SET price = price + :inc', 'ConditionExpression': 'price < :cap',
 'ExpressionAttributeValues': { ':inc': {'N': '20'}, ':cap': {'N': '70'}}, 'TableName':
 'inventory', 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'}},
           {'Update': { 'Key': {'sku': {'S':'F123'}, 'warehouse': {'S':'WITVEN2'}},
 'UpdateExpression': 'SET price = price + :inc', 'ConditionExpression': 'price < :cap',
 'ExpressionAttributeValues': { ':inc': {'N': '20'}, ':cap': {'N': '70'}}, 'TableName':
 'inventory', 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'}},
           {'Update': { 'Key': {'sku': {'S':'F123'}, 'warehouse': {'S':'WITVEN3'}},
 'UpdateExpression': 'SET price = price + :inc', 'ConditionExpression': 'price < :cap',
 'ExpressionAttributeValues': { ':inc': {'N': '20'}, ':cap': {'N': '70'}}, 'TableName':
 'inventory', 'ReturnValuesOnConditionCheckFailure': 'ALL_OLD'}},
          ],
          ReturnConsumedCapacity='TOTAL'
      )

after_image=client.query(TableName='inventory', KeyConditionExpression='sku=:pk_val
 AND begins_with(warehouse, :sk_val)', ExpressionAttributeValues={':pk_val':
{'S':'F123'},':sk_val':{'S':'WIT'}},
 ProjectionExpression='sku,warehouse,quantity,price')
print("After update: ", after_image['Items'])
```

Execution produces the below output on sample data:

```
Before update:  [{'quantity': {'N': '20'}, 'warehouse': {'S': 'WITROM1'}, 'price':
 {'N': '60'}, 'sku': {'S': 'F123'}}, {'quantity': {'N': '25'}, 'warehouse': {'S':
 'WITROM2'}, 'price': {'N': '55'}, 'sku': {'S': 'F123'}}, {'quantity': {'N':
 '28'}, 'warehouse': {'S': 'WITROM5'}, 'price': {'N': '53'}, 'sku': {'S': 'F123'}},
```

```
 {'quantity': {'N': '26'}, 'warehouse': {'S': 'WITTUR1'}, 'price': {'N': '55'}, 'sku':
 {'S': 'F123'}}, {'quantity': {'N': '10'}, 'warehouse': {'S': 'WITVEN1'}, 'price':
 {'N': '58'}, 'sku': {'S': 'F123'}}, {'quantity': {'N': '20'}, 'warehouse': {'S':
 'WITVEN2'}, 'price': {'N': '58'}, 'sku': {'S': 'F123'}}, {'quantity': {'N': '50'},
 'warehouse': {'S': 'WITVEN3'}, 'price': {'N': '50'}, 'sku': {'S': 'F123'}}]
After update:  [{'quantity': {'N': '20'}, 'warehouse': {'S': 'WITROM1'}, 'price': {'N':
 '80'}, 'sku': {'S': 'F123'}}, {'quantity': {'N': '25'}, 'warehouse': {'S': 'WITROM2'},
 'price': {'N': '75'}, 'sku': {'S': 'F123'}}, {'quantity': {'N': '28'}, 'warehouse':
 {'S': 'WITROM5'}, 'price': {'N': '73'}, 'sku': {'S': 'F123'}}, {'quantity': {'N':
 '26'}, 'warehouse': {'S': 'WITTUR1'}, 'price': {'N': '75'}, 'sku': {'S': 'F123'}},
 {'quantity': {'N': '10'}, 'warehouse': {'S': 'WITVEN1'}, 'price': {'N': '78'}, 'sku':
 {'S': 'F123'}}, {'quantity': {'N': '20'}, 'warehouse': {'S': 'WITVEN2'}, 'price':
 {'N': '78'}, 'sku': {'S': 'F123'}}, {'quantity': {'N': '50'}, 'warehouse': {'S':
 'WITVEN3'}, 'price': {'N': '70'}, 'sku': {'S': 'F123'}}]
```

There are multiple approaches to perform batch updates in DynamoDB. The suitable approach depends on factors such as ACID and/or idempotency requirements, number of items to be updated, and familiarity with APIs.

Efficient bulk operations

When to use this pattern

These patterns are useful to efficiently perform bulk updates on DynamoDB items.

- DynamoDB-shell is not a supported for production use case.
- `TransactWriteItems` – up to 100 individual updates with or without conditions, executing as an all or nothing ACID bundle

  Trade-off – Additional throughput is consumed, 2 WCUs per 1 KB write.
- PartiQL `BatchExecuteStatement` – up to 25 updates with or without conditions

  Trade-off – Additional logic is required to distribute requests in batches of 25.
- AWS Step Functions – rate-limited bulk operations for developers familiar with AWS Lambda.

  Trade-off – Execution time is inversely proportional to rate-limit. Limited by the maximum Lambda function timeout. The functionality entails that data changes that occur between the read and the write may be overwritten. For more info, see Backfilling an Amazon DynamoDB Time to Live attribute using Amazon EMR: Part 2.

- AWS Glue and Amazon EMR – rate-limited bulk operation with managed parallelism. For applications or updates that are not time-sensitive, these options can run in the background only consuming a small percentage of throughput. Both services uses the emr-dynamodb-connector to perform DynamoDB operations. These services perform a big read followed by a big write of updated items with an option to rate-limit.

  Trade-off – Execution time is inversely proportional to rate-limit. The functionality includes that data changes occurring between the read and the write can be overwritten. You can't read from Global Secondary Indexes (GSIs). See, Backfilling an Amazon DynamoDB Time to Live attribute using Amazon EMR: Part 2.

- DynamoDB Shell – rate-limited bulk operations using SQL-like queries. You can read from GSIs for better efficiency.

  Trade-off – Execution time is inversely proportional to rate-limit. See Rate limited bulk operations in DynamoDB Shell.

Using the pattern

Bulk updates can have significant cost implications especially if you use the on-demand throughput mode. There's a trade-off between speed and cost if you use the provisioned throughput mode. Setting the rate-limit parameter very strictly can lead to a very large processing time. You can roughly determine speed of the update using the average item size and the rate limit.

Alternatively, you can determine amount of throughput needed for the process based on the expected duration of the update process and the average item size. The blog references shared with each pattern provide details on the strategy, implementation and limitations of using the pattern. For more information, see Cost-effective bulk processing with Amazon DynamoDB.

There are multiple approaches to perform bulk-updates against a live DynamoDB table. The suitable approach depends on factors such as ACID and/or idempotency requirements, number of items to be updated and familiarity with APIs. It is important to consider the cost versus time trade-off, most approaches discussed above provide an option to rate-limit the throughput used by the bulk update job.

Best practices for implementing version control in DynamoDB

In distributed systems like DynamoDB, item version control using optimistic locking prevents conflicting updates. By tracking item versions and using conditional writes, applications can manage concurrent modifications, ensuring data integrity across high-concurrency environments.

Optimistic locking is a strategy used to ensure that data modifications are applied correctly without conflicts. Instead of locking data when it's read (as in pessimistic locking), optimistic locking checks if data has changed before writing it back. In DynamoDB, this is achieved through a form of version control, where each item includes an identifier that increments with every update. When updating an item, the operation will only succeed if that identifier matches the one expected by your application.

When to use this pattern

This pattern is useful in the following scenarios:

- Multiple users or processes may attempt to update the same item concurrently.
- Ensuring data integrity and consistency is paramount.
- There is a need to avoid the overhead and complexity of managing distributed locks.

Examples include:

- E-commerce applications where inventory levels are frequently updated.
- Collaborative platforms where multiple users edit the same data.
- Financial systems where transaction records must remain consistent.

Tradeoffs

While optimistic locking and conditional checks provide robust data integrity, they come with the following tradeoffs:

Concurrency conflicts

In high-concurrency environments, the likelihood of conflicts increases, potentially causing higher retries and write costs.

Implementation complexity

Adding version control to items and handling conditional checks can add complexity to the application logic.

Additional storage overhead

Storing version numbers for each item slightly increases the storage requirements.

Pattern design

To implement this pattern, the DynamoDB schema should include a version attribute for each item. Here is a simple schema design:

- Partition key – A unique identifier for each item (ex. `ItemId`).
- Attributes:
  - `ItemId` – The unique identifier for the item.
  - `Version` – An integer that represents the version number of the item.
  - `QuantityLeft` – The remaining inventory of the item.

When an item is first created, the `Version` attribute is set to 1. With each update, the version number increments by 1.

VersionControl

Primary key Partition key: ItemID	Attributes	
Bananas	Version	QuantityLeft
	1	10
Apples	Version	QuantityLeft
	1	5
Oranges	Version	QuantityLeft
	1	7

Using the pattern

To implement this pattern, follow these steps in your application flow:

1. Read the current version of the item.

   Retrieve the current item from DynamoDB and read its version number.

```
def get_document(item_id):
    response = table.get_item(Key={'ItemID': item_id})
    return response['Item']

document = get_document('Bananas')
current_version = document['Version']
```

2. Increment the version number in your application logic. This will be the expected version for the update.

```
new_version = current_version + 1
```

3. Attempt to update the item using a conditional expression to ensure the version number matches.

```
def update_document(item_id, qty_bought, current_version):
    try:
        response = table.update_item(
            Key={'ItemID': item_id},
            UpdateExpression="set #qty = :qty, Version = :v",
            ConditionExpression="Version = :expected_v",
            ExpressionAttributeNames={
                '#qty': 'QuantityLeft'
            },
            ExpressionAttributeValues={
                ':qty': qty_bought,
                ':v': current_version + 1,
                ':expected_v': current_version
            },
            ReturnValues="UPDATED_NEW"
        )
        return response
    except ClientError as e:
        if e.response['Error']['Code'] == 'ConditionalCheckFailedException':
            print("Update failed due to version conflict.")
        else:
            print("Unexpected error: %s" % e)
        return None
```

```
update_document('Bananas', 2, new_version)
```

If the update is successful, the QuantityLeft for the item will be reduced by 2.

VersionControl

Primary key Partition key: ItemID	Attributes	
Bananas	Version	QuantityLeft
	2	8
Apples	Version	QuantityLeft
	1	5
Oranges	Version	QuantityLeft
	1	7

4. Handle conflicts if they occur.

   If a conflict occurs (e.g., another process has updated the item since you last read it), handle the conflict appropriately, such as by retrying the operation or alerting the user.

   This will require an additional read of the item for each retry, so limit the total number of retries you allow before completely failing the request loop.

```
def update_document_with_retry(item_id, new_data, retries=3):
    for attempt in range(retries):
        document = get_document(item_id)
        current_version = document['Version']

        result = update_document(item_id, qty_bought, current_version)

        if result is not None:
            print("Update succeeded.")
            return result
        else:
            print(f"Retrying update... ({attempt + 1}/{retries})")

    print("Update failed after maximum retries.")
    return None

update_document_with_retry('Bananas', 2)
```

Implementing item version control using DynamoDB with optimistic locking and conditional checks is a powerful pattern for ensuring data integrity in distributed applications. While it introduces some complexity and potential performance tradeoffs, it is invaluable in scenarios requiring robust concurrency control. By carefully designing the schema and implementing the necessary checks in your application logic, you can effectively manage concurrent updates and maintain data consistency.

Additional guidance and strategies for ways to implement version control of your DynamoDB data can be found on the AWS Database Blog.

Best practices for understanding your AWS billing and usage reports in DynamoDB

This document explains the `UsageType` billing codes for charges related to DynamoDB.

AWS provides cost and usage reports (CUR) that contain data for the services used. You can use AWS Cost and Usage Report to publish billing reports to Amazon S3 in a CSV format. When setting up the CUR you can choose to break time periods down by hour, day, or month, and you can choose if you want to break out usage by resource ID or not. For more details on generating CUR, please see Creating Cost and Usage Reports

Within the CSV export, you will find relevant attributes listed for each line. The following are examples of attributes that may be included:

- **lineitem/UsageStartDate:** The start date and time for the line item in UTC, inclusive.
- **lineitem/UsageEndDate:** The end date and time for the corresponding line item in UTC, exclusive.
- **lineitem/ProductCode:** For DynamoDB this will be “AmazonDynamoDB”
- **lineitem/UsageType:** A specific description code for the type of usage, as enumerated in this document
- **lineitem/Operation:** A name that provides context to the charge such as the operation name that incurred the charge (optional).
- **lineitem/ResourceId:** The identifier for the resource that incurred the usage. Available if the CUR includes a breakdown by resource ID.
- **lineitem/UsageAmount:** The amount of usage incurred during the specified time period.

- **lineitem/UnblendedCost:** The cost of this usage.
- **lineitem/LineItemDescription:** Textual description of the line item.

For more information about the CUR data dictionary, see Cost and Usage Report (CUR) 2.0. Note that the exact names vary depending on context.

A `UsageType` is a string with a value such as `ReadCapacityUnit-Hrs`, `USW2-ReadRequestUnits`, `EU-WriteCapacityUnit-Hrs`, or `USE1-TimedPITRStorage-ByteHrs`. Each usage type begins with an optional Region prefix. If absent, that indicates the us-east-1 Region. If present, the below table maps the short billing Region code to the conventional Region code and name.

For example, the usage named `USW2-ReadRequestUnits` indicates read request units consumed in us-west-2.

Billing Region Code	Region Code	Region Name
AFS1	af-south-1	Africa (Cape Town)
APE1	ap-east-1	Asia Pacific (Hong Kong)
APN1	ap-northeast-1	Asia Pacific (Tokyo)
APN2	ap-northeast-2	Asia Pacific (Seoul)
APN3	ap-northeast-3	Asia Pacific (Osaka)
APS1	ap-southeast-1	Asia Pacific (Singapore)
APS2	ap-southeast-2	Asia Pacific (Sydney)
APS3	ap-south-1	Asia Pacific (Mumbai)
APS4	ap-southeast-3	Asia Pacific (Jakarta)
APS5	ap-south-2	Asia Pacific (Hyderabad)
APS6	ap-southeast-4	Asia Pacific (Melbourne)
CAN1	ca-central-1	Canada (Central)

Billing Region Code	Region Code	Region Name
EU	eu-west-1	Europe (Ireland)
EUC1	eu-central-1	Europe (Frankfurt)
EUC2	eu-central-2	Europe (Zurich)
EUN1	eu-north-1	Europe (Stockholm)
EUS1	eu-south-1	Europe (Milan)
EUS2	eu-south-2	Europe (Spain)
EUW1	eu-west-1	Europe (Ireland)
EUW2	eu-west-2	Europe (London)
EUW3	eu-west-3	Europe (Paris)
ILC1	Il-central-1	Israel (Tel Aviv)
MEC1	me-central-1	Middle East (UAE)
MES1	me-south-1	Middle East (Bahrain)
SAE1	sa-east-1	South America (São Paulo)
USE1 (default)	us-east-1	US East (N. Virginia)
USE2	us-east-2	US East (Ohio)
UGE1	us-gov-east-1	US Government East
UGW1	us-gov-west-1	US Government West
USW1	us-west-1	US West (N. California)
USW2	us-west-2	US West (Oregon)

In the following sections, we use `REG-UsageType` pattern when going through the charges for DynamoDB, where REG specifies the region where usage occurred and usageType is the code for the type of charge. For example if you see a line item for `USW1- ReadCapacityUnit-Hrs` in your CSV file, that means the usage was incurred in US-West-1 for provisioned read capacity. In that case the listing would say `REG-ReadCapacityUnit-Hrs`.

Throughput Capacity

Provisioned Capacity Reads and Writes

When you create a DynamoDB table in provisioned capacity mode, you specify the read and write capacity that you expect your application to require. The usage type depends on your table class (Standard or Standard-Infrequent Access). You provision read and writes based on consumption rate per second, but the charges are priced per hour based on provisioned capacity.

UsageType	Units	Granularity	Description
REG-ReadCapacityUnit-Hrs	RCU-hours	Hour	Charges for reads in provisioned capacity mode using the Standard table class.
REG-IA-ReadCapacityUnit-Hrs	RCU-hours	Hour	Charges for reads in provisioned capacity mode using the Standard-IA table class.

UsageType	Units	Granularity	Description
REG-WriteCapacityUnit-Hrs	WCU-hours	Hour	Charges for writes in provisioned capacity mode using the Standard table class.
REG-IA-WriteCapacityUnit-Hrs	WCU-hours	Hour	Charges for writes in provisioned capacity mode using the Standard-IA table class.

Reserved Capacity Reads and Writes

With reserved capacity, you pay a one-time upfront fee and commit to a minimum provisioned usage level over a period of time. Reserved capacity is billed at a discounted hourly rate. Any capacity that you provision in excess of your reserved capacity is billed at standard provisioned capacity rates. Reserved capacity is available for single-region, provisioned read and write capacity units (RCU and WCU) on DynamoDB tables that use the standard table class. Both 1-year and 3-year reserved capacity are billed using the same SKUs.

UsageType	Units	Granularity	Description
REG-HeavyUsage:dynamodb.read	RCU-hours	Up-front then monthly	Charges for reserved capacity reads: a one-time up-front charge and a monthly charge at the start of each month covering all the discounted committed RCU-hours during the month. Will have matching zero-cost

UsageType	Units	Granularity	Description
			REG-ReadCapacityUnit-Hrs line items.
REG-HeavyUsage:dynamodb.write	WCU-hours	Up-front then monthly	Charges for reserved capacity writes: a one-time up-front charge and a monthly charge at the start of each month covering all the discounted committed WCU-hours during the month. Will have matching zero-cost REG-WriteCapacityUnit-Hrs line items.

On-Demand Capacity Reads and Writes

When you create a DynamoDB table in on-demand capacity mode, you pay only for the reads and writes your application performs. The prices for read and write requests depend on your table class.

UsageType	Units	Granularity	Description
REG-ReadRequestUnits	RRUs	Unit	Charges for reads in on-demand capacity mode with Standard table class.
REG-IA-ReadRequestUnits	RRUs	Unit	Charges for reads in on-demand capacity mode with Standard-IA table class.
REG-WriteRequestUnits	WRUs	Unit	Charges for writes in on-demand capacity

UsageType	Units	Granularity	Description
			mode with Standard table class.
REG-IA-WriteRequestUnits	WRUs	Unit	Charges for writes in on-demand capacity mode with Standard-IA table class.

Global Tables Reads and Writes

DynamoDB charges for global tables usage based on the resources used on each replica table. For provisioned global tables, write requests for global tables are measured in replicated WCUs (rWCU) instead of standard WCUs and writes to global secondary indexes in global tables are measured in WCUs. For on-demand global tables, write requests are measured in replicated WRUs (rWRU) instead of standard WRUs. The number of rWCUs or rWRUs consumed for replication depends on the version of global tables you are using. The pricing depends on your table class.

Writes to global secondary indexes (GSIs) are billed using standard write units (WCUs and WRUs). Read requests and data storage are billed identically to single-region tables.

If you add a table replica to create or extend a global table in new Regions, DynamoDB charges for a table restore in the added Regions per gigabyte of data restored. Restored Data is charged as REG-RestoreDataSize-Bytes. Please refer to Backup and restore for DynamoDB for details. Cross-Region replication and adding replicas to tables that contain data also incur charges for data transfer out.

When you select on-demand capacity mode for your DynamoDB global tables, you pay only for the resources your application uses on each replica table.

UsageType	Units	Granularity	Description
REG-ReplWriteCapacityUnit-Hrs	rWCU-hours	Hour	Global table, provisioned, Standard table class.
REG-IA-ReplWriteCapacityUnit-Hrs	rWCU-hours	Hour	Global table, provisioned,

UsageType	Units	Granularity	Description
			Standard-IA table class.
REG-ReplWriteRequestUnits	rWRU	Unit	Global table, on-demand, Standard table class.
REG-IA-ReplWriteRequestUnits	rWRU	Unit	Global table, on-demand, Standard- IA table class

Streams

DynamoDB has two streaming technologies, DynamoDB Streams and Kinesis. Each have separate pricing.

DynamoDB Streams charges for reading data in read request units. Each `GetRecords` API call is billed as a streams read request. You are not charged for `GetRecords` API calls invoked by AWS Lambda as part of DynamoDB triggers or by DynamoDB global tables as part of replication.

UsageType	Units	Granularity	Description
REG-Streams-RequestsCount	Count	Unit	Read request units for DynamoDB Streams.

Amazon Kinesis Data Streams charges in change data capture units. DynamoDB charges one change data capture unit for each write (up to 1 KB). For items larger than 1 KB, additional change data capture units are required. You pay only for the writes your application performs without having to manage throughput capacity on the table.

UsageType	Units	Granularity	Description
REG-ChangeDataCaptureUnits-Kinesis	CDC Units	Unit	Change data capture units for Kinesis Data Streams.

Storage

DynamoDB measures the size of your billable data by adding the raw byte size of your data plus a per-item storage overhead that depends on the features you have enabled.

> **Note**
>
> Storage usage values in the CUR will be higher compared with the storage values when using `DescribeTable`, because `DescribeTable` does not include the per-item storage overhead.

Storage is calculated hourly but priced monthly as calculated from an average of the hourly charges.

Although the storage `UsageType` uses `ByteHrs` as a suffix, storage usage in the CUR is measured in GB and priced by GB-month.

UsageType	Units	Granularity	Description
REG-TimedStorage-ByteHrs	GB	Month	Amount of storage used by your DynamoDB tables and indexes, for tables with the Standard table class.
REG-IA-TimedStorage- ByteHrs	GB	Month	Amount of storage used by your DynamoDB tables

UsageType	Units	Granularity	Description
			and indexes, for tables with the Standard-IA table class.

Backup and Restore

DynamoDB offers two types of backups: Point In Time Recovery (PITR) backups and on- demand backups. Users can also restore from those backups into DynamoDB tables. The charges below refers to both backups and restores.

Backup storage charges are incurred on the first of the month with adjustments made throughout the month as backups are added or removed. See the Understanding Amazon DynamoDB On-demand Backups and Billing blog for more information

UsageType	Units	Granularity	Description
REG-TimedBackupStorage-ByteHrs	GB	Month	The storage consumed by on-demand backups of your DynamoDB tables and Local Secondary Indexes.
TimedPITRStorage-ByteHrs	GB	Month	The storage used by point-in-time recovery (PITR) backups. DynamoDB monitors the size of your PITR-enabled tables continuously throughout the month to determine your backup charges and bills for storage

UsageType	Units	Granularity	Description
			as long as PITR is enabled.
REG-RestoreDataSize-Bytes	GB	Size	The total size of data restored (including table data, local secondary indexes and global secondary indexes) measured in GB from DynamoDB backups.

AWS Backup

AWS Backup is a fully managed backup service that makes it easy to centralize and automate the backup of data across AWS services in the cloud as well as on premises. AWS Backup is charged for storage (warm or cold storage), restoration activities, and cross-Region data transfer. The following UsageType charges appear under the "AWSBackup" ProductCode rather than "AmazonDynamoDB".

UsageType	Units	Granularity	Description
REG-WarmStorage-ByteHrs-DynamoDB	GB	Month	The storage used by DynamoDB backups managed by AWS Backup throughout the month, measured in GB-Month.
REG-CrossRegion-WarmBytes-DynamoDB	GB	Size	The data transferred to a different AWS Region either within the same account or to a different AWS account. Cross-Reg

UsageType	Units	Granularity	Description
			ion transfers charges occur when copying backups from one Region to another Region. The charge is always billed to the account where the data is transferred from.
REG-Restore-WarmBytes-DynamoDB	GB	Size	The total size of the data restored from warm storage, measured in GB.
REG-ColdStorage-ByteHrs-DynamoDB	GB	Month	The cold storage used by DynamoDB backups managed by AWS Backup throughout the month, measured in GB-Month.
REG-Restore-ColdBytes-DynamoDB	GB	Month	The total size of the data restored from cold storage, measured in GB.

Export and Import

You can export data from DynamoDB to Amazon S3 or import data from Amazon S3 to a new DynamoDB table.

Although the `UsageType` uses `Bytes` as a suffix, export and import usage in the CUR is measured and priced in GB.

UsageType	Units	Granularity	Description
REG-ExportDataSize-Bytes	GB	Size	The charge for exporting data to S3. DynamoDB charges for data you export based on the size of the DynamoDB base table (table data and local secondary indexes) at the specified point in time when the export was created.
REG-ImportDataSize-Bytes	GB	Size	The charge for importing data from S3. The size is calculated based on the uncompressed object size of the data within Amazon S3. There are no extra charges for importing to tables with GSIs.
REG-IncrementalExportDataSize-Bytes	GB	Size	The charge for size of the data processed from the continuous backup to produce incremental exports.

Data Transfer

Data transfer activity may appear associated with the DynamoDB service. DynamoDB does not charge for inbound data transfer, and it does not charge for data transferred between DynamoDB

and other AWS services within the same AWS Region (in other words, $0.00 per GB). Data transferred across AWS Regions (such as between DynamoDB in the US East [N. Virginia] Region and Amazon EC2 in the EU [Ireland] Region) is charged on both sides of the transfer.

UsageType	Units	Granularity	Description
REG-DataTransfer-In-Bytes	GB	Units	Data transferred in to DynamoDB from the internet.
REG-DataTransfer-Out-Bytes	GB	Units	Data transferred out from DynamoDB to the internet.

CloudWatch Contributor Insights

CloudWatch Contributor Insights for DynamoDB is a diagnostic tool for identifying the most frequently accessed and throttled keys in your DynamoDB table. The following `UsageType` charges appear under the “AmazonCloudWatch” ProductCode rather than “AmazonDynamoDB”.

UsageType	Units	Granularity	Description
REG-CW:ContributorEventsManaged	Events processed	Units	The amount of DynamoDB events processed. For example for a table with CloudWatch Contributor Insights enabled, anytime an item is read or written, it’s counted as one event. If the table has a sort key, it results in charges for two events.

UsageType	Units	Granularity	Description
REG-CW:ContributorRulesManaged	Rule count	Month	DynamoDB creates rules to identify most accessed items and most throttled keys when you enable Cloud Watch Contributor Insights. This charge is incurred for the rules added for each entity (tables and GSIs) configured for logging CloudWatch contributor insights.

DynamoDB Accelerator (DAX)

DynamoDB Accelerator (DAX) is billed by the hour based on the instance type selected for the service. The charges below refers to the DynamoDB Accelerator instances provisioned. The following `UsageType` charges appear under the “AmazonDAX” ProductCode rather than “AmazonDynamoDB”.

UsageType	Units	Granularity	Description
REG-NodeUsage:dax-<INSTANCETYPE>	Node-hour	Hour	The hourly usage of a particular instance type. Pricing is per node-hour consumed, from the time a node is launched until it is terminated. Each partial node-hour consumed will be billed as a full hour.

UsageType	Units	Granularity	Description
			DAX charges for each node in a DAX cluster. If you have a cluster with multiple nodes, you would see multiple line items in your billing report.

The instance type will be one of the values from the following list. For details about node types, see Nodes.

- r3.2xlarge, r4.8xlarge, or r5.8xlarge
- r3.4xlarge, r4.large, or r5.large
- r3.8xlarge, r4.xlarge, or r5.xlarge
- r3.2xlarge, r5.12xlarge, or t2.medium
- r3.4xlarge, r4.large, or r5.large
- r3.xlarge, r5.16xlarge, or t2.small
- r4.16xlarge, r5.24xlarge, or t3.medium
- r4.2xlarge, r5.2xlarge, or t3.small
- r4.4xlarge or r5.4xlarge

Migrating a DynamoDB table from one account to another

You can migrate an Amazon DynamoDB table from one account to another to implement a multi-account strategy or a backup strategy. You can also do it for testing, debugging, or compliance reasons. A common use case is copying DynamoDB tables across production, staging, test, and development environments where each environment utilizes a different AWS account.

DynamoDB offers two options for migrating tables from one AWS account to another:

- **AWS Backup for Cross-Account Backup and Restore:** AWS Backup is a fully managed backup service that enables you to centrally manage backups across multiple AWS services. With its

cross-account backup and restore functionality, you can back up a DynamoDB table in one account and restore the backup to another account in the same AWS Organization.

- **DynamoDB Export and Import to Amazon S3:** Using the DynamoDB Export and Import to Amazon S3 features allows you to do a full export to an Amazon S3 bucket and then import that data into a new table in another AWS account. This approach is suitable when you need to migrate between accounts that are not part of the same AWS Organization or if you do not want to use AWS Backup.

> **Note**
>
> Import from Amazon S3 does not support tables with Local Secondary Indexes (LSIs), but it does support Global Secondary Indexes (GSIs). For more information on LSIs and GSIs, see Improving data access with secondary indexes in DynamoDB.

Topics

- Migrate a table using AWS Backup for cross-account backup and restore
- Migrate a table using export to S3 and import from S3

Migrate a table using AWS Backup for cross-account backup and restore

Prerequisites

- Source and target AWS accounts must belong to the same organization in the AWS Organizations service
- Valid AWS Identity and Access Management (IAM) permissions to create and use AWS Backup vaults

For more information about setting up cross-account backups, see Creating backup copies across AWS accounts.

Pricing information

AWS charges for the backup (based on the table size), any data copying between AWS Regions (based on the amount of data), for the restore (based on the amount of data), and for any ongoing

storage charges. To avoid ongoing charges, you can delete the backup if you don't need it after the restore.

For more information about pricing, see AWS Backup pricing .

Step 1: Enable advanced features for DynamoDB and cross-account backup

1. In both the source and target AWS account, access the AWS Management Console and open the AWS Backup console.
2. Choose the **Settings** option.
3. Under **Advanced features for Amazon DynamoDB backups**, confirm that **Advanced features** is enabled. If it isn't, choose **Enable**.
4. Under **Cross-account management**, for **Cross-account backup**, choose **Turn On**.

Step 2: Create a backup vault in the source account and target account

1. In the source AWS accounts, open the AWS Backup console.
2. Choose **Backup vaults**.
3. Choose **Create Backup vault**.
4. Copy and save the **Amazon Resource Name (ARN)** of the created backup vaults and the target AWS account.
5. You'll need the ARNs of both the source and target backup vaults when copying the DynamoDB table backup between accounts.

Step 3: Create a DynamoDB table backup in the source account

1. On the **AWS Backup Dashboard page**, choose **Create on-demand backup**.
2. In the **Settings** section, select **DynamoDB** as the **Resource type**, and then select the table name.
3. In the **Backup vault** dropdown list, select the backup vault you created in the source account.
4. Select the desired **Retention period**.
5. Choose **Create on-demand backup**.
6. Monitor the status of the backup job on the **Backup Jobs** tab of the **AWS Backup Jobs** page.

Step 4: Copy the DynamoDB table backup from the source account to the target account

1. After the backup job completes, open the AWS Backup console in the source account and choose **Backup vaults**.
2. Under **Backups**, choose the DynamoDB table backup. Choose **Actions** and then **Copy**.
3. Enter the AWS Region of the target account.
4. For **External vault ARN**, enter the ARN of the backup vault you created in the target account.
5. In the target account backup vault, enable access from a source account to allow copying backups.

Step 5: Restore the DynamoDB table backup in the target account

1. In the target AWS account, open the AWS Backup console and choose **Backup vaults**
2. Under **Backups**, select the backup you copied from the source account. Choose **Actions**, then **Restore**.
3. Enter the name for the new DynamoDB table, the encryption that this new table will have, the key you want the restore to be encrypted with, and any other options.
4. When the restore is completed, the table status will show as **Active**.

Migrate a table using export to S3 and import from S3

Prerequisites

- You must enable Point-in-Time Recovery (PITR) for your table in order to perform the export to S3. For more information, see Enable point-in-time recovery in DynamoDB.
- Valid IAM permissions to perform the export. For more information, see Requesting a table export in DynamoDB.
- Valid IAM permissions sufficient to perform the import. For more information, see Requesting a table import in DynamoDB.

Pricing information

AWS charges for PITR (based on the size of the table and how long PITR is enabled for). If you don't need PITR except for the export, you can turn it off after the export concludes. AWS also charges

for requests made against S3, for storing the exported data in S3 and for importing (based on the uncompressed size of the imported data).

For more information about DynamoDB pricing, see DynamoDB pricing.

> **Note**
>
> There are limits on the size and number of objects when importing from S3 to DynamoDB. For more information, see Import quotas.

Step 1: Request a table export to Amazon S3

1. Sign in to the AWS Management Console and open the DynamoDB console.
2. In the navigation pane on the left side of the console, choose **Exports to S3**.
3. Choose a source table and destination S3 bucket. enter the URL of the destination account bucket using the `s3://bucketname/prefix` format. The prefix is an optional folder to help keep your destination bucket organized.
4. Choose **Full export**. A full export outputs the full table snapshot of your table as it was at the point in time you specify.
   a. Select **Current time** to export the latest full table snapshot
   b. For **Exported file format**, choose between DynamoDB JSON and Amazon Ion. The default option is DynamoDB JSON.
5. Click the **Export** button to begin the export.
6. Small table exports should conclude in a matter of minutes, but tables in the terabyte range could take more than an hour.

Step 2: Request a table import from Amazon S3

1. Sign in to the AWS Management Console and open the DynamoDB console.
2. In the navigation pane on the left side of the console, choose **Import from S3**.
3. On the page that appears, select **Import from S3**.
4. Enter the Amazon S3 source URL. You can also find it by using the **Browse S3** button: `s3://bucket/prefix/AWSDynamoDB/<XXXXXXXX-XXXXXX>/Data/`.

5. Specify if you are the S3 bucket owner.
6. Under **Import file compression**, select **GZIP** to match the export.
7. Under **Import file format**, select **DynamoDB JSON** to match the export.
8. Select the **Next** button and choose the options for the new table that will be created to store your data.
9. Select **Next** again to review your import options, then click **Import** to begin the import task. You'll see your new table listed in the **Tables** with the status **Creating**. The table is not accessible during this time.
10. Once the import completes, the status will show as **Active** and you can start using the table.
11. Small imports should finish in a matter of minutes, but tables in the terabyte range could take more than an hour.

Keeping tables in sync during migration

If you can pause write operations on the source table for the duration of the migration, then the source and output should match up exactly after the migration. If you can't pause write operations, the target table would normally be a bit behind the source after the migration. To catch up the source table, you can use streaming (DynamoDB Streams or Kinesis Data Streams for DynamoDB) to replay the writes that happened in the source table since the backup or export.

You should start reading the stream records prior to the timestamp when you exported the source table to S3. For example, if the export to S3 occurred at 2:00 PM and the import to the target table was concluded at 11:00 PM, you should initiate the DynamoDB stream reading at 1:58 PM. The streaming options for change data capture table summarizes the features of each streaming model.

Using DynamoDB Streams with Lambda offers a streamlined approach for synchronizing data between the source and target DynamoDB tables. You can use a Lambda function to replay each write in the target table.

> **Note**
>
> Items are kept in the DynamoDB Streams for 24 hours, so you should plan to complete your backup and restore or export and import within that window.

Prescriptive guidance to integrate DAX with DynamoDB applications

DynamoDB Accelerator (DAX), is a DynamoDB-compatible caching service that provides fast in-memory performance for demanding applications, such as read-heavy applications. Using DAX, you can achieve response times in microseconds for accessing frequently requested data. This DynamoDB Accelerator prescriptive guide provides comprehensive insights and best practices for integrating DAX with your DynamoDB applications.

This guide provides foundational knowledge for those who are new to DAX or want to optimize their existing configurations. This guide covers various topics, for example, when to use DAX and creating a DAX cluster. It also includes practical examples and detailed explanations to help you effectively implement DAX in your projects. Finally, this guide offers advanced strategies that you need to implement to maximize DAX caching capabilities for ensuring fast and scalable applications.

Topics

- Evaluating the suitability of DAX for your use cases
- Configuring your DAX client
- Configuring your DAX cluster
- Sizing your DAX cluster
- Deploying a cluster
- Managing cluster operations
- Monitoring DAX

Evaluating the suitability of DAX for your use cases

This section explains when and why to use DAX. Using this guidance helps you to determine if integrating DAX with DynamoDB is advantageous for your application's workload patterns, performance requirements, and data consistency needs. It also covers scenarios where DAX might not be suitable, for example, write-heavy workloads and infrequently accessed data.

In this section

- When and why to choose DAX

- When not to use DAX

When and why to choose DAX

You can consider adding DAX to your application stack in several scenarios. For example, use DAX to reduce the overall latency of read requests against DynamoDB or to minimize repeated reads of the same data from a table. The following list presents examples of scenarios in which you can take advantage of integrating DAX with DynamoDB:

- **High-performance requirement**
  - **Low latency reads** – You should consider using DAX if your application requires response times in microseconds for eventually-consistent reads. DAX can also drastically reduce the response time for accessing frequently read data.
- **Read-intensive workloads**
  - **Read-heavy applications** – For applications with a high read-to-write ratio, for example, 10:1 or more, DAX results in more cache hits and less stale data. This reduces reads against a table. To avoid reading stale data from the cache if your application is write-heavy, make sure to set a lower Using time to live (TTL) in DynamoDB for the cache.
  - **Caching common queries** – If your application frequently reads the same data, for example, popular products on an e-commerce platform, DAX can serve these requests directly from its cache.
- **Bursty traffic patterns**
  - **Smoother table scaling** – DAX helps smooth out impacts of sudden traffic spikes. DAX provides a buffer to scale up DynamoDB table capacity gracefully, which reduces the risk of read throttling.
  - **Higher read throughput for each item** – DynamoDB allocates individual partitions for each item. However, a partition starts throttling reads of an item when it reaches 3,000 read capacity units (RCU). DAX lets you scale reads of a single item beyond 3,000 RCU.
- **Cost optimization**
  - **Reducing DynamoDB costs** – Reading from DAX can reduce reads sent to a DynamoDB table, which can then directly impact cost. With a high cache hit rate, the reduced table read cost can exceed a DAX cluster cost, which results in a net cost reduction.
- **Data consistency requirements**
  - **Eventual consistency** – DAX supports eventually consistent reads. This makes DAX suitable for use cases where immediate consistency isn't critical.

- **Write-through caching** – Writes that you make against DAX are write-through. Once DAX confirms that it's written an item to DynamoDB, it persists that item version in the item cache. This write-through mechanism helps maintain tighter data consistency between cache and database, but uses additional DAX cluster resources.

When not to use DAX

While DAX is powerful, it's not suitable for all scenarios. The following list presents examples of scenarios in which integrating DAX with DynamoDB is unsuitable:

- **Write-heavy workloads** – The primary advantage of DAX is speeding up reads, but writes use more DAX resources than reads. If your application is predominantly write-heavy, DAX benefits might be limited.
- **Infrequently read data** – If your application accesses data infrequently or a wide range of rarely reused data (cold data), you'll likely experience a low cache hit ratio. In this case, the overhead of maintaining the cache might not justify the performance gains.
- **Bulk reads or writes** – If your application performs more bulk writes than individual writes, you should write around DAX. In addition, for bulk reads, you should run full table scans directly against a DynamoDB table.
- **Strong consistency or transaction requirements** – DAX passes strongly consistent reads and TransactGetItems calls to a DynamoDB table. You should make these reads around the DAX cluster to avoid using cluster resources. Items read this way won't be cached; therefore, routing such items through DAX serves no purpose.
- **Simple applications with modest performance requirements** – For applications with modest performance requirements and tolerance for direct DynamoDB latency, the complexity and cost of adding DAX might not be necessary. On its own, DynamoDB handles high throughput and provides single-digit millisecond performance.
- **Complex querying needs beyond key-value access** – DAX is optimized for key-value access patterns. If your application requires complex querying capabilities with complex filtering, such as Query and Scan operations, DAX caching benefits might be limited.

  In these situations, use Amazon ElastiCache (Redis OSS) as an alternative. ElastiCache (Redis OSS) supports advanced data structures, such as, lists, sets, and hashes. It also offers features, such as pub/sub, geospatial indexes, and scripting.
- **Compliance requirements** – DAX doesn't currently offer the same compliance accreditations as as DynamoDB. For example, DAX hasn't obtained the SOC accreditation yet.

Configuring your DAX client

The DAX cluster is an instance-based cluster that can be accessed using various DAX SDKs. Each SDK provides developers with configurable options, such as requestTimeout and connections, to meet specific application requirements.

When configuring your DAX client, a crucial consideration is your client application's scale—specifically, the ratio of client instances to DAX server instances (which has a maximum of 11). Large client instance fleets can generate numerous connections to DAX server instances, potentially overwhelming them. This guide outlines best practices for DAX client configuration.

Best practices

1. **Client instances** – Implement singleton client instances to ensure instance reuse across requests. For implementation details, see the section called “Step 4: Run a sample application”.
2. **Request timeouts** – While applications often require low request timeouts to ensure minimal latency for upstream systems, setting timeouts too low can cause problems. Low timeouts may trigger frequent reconnection to server instances when DAX servers experience temporary latency spikes. When a timeout occurs, the DAX client terminates the existing server node connection and establishes a new one. Since connection establishment is resource-intensive, numerous consecutive connections can overload DAX servers. We recommend the following:
   - Maintaining default request timeout settings.
   - If lower timeouts are necessary, implement separate application threads with lower timeout values and include retry mechanisms with exponential back-off.
3. **Connection timeout** – For most applications, we recommend maintaining the default connection timeout settings.
4. **Concurrent connections** – Certain SDKs, such as JavaV2, allow adjustment of concurrent connections to the DAX server. Key considerations:
   - DAX server instances can handle up to 40,000 concurrent connections.
   - Default settings are suitable for most use cases.
   - Large client instances combined with high concurrent connections may overload servers.
   - Lower concurrent connection values reduce server overload risk.
   - Performance calculation example:
     - Assuming 1ms request latency, each connection can theoretically handle 1,000 requests/second.

- For a 3-node cluster, a single client instance connecting to all nodes can process 3,000 requests/second.
- With 10 connections, the client can handle approximately 30,000 requests/second.

  Recommendation – Begin with lower concurrent connection settings and validate through performance testing with expected production workload patterns.

Configuring your DAX cluster

The DAX cluster is a managed cluster, but you can adjust its configurations to fit your application requirements. Because of its close integration with DynamoDB API operations, you should consider the following aspects when integrating your application with DAX.

In this section

- DAX pricing
- Item cache and query cache
- Selecting TTL setting for the caches
- Caching multiple tables with a DAX cluster
- Data replication in DAX and DynamoDB global tables
- DAX Region availability
- DAX caching behavior

DAX pricing

The cost of a cluster depends on the number and size of nodes it has provisioned. Every node is billed for each hour it runs in the cluster. For more information, see Amazon DynamoDB pricing.

Cache hits don't incur DynamoDB cost, but impact DAX cluster resources. Cache misses incur DynamoDB read costs and require DAX resources. Writes incur DynamoDB write costs and impact DAX cluster resources to proxy the write.

Item cache and query cache

DAX maintains an item cache and a query cache. Understanding the differences between these caches can help you determine the performance and consistency characteristics they offer to your application.

Cache characteristic	Item cache	Query cache
Purpose	Stores the results of GetItem and BatchGetItem API operations.	Stores the results of Query and Scan API operations. These operations can return multiple items based on query conditions instead of specific item keys.
Access Type	Uses key-based access. When an application requests data using `GetItem` or `BatchGetItem` , DAX first checks the item cache using the primary key of the requested items. If the item is cached and unexpired , DAX returns it immediate ly without accessing the DynamoDB table.	Uses parameter-based access. DAX caches the result set of `Query` and `Scan` API operations. DAX serves subsequent requests with the same parameters that include the same query conditions, table, index, from the cache. This significantly reduces response times and DynamoDB read throughput consumption.
Cache Invalidation	DAX automatically replicates updated items into the item cache of the nodes in the DAX cluster in the following scenarios: • You write an item update through the cache. • Read an updated item version from the table.	The query cache is more challenging to invalidate than the item cache. Item updates might not directly map to cached queries or scans. You must carefully tune the query cache TTL to maintain data consistency. Writes through DAX or base table aren't reflected in query cache until the TTL expires the previousl y cached response and DAX performs a new query against DynamoDB.

Cache characteristic	Item cache	Query cache
Global secondary index	Because the `GetItem` API operation isn't supported on local secondary indexes or global secondary indexes, the item cache only caches reads from the base table.	Query cache caches queries against both tables and indexes.

Selecting TTL setting for the caches

TTL determines the period for which data is stored in the cache before it becomes stale. After this period, the data is automatically refreshed on the next request. Choosing the right TTL setting for your DAX caches involves balancing between the optimization of application performance and consistency of data. Because there doesn't exist a universal TTL setting that works for all applications, the optimal TTL setting varies based on your application's specific characteristics and requirements. We recommend that you start with a conservative TTL setting using this prescriptive guidance. Then, iteratively adjust your TTL setting based on your application's performance data and insights.

DAX maintains a least recently used (LRU) list for the item cache. The LRU list tracks when items are first written to or last read from the cache. When the DAX node memory is full, DAX evicts older items even if they haven't expired yet to make room for new items. The LRU algorithm is always enabled and not user-configurable.

To set a TTL duration that works for your applications, consider the following points:

Understand your data access patterns

- **Read-heavy workloads** – For applications with read-heavy workloads and infrequent data updates, set a longer TTL duration to reduce the number of cache misses. A longer TTL duration also reduces the need to access the underlying DynamoDB table.
- **Write-heavy workloads** – For applications with frequent updates that aren't written through DAX, set a shorter TTL duration to ensure the cache stays consistent with the database. A shorter TTL duration also reduces the risk of serving stale data.

Evaluate your application's performance requirements

- **Latency sensitivity** – If your application requires low latency over data freshness, use a longer TTL duration. A longer TTL duration maximizes cache hits, which reduces average read latency.
- **Throughput and scalability** – A longer TTL duration reduces load on DynamoDB tables and improves throughput and scalability. However, you should balance this with the need for up-to-date data.

Analyze cache eviction and memory usage

- **Cache memory limits** – Monitor your DAX cluster's memory usage. A longer TTL duration can store more data in the cache, which might reach memory limits and lead to LRU-based evictions.

Use metrics and monitoring to adjust TTL

Regularly review metrics, for example, cache hits and misses, and CPU and memory utilization. Adjust your TTL setting based on these metrics to find an optimal balance between performance and data freshness. If cache misses are high and memory utilization is low, increase the TTL duration to increase the cache hit rate.

Consider business requirements and compliance

Data retention policies might dictate the maximum TTL duration you can set for sensitive or personal information.

Cache behavior if you set TTL to zero

If you set TTL to 0, the item cache and query cache present the following behaviors:

- **Item cache** – Items in the cache are refeshed only when an LRU eviction or a write-through operation occurs.
- **Query cache** – Query responses aren't cached.

Caching multiple tables with a DAX cluster

For workloads with multiple small DynamoDB tables that don't need individual caches, a single DAX cluster caches requests for these tables. This provides more flexible and efficient use of DAX, particularly for applications that access multiple tables and require high-performance reads.

Similar to the DynamoDB data plane APIs, DAX requests require a table name. If you use multiple tables in the same DAX cluster, you don't need any specific configuration. However, you must ensure that the cluster's security permissions allow access to all cached tables.

Considerations for using DAX with multiple tables

When you use DAX with multiple DynamoDB tables, you should consider the following points:

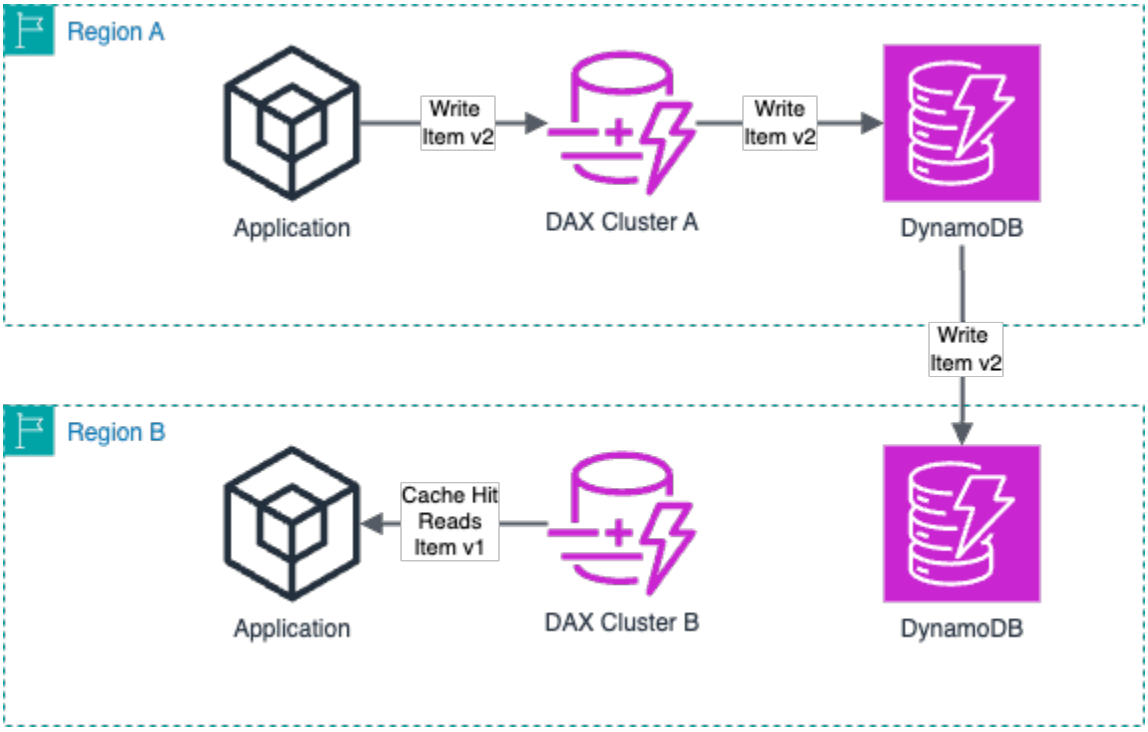
- **Memory management** – When you use DAX with multiple tables, you should consider the total size of your working data set. All the tables in your data set will share the same memory space of the node type you selected.
- **Resource allocation** – The DAX cluster's resources are shared among all the cached tables. However, a high-traffic table can cause eviction of data from the neighboring smaller tables.
- **Economies of scale** – Group smaller resources into a larger DAX cluster for averaging out traffic to a steadier pattern. For the total number of read resources that the DAX cluster requires, it's also economical to have three or more nodes. This also increases the availability of all the cached tables in the cluster.

Data replication in DAX and DynamoDB global tables

DAX is a Region-based service, so a cluster is only aware of the traffic within its AWS Region. Global tables write around the cache when they replicate data from another Region.

A longer TTL duration can cause stale data to remain in your secondary Region for longer than in the primary Region. This can result in cache misses in the local cache of the secondary Region.

The following diagram shows data replication occurring at the global table level in the source Region A. The DAX cluster in Region B isn't immediately aware of the newly replicated data from the source Region A.



DAX Region availability

Not all Regions that support DynamoDB tables support deploying DAX clusters. If your application requires low read latency through DAX, first review the list of Regions that support DAX. Then, select a Region for your DynamoDB table.

DAX caching behavior

DAX performs metadata and negative caching. Understanding these caching behaviors will help you effectively manage attribute metadata of cached items and negative cache entries.

- **Metadata caching** – DAX clusters indefinitely maintain metadata about the attribute names of cached items. This metadata persists even after the item expires or is evicted from the cache.

  Over time, applications that use unbounded number of attribute names can cause memory exhaustion in the DAX cluster. This limitation applies only to top-level attribute names, but not to the nested attribute names. Examples of unbounded attribute names include timestamps, UUIDs, and session IDs. Although you can use timestamps and session IDs as attribute values, we recommend to use shorter and more predictable attribute names.
- **Negative caching** – If a cache miss occurs and the read from a DynamoDB table yields no matching items, DAX adds a negative cache entry in the respective item or query cache. This

entry remains until the cache TTL duration expires or a write-through occurs. DAX continues to return this negative cache entry for future requests.

If the negative caching behavior doesn't fit your application pattern, read the DynamoDB table directly when DAX returns an empty result. We also recommend that you set a lower TTL cache duration to avoid long-lasting empty results in the cache and improve consistency with the table.

Sizing your DAX cluster

A DAX cluster's total capacity and availability depends on node type and count. More nodes in the cluster increase its read capacity, but not the write capacity. Larger node types (up to r5.8xlarge) can handle more writes, but too few nodes can impact availability when a node failure occurs. For more information about sizing your DAX cluster, see the DAX cluster sizing guide.

The following sections discuss the different sizing aspects that you should consider to balance node type and count for creating a scalable and cost-efficient cluster.

In this section

- Planning availability
- Planning write throughput
- Planning read throughput
- Planning dataset size
- Calculating approximate cluster capacity requirements
- Approximating cluster throughput capacity by node type
- Scaling write capacity in DAX clusters

Planning availability

When sizing a DAX cluster, you should first focus on its targeted availability. Availability of a clustered service, such as DAX, is a dimension of the total number of nodes in the cluster. Because a single node cluster has no tolerance for failure, its availability is equal to one node. In a 10-node cluster, the loss of a single node has a minimal impact to the cluster's overall capacity. This loss doesn't have a direct impact on availability because the remaining nodes can still fulfill read requests. To resume writes, DAX quickly nominates a new primary node.

DAX is VPC-based. It uses a subnet group to determine which Availability Zones it can run nodes in and which IP addresses to use from the subnets. For production workloads, we highly recommend that you use DAX with at least three nodes in different Availability Zones. This ensures that the cluster has more than one node left to handle requests even if a single node or Availability Zone fails. A cluster can have up to 11 nodes, where one is a primary node and 10 are read replicas.

Planning write throughput

All DAX clusters have a primary node for write-through requests. The size of the node type for the cluster determines its write capacity. Adding additional read replicas doesn't increase the cluster's write capacity. Therefore, you should consider the write capacity during cluster creation because you can't change the node type later.

If your application needs to write-through DAX to update the item cache, consider increased use of cluster resources to facilitate the write. Writes against DAX consume about 25 times more resources than cache-hit reads. This might require a larger node type than for read-only clusters.

For additional guidance about determining whether write-through or write-around will work best for your application, see Strategies for writes.

Planning read throughput

A DAX cluster's read capacity depends on the cache hit ratio of your workload. Because DAX reads data from DynamoDB when a cache miss occurs, it consumes approximately 10 times more cluster resources than a cache-hit. To increase cache hits, increase the TTL setting of the cache to define the period for which an item is stored in the cache. A higher TTL duration, however, increases the chance of reading older item versions unless updates are written through DAX.

To make sure that the cluster has sufficient read capacity, scale the cluster horizontally as mentioned in Scaling a cluster horizontally. Adding more nodes adds read replicas to the pool of resources, while removing nodes reduces read capacity. When you select the number of nodes and their sizes for a cluster, consider both the minimum and maximum amount of read capacity needed. If you can't horizontally scale a cluster with smaller node types to meet your read requirements, use a larger node type.

Planning dataset size

Each available node type has a set memory size for DAX to cache data. If a node type is too small, the working set of data that an application requests won't fit in memory and results in cache

misses. Because larger nodes support larger caches, use a node type larger than the estimated data set that you need to cache. A larger cache also improves the cache hit ratio.

You might get diminishing returns for caching items with few repeated reads. Calculate the memory size for frequently accessed items and make sure the cache is large enough to store that data set.

Calculating approximate cluster capacity requirements

You can estimate your workload's total capacity needs to help you select the appropriate size and quantity of cluster nodes. To do this estimation, calculate the variable *normalized request per second* (Normalized RPS). This variable represents the total units of work your application requires the DAX cluster to support, including cache hits, cache misses, and writes. To calculate the Normalized RPS, use the following inputs:

- `ReadRPS_CacheHit` – Specifies the number of reads per second that result in a cache hit.
- `ReadRPS_CacheMiss` – Specifies the number of reads per second that result in a cache miss.
- `WriteRPS` – Specifies the number of writes per second that will go through DAX.
- `DaxNodeCount` – Specifies the number of nodes in the DAX cluster.
- `Size` – Specifies the size of the item being written or read in KB rounded up to the nearest KB.
- `10x_ReadMissFactor` – Represents a value of 10. When a cache miss occurs, DAX uses approximately 10 times more resources than cache hits.
- `25x_WriteFactor` – Represents a value of 25 because a DAX write-through uses approximately 25 times more resources than cache hits.

Using the following formula, you can calculate the Normalized RPS.

```
Normalized RPS = (ReadRPS_CacheHit * Size) + (ReadRPS_CacheMiss * Size *
 10x_ReadMissFactor) + (WriteRequestRate * 25x_WriteFactor * Size * DaxNodeCount)
```

For example, consider the following input values:

- `ReadRPS_CacheHit` = 50,000
- `ReadRPS_CacheMiss` = 1,000
- `ReadMissFactor` = 1
- `Size` = 2 KB

- `WriteRPS` = 100
- `WriteFactor` = 1
- `DaxNodeCount` = 3

By substituting these values in the formula, you can calculate the Normalized RPS as follows.

```
Normalized RPS = (50,000 Cache Hits/Sec * 2KB) + (1,000 Cache Misses/Sec * 2KB * 10) +
 (100 Writes/Sec * 25 * 2KB * 3)
```

In this example, the calculated value of Normalized RPS is 135,000. However, this Normalized RPS value doesn't account for keeping cluster utilization below 100% or node loss. We recommend that you factor in additional capacity. To do this, determine the greater of two multiplying factors: target utilization or node loss tolerance. Then, multiply the Normalized RPS by the greater factor to obtain a *target request per second* (Target RPS).

- **Target utilization**

  Because performance impacts increase cache misses, we don't recommend running the DAX cluster at 100% utilization. Ideally, you should keep cluster utilization at or below 70%. To achieve this, multiply the Normalized RPS by 1.43.

- **Node loss tolerance**

  If a node fails, your application must be able to distribute its requests among the remaining nodes. To make sure nodes stay below 100% utilization, choose a node type large enough to absorb extra traffic until the failed node comes back online. For a cluster with fewer nodes, each node must tolerate larger traffic increases when one node fails.

  If a primary node fails, DAX automatically fails over to a read replica and designates it as the new primary. If a replica node fails, other nodes in the DAX cluster can still serve requests until the failed node is recovered.

  For example, a 3-node DAX cluster with a node failure requires an additional 50% capacity on the remaining two nodes. This requires a multiplying factor of 1.5. Conversely, an 11-node cluster with a failed node requires an additional 10% capacity on the remaining nodes or a multiplying factor of 1.1.

Using the following formula, you can calculate the Target RPS.

```
Target RPS = Normalized RPS * CEILING(TargetUtilization, NodeLossTolerance)
```

For example, to calculate Target RPS, consider the following values:

- `Normalized RPS` = 135,000
- `TargetUtilization` = 1.43

  Because we're aiming for a maximum cluster utilization of 70%, we're setting `TargetUtilization` to 1.43.
- `NodeLossTolerance` = 1.5

  Say that we're using a 3-node cluster, therefore, we're setting `NodeLossTolerance` to 50% capacity.

By substituting these values in the formula, you can calculate the Target RPS as follows.

```
Target RPS = 135,000 * CEILING(1.43, 1.5)
```

In this example, because the value of `NodeLossTolerance` is greater than `TargetUtilization`, we calculate the value of Target RPS with `NodeLossTolerance`. This gives us a Target RPS of 202,500, which is the total amount of capacity the DAX cluster must support. To determine the number of nodes you'll need in a cluster, map the Target RPS to an appropriate column in the following table. For this example of a Target RPS of 202,500, you need the dax.r5.large node type with three nodes.

Approximating cluster throughput capacity by node type

Using the Target RPS formula, you can estimate cluster capacity for different node types. The following table shows approximate capacities for clusters with 1, 3, 5, and 11 node types. These capacities don't replace the need to perform load testing of DAX with your own data and request patterns. Additionally, these capacities don't include t-type instances because of their lack of fixed CPU capacity. The unit for all values in the following table is Normalized RPS.

Node type (memory)	1 node	3 nodes	5 nodes	11 nodes
dax.r5.24xlarge (768GB)	1M	3M	5M	11M
dax.r5.16xlarge (512GB)	1M	3M	5M	11M
dax.r5.12xlarge (384GB)	1M	3M	5M	11M
dax.r5.8xlarge (256GB)	1M	3M	5M	11M
dax.r5.4xlarge (128GB)	600k	1.8M	3M	6.6M
dax.r5.2xlarge (64GB)	300k	900k	1.5M	3.3M
dax.r5.xlarge (32GB)	150k	450k	750k	1.65M
dax.r5.large (16GB)	75k	225k	375k	825k

Because of the maximum limit of 1 million NPS (network operations per second) for each node, nodes of types dax.r5.8xlarge or larger don't contribute additional cluster capacity. Node types larger than 8xlarge might not contribute to total throughput capacity of the cluster. However, such node types can be helpful for storing a larger working data set in memory.

Scaling write capacity in DAX clusters

Each write to DAX consumes 25 normalized requests on every node. Because there's a 1 million RPS limit for each node, a DAX cluster is limited to 40,000 writes per second, not accounting for read usage.

If your use case requires more than 40,000 writes per second in the cache, you must use separate DAX clusters and shard the writes among them. Similar to DynamoDB, you can hash the partition key for the data you're writing to the cache. Then, use modulus to determine which shard to write the data to.

The following example calculates the hash of an input string. It then calculates the modulus of the hash value with 10.

```
def hash_modulo(input_string):
    # Compute the hash of the input string
    hash_value = hash(input_string)

    # Compute the modulus of the hash value with 10
    bucket_number = hash_value % 10

    return bucket_number

#Example usage
if _name_ == "_main_":
    input_string = input("Enter a string: ")
    result = hash_modulo(input_string)
    print(f"The hash modulo 10 of '{input_string}' is: {result}.")
```

Deploying a cluster

Creating a new DAX cluster requires configurations beyond those needed for DynamoDB. These configurations are particularly for networking because DAX is based on Amazon VPC. This gives you complete control over your virtual networking environment, including resource placement, connectivity, and security. This section presents the best practices for the settings needed during cluster creation.

For information about choosing cluster nodes, see Sizing your DAX cluster.

In this section

- Configure networks
- Configure security
- Parameter group
- Maintenance window

Configure networks

DAX uses a subnet group to determine which Availability Zones it can run nodes in and which IP addresses to use from the subnets. To minimize latency between your application and DAX, the subnets and Availability Zones for your application servers and the DAX cluster should be the same.

We recommend that you spread the DAX nodes across multiple Availability Zones. The default option of Automatic allocation does this for you.

For best practices about setting up your VPC, see Get started with Amazon VPC in the *Amazon VPC User Guide*.

Configure security

This section discusses the security measures that you should implement for your applications that use DAX. This section also briefly discusses the support that DAX includes for data encryption.

IAM

DAX and DynamoDB have separate access control mechanisms. DAX requires an IAM role to access your DynamoDB tables. This role should follow the principle of least privilege and grant access only to specific tables and DynamoDB operations, such as GetItem and PutItem. For more information about the access control mechanisms provided by DAX, see DAX access control.

Encryption

You configure encryption at rest and encryption in transit while creating a DAX cluster. These are enabled by default. We recommend that you keep the default encryption settings unless business requirements prevent it. For more information, see DAX encryption at rest and DAX encryption in transit.

Parameter group

DAX applies a set of configurations on every node in a cluster called a parameter group. You can change this configuration after creating the cluster.

The DAX parameter group holds TTL settings for item cache and query cache. By default, the TTL duration is 5 minutes. You can override the TTL duration to any integer value greater than or equal to 1 millisecond.

You can't modify parameter groups when a running DAX instance is using them. You can change the parameter group values during the downtime of a DAX cluster.

Maintenance window

To allow for occasional software upgrades and patches to your nodes, a weekly maintenance window is configured for the DAX cluster. During this window, DAX performs rolling updates to the nodes. Clusters with more than one node don't lose availability of the cluster during these updates, but have reduced cluster capacity until the node returns. If your organization has a predictable time of low usage, consider setting the maintenance window manually to this time.

Managing cluster operations

DAX handles the cluster's maintenance and health for you. However, you need to provide operational input to scale the cluster horizontally or vertically to match your usage patterns. This section describes the recommended process to scale your DAX clusters.

In this section

- Scaling a cluster horizontally
- Scaling a cluster vertically

Scaling a cluster horizontally

Scaling a DAX cluster involves adjusting its capacity to meet throughput demands. This adjustment is done by increasing or decreasing the number of nodes (replicas) in the cluster while it's running. This process, known as horizontal scaling, helps distribute the workload across more nodes or consolidate to fewer nodes when demand is low.

You can horizontally scale your DAX cluster in and out using the `decrease-replication-factor` or `increase-replication-factor` commands in the AWS CLI.

Increase replication factor (scale out)

Increasing the replication factor of a DAX cluster adds more nodes to the cluster. The following example shows the usage of the `increase-replication-factor` command.

```
aws dax increase-replication-factor \
    --cluster-name yourClusterName  \
```

```
    --new-replication-factor desiredReplicationFactor
```

- In this command, the `cluster-name` argument specifies the name of your cluster. For example, *yourClusterName*.
- The `new-replication-factor` argument specifies the total number of nodes to add in the cluster after scaling. This includes the primary node and replica nodes. For example, if your cluster currently has 3 nodes and you want to add 2 more nodes, set the value of `new-replication-factor` to 5.

Decrease replication factor (scale in)

Decreasing the replication factor of a DAX cluster removes nodes from the cluster. Removing nodes can help reduce cost during periods of low demand. The following example shows the usage of the `decrease-replication-factor` command.

```
aws dax decrease-replication-factor \
    --cluster-name yourClusterName  \
    --new-replication-factor desiredReplicationFactor
```

- In this command, the `cluster-name` argument specifies the name of your cluster. For example, *yourClusterName*.
- The `new-replication-factor` argument specifies the reduced number of nodes in your cluster after scaling. This number must be lower than the current replication factor and must include the primary node. For instance, if your cluster has 5 nodes and you want to remove 2 nodes, set the value of `new-replication-factor` to 3.

Horizontal scaling considerations

Consider the following when you plan horizontal scaling:

- **Primary node** – The DAX cluster includes a primary node. The replication factor includes this primary node. For example, a replication factor of 3 means one primary node and two replica nodes.
- **Availability** – Adding or removing DAX nodes changes the cluster's availability and fault tolerance. More nodes can improve availability, but they also increase costs.
- **Data migration** – When you increase the replication factor, DAX automatically handles data distribution across the new set of nodes. When a new node begins serving traffic, its cache

is already warmed. However, during this process, there might be a temporary impact on performance during data migration.

Make sure you monitor your DAX clusters closely during and after the scaling process to ensure they're performing as expected and make further adjustments as necessary.

Scaling a cluster vertically

To vertically scale the node size of an existing cluster, you need to create a new cluster and migrate the application traffic to the new cluster. Migrating to a new cluster with different nodes involves several steps to ensure a smooth transition with minimal impact on your application's performance and availability.

To create a new cluster for scaling your node size vertically, consider the following points:

- **Access your current setup** – Review the metrics of your current DAX cluster to determine the new node size and quantity you need. Use this information as input to define your cluster size. For information, see Sizing your DAX cluster.
- **Set up a new DAX cluster** – Create a new DAX cluster with the node type and quantity you determined. You can use the existing configuration settings from your parameter group, unless you need to make adjustments.
- **Synchronize data** – Because DAX is a caching layer for DynamoDB, you don't need to migrate data directly. However, the new DAX cluster won't have any of your working dataset in memory until you send traffic to it.
- **Update application configuration** – Update your application's configuration to point to the new DAX cluster's endpoint. You might need to change code or update environment variables, depending on your application's configuration.

  To reduce impact when you switch to a new cluster, send canary traffic to the new cluster from a small portion of your application fleet. You can do this by slowly rolling out application updates or by using a weight-based routing DNS entry in front of your DAX endpoint.
- **Monitor and optimize** – After you switch to the new DAX cluster, closely monitor its performance metrics and logs for any issues. Be ready to adjust the number of nodes based on updated workload patterns.

  Until the new cluster caches your working dataset properly, you'll see higher cache miss rates and latencies.

- **Decommission old cluster** – When you're sure that the new cluster is performing as expected, safely decommission the old DAX cluster to avoid unnecessary costs.

Monitoring DAX

You can monitor key metrics, for example cache hit ratio, to ensure optimal DAX cluster performance, diagnose issues, and determine when you need to scale the cluster. Regularly checking key metrics helps you maintain performance, stability, and cost-efficiency by scaling the cluster to match your workload requirements. For more information about monitoring DAX, see Production monitoring.

The following list presents some of the key metrics you should monitor:

- **Cache hit ratio** – Shows how effectively DAX serves cached data, reducing the need to access the underlying DynamoDB tables. Few cache misses for the cluster indicate good caching efficiency. But few cache hits suggest that you might need to revisit the caching TTL setting or the workload isn't a good fit for caching.

  Use Amazon CloudWatch to calculate your DAX cluster's cache hit ratio. Compare the `ItemCacheHits`, `ItemCacheMisses`, `QueryCacheHits`, and `QueryCacheMisses` metrics to get this ratio. The following formula shows how the cache hit ratio is calculated. To calculate the ratio using this formula, divide your cache hits by the sum of your cache hits and misses.

  ```
  Cache hit ratio = Cache hits / (Cache hits + Cache misses)
  ```

  The cache hit ratio is a number between 0 and 1, which is represented as a percentage. A higher percentage indicates better overall cache utilization.
- **ErrorRequestCount** – Count of requests that resulted in user errors reported by the node or cluster. `ErrorRequestCount` includes requests that were throttled by the node or cluster. Monitoring user errors can help you identify scaling misconfigurations or hot item/partition patterns in your application.
- **Operation latencies** – Monitoring the latency of read and write operations to and from the DAX cluster can help you in identifying performance bottlenecks. Increasing latencies might indicate issues with your DAX cluster configuration, network, or the need to scale.
- **Network consumption** – Keep an eye on the `NetworkBytesIn` and `NetworkBytesOut` metrics to monitor your DAX cluster's network traffic. An unexpected increase in network throughput

could mean more client requests or inefficient query patterns that are causing more data to be transferred.

Monitoring network consumption helps you manage costs for your DAX cluster. It also ensures the network doesn't become a bottleneck for cluster performance.

- **Eviction rate** – Shows how often items are removed from your cache to make room for new items. If the eviction rate increases over time, your cache might be too small or your caching strategy isn't effective.

  Monitor the `EvictedSize` metric in CloudWatch to determine if your cache size is adequate for your workload. If the total evicted size keeps growing, you might need to scale up your DAX cluster to accommodate a larger cache.

- **CPU utilization** – Refers to the percentage of CPU utilization of the node or cluster. This is a critical metric to monitor for any database or caching system. High CPU utilization could mean your DAX cluster might be overloaded and needs scaling to handle the increased demand.

  Monitor the `CPUUtilization` metric for your DAX cluster. If your CPU utilization consistently approaches or exceeds 70-80%, consider scaling up your DAX cluster as described in the following section.

  If the number of requests sent to DAX exceeds a node's capacity, DAX limits the rate at which it accepts additional requests. It does this by returning a ThrottlingException. DAX continuously evaluates your cluster's CPU utilization to determine the request volume it can process while maintaining a healthy cluster state.

  You can monitor the `ThrottledRequestCount` metric that DAX publishes to CloudWatch. If you see these exceptions regularly, you should consider scaling up your cluster.

Scaling your DAX cluster using monitoring data

You can determine if you need to scale up or down your DAX cluster by monitoring its performance metrics.

- **Scale up or out** – If your DAX cluster has high CPU utilization, low cache hits (after optimizing the caching strategy), or high operation latencies, you should scale up your cluster. Adding more nodes, also called scaling out, can help distribute the load more evenly. For workloads with increasing writes per second, you might need to choose more powerful nodes (scaling up).

- **Scale down** – If you consistently see low CPU utilization and operation latencies below your thresholds, you might have over-provisioned resources. In such cases, scale down nodes to reduce costs. You can reduce the number of nodes down to 1 during low utilization periods, but you can't shut the cluster down entirely.

Using DynamoDB with other AWS services

Amazon DynamoDB is integrated with other AWS services, letting you automate repeating tasks or build applications that span multiple services.

Configuring AWS credentials using Amazon Cognito for DynamoDB

The recommended way to obtain AWS credentials for your web and mobile applications is to use Amazon Cognito. Amazon Cognito helps you avoid hardcoding your AWS credentials on your files. It uses AWS Identity and Access Management (IAM) roles to generate temporary credentials for your application's authenticated and unauthenticated users.

For example, to configure your JavaScript files to use an Amazon Cognito unauthenticated role to access the Amazon DynamoDB web service, do the following.

To configure credentials to integrate with Amazon Cognito

1. Create an Amazon Cognito identity pool that allows unauthenticated identities.

```
aws cognito-identity create-identity-pool \
    --identity-pool-name DynamoPool \
    --allow-unauthenticated-identities \
    --output json
```

```
{
    "IdentityPoolId": "us-west-2:12345678-1ab2-123a-1234-a12345ab12",
    "AllowUnauthenticatedIdentities": true,
    "IdentityPoolName": "DynamoPool"
}
```

2. Copy the following policy into a file named `myCognitoPolicy.json`. Replace the identity pool ID (*us-west-2:12345678-1ab2-123a-1234-a12345ab12*) with your own `IdentityPoolId` obtained in the previous step.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Federated": "cognito-identity.amazonaws.com"
      },
      "Action": "sts:AssumeRoleWithWebIdentity",
      "Condition": {
        "StringEquals": {
          "cognito-identity.amazonaws.com:aud": "us-west-2:12345678-1ab2-123a-1234-
a12345ab12"
        },
        "ForAnyValue:StringLike": {
          "cognito-identity.amazonaws.com:amr": "unauthenticated"
        }
      }
    }
  ]
}
```

3. Create an IAM role that assumes the previous policy. In this way, Amazon Cognito becomes a trusted entity that can assume the `Cognito_DynamoPoolUnauth` role.

```
aws iam create-role --role-name Cognito_DynamoPoolUnauth \
--assume-role-policy-document file://PathToFile/myCognitoPolicy.json --output json
```

4. Grant the `Cognito_DynamoPoolUnauth` role full access to DynamoDB by attaching a managed policy (`AmazonDynamoDBFullAccess`).

```
aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/
AmazonDynamoDBFullAccess \
--role-name Cognito_DynamoPoolUnauth
```

> **Note**
>
> Alternatively, you can grant fine-grained access to DynamoDB. For more information, see Using IAM policy conditions for fine-grained access control.

5. Obtain and copy the IAM role Amazon Resource Name (ARN).

```
aws iam get-role --role-name Cognito_DynamoPoolUnauth --output json
```

6. Add the `Cognito_DynamoPoolUnauth` role to the `DynamoPool` identity pool. The format to specify is `KeyName=string`, where `KeyName` is `unauthenticated` and the string is the role ARN obtained in the previous step.

```
aws cognito-identity set-identity-pool-roles \
--identity-pool-id "us-west-2:12345678-1ab2-123a-1234-a12345ab12" \
--roles unauthenticated=arn:aws:iam::123456789012:role/Cognito_DynamoPoolUnauth --
output json
```

7. Specify the Amazon Cognito credentials in your files. Modify the `IdentityPoolId` and `RoleArn` accordingly.

```
AWS.config.credentials = new AWS.CognitoIdentityCredentials({
IdentityPoolId: "us-west-2:12345678-1ab2-123a-1234-a12345ab12",
RoleArn: "arn:aws:iam::123456789012:role/Cognito_DynamoPoolUnauth"
});
```

You can now run your JavaScript programs against the DynamoDB web service using Amazon Cognito credentials. For more information, see Setting credentials in a web browser in the *AWS SDK for JavaScript Getting Started Guide*.

Integrating with Amazon Redshift

Amazon Redshift is a fast, fully managed, petabyte-scale data warehouse service that makes it simple and cost-effective to efficiently analyze all your data using your existing business intelligence tools.

DynamoDB and Amazon Redshift can be used together to address different data storage and processing needs within an application or data ecosystem.

See the topics below for more detailed topics on how to integrate DynamoDB with Amazon Redshift.

Topics

- DynamoDB zero-ETL integration with Amazon Redshift
- Loading data from DynamoDB into Amazon Redshift with the COPY command

DynamoDB zero-ETL integration with Amazon Redshift

Amazon DynamoDB zero-ETL integration with Amazon Redshift enables seamless analytics on DynamoDB data without any coding. This fully-managed feature automatically replicates DynamoDB tables into an Amazon Redshift database so users can run SQL queries and analytics on their DynamoDB data without having to set up complex ETL processes. The integration works by replicating data from the DynamoDB table to the Amazon Redshift database.

To set up the integration, simply specify a DynamoDB table as the source and an Amazon Redshift database as the target. On activation, the integration exports the full DynamoDB table to populate the Amazon Redshift database. The time it takes for this initial process to complete depends on the DynamoDB table size. The zero-ETL integration then incrementally replicates updates from DynamoDB to Amazon Redshift every 15-30 minutes using DynamoDB incremental exports. This means the replicated DynamoDB data in Amazon Redshift is kept up-to-date automatically.

Once configured, users can analyze the DynamoDB data in Amazon Redshift using standard SQL clients and tools, without impacting DynamoDB table performance. By eliminating cumbersome ETL, this zero-ETL integration provides a fast, easy way to unlock insights from DynamoDB through Amazon Redshift analytics and machine learning capabilities.

Topics

- Prerequisites before creating a DynamoDB zero-ETL integration with Amazon Redshift

- Limitations when using DynamoDB zero-ETL integrations with Amazon Redshift
- Creating a DynamoDB zero-ETL integration with Amazon Redshift
- Viewing DynamoDB zero-ETL integrations with Amazon Redshift
- Deleting DynamoDB zero-ETL integrations with Amazon Redshift

Prerequisites before creating a DynamoDB zero-ETL integration with Amazon Redshift

1. You must have your source DynamoDB table and target Amazon Redshift cluster created before creating an integration. This information is covered in Step 1: Configuring a source DynamoDB table and Step 2: Creating an Amazon Redshift data warehouse.
2. A zero-ETL integration between Amazon DynamoDB and Amazon Redshift requires your source DynamoDB table to have Point-in-time recovery (PITR) enabled.
3. For **resource-based policies**, if you create the integration where your DynamoDB table and Amazon Redshift data warehouse are in the same account, you can use the **Fix it for me** option during the create integration step to automatically apply the required resource policies to both DynamoDB and Amazon Redshift.

   If you create an integration where your DynamoDB table and Amazon Redshift data warehouse are in different AWS accounts, you will need to apply the following resource policy on your DynamoDB table.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Statement that allows Amazon Redshift service to DescribeTable
 and ExportTable",
            "Effect": "Allow",
            "Principal": {
                "Service": "redshift.amazonaws.com"
            },
            "Action": [
                "dynamodb:ExportTableToPointInTime",
                "dynamodb:DescribeTable"
            ],
            "Resource": "*",
            "Condition": {
```

```
                "StringEquals": {
                    "aws:SourceAccount": "<account>"
                },
                "ArnEquals": {
                    "aws:SourceArn":
 "arn:aws:redshift:<region>:<account>:integration:*"
                }
            }
        },
        {
            "Sid": "Statement that allows Amazon Redshift service to see all exports
 performed on the table",
            "Effect": "Allow",
            "Principal": {
                "Service": "redshift.amazonaws.com"
            },
            "Action": "dynamodb:DescribeExport",
            "Resource": "arn:aws:dynamodb:<region>:<account>:table/<table-name>/
export/*",
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "<account>"
                },
                "ArnEquals": {
                    "aws:SourceArn":
 "arn:aws:redshift:<region>:<account>:integration:*"
                }
            }
        }
    ]
}
```

You may also need to configure the resource policy on your Amazon Redshift data warehouse. For more information, see Configure authorization using the Amazon Redshift API.

4. **For Identity-based policies:**

   a. The user creating the integration requires an identity-based policy that authorizes the following actions: `GetResourcePolicy`, `PutResourcePolicy`, and `UpdateContinuousBackups`.

> **Note**
>
> The following policy examples will show the resource as `arn:aws:redshift{-serverless}`. This is an example to show that the arn can be either `arn:aws:redshift` or `arn:aws:redshift-serverless` depending on if your namespace is an Amazon Redshift cluster or Amazon Redshift Serverless namespace.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "dynamodb:ListTables"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "dynamodb:GetResourcePolicy",
                "dynamodb:PutResourcePolicy",
                "dynamodb:UpdateContinuousBackups"
            ],
            "Resource": [
                "arn:aws:dynamodb:<region>:<account>:table/<table-name>"
            ]
        },
        {
            "Sid": "AllowRedshiftDescribeIntegration",
            "Effect": "Allow",
            "Action": [
                "redshift:DescribeIntegrations"
            ],
            "Resource": "*"
        },
        {
            "Sid": "AllowRedshiftCreateIntegration",
            "Effect": "Allow",
            "Action": "redshift:CreateIntegration",
```

```
            "Resource": "arn:aws:redshift:<region>:<account>:integration:*"
        },
        {
            "Sid": "AllowRedshiftModifyDeleteIntegration",
            "Effect": "Allow",
            "Action": [
                "redshift:ModifyIntegration",
                "redshift:DeleteIntegration"
            ],
            "Resource": "arn:aws:redshift:<region>:<account>:integration:<uuid>"
        },
        {
            "Sid": "AllowRedshiftCreateInboundIntegration",
            "Effect": "Allow",
            "Action": "redshift:CreateInboundIntegration",
            "Resource":
            // The Amazon Resource Name (arn) for a Redshift provisioned cluster
 and a Redshift Serverless namespace have different formats.
            // Choose the one that applies to you:
            "arn:aws:redshift:<region>:<account>:namespace:<uuid>"
            "arn:aws:redshift-serverless:<region>:<account>:namespace/<uuid>"
        }
    ]
}
```

b. The user responsible for configuring the destination Amazon Redshift namespace requires an identity-based policy that authorizes the following actions: `PutResourcePolicy`, `DeleteResourcePolicy`, and `GetResourcePolicy`.

```
{
  "Statement": [
    # This statement authorizes the user to change, view or remove resource
 policies on a specific namespace
    {
       "Effect": "Allow",
       "Action": [
           "redshift:PutResourcePolicy",
           "redshift:DeleteResourcePolicy",
           "redshift:GetResourcePolicy"
       ],
       "Resource": [
           "arn:aws:redshift{-serverless}:<region>:<account>:namespace/
ExampleNamespace"
```

```
        ]
    },
    # This statement authorizes the user to view integrations connected to any
 target namespaces in the account
    {
        "Effect": "Allow",
        "Action": [
            "redshift:DescribeInboundIntegrations"
        ],
        "Resource": [
            "arn:aws:redshift{-serverless}:<region>:<account>:namespace/*"
        ]
    }
  ],
  "Version": "2012-10-17"
}
```

5. **Encryption key permissions**

   If the source DynamoDB table is encrypted using customer managed AWS KMS key, you will need to add the following policy on your KMS key. This policy allows Amazon Redshift to be able to export data from your encrypted table using your KMS key.

```
{
    "Sid": "Statement to allow Amazon Redshift service to perform Decrypt operation
 on the source DynamoDB Table",
    "Effect": "Allow",
    "Principal": {
        "Service": [
            "redshift.amazonaws.com"
        ]
    },
    "Action": "kms:Decrypt",
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "aws:SourceAccount": "<account>"
        },
        "ArnEquals": {
            "aws:SourceArn": "arn:aws:redshift:<region>:<account>:integration:*"
        }
    }
}
```

You can also follow the steps on Getting started with zero-ETL integrations in the Amazon Redshift management guide to configure the permissions of the Amazon Redshift namespace.

Limitations when using DynamoDB zero-ETL integrations with Amazon Redshift

The following general limitations apply to the current release of this integration. These limitations can change in subsequent releases.

> **Note**
>
> In addition to the limitations below, also review the general considerations when using zero-ETL integrations see Considerations when using zero-ETL integrations with Amazon Redshift in the *Amazon Redshift Management Guide*.

- The DynamoDB table and Amazon Redshift cluster need to be in the same Region.
- The source DynamoDB table must be encrypted with either an Amazon-owned or Customer-managed AWS KMS key. Amazon managed encryption is not supported for the source DynamoDB table.

Creating a DynamoDB zero-ETL integration with Amazon Redshift

Before creating a zero-ETL integration, you must first set up your source DynamoDB table and then the target Amazon Redshift data warehouse.

Step 1: Configuring a source DynamoDB table

To create a zero-ETL integration with Amazon Redshift, you need to enable point-in-time recovery (PITR) on your table. If you do not have PITR turned on, the console can fix this for you during the integration setup process. For details on how to enable PITR, see Point-in-time recovery.

Step 2: Creating an Amazon Redshift data warehouse

If you don't already have an Amazon Redshift data warehouse, you can create one. To create an Amazon Redshift Serverless workgroup, see Creating a workgroup with a namespace. To create an Amazon Redshift cluster, see Creating a cluster.

The target Amazon Redshift workgroup or cluster must have the enable_case_sensitive_identifier parameter turned on for the integration to be successful. For more information on enabling

case sensitivity, see Turn on case sensitivity for your data warehouse in the Amazon Redshift management guide.

After the Amazon Redshift workgroup or cluster setup is complete, you need to configure your data warehouse. See Zero-ETL integrations in the Amazon Redshift Management Guide for more information.

Step 3: Creating a DynamoDB zero-ETL integration

Before you create a zero-ETL integration, make sure to complete the tasks in the section titled Prerequisites before creating a DynamoDB zero-ETL integration with Amazon Redshift. Creating an integration between DynamoDB and Amazon Redshift is a two-step process. First create an integration from the DynamoDB, and then attach a Amazon Redshift database to this newly created integration.

Create a zero-ETL integration

1. Sign in to the AWS Management Console and open the Amazon DynamoDB console at https://console.aws.amazon.com/dynamodbv2.
2. In the navigation pane, choose **Integrations**.
3. Select **Create zero-ETL integration** and choose **Amazon Redshift**.
4. This will take you to the **Amazon Redshift console**. To continue with the procedure, see the **DynamoDB section** in Create a zero-ETL integration for DynamoDB.

Viewing DynamoDB zero-ETL integrations with Amazon Redshift

You can view the details of a zero-ETL integration to see its configuration information and current status.

To view the details of a zero-ETL integration in the Amazon DynamoDB console:

1. Sign in to the AWS Management Console and open the Amazon DynamoDB console at https://console.aws.amazon.com/dynamodbv2.
2. In the DynamoDB console, choose **Integrations**.
3. In the **Zero-ETL integration** pane, select the zero-ETL integration you want to view.

To view the details of a zero-ETL integration in the Amazon Redshift console:

1. Sign in to the AWS Management Console and open the Amazon Redshift console at https://console.aws.amazon.com/redshiftv2.
2. Follow the steps at Viewing zero-ETL integrations.

> **Note**
>
> The possible statuses of a zero-ETL integration with Amazon Redshift are listed in Viewing zero-ETL integrations in the *Amazon Redshift Management Guide*.

Deleting DynamoDB zero-ETL integrations with Amazon Redshift

When you delete a zero-ETL integration, your data isn't deleted from DynamoDB or Amazon Redshift, but DynamoDB stops sending data from your source table to the Amazon Redshift target.

To delete a zero-ETL integration

1. Sign in to the AWS Management Console and open the Amazon DynamoDB console at https://console.aws.amazon.com/dynamodbv2.
2. In the DynamoDB console, choose **Integrations**.
3. In the **Zero-ETL integration** pane, select the zero-ETL integration you want to delete.
4. Choose **Manage**. This will take you to the integration details page.
5. To confirm the deletion, choose **Delete**.

Loading data from DynamoDB into Amazon Redshift with the COPY command

Amazon Redshift works with Amazon DynamoDB with advanced business intelligence capabilities and a powerful SQL-based interface. When you copy data from a DynamoDB table into Amazon Redshift, you can perform complex data analysis queries on that data, including joins with other tables in your Amazon Redshift cluster.

In terms of provisioned throughput, a copy operation from a DynamoDB table counts against that table's read capacity. After the data is copied, your SQL queries in Amazon Redshift do not affect

DynamoDB in any way. This is because your queries act upon a copy of the data from DynamoDB, rather than upon DynamoDB itself.

Before you can load data from a DynamoDB table, you must first create an Amazon Redshift table to serve as the destination for the data. Keep in mind that you are copying data from a NoSQL environment into a SQL environment, and that there are certain rules in one environment that do not apply in the other. Here are some of the differences to consider:

- DynamoDB table names can contain up to 255 characters, including '.' (dot) and '-' (dash) characters, and are case-sensitive. Amazon Redshift table names are limited to 127 characters, cannot contain dots or dashes and are not case-sensitive. In addition, table names cannot conflict with any Amazon Redshift reserved words.
- DynamoDB does not support the SQL concept of NULL. You need to specify how Amazon Redshift interprets empty or blank attribute values in DynamoDB, treating them either as NULLs or as empty fields.
- DynamoDB data types do not correspond directly with those of Amazon Redshift. You need to ensure that each column in the Amazon Redshift table is of the correct data type and size to accommodate the data from DynamoDB.

Here is an example COPY command from Amazon Redshift SQL:

```
copy favoritemovies from 'dynamodb://my-favorite-movies-table'
credentials 'aws_access_key_id=<Your-Access-Key-ID>;aws_secret_access_key=<Your-Secret-
Access-Key>'
readratio 50;
```

In this example, the source table in DynamoDB is `my-favorite-movies-table`. The target table in Amazon Redshift is `favoritemovies`. The `readratio 50` clause regulates the percentage of provisioned throughput that is consumed; in this case, the COPY command will use no more than 50 percent of the read capacity units provisioned for `my-favorite-movies-table`. We highly recommend setting this ratio to a value less than the average unused provisioned throughput.

For detailed instructions on loading data from DynamoDB into Amazon Redshift, refer to the following sections in the *Amazon Redshift Database Developer Guide*:

- Loading data from a DynamoDB table
- The COPY command
- COPY examples

Processing DynamoDB data with Apache Hive on Amazon EMR

Amazon DynamoDB is integrated with Apache Hive, a data warehousing application that runs on Amazon EMR. Hive can read and write data in DynamoDB tables, allowing you to:

- Query live DynamoDB data using a SQL-like language (HiveQL).
- Copy data from a DynamoDB table to an Amazon S3 bucket, and vice-versa.
- Copy data from a DynamoDB table into Hadoop Distributed File System (HDFS), and vice-versa.
- Perform join operations on DynamoDB tables.

Topics

- Overview
- Tutorial: Working with Amazon DynamoDB and Apache Hive
- Creating an external table in Hive
- Processing HiveQL statements
- Querying data in DynamoDB
- Copying data to and from Amazon DynamoDB
- Performance tuning

Overview

Amazon EMR is a service that makes it easy to quickly and cost-effectively process vast amounts of data. To use Amazon EMR, you launch a managed cluster of Amazon EC2 instances running the Hadoop open source framework. *Hadoop* is a distributed application that implements the MapReduce algorithm, where a task is mapped to multiple nodes in the cluster. Each node processes its designated work, in parallel with the other nodes. Finally, the outputs are reduced on a single node, yielding the final result.

You can choose to launch your Amazon EMR cluster so that it is persistent or transient:

- A *persistent* cluster runs until you shut it down. Persistent clusters are ideal for data analysis, data warehousing, or any other interactive use.
- A *transient* cluster runs long enough to process a job flow, and then shuts down automatically. Transient clusters are ideal for periodic processing tasks, such as running scripts.

For information about Amazon EMR architecture and administration, see the Amazon EMR Management Guide.

When you launch an Amazon EMR cluster, you specify the initial number and type of Amazon EC2 instances. You also specify other distributed applications (in addition to Hadoop itself) that you want to run on the cluster. These applications include Hue, Mahout, Pig, Spark, and more.

For information about applications for Amazon EMR, see the Amazon EMR Release Guide.

Depending on the cluster configuration, you might have one or more of the following node types:

- Leader node — Manages the cluster, coordinating the distribution of the MapReduce executable and subsets of the raw data, to the core and task instance groups. It also tracks the status of each task performed and monitors the health of the instance groups. There is only one leader node in a cluster.
- Core nodes — Runs MapReduce tasks and stores data using the Hadoop Distributed File System (HDFS).
- Task nodes (optional) — Runs MapReduce tasks.

Tutorial: Working with Amazon DynamoDB and Apache Hive

In this tutorial, you will launch an Amazon EMR cluster, and then use Apache Hive to process data stored in a DynamoDB table.

Hive is a data warehouse application for Hadoop that allows you to process and analyze data from multiple sources. Hive provides a SQL-like language, *HiveQL*, that lets you work with data stored locally in the Amazon EMR cluster or in an external data source (such as Amazon DynamoDB).

For more information, see to the Hive Tutorial.

Topics

- Before you begin
- Step 1: Create an Amazon EC2 key pair
- Step 2: Launch an Amazon EMR cluster
- Step 3: Connect to the Leader node
- Step 4: Load data into HDFS

- Step 5: Copy data to DynamoDB
- Step 6: Query the data in the DynamoDB table
- Step 7: (Optional) clean up

Before you begin

For this tutorial, you will need the following:

- An AWS account. If you do not have one, see Signing up for AWS.
- An SSH client (Secure Shell). You use the SSH client to connect to the leader node of the Amazon EMR cluster and run interactive commands. SSH clients are available by default on most Linux, Unix, and Mac OS X installations. Windows users can download and install the PuTTY client, which has SSH support.

Next step

Step 1: Create an Amazon EC2 key pair

Step 1: Create an Amazon EC2 key pair

In this step, you will create the Amazon EC2 key pair you need to connect to an Amazon EMR leader node and run Hive commands.

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose a region (for example, `US West (Oregon)`). This should be the same region in which your DynamoDB table is located.
3. In the navigation pane, choose **Key Pairs**.
4. Choose **Create Key Pair**.
5. In **Key pair name**, type a name for your key pair (for example, `mykeypair`), and then choose **Create**.
6. Download the private key file. The file name will end with `.pem` (such as `mykeypair.pem`). Keep this private key file in a safe place. You will need it to access any Amazon EMR cluster that you launch with this key pair.

> **Important**
>
> If you lose the key pair, you cannot connect to the leader node of your Amazon EMR cluster.

For more information about key pairs, see Amazon EC2 Key Pairs in the *Amazon EC2 User Guide*.

Next step

Step 2: Launch an Amazon EMR cluster

Step 2: Launch an Amazon EMR cluster

In this step, you will configure and launch an Amazon EMR cluster. Hive and a storage handler for DynamoDB will already be installed on the cluster.

1. Open the Amazon EMR console at https://console.aws.amazon.com/emr.
2. Choose **Create Cluster**.
3. On the **Create Cluster - Quick Options** page, do the following:
   a. In **Cluster name**, type a name for your cluster (for example: `My EMR cluster`).
   b. In **EC2 key pair**, choose the key pair you created earlier.

   Leave the other settings at their defaults.
4. Choose **Create cluster**.

It will take several minutes to launch your cluster. You can use the **Cluster Details** page in the Amazon EMR console to monitor its progress.

When the status changes to `Waiting`, the cluster is ready for use.

Cluster log files and Amazon S3

An Amazon EMR cluster generates log files that contain information about the cluster status and debugging information. The default settings for **Create Cluster - Quick Options** include setting up Amazon EMR logging.

If one does not already exist, the AWS Management Console creates an Amazon S3 bucket. The bucket name is `aws-logs-`*`account-id`*`-`*`region`*, where *`account-id`* is your AWS account number and *`region`* is the region in which you launched the cluster (for example, `aws-logs-123456789012-us-west-2`).

> **Note**
>
> You can use the Amazon S3 console to view the log files. For more information, see View Log Files in the *Amazon EMR Management Guide*.

You can use this bucket for purposes in addition to logging. For example, you can use the bucket as a location for storing a Hive script or as a destination when exporting data from Amazon DynamoDB to Amazon S3.

Next step

Step 3: Connect to the Leader node

Step 3: Connect to the Leader node

When the status of your Amazon EMR cluster changes to `Waiting`, you will be able to connect to the leader node using SSH and perform command line operations.

1. In the Amazon EMR console, choose your cluster's name to view its status.
2. On the **Cluster Details** page, find the **Leader public DNS** field. This is the public DNS name for the leader node of your Amazon EMR cluster.
3. To the right of the DNS name, choose the **SSH** link.
4. Follow the instructions in **Connect to the Leader Node Using SSH** .

   Depending on your operating system, choose the **Windows** tab or the **Mac/Linux** tab, and follow the instructions for connecting to the leader node.

After you connect to the leader node using either SSH or PuTTY, you should see a command prompt similar to the following:

```
[hadoop@ip-192-0-2-0 ~]$
```

Next step

Step 4: Load data into HDFS

Step 4: Load data into HDFS

In this step, you will copy a data file into Hadoop Distributed File System (HDFS), and then create an external Hive table that maps to the data file.

Download the sample data

1. Download the sample data archive (`features.zip`):

   ```
   wget https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/samples/
   features.zip
   ```

2. Extract the `features.txt` file from the archive:

   ```
   unzip features.zip
   ```

3. View the first few lines of the `features.txt` file:

   ```
   head features.txt
   ```

   The result should look similar to this:

   ```
   1535908|Big Run|Stream|WV|38.6370428|-80.8595469|794
   875609|Constable Hook|Cape|NJ|40.657881|-74.0990309|7
   1217998|Gooseberry Island|Island|RI|41.4534361|-71.3253284|10
   26603|Boone Moore Spring|Spring|AZ|34.0895692|-111.410065|3681
   1506738|Missouri Flat|Flat|WA|46.7634987|-117.0346113|2605
   1181348|Minnow Run|Stream|PA|40.0820178|-79.3800349|1558
   1288759|Hunting Creek|Stream|TN|36.343969|-83.8029682|1024
   533060|Big Charles Bayou|Bay|LA|29.6046517|-91.9828654|0
   829689|Greenwood Creek|Stream|NE|41.596086|-103.0499296|3671
   541692|Button Willow Island|Island|LA|31.9579389|-93.0648847|98
   ```

The `features.txt` file contains a subset of data from the United States Board on Geographic Names (http://geonames.usgs.gov/domestic/download_data.htm). The fields in each line represent the following:

- Feature ID (unique identifier)
- Name
- Class (lake; forest; stream; and so on)
- State
- Latitude (degrees)
- Longitude (degrees)
- Height (in feet)

4. At the command prompt, enter the following command:

```
hive
```

The command prompt changes to this: `hive>`

5. Enter the following HiveQL statement to create a native Hive table:

```
CREATE TABLE hive_features
    (feature_id             BIGINT,
    feature_name            STRING ,
    feature_class           STRING ,
    state_alpha             STRING,
    prim_lat_dec            DOUBLE ,
    prim_long_dec           DOUBLE ,
    elev_in_ft              BIGINT)
    ROW FORMAT DELIMITED
    FIELDS TERMINATED BY '|'
    LINES TERMINATED BY '\n';
```

6. Enter the following HiveQL statement to load the table with data:

```
LOAD DATA
LOCAL
INPATH './features.txt'
OVERWRITE
INTO TABLE hive_features;
```

7. You now have a native Hive table populated with data from the `features.txt` file. To verify, enter the following HiveQL statement:

```
SELECT state_alpha, COUNT(*)
FROM hive_features
GROUP BY state_alpha;
```

   The output should show a list of states and the number of geographic features in each.

Next step

Step 5: Copy data to DynamoDB

Step 5: Copy data to DynamoDB

In this step, you will copy data from the Hive table (`hive_features`) to a new table in DynamoDB.

1. Open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. Choose **Create Table**.
3. On the **Create DynamoDB table** page, do the following:

   a. In **Table**, type **`Features`**.

   b. For **Primary key**, in the **Partition key** field, type **`Id`**. Set the data type to **Number**.

   Clear **Use Default Settings**. For **Provisioned Capacity**, type the following:

   - **Read Capacity Units**—`10`
   - **Write Capacity Units**—`10`

   Choose **Create**.
4. At the Hive prompt, enter the following HiveQL statement:

```
CREATE EXTERNAL TABLE ddb_features
    (feature_id   BIGINT,
    feature_name  STRING,
    feature_class STRING,
    state_alpha   STRING,
    prim_lat_dec  DOUBLE,
```

```
    prim_long_dec DOUBLE,
    elev_in_ft    BIGINT)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES(
    "dynamodb.table.name" = "Features",

 "dynamodb.column.mapping"="feature_id:Id,feature_name:Name,feature_class:Class,state_alpha
);
```

You have now established a mapping between Hive and the Features table in DynamoDB.

5. Enter the following HiveQL statement to import data to DynamoDB:

```
INSERT OVERWRITE TABLE ddb_features
SELECT
    feature_id,
    feature_name,
    feature_class,
    state_alpha,
    prim_lat_dec,
    prim_long_dec,
    elev_in_ft
FROM hive_features;
```

Hive will submit a MapReduce job, which will be processed by your Amazon EMR cluster. It will take several minutes to complete the job.

6. Verify that the data has been loaded into DynamoDB:

   a. In the DynamoDB console navigation pane, choose **Tables**.

   b. Choose the Features table, and then choose the **Items** tab to view the data.

Next step

Step 6: Query the data in the DynamoDB table

Step 6: Query the data in the DynamoDB table

In this step, you will use HiveQL to query the Features table in DynamoDB. Try the following Hive queries:

1. All of the feature types (`feature_class`) in alphabetical order:

```
SELECT DISTINCT feature_class
FROM ddb_features
ORDER BY feature_class;
```

2. All of the lakes that begin with the letter "M":

```
SELECT feature_name, state_alpha
FROM ddb_features
WHERE feature_class = 'Lake'
AND feature_name LIKE 'M%'
ORDER BY feature_name;
```

3. States with at least three features higher than a mile (5,280 feet):

```
SELECT state_alpha, feature_class, COUNT(*)
FROM ddb_features
WHERE elev_in_ft > 5280
GROUP by state_alpha, feature_class
HAVING COUNT(*) >= 3
ORDER BY state_alpha, feature_class;
```

Next step

Step 7: (Optional) clean up

Step 7: (Optional) clean up

Now that you have completed the tutorial, you can continue reading this section to learn more about working with DynamoDB data in Amazon EMR. You might decide to keep your Amazon EMR cluster up and running while you do this.

If you don't need the cluster anymore, you should terminate it and remove any associated resources. This will help you avoid being charged for resources you don't need.

1. Terminate the Amazon EMR cluster:

   a. Open the Amazon EMR console at https://console.aws.amazon.com/emr.

   b. Choose the Amazon EMR cluster, choose **Terminate**, and then confirm.

2. Delete the Features table in DynamoDB:

a. Open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
b. In the navigation pane, choose **Tables**.
c. Choose the Features table. From the **Actions** menu, choose **Delete Table**.

3. Delete the Amazon S3 bucket containing the Amazon EMR log files:

a. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
b. From the list of buckets, choose `aws-logs-` *`accountID`*`-`*`region`*, where *`accountID`* is your AWS account number and *`region`* is the region in which you launched the cluster.
c. From the **Action** menu, choose **Delete**.

Creating an external table in Hive

In Tutorial: Working with Amazon DynamoDB and Apache Hive, you created an external Hive table that mapped to a DynamoDB table. When you issued HiveQL statements against the external table, the read and write operations were passed through to the DynamoDB table.

You can think of an external table as a pointer to a data source that is managed and stored elsewhere. In this case, the underlying data source is a DynamoDB table. (The table must already exist. You cannot create, update, or delete a DynamoDB table from within Hive.) You use the `CREATE EXTERNAL TABLE` statement to create the external table. After that, you can use HiveQL to work with data in DynamoDB, as if that data were stored locally within Hive.

> **Note**
>
> You can use `INSERT` statements to insert data into an external table and `SELECT` statements to select data from it. However, you cannot use `UPDATE` or `DELETE` statements to manipulate data in the table.

If you no longer need the external table, you can remove it using the `DROP TABLE` statement. In this case, `DROP TABLE` only removes the external table in Hive. It does not affect the underlying DynamoDB table or any of its data.

Topics

- CREATE EXTERNAL TABLE syntax
- Data type mappings

CREATE EXTERNAL TABLE syntax

The following shows the HiveQL syntax for creating an external Hive table that maps to a DynamoDB table:

```
CREATE EXTERNAL TABLE hive_table

 (hive_column1_name hive_column1_datatype, hive_column2_name hive_column2_datatype...)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES (
    "dynamodb.table.name" = "dynamodb_table",
    "dynamodb.column.mapping" =
 "hive_column1_name:dynamodb_attribute1_name,hive_column2_name:dynamodb_attribute2_name..."
);
```

Line 1 is the start of the `CREATE EXTERNAL TABLE` statement, where you provide the name of the Hive table (*hive_table*) you want to create.

Line 2 specifies the columns and data types for *hive_table*. You need to define columns and data types that correspond to the attributes in the DynamoDB table.

Line 3 is the `STORED BY` clause, where you specify a class that handles data management between the Hive and the DynamoDB table. For DynamoDB, `STORED BY` should be set to `'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'`.

Line 4 is the start of the `TBLPROPERTIES` clause, where you define the following parameters for `DynamoDBStorageHandler`:

- `dynamodb.table.name`—the name of the DynamoDB table.
- `dynamodb.column.mapping`—pairs of column names in the Hive table and their corresponding attributes in the DynamoDB table. Each pair is of the form *hive_column_name:dynamodb_attribute_name*, and the pairs are separated by commas.

Note the following:

- The name of the Hive table name does not have to be the same as the DynamoDB table name.
- The Hive table column names do not have to be the same as those in the DynamoDB table.
- The table specified by `dynamodb.table.name` must exist in DynamoDB.

- For `dynamodb.column.mapping`:
  - You must map the key schema attributes for the DynamoDB table. This includes the partition key and the sort key (if present).
  - You do not have to map the non-key attributes of the DynamoDB table. However, you will not see any data from those attributes when you query the Hive table.
  - If the data types of a Hive table column and a DynamoDB attribute are incompatible, you will see `NULL` in these columns when you query the Hive table.

> **Note**
>
> The `CREATE EXTERNAL TABLE` statement does not perform any validation on the `TBLPROPERTIES` clause. The values you provide for `dynamodb.table.name` and `dynamodb.column.mapping` are only evaluated by the `DynamoDBStorageHandler` class when you attempt to access the table.

Data type mappings

The following table shows DynamoDB data types and compatible Hive data types:

DynamoDB Data Type	Hive Data Type
String	`STRING`
Number	`BIGINT` or `DOUBLE`
Binary	`BINARY`
String Set	`ARRAY<STRING>`
Number Set	`ARRAY<BIGINT>` or `ARRAY<DOUBLE>`
Binary Set	`ARRAY<BINARY>`

Note

The following DynamoDB data types are not supported by the `DynamoDBStorageHandler` class, so they cannot be used with `dynamodb.column.mapping`:

- Map
- List
- Boolean
- Null

However, if you need to work with these data types, you can create a single entity called `item` that represents the entire DynamoDB item as a map of strings for both keys and values in the map. For more information, see Copying data without a column mapping

If you want to map a DynamoDB attribute of type Number, you must choose an appropriate Hive type:

- The Hive `BIGINT` type is for 8-byte signed integers. It is the same as the `long` data type in Java.
- The Hive `DOUBLE` type is for 8-bit double precision floating point numbers. It is the same as the `double` type in Java.

If you have numeric data stored in DynamoDB that has a higher precision than the Hive data type you choose, then accessing the DynamoDB data could cause a loss of precision.

If you export data of type Binary from DynamoDB to (Amazon S3) or HDFS, the data is stored as a Base64-encoded string. If you import data from Amazon S3 or HDFS into the DynamoDB Binary type, you must ensure the data is encoded as a Base64 string.

Processing HiveQL statements

Hive is an application that runs on Hadoop, which is a batch-oriented framework for running MapReduce jobs. When you issue a HiveQL statement, Hive determines whether it can return the results immediately or whether it must submit a MapReduce job.

For example, consider the *ddb_features* table (from Tutorial: Working with Amazon DynamoDB and Apache Hive). The following Hive query prints state abbreviations and the number of summits in each:

```
SELECT state_alpha, count(*)
FROM ddb_features
WHERE feature_class = 'Summit'
GROUP BY state_alpha;
```

Hive does not return the results immediately. Instead, it submits a MapReduce job, which is processed by the Hadoop framework. Hive will wait until the job is complete before it shows the results from the query:

```
AK  2
AL  2
AR  2
AZ  3
CA  7
CO  2
CT  2
ID  1
KS  1
ME  2
MI  1
MT  3
NC  1
NE  1
NM  1
NY  2
OR  5

Time taken: 8.753 seconds, Fetched: 25 row(s)
```

Monitoring and canceling jobs

When Hive launches a Hadoop job, it prints output from that job. The job completion status is updated as the job progresses. In some cases, the status might not be updated for a long time. (This can happen when you are querying a large DynamoDB table that has a low provisioned read capacity setting.)

If you need to cancel the job before it is complete, you can type **Ctrl+C** at any time.

Querying data in DynamoDB

The following examples show some ways that you can use HiveQL to query data stored in DynamoDB.

These examples refer to the *ddb_features* table in the tutorial (Step 5: Copy data to DynamoDB).

Topics

- Using aggregate functions
- Using the GROUP BY and HAVING clauses
- Joining two DynamoDB tables
- Joining tables from different sources

Using aggregate functions

HiveQL provides built-in functions for summarizing data values. For example, you can use the `MAX` function to find the largest value for a selected column. The following example returns the elevation of the highest feature in the state of Colorado.

```
SELECT MAX(elev_in_ft)
FROM ddb_features
WHERE state_alpha = 'CO';
```

Using the GROUP BY and HAVING clauses

You can use the `GROUP BY` clause to collect data across multiple records. This is often used with an aggregate function such as `SUM`, `COUNT`, `MIN`, or `MAX`. You can also use the `HAVING` clause to discard any results that do not meet certain criteria.

The following example returns a list of the highest elevations from states that have more than five features in the *ddb_features* table.

```
SELECT state_alpha, max(elev_in_ft)
FROM ddb_features
GROUP BY state_alpha
HAVING count(*) >= 5;
```

Joining two DynamoDB tables

The following example maps another Hive table (*east_coast_states*) to a table in DynamoDB. The SELECT statement is a join across these two tables. The join is computed on the cluster and returned. The join does not take place in DynamoDB.

Consider a DynamoDB table named EastCoastStates that contains the following data:

```
StateName       StateAbbrev

Maine           ME
New Hampshire   NH
Massachusetts   MA
Rhode Island    RI
Connecticut     CT
New York        NY
New Jersey      NJ
Delaware        DE
Maryland        MD
Virginia        VA
North Carolina  NC
South Carolina  SC
Georgia         GA
Florida         FL
```

Let's assume the table is available as a Hive external table named east_coast_states:

```
CREATE EXTERNAL TABLE ddb_east_coast_states (state_name STRING, state_alpha STRING)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "EastCoastStates",
"dynamodb.column.mapping" = "state_name:StateName,state_alpha:StateAbbrev");
```

The following join returns the states on the East Coast of the United States that have at least three features:

```
SELECT ecs.state_name, f.feature_class, COUNT(*)
FROM ddb_east_coast_states ecs
JOIN ddb_features f on ecs.state_alpha = f.state_alpha
GROUP BY ecs.state_name, f.feature_class
HAVING COUNT(*) >= 3;
```

Joining tables from different sources

In the following example, s3_east_coast_states is a Hive table associated with a CSV file stored in Amazon S3. The *ddb_features* table is associated with data in DynamoDB. The following example joins these two tables, returning the geographic features from states whose names begin with "New."

```
create external table s3_east_coast_states (state_name STRING, state_alpha STRING)
ROW FORMAT DELIMITED FIELDS TERMINATED BY ','
LOCATION 's3://bucketname/path/subpath/';
```

```
SELECT ecs.state_name, f.feature_name, f.feature_class
FROM s3_east_coast_states ecs
JOIN ddb_features f
ON ecs.state_alpha = f.state_alpha
WHERE ecs.state_name LIKE 'New%';
```

Copying data to and from Amazon DynamoDB

In the Tutorial: Working with Amazon DynamoDB and Apache Hive, you copied data from a native Hive table into an external DynamoDB table, and then queried the external DynamoDB table. The table is external because it exists outside of Hive. Even if you drop the Hive table that maps to it, the table in DynamoDB is not affected.

Hive is an excellent solution for copying data among DynamoDB tables, Amazon S3 buckets, native Hive tables, and Hadoop Distributed File System (HDFS). This section provides examples of these operations.

Topics

- Copying data between DynamoDB and a native Hive table
- Copying data between DynamoDB and Amazon S3
- Copying data between DynamoDB and HDFS

- Using data compression
- Reading non-printable UTF-8 character data

Copying data between DynamoDB and a native Hive table

If you have data in a DynamoDB table, you can copy the data to a native Hive table. This will give you a snapshot of the data, as of the time you copied it.

You might decide to do this if you need to perform many HiveQL queries, but do not want to consume provisioned throughput capacity from DynamoDB. Because the data in the native Hive table is a copy of the data from DynamoDB, and not "live" data, your queries should not expect that the data is up-to-date.

> **Note**
>
> The examples in this section are written with the assumption you followed the steps in Tutorial: Working with Amazon DynamoDB and Apache Hive and have an external table in DynamoDB named *ddb_features*.

Example From DynamoDB to native Hive table

You can create a native Hive table and populate it with data from *ddb_features*, like this:

```
CREATE TABLE features_snapshot AS
SELECT * FROM ddb_features;
```

You can then refresh the data at any time:

```
INSERT OVERWRITE TABLE features_snapshot
SELECT * FROM ddb_features;
```

In these examples, the subquery `SELECT * FROM ddb_features` will retrieve all of the data from *ddb_features*. If you only want to copy a subset of the data, you can use a `WHERE` clause in the subquery.

The following example creates a native Hive table, containing only some of the attributes for lakes and summits:

```
CREATE TABLE lakes_and_summits AS
SELECT feature_name, feature_class, state_alpha
FROM ddb_features
WHERE feature_class IN ('Lake','Summit');
```

Example From native Hive table to DynamoDB

Use the following HiveQL statement to copy the data from the native Hive table to *ddb_features*:

```
INSERT OVERWRITE TABLE ddb_features
SELECT * FROM features_snapshot;
```

Copying data between DynamoDB and Amazon S3

If you have data in a DynamoDB table, you can use Hive to copy the data to an Amazon S3 bucket.

You might do this if you want to create an archive of data in your DynamoDB table. For example, suppose you have a test environment where you need to work with a baseline set of test data in DynamoDB. You can copy the baseline data to an Amazon S3 bucket, and then run your tests. Afterward, you can reset the test environment by restoring the baseline data from the Amazon S3 bucket to DynamoDB.

If you worked through Tutorial: Working with Amazon DynamoDB and Apache Hive, then you already have an Amazon S3 bucket that contains your Amazon EMR logs. You can use this bucket for the examples in this section, if you know the root path for the bucket:

1. Open the Amazon EMR console at https://console.aws.amazon.com/emr.
2. For **Name**, choose your cluster.
3. The URI is listed in **Log URI** under **Configuration Details**.
4. Make a note of the root path of the bucket. The naming convention is:

   `s3://aws-logs-`*`accountID`*`-`*`region`*

   where *`accountID`* is your AWS account ID and region is the AWS region for the bucket.

> **Note**
>
> For these examples, we will use a subpath within the bucket, as in this example:

```
    s3://aws-logs-123456789012-us-west-2/hive-test
```

The following procedures are written with the assumption you followed the steps in the tutorial and have an external table in DynamoDB named *ddb_features*.

Topics

- Copying data using the Hive default format
- Copying data with a user-specified format
- Copying data without a column mapping
- Viewing the data in Amazon S3

Copying data using the Hive default format

Example From DynamoDB to Amazon S3

Use an `INSERT OVERWRITE` statement to write directly to Amazon S3.

```
INSERT OVERWRITE DIRECTORY 's3://aws-logs-123456789012-us-west-2/hive-test'
SELECT * FROM ddb_features;
```

The data file in Amazon S3 looks like this:

```
920709^ASoldiers Farewell Hill^ASummit^ANM^A32.3564729^A-108.33004616135
1178153^AJones Run^AStream^APA^A41.2120086^A-79.25920781260
253838^ASentinel Dome^ASummit^ACA^A37.7229821^A-119.584338133
264054^ANeversweet Gulch^AValley^ACA^A41.6565269^A-122.83614322900
115905^AChacaloochee Bay^ABay^AAL^A30.6979676^A-87.97388530
```

Each field is separated by an SOH character (start of heading, 0x01). In the file, SOH appears as **^A**.

Example From Amazon S3 to DynamoDB

1. Create an external table pointing to the unformatted data in Amazon S3.

```
CREATE EXTERNAL TABLE s3_features_unformatted
    (feature_id       BIGINT,
    feature_name      STRING ,
    feature_class     STRING ,
```

```
    state_alpha       STRING,
    prim_lat_dec      DOUBLE ,
    prim_long_dec     DOUBLE ,
    elev_in_ft        BIGINT)
LOCATION 's3://aws-logs-123456789012-us-west-2/hive-test';
```

2. Copy the data to DynamoDB.

```
INSERT OVERWRITE TABLE ddb_features
SELECT * FROM s3_features_unformatted;
```

Copying data with a user-specified format

If you want to specify your own field separator character, you can create an external table that maps to the Amazon S3 bucket. You might use this technique for creating data files with comma-separated values (CSV).

Example From DynamoDB to Amazon S3

1. Create a Hive external table that maps to Amazon S3. When you do this, ensure that the data types are consistent with those of the DynamoDB external table.

```
CREATE EXTERNAL TABLE s3_features_csv
    (feature_id       BIGINT,
    feature_name      STRING,
    feature_class     STRING,
    state_alpha       STRING,
    prim_lat_dec      DOUBLE,
    prim_long_dec     DOUBLE,
    elev_in_ft        BIGINT)
ROW FORMAT DELIMITED
FIELDS TERMINATED BY ','
LOCATION 's3://aws-logs-123456789012-us-west-2/hive-test';
```

2. Copy the data from DynamoDB.

```
INSERT OVERWRITE TABLE s3_features_csv
SELECT * FROM ddb_features;
```

The data file in Amazon S3 looks like this:

```
920709,Soldiers Farewell Hill,Summit,NM,32.3564729,-108.3300461,6135
1178153,Jones Run,Stream,PA,41.2120086,-79.2592078,1260
253838,Sentinel Dome,Summit,CA,37.7229821,-119.58433,8133
264054,Neversweet Gulch,Valley,CA,41.6565269,-122.8361432,2900
115905,Chacaloochee Bay,Bay,AL,30.6979676,-87.9738853,0
```

Example From Amazon S3 to DynamoDB

With a single HiveQL statement, you can populate the DynamoDB table using the data from Amazon S3:

```
INSERT OVERWRITE TABLE ddb_features
SELECT * FROM s3_features_csv;
```

Copying data without a column mapping

You can copy data from DynamoDB in a raw format and write it to Amazon S3 without specifying any data types or column mapping. You can use this method to create an archive of DynamoDB data and store it in Amazon S3.

Example From DynamoDB to Amazon S3

1. Create an external table associated with your DynamoDB table. (There is no `dynamodb.column.mapping` in this HiveQL statement.)

   ```
   CREATE EXTERNAL TABLE ddb_features_no_mapping
       (item MAP<STRING, STRING>)
   STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
   TBLPROPERTIES ("dynamodb.table.name" = "Features");
   ```

2. Create another external table associated with your Amazon S3 bucket.

   ```
   CREATE EXTERNAL TABLE s3_features_no_mapping
       (item MAP<STRING, STRING>)
   ROW FORMAT DELIMITED
   FIELDS TERMINATED BY '\t'
   LINES TERMINATED BY '\n'
   LOCATION 's3://aws-logs-123456789012-us-west-2/hive-test';
   ```

3. Copy the data from DynamoDB to Amazon S3.

```
INSERT OVERWRITE TABLE s3_features_no_mapping
SELECT * FROM ddb_features_no_mapping;
```

The data file in Amazon S3 looks like this:

```
Name^C{"s":"Soldiers Farewell
 Hill"}^BState^C{"s":"NM"}^BClass^C{"s":"Summit"}^BElevation^C{"n":"6135"}^BLatitude^C{"n":"32.
Name^C{"s":"Jones
 Run"}^BState^C{"s":"PA"}^BClass^C{"s":"Stream"}^BElevation^C{"n":"1260"}^BLatitude^C{"n":"41.2
Name^C{"s":"Sentinel
 Dome"}^BState^C{"s":"CA"}^BClass^C{"s":"Summit"}^BElevation^C{"n":"8133"}^BLatitude^C{"n":"37.
Name^C{"s":"Neversweet
 Gulch"}^BState^C{"s":"CA"}^BClass^C{"s":"Valley"}^BElevation^C{"n":"2900"}^BLatitude^C{"n":"41
Name^C{"s":"Chacaloochee
 Bay"}^BState^C{"s":"AL"}^BClass^C{"s":"Bay"}^BElevation^C{"n":"0"}^BLatitude^C{"n":"30.6979676
```

Each field begins with an STX character (start of text, 0x02) and ends with an ETX character (end of text, 0x03). In the file, STX appears as **^B** and ETX appears as **^C**.

Example From Amazon S3 to DynamoDB

With a single HiveQL statement, you can populate the DynamoDB table using the data from Amazon S3:

```
INSERT OVERWRITE TABLE ddb_features_no_mapping
SELECT * FROM s3_features_no_mapping;
```

Viewing the data in Amazon S3

If you use SSH to connect to the leader node, you can use the AWS Command Line Interface (AWS CLI) to access the data that Hive wrote to Amazon S3.

The following steps are written with the assumption you have copied data from DynamoDB to Amazon S3 using one of the procedures in this section.

1. If you are currently at the Hive command prompt, exit to the Linux command prompt.

```
hive> exit;
```

2. List the contents of the hive-test directory in your Amazon S3 bucket. (This is where Hive copied the data from DynamoDB.)

   ```
   aws s3 ls s3://aws-logs-123456789012-us-west-2/hive-test/
   ```

   The response should look similar to this:

   ```
   2016-11-01 23:19:54 81983 000000_0
   ```

   The file name (*000000_0*) is system-generated.

3. (Optional) You can copy the data file from Amazon S3 to the local file system on the leader node. After you do this, you can use standard Linux command line utilities to work with the data in the file.

   ```
   aws s3 cp s3://aws-logs-123456789012-us-west-2/hive-test/000000_0 .
   ```

   The response should look similar to this:

   ```
   download: s3://aws-logs-123456789012-us-west-2/hive-test/000000_0
   to ./000000_0
   ```

   > **Note**
   >
   > The local file system on the leader node has limited capacity. Do not use this command with files that are larger than the available space in the local file system.

Copying data between DynamoDB and HDFS

If you have data in a DynamoDB table, you can use Hive to copy the data to the Hadoop Distributed File System (HDFS).

You might do this if you are running a MapReduce job that requires data from DynamoDB. If you copy the data from DynamoDB into HDFS, Hadoop can process it, using all of the available nodes in the Amazon EMR cluster in parallel. When the MapReduce job is complete, you can then write the results from HDFS to DDB.

In the following examples, Hive will read from and write to the following HDFS directory: `/user/hadoop/hive-test`

> **Note**
>
> The examples in this section are written with the assumption you followed the steps in Tutorial: Working with Amazon DynamoDB and Apache Hive and you have an external table in DynamoDB named *ddb_features*.

Topics

- Copying data using the Hive default format
- Copying data with a user-specified format
- Copying data without a column mapping
- Accessing the data in HDFS

Copying data using the Hive default format

Example From DynamoDB to HDFS

Use an `INSERT OVERWRITE` statement to write directly to HDFS.

```
INSERT OVERWRITE DIRECTORY 'hdfs:///user/hadoop/hive-test'
SELECT * FROM ddb_features;
```

The data file in HDFS looks like this:

```
920709^ASoldiers Farewell Hill^ASummit^ANM^A32.3564729^A-108.33004616135
1178153^AJones Run^AStream^APA^A41.2120086^A-79.25920781260
253838^ASentinel Dome^ASummit^ACA^A37.7229821^A-119.584338133
264054^ANeversweet Gulch^AValley^ACA^A41.6565269^A-122.83614322900
115905^AChacaloochee Bay^ABay^AAL^A30.6979676^A-87.97388530
```

Each field is separated by an SOH character (start of heading, 0x01). In the file, SOH appears as **^A**.

Example From HDFS to DynamoDB

1. Create an external table that maps to the unformatted data in HDFS.

   ```
   CREATE EXTERNAL TABLE hdfs_features_unformatted
   ```

```
    (feature_id       BIGINT,
    feature_name      STRING ,
    feature_class     STRING ,
    state_alpha       STRING,
    prim_lat_dec      DOUBLE ,
    prim_long_dec     DOUBLE ,
    elev_in_ft        BIGINT)
LOCATION 'hdfs:///user/hadoop/hive-test';
```

2. Copy the data to DynamoDB.

```
INSERT OVERWRITE TABLE ddb_features
SELECT * FROM hdfs_features_unformatted;
```

Copying data with a user-specified format

If you want to use a different field separator character, you can create an external table that maps to the HDFS directory. You might use this technique for creating data files with comma-separated values (CSV).

Example From DynamoDB to HDFS

1. Create a Hive external table that maps to HDFS. When you do this, ensure that the data types are consistent with those of the DynamoDB external table.

```
CREATE EXTERNAL TABLE hdfs_features_csv
    (feature_id       BIGINT,
    feature_name      STRING ,
    feature_class     STRING ,
    state_alpha       STRING,
    prim_lat_dec      DOUBLE ,
    prim_long_dec     DOUBLE ,
    elev_in_ft        BIGINT)
ROW FORMAT DELIMITED
FIELDS TERMINATED BY ','
LOCATION 'hdfs:///user/hadoop/hive-test';
```

2. Copy the data from DynamoDB.

```
INSERT OVERWRITE TABLE hdfs_features_csv
SELECT * FROM ddb_features;
```

The data file in HDFS looks like this:

```
920709,Soldiers Farewell Hill,Summit,NM,32.3564729,-108.3300461,6135
1178153,Jones Run,Stream,PA,41.2120086,-79.2592078,1260
253838,Sentinel Dome,Summit,CA,37.7229821,-119.58433,8133
264054,Neversweet Gulch,Valley,CA,41.6565269,-122.8361432,2900
115905,Chacaloochee Bay,Bay,AL,30.6979676,-87.9738853,0
```

Example From HDFS to DynamoDB

With a single HiveQL statement, you can populate the DynamoDB table using the data from HDFS:

```
INSERT OVERWRITE TABLE ddb_features
SELECT * FROM hdfs_features_csv;
```

Copying data without a column mapping

You can copy data from DynamoDB in a raw format and write it to HDFS without specifying any data types or column mapping. You can use this method to create an archive of DynamoDB data and store it in HDFS.

> **Note**
>
> If your DynamoDB table contains attributes of type Map, List, Boolean or Null, then this is the only way you can use Hive to copy data from DynamoDB to HDFS.

Example From DynamoDB to HDFS

1. Create an external table associated with your DynamoDB table. (There is no `dynamodb.column.mapping` in this HiveQL statement.)

   ```
   CREATE EXTERNAL TABLE ddb_features_no_mapping
       (item MAP<STRING, STRING>)
   STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
   TBLPROPERTIES ("dynamodb.table.name" = "Features");
   ```

2. Create another external table associated with your HDFS directory.

```
CREATE EXTERNAL TABLE hdfs_features_no_mapping
    (item MAP<STRING, STRING>)
ROW FORMAT DELIMITED
FIELDS TERMINATED BY '\t'
LINES TERMINATED BY '\n'
LOCATION 'hdfs:///user/hadoop/hive-test';
```

3. Copy the data from DynamoDB to HDFS.

```
INSERT OVERWRITE TABLE hdfs_features_no_mapping
SELECT * FROM ddb_features_no_mapping;
```

The data file in HDFS looks like this:

```
Name^C{"s":"Soldiers Farewell
 Hill"}^BState^C{"s":"NM"}^BClass^C{"s":"Summit"}^BElevation^C{"n":"6135"}^BLatitude^C{"n":"32.
Name^C{"s":"Jones
 Run"}^BState^C{"s":"PA"}^BClass^C{"s":"Stream"}^BElevation^C{"n":"1260"}^BLatitude^C{"n":"41.2
Name^C{"s":"Sentinel
 Dome"}^BState^C{"s":"CA"}^BClass^C{"s":"Summit"}^BElevation^C{"n":"8133"}^BLatitude^C{"n":"37.
Name^C{"s":"Neversweet
 Gulch"}^BState^C{"s":"CA"}^BClass^C{"s":"Valley"}^BElevation^C{"n":"2900"}^BLatitude^C{"n":"41
Name^C{"s":"Chacaloochee
 Bay"}^BState^C{"s":"AL"}^BClass^C{"s":"Bay"}^BElevation^C{"n":"0"}^BLatitude^C{"n":"30.6979676
```

Each field begins with an STX character (start of text, 0x02) and ends with an ETX character (end of text, 0x03). In the file, STX appears as **^B** and ETX appears as **^C**.

Example From HDFS to DynamoDB

With a single HiveQL statement, you can populate the DynamoDB table using the data from HDFS:

```
INSERT OVERWRITE TABLE ddb_features_no_mapping
SELECT * FROM hdfs_features_no_mapping;
```

Accessing the data in HDFS

HDFS is a distributed file system, accessible to all of the nodes in the Amazon EMR cluster. If you use SSH to connect to the leader node, you can use command line tools to access the data that Hive wrote to HDFS.

HDFS is not the same thing as the local file system on the leader node. You cannot work with files and directories in HDFS using standard Linux commands (such as `cat`, `cp`, `mv`, or `rm`). Instead, you perform these tasks using the `hadoop fs` command.

The following steps are written with the assumption you have copied data from DynamoDB to HDFS using one of the procedures in this section.

1. If you are currently at the Hive command prompt, exit to the Linux command prompt.

   ```
   hive> exit;
   ```

2. List the contents of the /user/hadoop/hive-test directory in HDFS. (This is where Hive copied the data from DynamoDB.)

   ```
   hadoop fs -ls /user/hadoop/hive-test
   ```

   The response should look similar to this:

   ```
   Found 1 items
   -rw-r--r-- 1 hadoop hadoop 29504 2016-06-08 23:40 /user/hadoop/hive-test/000000_0
   ```

   The file name (*000000_0*) is system-generated.

3. View the contents of the file:

   ```
   hadoop fs -cat /user/hadoop/hive-test/000000_0
   ```

   > **Note**
   >
   > In this example, the file is relatively small (approximately 29 KB). Be careful when you use this command with files that are very large or contain non-printable characters.

4. (Optional) You can copy the data file from HDFS to the local file system on the leader node. After you do this, you can use standard Linux command line utilities to work with the data in the file.

   ```
   hadoop fs -get /user/hadoop/hive-test/000000_0
   ```

   This command will not overwrite the file.

> **Note**
>
> The local file system on the leader node has limited capacity. Do not use this command with files that are larger than the available space in the local file system.

Using data compression

When you use Hive to copy data among different data sources, you can request on-the-fly data compression. Hive provides several compression codecs. You can choose one during your Hive session. When you do this, the data is compressed in the specified format.

The following example compresses data using the Lempel-Ziv-Oberhumer (LZO) algorithm.

```
SET hive.exec.compress.output=true;
SET io.seqfile.compression.type=BLOCK;
SET mapred.output.compression.codec = com.hadoop.compression.lzo.LzopCodec;

CREATE EXTERNAL TABLE lzo_compression_table (line STRING)
ROW FORMAT DELIMITED FIELDS TERMINATED BY '\t' LINES TERMINATED BY '\n'
LOCATION 's3://bucketname/path/subpath/';

INSERT OVERWRITE TABLE lzo_compression_table SELECT *
FROM hiveTableName;
```

The resulting file in Amazon S3 will have a system-generated name with `.lzo` at the end (for example, `8d436957-57ba-4af7-840c-96c2fc7bb6f5-000000.lzo`).

The available compression codecs are:

- `org.apache.hadoop.io.compress.GzipCodec`
- `org.apache.hadoop.io.compress.DefaultCodec`
- `com.hadoop.compression.lzo.LzoCodec`
- `com.hadoop.compression.lzo.LzopCodec`
- `org.apache.hadoop.io.compress.BZip2Codec`
- `org.apache.hadoop.io.compress.SnappyCodec`

Reading non-printable UTF-8 character data

To read and write non-printable UTF-8 character data, you can use the `STORED AS SEQUENCEFILE` clause when you create a Hive table. A SequenceFile is a Hadoop binary file format. You need to use Hadoop to read this file. The following example shows how to export data from DynamoDB into Amazon S3. You can use this functionality to handle non-printable UTF-8 encoded characters.

```
CREATE EXTERNAL TABLE s3_export(a_col string, b_col bigint, c_col array<string>)
STORED AS SEQUENCEFILE
LOCATION 's3://bucketname/path/subpath/';

INSERT OVERWRITE TABLE s3_export SELECT *
FROM hiveTableName;
```

Performance tuning

When you create a Hive external table that maps to a DynamoDB table, you do not consume any read or write capacity from DynamoDB. However, read and write activity on the Hive table (such as `INSERT` or `SELECT`) translates directly into read and write operations on the underlying DynamoDB table.

Apache Hive on Amazon EMR implements its own logic for balancing the I/O load on the DynamoDB table and seeks to minimize the possibility of exceeding the table's provisioned throughput. At the end of each Hive query, Amazon EMR returns runtime metrics, including the number of times your provisioned throughput was exceeded. You can use this information, together with CloudWatch metrics on your DynamoDB table, to improve performance in subsequent requests.

The Amazon EMR console provides basic monitoring tools for your cluster. For more information, see View and Monitor a Cluster in the *Amazon EMR Management Guide*.

You can also monitor your cluster and Hadoop jobs using web-based tools, such as Hue, Ganglia, and the Hadoop web interface. For more information, see View Web Interfaces Hosted on Amazon EMR Clusters in the *Amazon EMR Management Guide*.

This section describes steps you can take to performance-tune Hive operations on external DynamoDB tables.

Topics

- DynamoDB provisioned throughput
- Adjusting the mappers
- Additional topics

DynamoDB provisioned throughput

When you issue HiveQL statements against the external DynamoDB table, the `DynamoDBStorageHandler` class makes the appropriate low-level DynamoDB API requests, which consume provisioned throughput. If there is not enough read or write capacity on the DynamoDB table, the request will be throttled, resulting in slow HiveQL performance. For this reason, you should ensure that the table has enough throughput capacity.

For example, suppose that you have provisioned 100 read capacity units for your DynamoDB table. This will let you read 409,600 bytes per second (100 × 4 KB read capacity unit size). Now suppose that the table contains 20 GB of data (21,474,836,480 bytes) and you want to use the `SELECT` statement to select all of the data using HiveQL. You can estimate how long the query will take to run like this:

21,474,836,480 / 409,600 = 52,429 seconds = 14.56 hours

In this scenario, the DynamoDB table is a bottleneck. It won't help to add more Amazon EMR nodes, because the Hive throughput is constrained to only 409,600 bytes per second. The only way to decrease the time required for the `SELECT` statement is to increase the provisioned read capacity of the DynamoDB table.

You can perform a similar calculation to estimate how long it would take to bulk-load data into a Hive external table mapped to a DynamoDB table. Determine the total number of write capacity units needed per item (less than 1KB = 1, 1-2KB = 2, etc), and multiply that by the number of items to load. This will give you the number of write capacity units required. Divide that number by the number of write capacity units that are allocated per second. This will yield the number of seconds it will take to load the table.

You should regularly monitor the CloudWatch metrics for your table. For a quick overview in the DynamoDB console, choose your table and then choose the **Metrics** tab. From here, you can view read and write capacity units consumed and read and write requests that have been throttled.

Read capacity

Amazon EMR manages the request load against your DynamoDB table, according to the table's provisioned throughput settings. However, if you notice a large number of `ProvisionedThroughputExceeded` messages in the job output, you can adjust the default read rate. To do this, you can modify the `dynamodb.throughput.read.percent` configuration variable. You can use the `SET` command to set this variable at the Hive command prompt:

```
SET dynamodb.throughput.read.percent=1.0;
```

This variable persists for the current Hive session only. If you exit Hive and return to it later, `dynamodb.throughput.read.percent` will return to its default value.

The value of `dynamodb.throughput.read.percent` can be between `0.1` and `1.5`, inclusively. `0.5` represents the default read rate, meaning that Hive will attempt to consume half of the read capacity of the table. If you increase the value above `0.5`, Hive will increase the request rate; decreasing the value below `0.5` decreases the read request rate. (The actual read rate will vary, depending on factors such as whether there is a uniform key distribution in the DynamoDB table.)

If you notice that Hive is frequently depleting the provisioned read capacity of the table, or if your read requests are being throttled too much, try reducing `dynamodb.throughput.read.percent` below `0.5`. If you have sufficient read capacity in the table and want more responsive HiveQL operations, you can set the value above `0.5`.

Write capacity

Amazon EMR manages the request load against your DynamoDB table, according to the table's provisioned throughput settings. However, if you notice a large number of `ProvisionedThroughputExceeded` messages in the job output, you can adjust the default write rate. To do this, you can modify the `dynamodb.throughput.write.percent` configuration variable. You can use the `SET` command to set this variable at the Hive command prompt:

```
SET dynamodb.throughput.write.percent=1.0;
```

This variable persists for the current Hive session only. If you exit Hive and return to it later, `dynamodb.throughput.write.percent` will return to its default value.

The value of `dynamodb.throughput.write.percent` can be between `0.1` and `1.5`, inclusively. `0.5` represents the default write rate, meaning that Hive will attempt to consume half of the write capacity of the table. If you increase the value above `0.5`, Hive will increase the request rate;

decreasing the value below `0.5` decreases the write request rate. (The actual write rate will vary, depending on factors such as whether there is a uniform key distribution in the DynamoDB table.)

If you notice that Hive is frequently depleting the provisioned write capacity of the table, or if your write requests are being throttled too much, try reducing `dynamodb.throughput.write.percent` below `0.5`. If you have sufficient capacity in the table and want more responsive HiveQL operations, you can set the value above `0.5`.

When you write data to DynamoDB using Hive, ensure that the number of write capacity units is greater than the number of mappers in the cluster. For example, consider an Amazon EMR cluster consisting of 10 *m1.xlarge* nodes. The *m1.xlarge* node type provides 8 mapper tasks, so the cluster would have a total of 80 mappers (10 × 8). If your DynamoDB table has fewer than 80 write capacity units, then a Hive write operation could consume all of the write throughput for that table.

To determine the number of mappers for Amazon EMR node types, see Task Configuration in the *Amazon EMR Developer Guide*.

For more information on mappers, see Adjusting the mappers.

Adjusting the mappers

When Hive launches a Hadoop job, the job is processed by one or more mapper tasks. Assuming that your DynamoDB table has sufficient throughput capacity, you can modify the number of mappers in the cluster, potentially improving performance.

> **Note**
>
> The number of mapper tasks used in a Hadoop job are influenced by *input splits*, where Hadoop subdivides the data into logical blocks. If Hadoop does not perform enough input splits, then your write operations might not be able to consume all the write throughput available in the DynamoDB table.

Increasing the number of mappers

Each mapper in an Amazon EMR has a maximum read rate of 1 MiB per second. The number of mappers in a cluster depends on the size of the nodes in your cluster. (For information about node sizes and the number of mappers per node, see Task Configuration in the *Amazon EMR Developer Guide*.)

If your DynamoDB table has ample throughput capacity for reads, you can try increasing the number of mappers by doing one of the following:

- Increase the size of the nodes in your cluster. For example, if your cluster is using *m1.large* nodes (three mappers per node), you can try upgrading to *m1.xlarge* nodes (eight mappers per node).
- Increase the number of nodes in your cluster. For example, if you have three-node cluster of *m1.xlarge* nodes, you have a total of 24 mappers available. If you were to double the size of the cluster, with the same type of node, you would have 48 mappers.

You can use the AWS Management Console to manage the size or the number of nodes in your cluster. (You might need to restart the cluster for these changes to take effect.)

Another way to increase the number of mappers is to modify the `mapred.tasktracker.map.tasks.maximum` Hadoop configuration parameter. (This is a Hadoop parameter, not a Hive parameter. You cannot modify it interactively from the command prompt.). If you increase the value of `mapred.tasktracker.map.tasks.maximum`, you can increase the number of mappers without increasing the size or number of nodes. However, it is possible for the cluster nodes to run out of memory if you set the value too high.

You set the value for `mapred.tasktracker.map.tasks.maximum` as a bootstrap action when you first launch your Amazon EMR cluster. For more information, see (Optional) Create Bootstrap Actions to Install Additional Software in the *Amazon EMR Management Guide*.

Decreasing the number of mappers

If you use the `SELECT` statement to select data from an external Hive table that maps to DynamoDB, the Hadoop job can use as many tasks as necessary, up to the maximum number of mappers in the cluster. In this scenario, it is possible that a long-running Hive query can consume all of the provisioned read capacity of the DynamoDB table, negatively impacting other users.

You can use the `dynamodb.max.map.tasks` parameter to set an upper limit for map tasks:

```
SET dynamodb.max.map.tasks=1
```

This value must be equal to or greater than 1. When Hive processes your query, the resulting Hadoop job will use no more than `dynamodb.max.map.tasks` when reading from the DynamoDB table.

Additional topics

The following are some more ways to tune applications that use Hive to access DynamoDB.

Retry duration

By default, Hive will rerun a Hadoop job if it has not returned any results from DynamoDB within two minutes. You can adjust this interval by modifying the `dynamodb.retry.duration` parameter:

```
SET dynamodb.retry.duration=2;
```

The value must be a nonzero integer, representing the number of minutes in the retry interval. The default for `dynamodb.retry.duration` is 2 (minutes).

Parallel data requests

Multiple data requests, either from more than one user or more than one application to a single table can drain read provisioned throughput and slow performance.

Process duration

Data consistency in DynamoDB depends on the order of read and write operations on each node. While a Hive query is in progress, another application might load new data into the DynamoDB table or modify or delete existing data. In this case, the results of the Hive query might not reflect changes made to the data while the query was running.

Request time

Scheduling Hive queries that access a DynamoDB table when there is lower demand on the DynamoDB table improves performance. For example, if most of your application's users live in San Francisco, you might choose to export daily data at 4:00 A.M. PST when the majority of users are asleep and not updating records in your DynamoDB database.

Integrating DynamoDB with Amazon S3

Amazon DynamoDB import and export capabilities provide a simple and efficient way to move data between Amazon S3 and DynamoDB tables without writing any code.

DynamoDB import and export features help you move, transform, and copy DynamoDB table accounts. You can import from your S3 sources, and you can export your DynamoDB table data to

Amazon S3 and use AWS services such as Athena, Amazon SageMaker AI, and AWS Lake Formation to analyze your data and extract actionable insights. You can also import data directly into new DynamoDB tables to build new applications with single-digit millisecond performance at scale, facilitate data sharing between tables and accounts, and simplify your disaster recovery and business continuity plans.

DynamoDB data import from Amazon S3: how it works

To import data into DynamoDB, your data must be in an Amazon S3 bucket in CSV, DynamoDB JSON, or Amazon Ion format. Data can be compressed in ZSTD or GZIP format, or can be directly imported in uncompressed form. Source data can either be a single Amazon S3 object or multiple Amazon S3 objects that use the same prefix.

Your data will be imported into a new DynamoDB table, which will be created when you initiate the import request. You can create this table with secondary indexes, then query and update your data across all primary and secondary indexes as soon as the import is complete. You can also add a global table replica after the import is complete.

> **Note**
>
> During the Amazon S3 import process, DynamoDB creates a new target table that will be imported into. Import into existing tables is not currently supported by this feature.

Import from Amazon S3 does not consume write capacity on the new table, so you do not need to provision any extra capacity for importing data into DynamoDB. Data import pricing is based on the uncompressed size of the source data in Amazon S3, that is processed as a result of the import. Items that are processed but fail to load into the table due to formatting or other inconsistencies in the source data are also billed as part of the import process. See Amazon DynamoDB pricing for details.

You can import data from an Amazon S3 bucket owned by a different account if you have the correct permissions to read from that specific bucket. The new table may also be in a different

Region from the source Amazon S3 bucket. For more information, see Amazon Simple Storage Service setup and permissions .

Import times are directly related to your data's characteristics in Amazon S3. This includes data size, data format, compression scheme, uniformity of data distribution, number of Amazon S3 objects, and other related variables. In particular, data sets with uniformly distributed keys will be faster to import than skewed data sets. For example, if your secondary index's key is using the month of the year for partitioning, and all your data is from the month of December, then importing this data may take significantly longer.

The attributes associated with keys are expected to be unique on the base table. If any keys are not unique, the import will overwrite the associated items until only the last overwrite remains. For example, if the primary key is the month and multiple items are set to the month of September, each new item will overwrite the previously written items and only one item with the primary key of "month" set to September will remain. In such cases, the number of items processed in the import table description will not match the number of items in the target table.

AWS CloudTrail logs all console and API actions for table import. For more information, see Logging DynamoDB operations by using AWS CloudTrail.

The following video is an introduction to importing directly from Amazon S3 into DynamoDB.

Import from Amazon S3

Requesting a table import in DynamoDB

DynamoDB import allows you to import data from an Amazon S3 bucket to a new DynamoDB table. You can request a table import using the DynamoDB console, the CLI, CloudFormation or the DynamoDB API.

If you want to use the AWS CLI, you must configure it first. For more information, see Accessing DynamoDB.

Note

- The Import Table feature interacts with multiple different AWS Services such as Amazon S3 and CloudWatch. Before you begin an import, make sure that the user or role that invokes the import APIs has permissions to all services and resources the feature depends on.
- Do not modify the Amazon S3 objects while the import is in progress, as this can cause the operation to fail or be cancelled.

For more information on errors and troubleshooting, see Import format quotas and validation

- Requesting an import using the AWS Management Console
- Getting details about past imports in the AWS Management Console
- Requesting an import using the AWS CLI
- Getting details about past imports in the AWS CLI

Setting up IAM permissions

You can import data from any Amazon S3 bucket you have permission to read from. The source bucket does not need to be in the same Region or have the same owner as the source table. Your AWS Identity and Access Management (IAM) must include the relevant actions on the source Amazon S3 bucket, and required CloudWatch permissions for providing debugging information. An example policy is shown below.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowDynamoDBImportAction",
      "Effect": "Allow",
      "Action": [
        "dynamodb:ImportTable",
```

```
        "dynamodb:DescribeImport"
      ],
      "Resource": "arn:aws:dynamodb:us-east-1:111122223333:table/my-table*"
    },
    {
      "Sid": "AllowS3Access",
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:ListBucket"
      ],
      "Resource": [
        "arn:aws:s3:::your-bucket/*",
        "arn:aws:s3:::your-bucket"
      ]
    },
    {
      "Sid": "AllowCloudwatchAccess",
      "Effect": "Allow",
      "Action": [
        "logs:CreateLogGroup",
        "logs:CreateLogStream",
        "logs:DescribeLogGroups",
        "logs:DescribeLogStreams",
        "logs:PutLogEvents",
        "logs:PutRetentionPolicy"
      ],
      "Resource": "arn:aws:logs:us-east-1:111122223333:log-group/aws-dynamodb/*"
    },
    {
      "Sid": "AllowDynamoDBListImports",
      "Effect": "Allow",
      "Action": "dynamodb:ListImports",
      "Resource": "*"
    }
  ]
}
```

Amazon S3 permissions

When starting an import on an Amazon S3 bucket source that is owned by another account, ensure that the role or user has access to the Amazon S3 objects. You can check that by executing an Amazon S3 `GetObject` command and using the credentials. When using the API, the Amazon

S3 bucket owner parameter defaults to the current user's account ID. For cross account imports, ensure that this parameter is correctly populated with the bucket owner's account ID. The following code is an example Amazon S3 bucket policy in the source account.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {"Sid": "ExampleStatement",
            "Effect": "Allow",
            "Principal": {"AWS": "arn:aws:iam::123456789012:user/Dave"
            },
            "Action": [
                "s3:GetObject",
                "s3:ListBucket"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
        }
    ]
}
```

AWS Key Management Service

When creating the new table for import, if you select an encryption at rest key that is not owned by DynamoDB then you must provide the AWS KMS permissions required to operate a DynamoDB table encrypted with customer managed keys. For more information see Authorizing use of your AWS KMS key. If the Amazon S3 objects are encrypted with server side encryption KMS (SSE-KMS), ensure that the role or user initiating the import has access to decrypt using the AWS KMS key. This feature does not support customer-provided encryption keys (SSE-C) encrypted Amazon S3 objects.

CloudWatch permissions

The role or user that is initiating the import will need create and manage permissions for the log group and log streams associated with the import.

Requesting an import using the AWS Management Console

The following example demonstrates how to use the DynamoDB console to import existing data to a new table named `MusicCollection`.

To request a table import

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. In the navigation pane on the left side of the console, choose **Import from S3**.
3. On the page that appears, select **Import from S3**.
4. Choose **Import from S3**.
5. In **Source S3 URL**, enter the Amazon S3 source URL.

   If you own the source bucket, choose **Browse S3** to search for it. Alternatively, enter the bucket's URL in the following format – `s3://bucket/prefix`. The `prefix` is an Amazon S3 key prefix. It's either the Amazon S3 object name that you want to import or the key prefix shared by all the Amazon S3 objects that you want to import.

   > **Note**
   >
   > You can't use the same prefix as your DynamoDB export request. The export feature creates a folder structure and manifest files for all the exports. If you use the same Amazon S3 path, it will result in an error.
   > Instead, point the import at the folder, which contains data from that specific export. The format of the correct path in this case will be `s3://bucket/prefix/AWSDynamoDB/<XXXXXXXX-XXXXXX>/Data/`, where `XXXXXXXX-XXXXXX` is the export ID. You can find export ID in the export ARN, which has the following format – `arn:aws:dynamodb:<Region>:<AccountID>:table/<TableName>/export/<XXXXXXXX-XXXXXX>`. For example, `arn:aws:dynamodb:`*`us-east-1`*`:`*`123456789012`*`:table/`*`ProductCatalog`*`/export/`*`01234567890123-a1b2c3d4`*.

6. Specify if you are the **S3 bucket owner**. If the source bucket is owned by a different account, select **A different AWS account**. Then enter the account ID of the bucket owner.
7. Under **Import file compression**, select either **No compression**, **GZIP** or **ZSTD** as appropriate.
8. Select the appropriate Import file format. The options are **DynamoDB JSON**, **Amazon Ion** or **CSV**. If you select **CSV**, you will have two additional options: **CSV header** and **CSV delimiter character**.

   For **CSV header**, choose if the header will either be taken from the first line of the file or be customized. If you select **Customize your headers**, you can specify the header values you want

to import with. CSV Headers specified by this method are case-sensitive and are expected to contain the keys of the target table.

For **CSV delimiter character**, you set the character which will separate items. Comma is selected by default. If you select **Custom delimiter character**, the delimiter must match the regex pattern: `[,;:|\t ]`.

9. Select the **Next** button and select the options for the new table that will be created to store your data.

> **Note**
>
> Primary Key and Sort Key must match the attributes in the file, or the import will fail. The attributes are case sensitive.

10. Select **Next** again to review your import options, then click **Import** to begin the import task. You will first see your new table listed in the “Tables” with the status “Creating”. At this time the table is not accessible.
11. Once the import completes, the status will show as "Active" and you can start using the table.

Getting details about past imports in the AWS Management Console

You can find information about import tasks you've run in the past by clicking **Import from S3** in the navigation sidebar, then selecting the **Imports** tab. The import panel contains a list of all imports you've created in the past 90 days. Selecting the ARN of a task listed in the Imports tab will retrieve information about that import, including any advanced configuration settings you chose.

Requesting an import using the AWS CLI

The following example imports CSV formatted data from an S3 bucket called bucket with a prefix of prefix to a new table called target-table.

```
aws dynamodb import-table --s3-bucket-source S3Bucket=bucket,S3KeyPrefix=prefix \
            --input-format CSV --table-creation-parameters '{"TableName":"target-
table","KeySchema":  \
            [{"AttributeName":"hk","KeyType":"HASH"}],"AttributeDefinitions":
[{"AttributeName":"hk","AttributeType":"S"}],"BillingMode":"PAY_PER_REQUEST"}' \
            --input-format-options '{"Csv": {"HeaderList": ["hk", "title", "artist",
 "year_of_release"], "Delimiter": ";"}}'
```

> **Note**
>
> If you choose to encrypt your import using a key protected by AWS Key Management Service (AWS KMS), the key must be in the same Region as the destination Amazon S3 bucket.

Getting details about past imports in the AWS CLI

You can find information about import tasks you've run in the past by using the `list-imports` command. This command returns a list of all imports you've created in the past 90 days. Note that although import task metadata expires after 90 days and jobs older than that are no longer found on this list, DynamoDB does not delete any of the objects in your Amazon S3 bucket or the table created during import.

```
aws dynamodb list-imports
```

To retrieve detailed information about a specific import task, including any advanced configuration settings, use the `describe-import` command.

```
aws dynamodb describe-import \
    --import-arn arn:aws:dynamodb:us-east-1:123456789012:table/ProductCatalog/exp
```

Amazon S3 import formats for DynamoDB

DynamoDB can import data in three formats: CSV, DynamoDB JSON, and Amazon Ion.

Topics

- CSV
- DynamoDB Json
- Amazon Ion

CSV

A file in CSV format consists of multiple items delimited by newlines. By default, DynamoDB interprets the first line of an import file as the header and expects columns to be delimited by commas. You can also define headers that will be applied, as long as they match the number of

columns in the file. If you define headers explicitly, the first line of the file will be imported as values.

> **Note**
>
> When importing from CSV files, all columns other than the hash range and keys of your base table and secondary indexes are imported as DynamoDB strings.

Escaping double quotes

Any double quotes characters that exist in the CSV file must be escaped. If they are not escaped, such as in this following example, the import will fail:

```
id,value
"123",Women's Full Lenth Dress
```

This same import will succeed if the quotes are escaped with two sets of double quotes:

```
id,value
"""123""",Women's Full Lenth Dress
```

Once the text has been properly escaped and imported, it will appear as it did in the original CSV file:

```
id,value
"123",Women's Full Lenth Dress
```

DynamoDB Json

A file in DynamoDB JSON format can consist of multiple Item objects. Each individual object is in DynamoDB's standard marshalled JSON format, and newlines are used as item delimiters. As an added feature, exports from point in time are supported as an import source by default.

> **Note**
>
> New lines are used as item delimiters for a file in DynamoDB JSON format and shouldn't be used within an item object.

```
[{
    "Item": {
        "Authors": {
            "SS": ["Author1", "Author2"]
        },
        "Dimensions": {
            "S": "8.5 x 11.0 x 1.5"
        },
        "ISBN": {
            "S": "333-3333333333"
        },
        "Id": {
            "N": "103"
        },
        "InPublication": {
            "BOOL": false
        },
        "PageCount": {
            "N": "600"
        },
        "Price": {
            "N": "2000"
        },
        "ProductCategory": {
            "S": "Book"
        },
        "Title": {
            "S": "Book 103 Title"
        }
    }
}]
```

Note

New lines are used as item delimiters for a file in DynamoDB JSON format and shouldn't be used within an item object.

```
[{
    "Item": {
        "Authors": {
            "SS": ["Author1", "Author2"]
```

```
        },
        "Dimensions": {
            "S": "8.5 x 11.0 x 1.5"
        },
        "ISBN": {
            "S": "333-3333333333"
        },
        "Id": {
            "N": "103"
        },
        "InPublication": {
            "BOOL": false
        },
        "PageCount": {
            "N": "600"
        },
        "Price": {
            "N": "2000"
        },
        "ProductCategory": {
            "S": "Book"
        },
        "Title": {
            "S": "Book 103 Title"
        }
    }
},{
    "Item": {
        "Authors": {
            "SS": ["Author1", "Author2"]
        },
        "Dimensions": {
            "S": "8.5 x 11.0 x 1.5"
        },
        "ISBN": {
            "S": "444-444444444"
        },

Amazon Ion

Amazon Ion is a richly-typed, self-describing, hierarchical data serialization format built to address rapid development, decoupling, and efficiency challenges faced every day while engineering large-scale, service-oriented architectures.

When you import data in Ion format, the Ion datatypes are mapped to DynamoDB datatypes in the new DynamoDB table.

S. No.	Ion to DynamoDB datatype conversion	B
1	`Ion Data Type`	`DynamoDB Representation`
2	`string`	`String (s)`
3	`bool`	`Boolean (BOOL)`
4	`decimal`	`Number (N)`
5	`blob`	`Binary (B)`
6	`list (with type annotation $dynamodb_SS, $dynamodb_NS, or $dynamodb_BS)`	`Set (SS, NS, BS)`
7	`list`	`List`
8	`struct`	`Map`

Items in an Ion file are delimited by newlines. Each line begins with an Ion version marker, followed by an item in Ion format.

> **Note**
>
> In the following example, we've formatted items from an Ion-formatted file on multiple lines to improve readability.

```
$ion_1_0
[
  {
    Item:{
      Authors:$dynamodb_SS::["Author1","Author2"],
      Dimensions:"8.5 x 11.0 x 1.5",

]
```

Import format quotas and validation

Import quotas

DynamoDB Import from Amazon S3 can support up to 50 concurrent import jobs with a total import source object size of 15TB at a time in us-east-1, us-west-2, and eu-west-1 regions. In all other regions, up to 50 concurrent import tasks with a total size of 1TB is supported. Each import job can take up to 50,000 Amazon S3 objects in all regions. These default quotas are applied to every account. If you feel you need to revise these quotas, please contact your account team, and this will be considered on a case-by-case basis. For more details on DynamoDB limits, see Service Quotas.

Validation errors

During the import process, DynamoDB may encounter errors while parsing your data. For each error, DynamoDB emits a CloudWatch log and keeps a count of the total number of errors encountered. If the Amazon S3 object itself is malformed or if its contents cannot form a DynamoDB item, then we may skip processing the remaining portion of the object.

> **Note**
>
> If the Amazon S3 data source has multiple items that share the same key, the items will overwrite until one remains. This can appear as if 1 item was imported and the others were ignored. The duplicate items will be overwritten in random order, are not counted as errors, and are not emitted to CloudWatch logs.
> Once the import is complete you can see the total count of items imported, total count of errors, and total count of items processed. For further troubleshooting you can also check the total size of items imported and total size of data processed.

There are three categories of import errors: API validation errors, data validation errors, and configuration errors.

API validation errors

API validation errors are item-level errors from the sync API. Common causes are permissions issues, missing required parameters and parameter validation failures. Details on why the API call failed are contained in the exceptions thrown by the `ImportTable` request.

Data validation errors

Data validation errors can occur at either the item level or file level. During import, items are validated based on DynamoDB rules before importing into the target table. When an item fails validation and is not imported, the import job skips over that item and continues on with the next item. At the end of job, the import status is set to FAILED with a FailureCode, ItemValidationError and the FailureMessage "Some of the items failed validation checks and were not imported. Please check CloudWatch error logs for more details."

Common causes for data validation errors include objects being unparsable, objects being in the incorrect format (input specifies DYNAMODB_JSON but the object is not in DYNAMODB_JSON), and schema mismatch with specified source table keys.

Configuration errors

Configuration errors are typically workflow errors due to permission validation. The Import workflow checks some permissions after accepting the request. If there are issues calling any of the required dependencies like Amazon S3 or CloudWatch the process marks the import status as FAILED. The `failureCode` and `failureMessage` point to the reason for failure. Where applicable, the failure message also contains the request id that you can use to investigate the reason for failure in CloudTrail.

Common configuration errors include having the wrong URL for the Amazon S3 bucket, and not having permission to access the Amazon S3 bucket, CloudWatch Logs, and AWS KMS keys used to decrypt the Amazon S3 object. For more information see Using and data keys.

Validating source Amazon S3 objects

In order to validate source S3 objects, take the following steps.

1. Validate the data format and compression type

   - Make sure that all matching Amazon S3 objects under the specified prefix have the same format (DYNAMODB_JSON, DYNAMODB_ION, CSV)
   - Make sure that all matching Amazon S3 objects under the specified prefix are compressed the same way (GZIP, ZSTD, NONE)

> **Note**
>
> The Amazon S3 objects do not need to have the corresponding extension (.csv / .json / .ion / .gz / .zstd etc) as the input format specified in ImportTable call takes precedence.

2. Validate that the import data conforms to the desired table schema

   - Make sure that each item in the source data has the primary key. A sort key is optional for imports.
   - Make sure that the attribute type associated with the primary key and any sort key matches the attribute type in the Table and the GSI schema, as specified in table creation parameters

Troubleshooting

CloudWatch logs

For Import jobs that fail, detailed error messages are posted to CloudWatch logs. To access these logs, first retrieve the ImportArn from the output and describe-import using this command:

```
aws dynamodb describe-import --import-arn arn:aws:dynamodb:us-east-1:ACCOUNT:table/
target-table/import/01658528578619-c4d4e311
}
```

Example output:

```
aws dynamodb describe-import --import-arn "arn:aws:dynamodb:us-
east-1:531234567890:table/target-table/import/01658528578619-c4d4e311"
{
    "ImportTableDescription": {
        "ImportArn": "arn:aws:dynamodb:us-east-1:ACCOUNT:table/target-table/
import/01658528578619-c4d4e311",
        "ImportStatus": "FAILED",
        "TableArn": "arn:aws:dynamodb:us-east-1:ACCOUNT:table/target-table",
        "TableId": "7b7ecc22-302f-4039-8ea9-8e7c3eb2bcb8",
        "ClientToken": "30f8891c-e478-47f4-af4a-67a5c3b595e3",
        "S3BucketSource": {
            "S3BucketOwner": "ACCOUNT",
            "S3Bucket": "my-import-source",
```

```
            "S3KeyPrefix": "import-test"
        },
        "ErrorCount": 1,
        "CloudWatchLogGroupArn": "arn:aws:logs:us-east-1:ACCOUNT:log-group:/aws-
dynamodb/imports:*",
        "InputFormat": "CSV",
        "InputCompressionType": "NONE",
        "TableCreationParameters": {
            "TableName": "target-table",
            "AttributeDefinitions": [
                {
                    "AttributeName": "pk",
                    "AttributeType": "S"
                }
            ],
            "KeySchema": [
                {
                    "AttributeName": "pk",
                    "KeyType": "HASH"
                }
            ],
            "BillingMode": "PAY_PER_REQUEST"
        },
        "StartTime": 1658528578.619,
        "EndTime": 1658528750.628,
        "ProcessedSizeBytes": 70,
        "ProcessedItemCount": 1,
        "ImportedItemCount": 0,
        "FailureCode": "ItemValidationError",
        "FailureMessage": "Some of the items failed validation checks and were not
 imported. Please check CloudWatch error logs for more details."
    }
}
```

Retrieve the log group and the import id from the above response and use it to retrieve the error logs. The import ID is the last path element of the `ImportArn` field. The log group name is `/aws-dynamodb/imports`. The error log stream name is `import-id/error`. For this example, it would be `01658528578619-c4d4e311/error`.

Missing the key pk in the item

If the source S3 object does not contain the primary key that was provided as a parameter, the import will fail. For example, when you define the primary key for the import as column name “pk”.

```
aws dynamodb import-table –s3-bucket-source S3Bucket=my-import-
source,S3KeyPrefix=import-test.csv \
            –input-format CSV --table-creation-parameters '{"TableName":"target-
table","KeySchema":  \
            [{"AttributeName":"pk","KeyType":"HASH"}],"AttributeDefinitions":
[{"AttributeName":"pk","AttributeType":"S"}],"BillingMode":"PAY_PER_REQUEST"}'
```

The column “pk” is missing from the the source object `import-test.csv` which has the following contents:

```
title,artist,year_of_release
The Dark Side of the Moon,Pink Floyd,1973
```

This import will fail due to item validation error because of the missing primary key in the data source.

Example CloudWatch error log:

```
aws logs get-log-events –log-group-name /aws-dynamodb/imports –log-stream-name
 01658528578619-c4d4e311/error
{
"events": [
{
"timestamp": 1658528745319,
"message": "{\"itemS3Pointer\":{\"bucket\":\"my-import-source\",\"key\":
\"import-test.csv\",\"itemIndex\":0},\"importArn\":\"arn:aws:dynamodb:us-
east-1:531234567890:table/target-table/import/01658528578619-c4d4e311\",\"errorMessages
\":[\"One or more parameter values were invalid: Missing the key pk in the item\"]}",
"ingestionTime": 1658528745414
}
],
"nextForwardToken": "f/36986426953797707963335499204463414460239026137054642176/s",
"nextBackwardToken": "b/36986426953797707963335499204463414460239026137054642176/s"
}
```

This error log indicates that “One or more parameter values were invalid: Missing the key pk in the item”. Since this import job failed, the table “target-table” now exists and is empty because no items were imported. The first item was processed and the object failed Item Validation.

To fix the issue, first delete “target-table” if it is no longer needed. Then either use a primary key column name that exists in the source object, or update the source data to:

```
pk,title,artist,year_of_release
Albums::Rock::Classic::1973::AlbumId::ALB25,The Dark Side of the Moon,Pink Floyd,1973
```

Target table exists

When you start an import job and receive a response as follows:

```
An error occurred (ResourceInUseException) when calling the ImportTable operation:
 Table already exists: target-table
```

To fix this error, you will need to choose a table name that doesn't already exist and retry the import.

The specified bucket does not exist

If the source bucket does not exist, the import will fail and log the error message details in CloudWatch.

Example describe import:

```
aws dynamodb –endpoint-url $ENDPOINT describe-import –import-arn "arn:aws:dynamodb:us-
east-1:531234567890:table/target-table/import/01658530687105-e6035287"
{
"ImportTableDescription": {
"ImportArn": "arn:aws:dynamodb:us-east-1:ACCOUNT:table/target-table/
import/01658530687105-e6035287",
"ImportStatus": "FAILED",
"TableArn": "arn:aws:dynamodb:us-east-1:ACCOUNT:table/target-table",
"TableId": "e1215a82-b8d1-45a8-b2e2-14b9dd8eb99c",
"ClientToken": "3048e16a-069b-47a6-9dfb-9c259fd2fb6f",
"S3BucketSource": {
"S3BucketOwner": "531234567890",
"S3Bucket": "BUCKET_DOES_NOT_EXIST",
"S3KeyPrefix": "import-test"
},
"ErrorCount": 0,
"CloudWatchLogGroupArn": "arn:aws:logs:us-east-1:ACCOUNT:log-group:/aws-dynamodb/
imports:*",
"InputFormat": "CSV",
"InputCompressionType": "NONE",
"TableCreationParameters": {
"TableName": "target-table",
```

```
"AttributeDefinitions": [
{
"AttributeName": "pk",
"AttributeType": "S"
}
],
"KeySchema": [
{
"AttributeName": "pk",
"KeyType": "HASH"
}
],
"BillingMode": "PAY_PER_REQUEST"
},
"StartTime": 1658530687.105,
"EndTime": 1658530701.873,
"ProcessedSizeBytes": 0,
"ProcessedItemCount": 0,
"ImportedItemCount": 0,
"FailureCode": "S3NoSuchBucket",
"FailureMessage": "The specified bucket does not exist (Service: Amazon S3; Status
 Code: 404; Error Code: NoSuchBucket; Request ID: Q4W6QYYFDWY6WAKH; S3 Extended Request
 ID: ObqSlLeIMJpQqHLRX2C5Sy7n+8g6iGPwy7ixg7eEeTuEkg/+chU/JF+RbliWytMlkUlUcuCLTrI=;
 Proxy: null)"
}
}
```

The `FailureCode` is `S3NoSuchBucket`, with `FailureMessag` containing details such as request id and the service that threw the error. Since the error was caught before the data was imported into the table, a new DynamoDB table is not created. In some cases, when these errors are encountered after the data import has started, the table with partially imported data is retained.

To fix this error, make sure that the source Amazon S3 bucket exists and then restart the import process.

Best practices for importing from Amazon S3 into DynamoDB

The following are the best practices for importing data from Amazon S3 into DynamoDB.

Stay under the limit of 50,000 S3 objects

Each import job supports a maximum of 50,000 S3 objects. If your dataset contains more than 50,000 objects, consider consolidating them into larger objects.

Avoid excessively large S3 objects

S3 objects are imported in parallel. Having numerous mid-sized S3 objects allows for parallel execution without excessive overhead. For items under 1 KB, consider placing 4,000,000 items into each S3 object. If you have a larger average item size, place proportionally fewer items into each S3 object.

Randomize sorted data

If an S3 object holds data in sorted order, it can create a *rolling hot partition*. This is a situation where one partition receives all the activity, and then the next partition after that, and so on. Data in sorted order is defined as items in sequence in the S3 object that will be written to the same target partition during the import. One common situation where data is in sorted order is a CSV file where items are sorted by partition key so that repeated items share the same partition key.

To avoid a rolling hot partition, we recommend that you randomize the order in these cases. This can improve performance by spreading the write operations. For more information, see Distributing write activity efficiently during data upload in DynamoDB.

Compress data to keep the total S3 object size below the Regional limit

In the import from S3 process, there is a limit on the sum total size of the S3 object data to be imported. The limit is 15 TB in the us-east-1, us-west-2, and eu-west-1 Regions, and 1 TB in all other Regions. The limit is based on the raw S3 object sizes.

Compression allows more raw data to fit within the limit. If compression alone isn't sufficient to fit the import within the limit, you can also contact AWS Premium Support for a quota increase.

Be aware of how item size impacts performance

If your average item size is very small (below 200 bytes), the import process might take a little longer than for larger item sizes.

Consider importing without any Global Secondary Indexes

The duration of an import task may depend on the presence of one or multiple global secondary indexes (GSIs). If you plan to establish indexes with partition keys that have low cardinality, you may see a faster import if you defer index creation until after the import task is finished (rather than including them in the import job).

> **Note**
>
> Creating a GSI during the import does not incur write charges (creating a GSI after the import would).

DynamoDB data export to Amazon S3: how it works

DynamoDB export to S3 is a fully managed solution for exporting your DynamoDB data to an Amazon S3 bucket at scale. Using DynamoDB export to S3, you can export data from an Amazon DynamoDB table from any time within your point-in-time recovery (PITR) window to an Amazon S3 bucket. You need to enable PITR on your table to use the export functionality. This feature enables you to perform analytics and complex queries on your data using other AWS services such as Athena, AWS Glue, Amazon SageMaker AI, Amazon EMR, and AWS Lake Formation.

DynamoDB export to S3 allows you to export both full and incremental data from your DynamoDB table. Exports are asynchronous, they don't consume read capacity units (RCUs) and have no impact on table performance and availability. The export file formats supported are DynamoDB JSON and Amazon Ion formats. You can also export data to an S3 bucket owned by another AWS account and to a different AWS region. Your data is always encrypted end-to-end.

DynamoDB full exports are charged based on the size of the DynamoDB table (table data and local secondary indexes) at the point in time for which the export is done. DynamoDB incremental exports are charged based on the size of data processed from your continuous backups for the time period being exported. Incremental export has a minimum charge of 10MB. Additional charges apply for storing exported data in Amazon S3 and for PUT requests made against your Amazon S3 bucket. For more information about these charges, see Amazon DynamoDB pricing and Amazon S3 pricing.

For specifics on service quotas, see Table export to Amazon S3.

Topics

- Requesting a table export in DynamoDB
- DynamoDB table export output format

Requesting a table export in DynamoDB

DynamoDB table exports allow you to export table data to an Amazon S3 bucket, enabling you to perform analytics and complex queries on your data using other AWS services such as Athena, AWS Glue, Amazon SageMaker AI, Amazon EMR, and AWS Lake Formation. You can request a table export using the AWS Management Console, the AWS CLI, or the DynamoDB API.

> **Note**
>
> Requester pays Amazon S3 buckets aren't supported.

DynamoDB supports both full export and incremental export:

- With **full exports**, you can export a full snapshot of your table from any point in time within the point-in-time recovery (PITR) window to your Amazon S3 bucket.
- With **incremental exports**, you can export data from your DynamoDB table that was changed, updated, or deleted between a specified time period, within your PITR window, to your Amazon S3 bucket.

Topics

- Prerequisites
- Requesting an export using the AWS Management Console
- Getting details about past exports in the AWS Management Console
- Requesting an export using the AWS CLI
- Getting details about past exports in the AWS CLI
- Requesting an export using the AWS SDK
- Getting details about past exports using the AWS SDK

Prerequisites

Enable PITR

To use the export to S3 feature, you must enable PITR on your table. For details about how to enable PITR, see Point-in-time recovery. If you request an export for a table that doesn't

have PITR enabled, your request will fail with an exception message: “An error occurred (PointInTimeRecoveryUnavailableException) when calling the `ExportTableToPointInTime` operation: Point in time recovery is not enabled for table 'my-dynamodb-table”. You can only request and export from a point in time that is within your configured PITR `RecoveryPeriodInDays`.

Set up S3 permissions

You can export your table data to any Amazon S3 bucket you have permission to write to. The destination bucket doesn't need to be in the same AWS Region or have the same owner as the source table owner. Your AWS Identity and Access Management (IAM) policy needs to allow you to be able to perform S3 actions (`s3:AbortMultipartUpload`, `s3:PutObject`, and `s3:PutObjectAcl`) and the DynamoDB export action (`dynamodb:ExportTableToPointInTime`). Here's an example of a sample policy that will grant your user permissions to perform exports to an S3 bucket.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowDynamoDBExportAction",
            "Effect": "Allow",
            "Action": "dynamodb:ExportTableToPointInTime",
            "Resource": "arn:aws:dynamodb:us-east-1:111122223333:table/my-table"
        },
        {
            "Sid": "amzn-s3-demo-bucket-AllowWrites",
            "Effect": "Allow",
            "Action": [
                "s3:AbortMultipartUpload",
                "s3:PutObject",
                "s3:PutObjectAcl"
            ],
            "Resource": "arn:aws:s3:::your-bucket/*"
        }
    ]
}
```

If you need to write to an Amazon S3 bucket that is in another account or you don't have permissions to write to, the Amazon S3 bucket owner must add a bucket policy to allow you to export from DynamoDB to that bucket. Here's an example policy on the target Amazon S3 bucket.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ExampleStatement",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:user/Dave"
            },
            "Action": [
                "s3:AbortMultipartUpload",
                "s3:PutObject",
                "s3:PutObjectAcl"
            ],
            "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
        }
    ]
}
```

Revoking these permissions while an export is in progress will result in partial files.

> **Note**
>
> If the table or bucket you're exporting to is encrypted with customer managed keys, that KMS key's policies must give DynamoDB permission to use it. This permission is given through the IAM User/Role that triggers the export job. For more information on encryption including best practices, see How DynamoDB uses AWS KMS and Using a custom KMS key.

Requesting an export using the AWS Management Console

The following example demonstrates how to use the DynamoDB console to export an existing table named `MusicCollection`.

> **Note**
>
> This procedure assumes that you have enabled point-in-time recovery. To enable it for the `MusicCollection` table, on the table's **Overview** tab, in the **Table details** section, choose **Enable** for **Point-in-time recovery**.

To request a table export

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. In the navigation pane on the left side of the console, choose **Exports to S3**.
3. Select the **Export to S3** button.
4. Choose a source table and destination S3 bucket. If the destination bucket is owned by your account, you can use the **Browse S3** button to find it. Otherwise, enter the URL of the bucket using the `s3://bucketname/prefix format.` the **`prefix`** is an optional folder to help keep your destination bucket organized.
5. Choose **Full export** or **Incremental export**. A **full export** outputs the full table snapshot of your table as it was at the point in time you specify. An **incremental export** outputs the changes made to your table during the specified export period. Your output is compacted so it only contains the final state of the item from the export period. The item will only appear once in the export even if it has multiple updates within the same export period.

   Full export

   1. Select the point in time you want to export the full table snapshot from. This can be any point in time within the PITR window. Alternatively, you can select **Current time** to export the latest snapshot.
   2. For **Exported file format**, choose between **DynamoDB JSON** and **Amazon Ion**. By default, your table will be exported in DynamoDB JSON format from the latest restorable time in the point in time recovery window and encrypted using an Amazon S3 key (SSE-S3). You can change these export settings if necessary.

      > **Note**
      >
      > If you choose to encrypt your export using a key protected by AWS Key Management Service (AWS KMS), the key must be in the same Region as the destination S3 bucket.

   Incremental export

   1. Select the **Export period** you want to export the incremental data for. Pick a start time within the PITR window. The export period duration must be at least 15 minutes and

be no longer than 24 hours. The export period's start time is inclusive and the end time is exclusive.

2. Choose between **Absolute mode** or **Relative mode**.

   a. **Absolute mode** will export incremental data for the time period you specify.

   b. **Relative mode** will export incremental data for an export period that is relative to your export job submission time.

3. For **Exported file format**, choose between **DynamoDB JSON** and **Amazon Ion**. By default, your table will be exported in DynamoDB JSON format from the latest restorable time in the point in time recovery window and encrypted using an Amazon S3 key (SSE-S3). You can change these export settings if necessary.

   > **Note**
   >
   > If you choose to encrypt your export using a key protected by AWS Key Management Service (AWS KMS), the key must be in the same Region as the destination S3 bucket.

4. For **Export view type**, select either **New and old images** or **New images only**. New image provides the latest state of the item. Old image provides the state of the item right before the specified “start date and time”. The default setting is **New and old images**. For more information on new images and old images, see Incremental export output.

6. Choose **Export** to begin.

Exported data isn't transactionally consistent. Your transaction operations can be torn between two export outputs. A subset of items can be modified by a transaction operation reflected in the export, while another subset of modifications in the same transaction isn't reflected in the same export request. However, exports are eventually consistent. If a transaction is torn during an export, you'll have the remaining transaction in your next contiguous export, without duplicates. The time periods used for exports are based on an internal system clock and can vary by one minute of your application’s local clock.

Getting details about past exports in the AWS Management Console

You can find information about export tasks you've run in the past by choosing the **Exports to S3** section in the navigation sidebar. This section contains a list of all exports you've created in the

past 90 days. Select the ARN of a task listed in the **Exports** tab to retrieve information about that export, including any advanced configuration settings you chose. Note that although export task metadata expires after 90 days and jobs older than that are no longer found in this list, the objects in your S3 bucket remain as long as their bucket policies allow. DynamoDB never deletes any of the objects it creates in your S3 bucket during an export.

Requesting an export using the AWS CLI

The following example shows how to use the AWS CLI to export an existing table named `MusicCollection` to an S3 bucket called `ddb-export-musiccollection`.

> **Note**
>
> This procedure assumes that you have enabled point-in-time recovery. To enable it for the `MusicCollection` table, run the following command.
>
> ```
> aws dynamodb update-continuous-backups \
>     --table-name MusicCollection \
>     --point-in-time-recovery-specification PointInTimeRecoveryEnabled=True
> ```

Full export

The following command exports the `MusicCollection` to an S3 bucket called `ddb-export-musiccollection-9012345678` with a prefix of `2020-Nov`. Table data will be exported in DynamoDB JSON format from a specific time within the point in time recovery window and encrypted using an Amazon S3 key (SSE-S3).

> **Note**
>
> If requesting a cross-account table export, make sure to include the `--s3-bucket-owner` option.

```
aws dynamodb export-table-to-point-in-time \
  --table-arn arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection \
  --s3-bucket ddb-export-musiccollection-9012345678 \
  --s3-prefix 2020-Nov \
  --export-format DYNAMODB_JSON \
  --export-time 1604632434 \
```

```
  --s3-bucket-owner 9012345678 \
  --s3-sse-algorithm AES256
```

Incremental export

The following command performs an incremental export by providing a new `--export-type` and `--incremental-export-specification`. Substitute your own values for anything in italics. Times are specified as seconds since epoch.

```
aws dynamodb export-table-to-point-in-time \
  --table-arn arn:aws:dynamodb:REGION:ACCOUNT:table/TABLENAME \
  --s3-bucket BUCKET --s3-prefix PREFIX \
  --incremental-export-specification
 ExportFromTime=1693569600,ExportToTime=1693656000,ExportViewType=NEW_AND_OLD_IMAGES
 \
  --export-type INCREMENTAL_EXPORT
```

Note

If you choose to encrypt your export using a key protected by AWS Key Management Service (AWS KMS), the key must be in the same Region as the destination S3 bucket.

Getting details about past exports in the AWS CLI

You can find information about export requests you've run in the past by using the `list-exports` command. This command returns a list of all exports you've created in the past 90 days. Note that although export task metadata expires after 90 days and jobs older than that are no longer returned by the `list-exports` command, the objects in your S3 bucket remain as long as their bucket policies allow. DynamoDB never deletes any of the objects it creates in your S3 bucket during an export.

Exports have a status of `PENDING` until they either succeed or fail. If they succeed, the status changes to `COMPLETED`. If they fail, the status changes to `FAILED` with a `failure_message` and `failure_reason`.

In the following example, we use the optional `table-arn` parameter to list only exports of a specific table.

```
aws dynamodb list-exports \
```

```
    --table-arn arn:aws:dynamodb:us-east-1:123456789012:table/ProductCatalog
```

To retrieve detailed information about a specific export task, including any advanced configuration settings, use the `describe-export` command.

```
aws dynamodb describe-export \
    --export-arn arn:aws:dynamodb:us-east-1:123456789012:table/ProductCatalog/
export/01234567890123-a1b2c3d4
```

Requesting an export using the AWS SDK

Use these code snippets to request a table export using the AWS SDK of your choice.

Python

Full export

```
import boto3
from datetime import datetime

# remove endpoint_url for real use
client = boto3.client('dynamodb')

# https://boto3.amazonaws.com/v1/documentation/api/latest/reference/services/
dynamodb/client/export_table_to_point_in_time.html
client.export_table_to_point_in_time(
    TableArn='arn:aws:dynamodb:us-east-1:0123456789:table/TABLE',
    ExportTime=datetime(2023, 9, 20, 12, 0, 0),
    S3Bucket='bucket',
    S3Prefix='prefix',
    S3SseAlgorithm='AES256',
    ExportFormat='DYNAMODB_JSON'
)
```

Incremental export

```
import boto3
from datetime import datetime

client = boto3.client('dynamodb')

client.export_table_to_point_in_time(
    TableArn='arn:aws:dynamodb:us-east-1:0123456789:table/TABLE',
```

```
    IncrementalExportSpecification={
      'ExportFromTime': datetime(2023, 9, 20, 12, 0, 0),
      'ExportToTime': datetime(2023, 9, 20, 13, 0, 0),
      'ExportViewType': 'NEW_AND_OLD_IMAGES'
    },
    ExportType='INCREMENTAL_EXPORT',
    S3Bucket='bucket',
    S3Prefix='prefix',
    S3SseAlgorithm='AES256',
    ExportFormat='DYNAMODB_JSON'
)
```

Getting details about past exports using the AWS SDK

Use these code snippets to get details about past table exports using the AWS SDK of your choice.

Python

List

```
import boto3

client = boto3.client('dynamodb')

# https://boto3.amazonaws.com/v1/documentation/api/latest/reference/services/
dynamodb/client/list_exports.html

print(
  client.list_exports(
     TableArn='arn:aws:dynamodb:us-east-1:0123456789:table/TABLE',
  )
)
```

Describe

```
import boto3

client = boto3.client('dynamodb')

# https://boto3.amazonaws.com/v1/documentation/api/latest/reference/services/
dynamodb/client/describe_export.html
```

```
print(
  client.describe_export(
     ExportArn='arn:aws:dynamodb:us-east-1:0123456789:table/TABLE/
export/01695353076000-06e2188f',
  )['ExportDescription']
)
```

DynamoDB table export output format

A DynamoDB table export includes manifest files in addition to the files containing your table data. These files are all saved in the Amazon S3 bucket that you specify in your export request. The following sections describe the format and contents of each output object.

Full export output

Manifest files

DynamoDB creates manifest files, along with their checksum files, in the specified S3 bucket for each export request.

```
export-prefix/AWSDynamoDB/ExportId/manifest-summary.json
export-prefix/AWSDynamoDB/ExportId/manifest-summary.checksum
export-prefix/AWSDynamoDB/ExportId/manifest-files.json
export-prefix/AWSDynamoDB/ExportId/manifest-files.checksum
```

You choose an **`export-prefix`** when you request a table export. This helps you keep files in the destination S3 bucket organized. The **`ExportId`** is a unique token generated by the service to ensure that multiple exports to the same S3 bucket and `export-prefix` don't overwrite each other.

The export creates at least 1 file per partition. For partitions that are empty, your export request will create an empty file. All of the items in each file are from that particular partition's hashed keyspace.

> **Note**
>
> DynamoDB also creates an empty file named `_started` in the same directory as the manifest files. This file verifies that the destination bucket is writable and that the export has begun. It can safely be deleted.

The summary manifest

The `manifest-summary.json` file contains summary information about the export job. This allows you to know which data files in the shared data folder are associated with this export. Its format is as follows:

```
{
   "version": "2020-06-30",
   "exportArn": "arn:aws:dynamodb:us-east-1:123456789012:table/ProductCatalog/
export/01234567890123-a1b2c3d4",
   "startTime": "2020-11-04T07:28:34.028Z",
   "endTime": "2020-11-04T07:33:43.897Z",
   "tableArn": "arn:aws:dynamodb:us-east-1:123456789012:table/ProductCatalog",
   "tableId": "12345a12-abcd-123a-ab12-1234abc12345",
   "exportTime": "2020-11-04T07:28:34.028Z",
   "s3Bucket": "ddb-productcatalog-export",
   "s3Prefix": "2020-Nov",
   "s3SseAlgorithm": "AES256",
   "s3SseKmsKeyId": null,
   "manifestFilesS3Key": "AWSDynamoDB/01693685827463-2d8752fd/manifest-files.json",
   "billedSizeBytes": 0,
   "itemCount": 8,
   "outputFormat": "DYNAMODB_JSON",
   "exportType": "FULL_EXPORT"
}
```

The files manifest

The `manifest-files.json` file contains information about the files that contain your exported table data. The file is in JSON lines format, so newlines are used as item delimiters. In the following example, the details of one data file from a files manifest are formatted on multiple lines for the sake of readability.

```
{
"itemCount": 8,
   "md5Checksum": "sQMSpEILNgoQmarvDFonGQ==",
   "etag": "af83d6f217c19b8b0fff8023d8ca4716-1",
   "dataFileS3Key": "AWSDynamoDB/01693685827463-2d8752fd/data/asdl123dasas.json.gz"
}
```

Data files

DynamoDB can export your table data in two formats: DynamoDB JSON and Amazon Ion. Regardless of the format you choose, your data will be written to multiple compressed files named by the keys. These files are also listed in the `manifest-files.json` file.

The directory structure of your Amazon S3 bucket after a full export will contain all of your manifest files and data files under the export Id folder.

```
amzn-s3-demo-bucket/DestinationPrefix
.
### AWSDynamoDB
    ### 01693685827463-2d8752fd     // the single full export
    #   ### manifest-files.json     // manifest points to files under 'data' subfolder
    #   ### manifest-files.checksum
    #   ### manifest-summary.json   // stores metadata about request
    #   ### manifest-summary.md5
    #   ### data                    // The data exported by full export
    #   #   ### asdl123dasas.json.gz
    #   #   ...
    #   ### _started                // empty file for permission check
```

DynamoDB JSON

A table export in DynamoDB JSON format consists of multiple `Item` objects. Each individual object is in DynamoDB's standard marshalled JSON format.

When creating custom parsers for DynamoDB JSON export data, the format is JSON lines. This means that newlines are used as item delimiters. Many AWS services, such as Athena and AWS Glue, will parse this format automatically.

In the following example, a single item from a DynamoDB JSON export has been formatted on multiple lines for the sake of readability.

```
{
    "Item":{
        "Authors":{
            "SS":[
                "Author1",
                "Author2"
            ]
```

```
        },
        "Dimensions":{
            "S":"8.5 x 11.0 x 1.5"
        },
        "ISBN":{
            "S":"333-3333333333"
        },
        "Id":{
            "N":"103"
        },
        "InPublication":{
            "BOOL":false
        },
        "PageCount":{
            "N":"600"
        },
        "Price":{
            "N":"2000"
        },
        "ProductCategory":{
            "S":"Book"
        },
        "Title":{
            "S":"Book 103 Title"
        }
    }
}
```

Amazon Ion

Amazon Ion is a richly-typed, self-describing, hierarchical data serialization format built to address rapid development, decoupling, and efficiency challenges faced every day while engineering large-scale, service-oriented architectures. DynamoDB supports exporting table data in Ion's text format, which is a superset of JSON.

When you export a table to Ion format, the DynamoDB datatypes used in the table are mapped to Ion datatypes. DynamoDB sets use Ion type annotations to disambiguate the datatype used in the source table.

The following table lists the mapping of DynamoDB data types to ion data types:

DynamoDB data type	Ion representation
String (S)	string
Boolean (BOOL)	bool
Number (N)	decimal
Binary (B)	blob
Set (SS, NS, BS)	list (with type annotation $dynamodb_SS, $dynamodb_NS, or $dynamodb_BS)
List	list
Map	struct

Items in an Ion export are delimited by newlines. Each line begins with an Ion version marker, followed by an item in Ion format. In the following example, an item from an Ion export has been formatted on multiple lines for the sake of readability.

```
$ion_1_0 {
    Item:{
        Authors:$dynamodb_SS::["Author1","Author2"],
        Dimensions:"8.5 x 11.0 x 1.5",
        ISBN:"333-3333333333",
        Id:103.,
        InPublication:false,
        PageCount:6d2,
        Price:2d3,
        ProductCategory:"Book",
        Title:"Book 103 Title"
    }
}
```

Incremental export output

Manifest files

DynamoDB creates manifest files, along with their checksum files, in the specified S3 bucket for each export request.

```
export-prefix/AWSDynamoDB/ExportId/manifest-summary.json
export-prefix/AWSDynamoDB/ExportId/manifest-summary.checksum
export-prefix/AWSDynamoDB/ExportId/manifest-files.json
export-prefix/AWSDynamoDB/ExportId/manifest-files.checksum
```

You choose an **`export-prefix`** when you request a table export. This helps you keep files in the destination S3 bucket organized. The **`ExportId`** is a unique token generated by the service to ensure that multiple exports to the same S3 bucket and `export-prefix` don't overwrite each other.

The export creates at least 1 file per partition. For partitions that are empty, your export request will create an empty file. All of the items in each file are from that particular partition's hashed keyspace.

> **Note**
>
> DynamoDB also creates an empty file named `_started` in the same directory as the manifest files. This file verifies that the destination bucket is writable and that the export has begun. It can safely be deleted.

The summary manifest

The `manifest-summary.json` file contains summary information about the export job. This allows you to know which data files in the shared data folder are associated with this export. Its format is as follows:

```
{
 "version": "2023-08-01",
 "exportArn": "arn:aws:dynamodb:us-east-1:599882009758:table/export-test/
export/01695097218000-d6299cbd",
 "startTime": "2023-09-19T04:20:18.000Z",
 "endTime": "2023-09-19T04:40:24.780Z",
 "tableArn": "arn:aws:dynamodb:us-east-1:599882009758:table/export-test",
 "tableId": "b116b490-6460-4d4a-9a6b-5d360abf4fb3",
 "exportFromTime": "2023-09-18T17:00:00.000Z",
 "exportToTime": "2023-09-19T04:00:00.000Z",
 "s3Bucket": "jason-exports",
 "s3Prefix": "20230919-prefix",
 "s3SseAlgorithm": "AES256",
```

```
 "s3SseKmsKeyId": null,
 "manifestFilesS3Key": "20230919-prefix/AWSDynamoDB/01693685934212-ac809da5/manifest-
files.json",
 "billedSizeBytes": 20901239349,
 "itemCount": 169928274,
 "outputFormat": "DYNAMODB_JSON",
 "outputView": "NEW_AND_OLD_IMAGES",
 "exportType": "INCREMENTAL_EXPORT"
}
```

The files manifest

The `manifest-files.json` file contains information about the files that contain your exported table data. The file is in JSON lines format, so newlines are used as item delimiters. In the following example, the details of one data file from a files manifest are formatted on multiple lines for the sake of readability.

```
{
"itemCount": 8,
   "md5Checksum": "sQMSpEILNgoQmarvDFonGQ==",
   "etag": "af83d6f217c19b8b0fff8023d8ca4716-1",
   "dataFileS3Key": "AWSDynamoDB/data/sgad6417s6vss4p7owp0471bcq.json.gz"
}
```

Data files

DynamoDB can export your table data in two formats: DynamoDB JSON and Amazon Ion. Regardless of the format you choose, your data will be written to multiple compressed files named by the keys. These files are also listed in the `manifest-files.json` file.

The data files for incremental exports are all contained in a common data folder in your S3 bucket. Your manifest files are under your export ID folder.

```
amzn-s3-demo-bucket/DestinationPrefix
.
### AWSDynamoDB
    ### 01693685934212-ac809da5     // an incremental export ID
    #   ### manifest-files.json     // manifest points to files under 'data' folder
    #   ### manifest-files.checksum
    #   ### manifest-summary.json   // stores metadata about request
    #   ### manifest-summary.md5
```

```
    #   ### _started                // empty file for permission check
    ### 01693686034521-ac809da5
    #   ### manifest-files.json
    #   ### manifest-files.checksum
    #   ### manifest-summary.json
    #   ### manifest-summary.md5
    #   ### _started
    ### data                        // stores all the data files for incremental
 exports
    #   ### sgad6417s6vss4p7owp0471bcq.json.gz
    #   ...
```

In you export files, each item's output includes a timestamp that represents when that item was updated in your table and a data structure that indicates if it was an `insert`, `update`, or `delete` operation. The timestamp is based on an internal system clock and can vary from your application clock. For incremental exports, you can choose between two export view types for your output structure: **new and old images** or **new images only**.

- **New image** provides the latest state of the item
- **Old image** provides the state of the item right before the specified **start date and time**

View types can be helpful if you want to see how the item was changed within the export period. It can also be useful for efficiently updating your downstream systems, especially if those downstream systems have a partition key that is not the same as your DynamoDB partition key.

You can infer whether an item in your incremental export output was an `insert`, `update`, or `delete` by looking at the structure of the output. The incremental export structure and its corresponding operations are summarized in the table below for both export view types.

Operation	New images only	New and old images
Insert	Keys + new image	Keys + new image
Update	Keys + new image	Keys + new image + old image
Delete	Keys	Keys + old image
Insert + delete	No output	No output

DynamoDB JSON

A table export in DynamoDB JSON format consists of a metadata timestamp that indicates the write time of the item, followed by the keys of the item and the values. The following shows an example DynamoDB JSON output using export view type as **New and Old images**.

```
// Ex 1: Insert
//   An insert means the item did not exist before the incremental export window
//   and was added during the incremental export window

{
   "Metadata": {
     "WriteTimestampMicros": "1680109764000000"
   },
   "Keys": {
     "PK": {
       "S": "CUST#100"
     }
   },
   "NewImage": {
     "PK": {
       "S": "CUST#100"
     },
     "FirstName": {
       "S": "John"
     },
     "LastName": {
       "S": "Don"
     }
   }
}

// Ex 2: Update
//   An update means the item existed before the incremental export window
//   and was updated during the incremental export window.
//   The OldImage would not be present if choosing "New images only".

{
   "Metadata": {
     "WriteTimestampMicros": "1680109764000000"
   },
   "Keys": {
     "PK": {
```

```
        "S": "CUST#200"
      }
    },
    "OldImage": {
      "PK": {
        "S": "CUST#200"
      },
      "FirstName": {
        "S": "Mary"
      },
      "LastName": {
        "S": "Grace"
      }
    },
    "NewImage": {
      "PK": {
        "S": "CUST#200"
      },
      "FirstName": {
        "S": "Mary"
      },
      "LastName": {
        "S": "Smith"
      }
    }
}

// Ex 3: Delete
//   A delete means the item existed before the incremental export window
//   and was deleted during the incremental export window
//   The OldImage would not be present if choosing "New images only".

{
    "Metadata": {
      "WriteTimestampMicros": "1680109764000000"
    },
    "Keys": {
      "PK": {
        "S": "CUST#300"
      }
    },
    "OldImage": {
      "PK": {
        "S": "CUST#300"
```

```
      },
      "FirstName": {
        "S": "Jose"
      },
      "LastName": {
        "S": "Hernandez"
      }
    }
}

// Ex 4: Insert + Delete
//   Nothing is exported if an item is inserted and deleted within the
//   incremental export window.
```

Amazon Ion

Amazon Ion is a richly-typed, self-describing, hierarchical data serialization format built to address rapid development, decoupling, and efficiency challenges faced every day while engineering large-scale, service-oriented architectures. DynamoDB supports exporting table data in Ion's text format, which is a superset of JSON.

When you export a table to Ion format, the DynamoDB datatypes used in the table are mapped to Ion datatypes. DynamoDB sets use Ion type annotations to disambiguate the datatype used in the source table.

The following table lists the mapping of DynamoDB data types to ion data types:

DynamoDB data type	Ion representation
String (S)	string
Boolean (BOOL)	bool
Number (N)	decimal
Binary (B)	blob
Set (SS, NS, BS)	list (with type annotation $dynamodb_SS, $dynamodb_NS, or $dynamodb_BS)
List	list

DynamoDB data type	Ion representation
Map	struct

Items in an Ion export are delimited by newlines. Each line begins with an Ion version marker, followed by an item in Ion format. In the following example, an item from an Ion export has been formatted on multiple lines for the sake of readability.

```
$ion_1_0 {
    Record:{
        Keys:{
             ISBN:"333-3333333333"
         },
        Metadata:{
            WriteTimestampMicros:1684374845117899.
        },
        OldImage:{
            Authors:$dynamodb_SS::["Author1","Author2"],
            ISBN:"333-3333333333",
            Id:103.,
            InPublication:false,
            ProductCategory:"Book",
            Title:"Book 103 Title"
        },
        NewImage:{
            Authors:$dynamodb_SS::["Author1","Author2"],
            Dimensions:"8.5 x 11.0 x 1.5",
            ISBN:"333-3333333333",
            Id:103.,
            InPublication:true,
            PageCount:6d2,
            Price:2d3,
            ProductCategory:"Book",
            Title:"Book 103 Title"
        }
    }
}
```

DynamoDB zero-ETL integration with Amazon SageMaker Lakehouse

DynamoDB zero-ETL integration with Amazon SageMaker Lakehouse eliminates the need to build custom data movement pipelines by automatically replicating DynamoDB data to Amazon SageMaker Lakehouse. This no-code integration helps customers run analytics workloads on their DynamoDB data using Amazon SageMaker Lakehouse without consuming any DynamoDB table capacity. The integration automatically exports data from your table and keeps the target fresh, typically within 15 to 30 minutes.

Topics

- DynamoDB zero-ETL integration with Amazon SageMaker Lakehouse

DynamoDB zero-ETL integration with Amazon SageMaker Lakehouse

Setting up an integration between the DynamoDB table and Amazon SageMaker Lakehouse require prerequisites such as configuring IAM roles which AWS Glue uses to access data from the source and write to the target, and the use of KMS keys to encrypt the data in intermediate or the target location.

Topics

- Prerequisites before creating a DynamoDB zero-ETL integration with Amazon SageMaker Lakehouse
- Creating a DynamoDB zero-ETL integration with Amazon SageMaker Lakehouse
- Viewing CloudWatch metrics for integration

Prerequisites before creating a DynamoDB zero-ETL integration with Amazon SageMaker Lakehouse

To configure a zero-ETL integration with an DynamoDB source, you need to set up a Resource-Based Access (RBAC) policy that allows AWS Glue to access and export data from the DynamoDB table. The policy should include specific permissions like `ExportTableToPointInTime`, `DescribeTable`, and `DescribeExport` with conditions restricting access to a specific AWS account and region. See, Configuring an Amazon DynamoDB source for more information.

Point-in-time recovery (PITR) must be enabled for the table, and you can apply the policy using AWS CLI commands. The policy can be further refined by specifying the full integration ARN for more restrictive access control. For more information, see Prerequisites for setting up a zero-ETL integration.

Creating a DynamoDB zero-ETL integration with Amazon SageMaker Lakehouse

After completing integration prerequisites, you can create, modify, or delete the zero-ETL integration following the guidance below:

Creating an integration

To create an integration

1. Sign in to the AWS Management Console and open the Amazon DynamoDB console at https://console.aws.amazon.com/dynamodbv2.
2. In the navigation pane, choose **Integrations**.
3. Select **Create zero-ETL integration with Amazon SageMaker Lakehouse**, and then choose **Next**.
4. To create an integration, see Creating an integration.
5. To modify an integration, see Modifying an integration.
6. To delete an integration, see Deleting an integration.
7. To set up a cross-account integration, see Setting up cross-account integration.

Enabling compaction on target Amazon S3 tables

You can enable compaction to improve query performance in Amazon Athena.

First, complete the prerequisite setup for compaction resources, including configuring the necessary IAM role. Refer to the Lake Formation documentation for detailed IAM role configuration steps. See, Optimizing tables for compaction.

To enable compaction on the AWS Glue table created during integration, follow the Lake Formation compaction enabling process. This will help optimize your table's performance and query efficiency.

Viewing CloudWatch metrics for integration

Once an integration completes, you can see these CloudWatch metrics and EventBridge notifications generated in your account for each AWS Glue job. For more information, see Monitoring an integration.

DynamoDB zero-ETL integration with Amazon OpenSearch Service

Amazon DynamoDB offers a zero-ETL integration with Amazon OpenSearch Service through the **DynamoDB plugin for OpenSearch Ingestion**. Amazon OpenSearch Ingestion offers a fully managed, no-code experience for ingesting data into Amazon OpenSearch Service.

With the DynamoDB plugin for OpenSearch Ingestion, you can use one or more DynamoDB tables as a source for ingestion to one or more OpenSearch Service indexes. You can browse and configure your OpenSearch Ingestion pipelines with DynamoDB as a source from either OpenSearch Ingestion or DynamoDB Integrations in the AWS Management Console.

- Get started with OpenSearch Ingestion by following along in the OpenSearch Ingestion getting started guide.
- Learn about the prerequisites and all the configuration options for the DynamoDB plugin at DynamoDB plugin for OpenSearch Ingestion documentation.

How it works

The plugin uses DynamoDB export to Amazon S3 to create an initial snapshot to load into OpenSearch. After the snapshot has been loaded, the plugin uses DynamoDB Streams to replicate any further changes in near real time. Every item is processed as an event in OpenSearch Ingestion and can be modified with processor plugins. You can drop attributes or create composite attributes and send them to different indexes through routes.

You must have point-in-time recovery (PITR) enabled to use export to Amazon S3. You must also have DynamoDB Streams enabled (with the **new & old images** option selected) to be able to use it. It's possible to create a pipeline without taking a snapshot by excluding export settings.

You can also create a pipeline with only a snapshot and no updates by excluding streams settings. The plugin does not use read or write throughput on your table, so it is safe to use without

impacting your production traffic. There are limits to the number of parallel consumers on a stream that you should consider before creating this or other integrations. For other considerations, see the section called “Integration best practices”.

For simple pipelines, a single OpenSearch Compute Unit (OCU) can process about 1 MB per second of writes. This is the equivalent of about 1000 write request units (WCU). Depending on your pipeline's complexity and other factors, you might achieve more or less than this.

OpenSearch Ingestion supports a dead-letter queue (DLQ) for events that cause unrecoverable errors. Additionally, the pipeline can resume from where it left off without user intervention even if there's an interruption of service with either DynamoDB, the pipeline, or Amazon OpenSearch Service.

If interruption goes on for longer than 24 hours, this can cause a loss of updates. However, the pipeline would continue to process the updates that were still available when availability is restored. You would need to do a fresh index build to fix any irregularities due to the dropped events unless they were in the dead-letter queue.

For all the settings and details for the plugin, see OpenSearch Ingestion DynamoDB plugin documentation.

Integrated create experience through the console

DynamoDB and OpenSearch Service have an integrated experience in the AWS Management Console, which streamlines the getting started process. When you go through these steps, the service will automatically select the DynamoDB blueprint and add the appropriate DynamoDB information for you.

To create an integration, follow along in the OpenSearch Ingestion getting started guide. When you get to Step 3: Create a pipeline, replace Steps 1 and 2 with the following steps:

1. Navigate to the DynamoDB console.
2. In the left-hand navigation pane, choose **Integration**.
3. Select the DynamoDB table that you'd like to replicate to OpenSearch.
4. Choose **Create**.

From here, you can continue on with the rest of the tutorial.

Next steps

For a better understanding of how DynamoDB integrates with OpenSearch Service, see the following:

- Getting started with Amazon OpenSearch Ingestion
- DynamoDB plugin configuration and requirements

Handling breaking changes to your index

OpenSearch can dynamically add new attributes to your index. However, after your mapping template has been set for a given key, you'll need to take additional action to change it. Additionally, if your change requires you to reprocess all the data in your DynamoDB table, you'll need to take steps to initiate a fresh export.

> **Note**
>
> In all these options, you might still run into issues if your DynamoDB table has type conflicts with the mapping template you've specified. Ensure that you have a dead-letter queue (DLQ) enabled (even in development). This makes it easier to understand what might be wrong with the record that causes a conflict when it's being indexed into your index on OpenSearch.

Topics

- How it works
- Delete your index and reset the pipeline (pipeline-centric option)
- Recreate your index and reset the pipeline (index-centric option)
- Create a new index and sink (online option)
- Best practices for avoiding and debugging type conflicts

How it works

Here's a quick overview of the actions taken when handling breaking changes to your index. See the step-by-step procedures in the sections that follow.

- **Stop and start the pipeline**: This option resets the pipeline's state, and the pipeline will restart with a new full export. It is non-destructive, so it does **not** delete your index or any data in DynamoDB. If you don't create a fresh index before you do this, you might see a high number of errors from version conflicts because the export tries to insert older documents than the current `_version` in the index. You can safely ignore these errors. You will not be billed for the pipeline while it is stopped.
- **Update the pipeline**: This option updates the configuration in the pipeline with a blue/green approach, without losing any state. If you make significant changes to your pipeline (such as adding new routes, indexes, or keys to existing indexes), you might need to do a full reset of the pipeline and recreate your index. This option does **not** perform a full export.
- **Delete and recreate the index**: This option removes your data and mapping settings on your index. You should do this before making any breaking changes to your mappings. It will break any applications that rely on the index until the index is recreated and synchronized. Deleting the index does **not** initiate a fresh export. You should delete your index only after you've updated your pipeline. Otherwise, your index might be recreated before you update your settings.

Delete your index and reset the pipeline (pipeline-centric option)

This method is often the fastest option if you're still in development. You'll delete your index in OpenSearch Service, and then stop and start your pipeline to initiate a fresh export of all your data. This ensures that there are no mapping template conflicts with existing indexes, and no loss of data from an incomplete processed table.

1. Stop the pipeline either through the AWS Management Console, or by using the StopPipeline API operation with the AWS CLI or an SDK.
2. Update your pipeline configuration with your new changes.
3. Delete your index in OpenSearch Service, either through a REST API call or your OpenSearch Dashboard.
4. Start the pipeline either through the console, or by using the `StartPipeline` API operation with the AWS CLI or an SDK.

   > **Note**
   >
   > This initiates a fresh full export, which will incur additional costs.

5. Monitor for any unexpected issues because a fresh export is generated to create the new index.

6. Confirm that the index matches your expectations in OpenSearch Service.

After the export has completed and it resumes reading from the stream, your DynamoDB table data will now be available in the index.

Recreate your index and reset the pipeline (index-centric option)

This method works well if you need to do a lot of iterations on the index design in OpenSearch Service before resuming the pipeline from DynamoDB. This can be useful for development when you want to iterate very quickly on your search patterns, and want to avoid waiting on fresh exports to complete between each iteration.

1. Stop the pipeline either through the AWS Management Console, or by calling the StopPipeline API operation with the AWS CLI or an SDK.
2. Delete and recreate your index in OpenSearch with the mapping template you want to use. You can manually insert some sample data to confirm that your searches are working as intended. If your sample data might conflict with any data from DynamoDB, be sure to delete it before moving onto the next step.
3. If you have an indexing template in your pipeline, remove it or replace it with the one you've created already in OpenSearch Service. Ensure that the name of your index matches the name in the pipeline.
4. Start the pipeline either through console, or by calling the `StartPipeline` API operation with the AWS CLI or an SDK.

   > **Note**
   >
   > This will initiate a fresh full export, which will incur additional costs.

5. Monitor for any unexpected issues because a fresh export is generated to create the new index.

After the export has completed and it resumes reading from the stream, you should be your DynamoDB table data will now be available in the index.

Create a new index and sink (online option)

This method works well if you need to update your mapping template but are currently using your index in production. This creates a brand new index, which you'll need to move your application over to after it's synchronized and validated.

> **Note**
>
> This will create another consumer on the stream. This can be an issue if you also have other consumers like AWS Lambda or global tables. You might need to pause updates to your existing pipeline to create capacity to load the new index.

1. Create a new pipeline with new settings and a different index name.
2. Monitor the new index for any unexpected issues.
3. Swap the application over to the new index.
4. Stop and delete the old pipeline after validating that everything is working correctly.

Best practices for avoiding and debugging type conflicts

- Always use a dead-letter queue (DLQ) to make it easier to debug when there are type conflicts.
- Always use an index template with mappings and set `include_keys`. While OpenSearch Service dynamically maps new keys, this can cause issues with unexpected behaviors (such as expecting something to be a `GeoPoint`, but it's created as a `string` or `object`) or errors (such as having a `number` that is a mix of `long` and `float` values).
- If you need to keep your existing index working in production, you can also replace any of the previous delete index steps with just renaming your index in your pipeline config file. This creates a brand new index. Your application will then need to be updated to point to the new index after it's complete.
- If you have a type conversion issue that you fix with a processor, you can test this with `UpdatePipeline`. To do this, you'll need to do a stop and start or process your dead-letter queues to fix any previously skipped documents that had errors.

Best practices for working with DynamoDB zero-ETL integration and OpenSearch Service

DynamoDB has a DynamoDB zero-ETL integration with Amazon OpenSearch Service. For more information, see the DynamoDB plugin for OpenSearch Ingestion and specific best practices for Amazon OpenSearch Service.

Configuration

- Only index data that you need to perform searches on. Always use a mapping template (`template_type: index_template` and `template_content`) and `include_keys` to implement this.
- Monitor your logs for errors that are related to type conflicts. OpenSearch Service expects all values for a given key to have the same type. It generates exceptions if there's a mismatch. If you encounter one of these errors, you can add a processor to catch that a given key is always be the same value.
- Generally use the `primary_key` metadata value for the `document_id` value. In OpenSearch Service, the document ID is the equivalent of the primary key in DynamoDB. Using the primary key will make it easy to find your document and ensure that updates are consistently replicated to it without conflicts.

  You can use the helper function `getMetadata` to get your primary key (for example, `document_id: "${getMetadata('primary_key')}"`). If you're using a composite primary key, the helper function will concatenate them together for you.
- In general, use the `opensearch_action` metadata value for the `action` setting. This will ensure that updates are replicated in such a way that the data in OpenSearch Service matches the latest state in DynamoDB.

  You can use the helper function `getMetadata` to get your primary key (for example, `action: "${getMetadata('opensearch_action')}"`). You can also get the stream event type through `dynamodb_event_name` for use cases like filtering. However, you should typically not use it for the `action` setting.

Observability

- Always use a dead-letter queue (DLQ) on your OpenSearch sinks to handle dropped events. DynamoDB is generally less structured than OpenSearch Service, and it's always possible for something unexpected to happen. With a dead-letter queue, you can recover individual events, and even automate the recovery process. This will help you to avoid needing to rebuild your entire index.
- Always set alerts that your replication delay doesn't go over an expected amount. It is typically safe to assume one minute without the alert being too noisy. This can vary depending on how spiky your write traffic is and your OpenSearch Compute Unit (OCU) settings on the pipeline.

If your replication delay goes over 24 hours, your stream will start to drop events, and you'll have accuracy issues unless you do a full rebuild of your index from scratch.

Scaling

- Use auto scaling for pipelines to help scale up or down the OCUs to best fit the workload.
- For provisioned throughput tables without auto scaling, we recommend setting OCUs based on your write capacity units (WCUs) divided by 1000. Set the minimum to 1 OCU below that amount (but at least 1), and set the maximum to at least 1 OCU above that amount.
  - **Formula:**

```
OCU_minimum = GREATEST((table_WCU / 1000) - 1, 1)
OCU_maximum = (table_WCU / 1000) + 1
```

  - **Example:** Your table has 25000 WCUs provisioned. Your pipeline's OCUs should be set with a minimum of 24 (25000/1000 - 1) and maximum of at least 26 (25000/1000 + 1).
- For provisioned throughput tables with auto scaling, we recommend setting OCUs based on your minimum and maximum WCUs, divided by 1000. Set the minimum to 1 OCU below the minimum from DynamoDB, and set the maximum to at least 1 OCU above the maximum from DynamoDB.
  - **Formula:**

```
OCU_minimum = GREATEST((table_minimum_WCU / 1000) - 1, 1)
OCU_maximum = (table_maximum_WCU / 1000) + 1
```

  - **Example:** Your table has an auto scaling policy with a minimum of 8000 and maximum of 14000. Your pipeline's OCUs should be set with a minimum of 7 (8000/1000 - 1) and a maximum of 15 (14000/1000 + 1).
- For on-demand throughput tables, we recommend setting OCUs based on your typical peak and valley for write request units per second. You might need to average over a longer time period, depending on the aggregation that's available to you. Set the minimum to 1 OCU below the minimum from DynamoDB, and set the maximum to at least 1 OCU above the maximum from DynamoDB.
  - **Formula:**

```
# Assuming we have writes aggregated at the minute level
OCU_minimum = GREATEST((min(table_writes_1min) / (60 * 1000)) - 1, 1)
```

```
OCU_maximum = (max(table_writes_1min) / (60 * 1000)) + 1
```

- **Example:** Your table has an average valley of 300 write request units per second and an average peak of 4300. Your pipeline's OCUs should be set with a minimum of 1 (300/1000 - 1, but at least 1) and a maximum of 5 (4300/1000 + 1).

- Follow best practices on scaling your destination OpenSearch Service indexes. If your indexes are under-scaled, it will slow down ingestion from DynamoDB, and might cause delays.

> **Note**
>
> `GREATEST` is a SQL function that, given a set of arguments, returns the argument with the greatest value.

Integrating DynamoDB with Amazon EventBridge

Amazon DynamoDB offers DynamoDB Streams for change data capture, enabling the capture of item-level changes in DynamoDB tables. DynamoDB Streams can invoke Lambda functions to process those changes, allowing event driven integration with other services and applications. DynamoDB Streams also supports filtering, which allows for efficient and targeted event processing.

DynamoDB Streams supports up to two simultaneous consumers per shard and supports filtering through Lambda event filtering so that only items which match specific criteria are processed. Some customers may have requirements to support more than two consumers. Others may need to enrich change events before they are processed, or use more advanced filtering and routing.

Integrating DynamoDB with EventBridge can support those requirements.

Amazon EventBridge is a serverless service that uses events to connect application components together, making it easier for you to build scalable event-driven applications. EventBridge offers native integration with Amazon DynamoDB through EventBridge Pipes, enabling seamless data flow from DynamoDB to an EventBridge bus. That bus can then fan-out to multiple applications and services through a set of rules and targets.

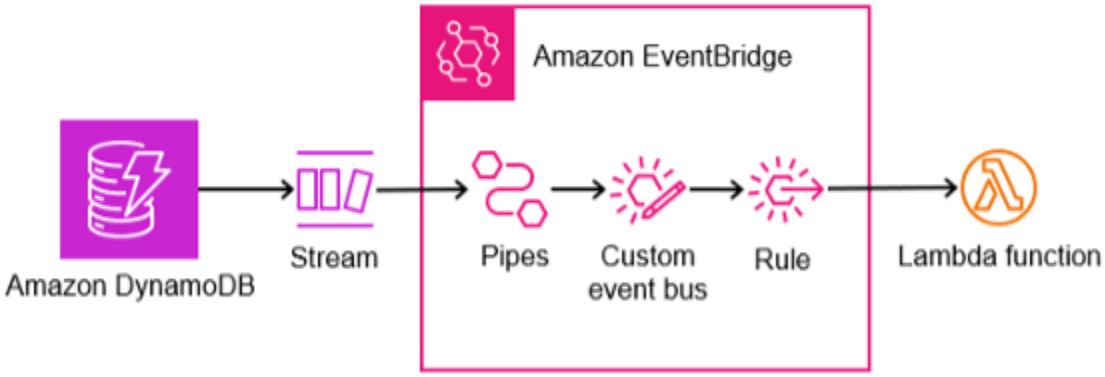
Topics

- How it works

- Creating an integration through the console
- Next steps

How it works

The integration between DynamoDB and EventBridge pipes uses DynamoDB Streams to capture a time-ordered sequence of item-level changes in a DynamoDB table. Each record captured this way contains the data modified in the table.



An EventBridge pipe consumes events from DynamoDB Streams and routes them to a target such as an EventBridge bus (an event bus is a router that receives events and delivers them to destinations, also called targets). Delivery is based on which rules match the contents of the event. Optionally, the pipe also includes the ability to filter for specific events and perform enrichments on the event data before sending it to the target.

While EventBridge supports multiple target types, a common choice when implementing a fan-out design is to use a Lambda function as the target. The following example demonstrates an integration with a Lambda function target.

Creating an integration through the console

Follow the steps below to create an integration through the AWS Management Console.

1. Enable DynamoDB Streams on the source table by following the steps in the Enabling a stream section of the DynamoDB developer guide. If DynamoDB Streams is already enabled on the source table, verify that there are currently fewer than two consumers. Consumers could be

Lambda functions, DynamoDB Global Tables, Amazon DynamoDB zero-ETL integrations with Amazon OpenSearch Service, or applications that read directly from streams such as through the DynamoDB Streams Kinesis adapter.

2. Create an EventBridge event bus by following the steps in the Creating an Amazon EventBridge event bus section of the EventBridge user guide.
   a. When creating the event bus, enable **Schema discovery**.
3. Create an EventBridge pipe by following the steps in the Creating an Amazon EventBridge pipe section of the EventBridge user guide.
   a. When configuring the source, in the **Source** field select *DynamoDB* and in the **DynamoDB Streams** field select the name of the source table stream.
   b. When configuring the target, in the **Target service** field select *EventBridge event bus* and in the **Event bus as target** field select the event bus created in step 2.
4. Write an example item to the source DynamoDB table to trigger an event. This will allow EventBridge to infer schema from the example item. This schema can be used to create rules for routing events. For example, if you are implementing a design pattern that involves overloading attributes, you may want to trigger different rules depending on the value of your sort key. Details on how to write an item to DynamoDB can be found in the Working with items and attributes section of the DynamoDB developer guide.
5. Create an example Python Lambda function to be used as a target by following the steps in the Building Lambda functions with Python section of the Lambda developer guide. When creating your function, you can use the below example code to demonstrate the integration. When invoked, it will print the `NewImage` and `OldImage` received with the event which can be viewed in CloudWatch Logs.

```
import json

def lambda_handler(event, context):
    dynamodb = event.get('detail', {}).get('dynamodb', {})
    new_image = dynamodb.get('NewImage')
    old_image = dynamodb.get('OldImage')

    if new_image:
        print("NewImage:", json.dumps(new_image, indent=2))
    if old_image:
        print("OldImage:", json.dumps(old_image, indent=2))

    return {'statusCode': 200, 'body': json.dumps(event)}
```

6. Create an EventBridge rule that will route events to your new Lambda function by following the steps in the Create a rule section that reacts to events EventBridge user guide.

   a. When defining the rule detail, select the name of the event bus you created in step 2 as the **Event bus**.

   b. When building the event pattern, follow the guide for **Existing schema**. Here, you can select the *discovered-schemas* registry and the discovered schema for your event. This allows you to configure an event pattern specific to your use case that only routes messages that match specific attributes. For example, if you wanted to match only on DynamoDB items where the SK begins with "`user#`", you'd use a configuration like this.

   c. Click **Generate event pattern in JSON** after you've finished designing a pattern against your schema. If you instead want to match all events that appear on DynamoDB Streams, use the following JSON for the event pattern.

```
{
  "source": ["aws.dynamodb"]
}
```

   d. When selecting targets, follow the guide for AWS service. In the Select a target field, choose "Lambda function". In the Function field, select the Lambda function you created in step 5.

7. You can now stop schema discovery on your event bus by following the steps in the Starting or stopping schema discovery on event buses section of the EventBridge user guide.

8. Write a second example item to the source DynamoDB table to trigger an event. Validate that the event was successfully processed at each step.
   a. View the CloudWatch metric **PutEventsApproximateSuccessCount** for your event bus by following the Monitoring Amazon EventBridge section of the EventBridge user guide.
   b. View function logs for your Lambda function by following the Monitoring and troubleshooting Lambda functions section of the Lambda developer guide. If your Lambda function uses the example code provided, you should see the `NewImage` and `OldImage` from DynamoDB Streams printed in the CloudWatch Logs log group.
   c. View the **Error count and success rate (%)** metric for your Lambda function by following the Monitoring and troubleshooting Lambda functions section of the Lambda developer guide.

Next steps

This example provides a basic integration with a single Lambda function as a target. For a better understanding of more complex configurations, such as creating multiple rules, creating multiple targets, integrating with other services, and enriching events see the complete EventBridge user guide: Getting started with EventBridge.

> **Note**
>
> Be aware of any EventBridge quotas that might be relevant to your application. While DynamoDB Streams capacity scales with your table, EventBridge quotas are separate. Common quotas to be aware of in a large application would be **Invocations throttle limit in transactions per second** and **PutEvents throttle limit in transactions per second**. These quotas specify the number of invocations that can be sent to targets and the number of events that can be put into the bus per second.

Integrating DynamoDB with Amazon Managed Streaming for Apache Kafka

Amazon Managed Streaming for Apache Kafka (Amazon MSK) makes it easy to ingest and process streaming data in real time with a fully managed, highly available Apache Kafka service.

Apache Kafka is a distributed data store optimized for ingesting and processing streaming data in real-time. Kafka can process streams of records, effectively store streams of records in the order in which records were generated, and publish and subscribe to streams of records.

Because of these features, Apache Kafka is often used to build real-time streaming data pipelines. A *data pipeline* reliably processes and moves data from one system to another and can be an important part of adopting a purpose-built database strategy by facilitating the use of multiple databases which each support different use cases.

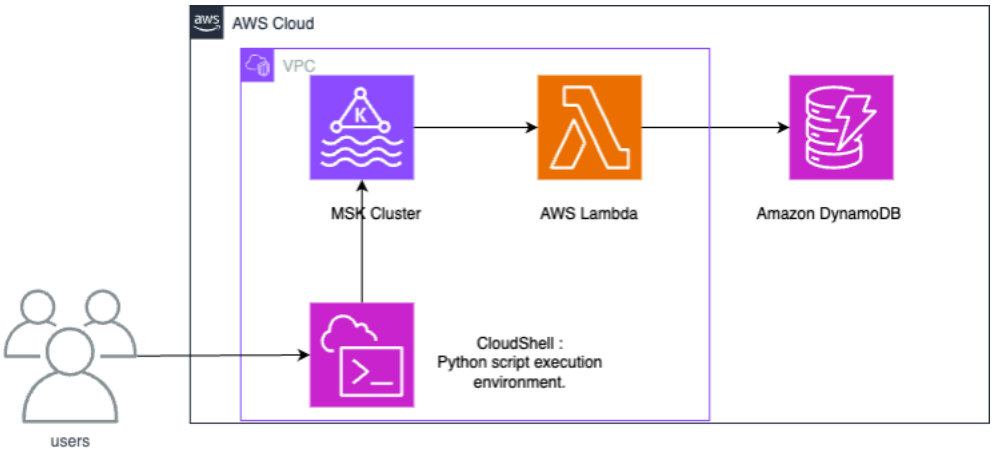
Amazon DynamoDB is common target in these data pipelines to support applications that use key-value or document data models and desire limitless scalability with consistent single-digit millisecond performance.

Topics

- How it works
- Set up an integration between Amazon MSK and DynamoDB
- Next steps

How it works

An Integration between Amazon MSK and DynamoDB uses a Lambda function to consume records from Amazon MSK and write them to DynamoDB.



Lambda internally polls for new messages from Amazon MSK and then synchronously invokes the target Lambda function. The Lambda function's event payload contains batches of messages from Amazon MSK. For the integration between Amazon MSK and DynamoDB, the Lambda function writes these messages to DynamoDB.

Set up an integration between Amazon MSK and DynamoDB

> **Note**
>
> You can download the resources used in this example at the following GitHub repository.

The steps below show how to set up a sample integration between Amazon MSK and Amazon DynamoDB. The example represents data generated by Internet of Things (IoT) devices and ingested into Amazon MSK. As data is ingested into Amazon MSK, it can be integrated with analytics services or third-party tools compatible with Apache Kafka, enabling various analytics use cases. Integrating DynamoDB as well provides key value lookup of individual device records.

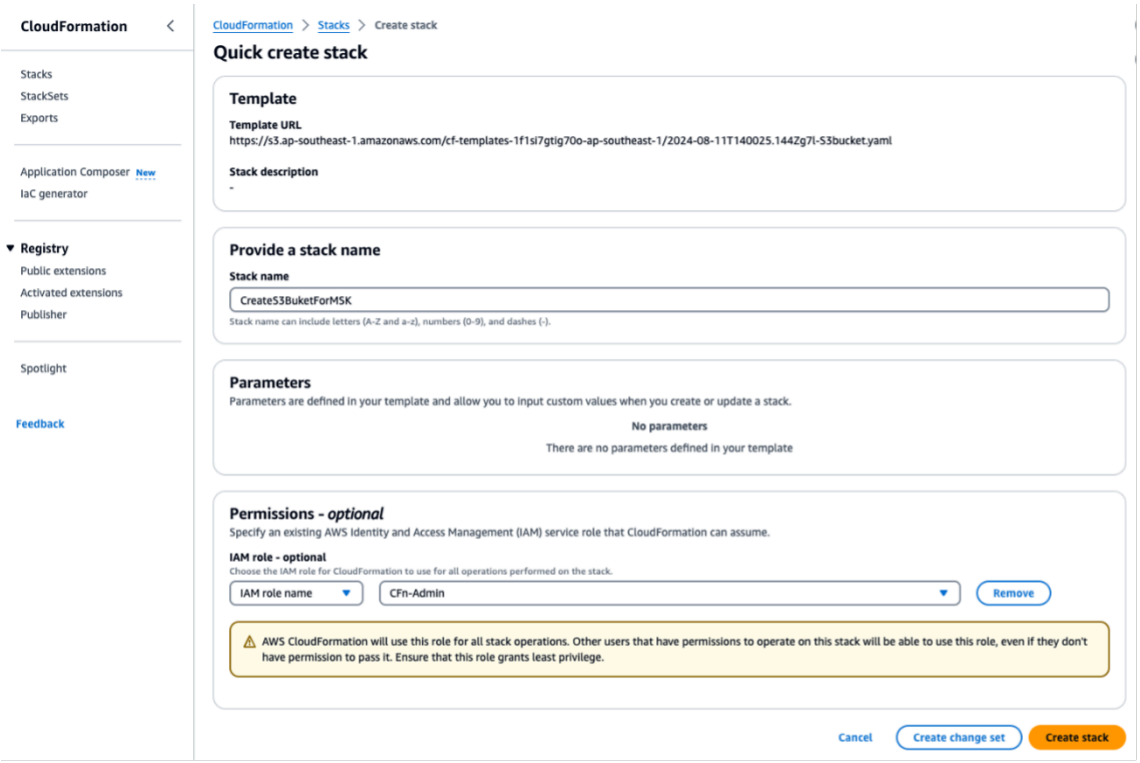
This example will demonstrate how a Python script writes IoT sensor data to Amazon MSK. Then, a Lambda function writes items with the partition key "`deviceid`" to DynamoDB.

The provided CloudFormation template will create the following resources: An Amazon S3 bucket, an Amazon VPC, a Amazon MSK cluster, and an AWS CloudShell for testing data operations.

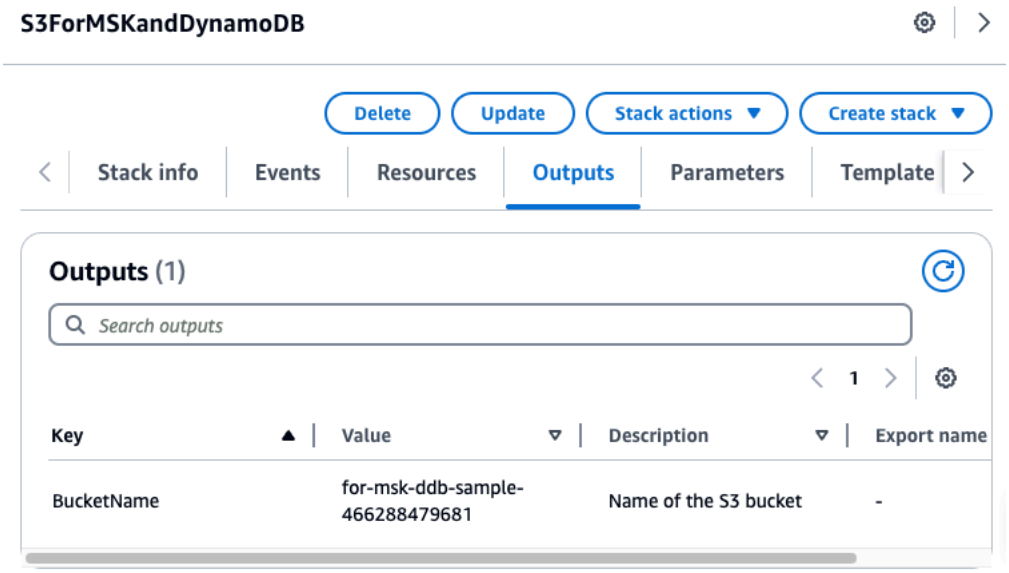
To generate test data, create an Amazon MSK topic and then create a DynamoDB table. You can use Session Manager from the management console to log into the CloudShell's operating system and run Python scripts.

After running the CloudFormation template, you can finish building this architecture by performing the following operations.

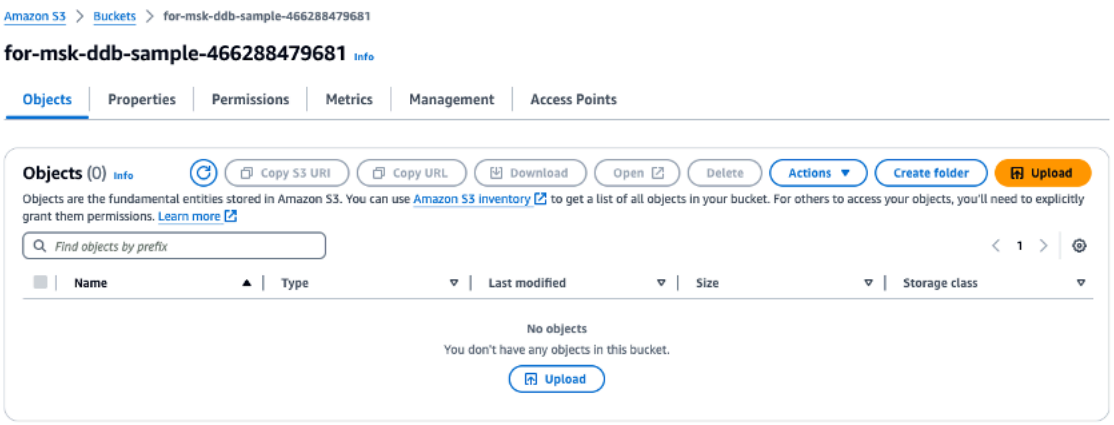
1. Run the CloudFormation template `S3bucket.yaml` to create an S3 bucket. For any subsequent scripts or operations, please run them in the same Region. Enter `ForMSKTestS3` as the CloudFormation stack name.



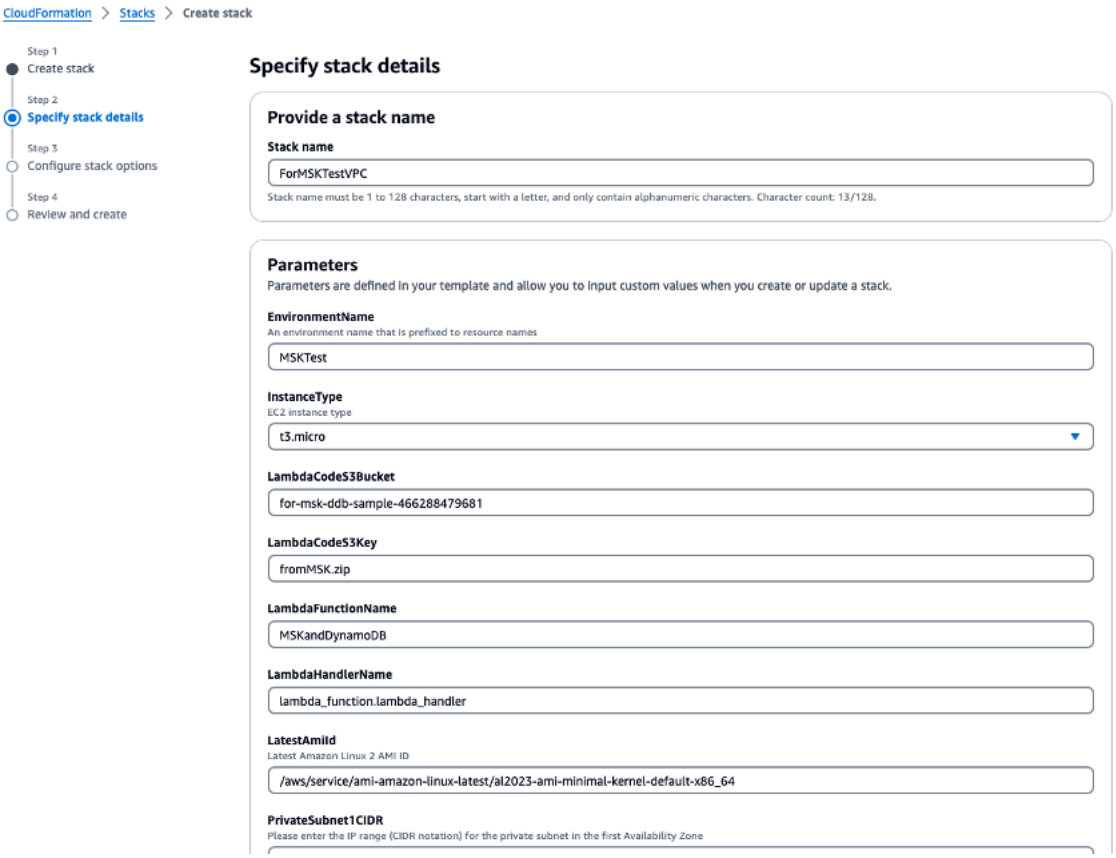
After this is completed, note down the S3 bucket name output under *Outputs*. You will need the name in Step 3.



2. Upload the downloaded ZIP file `fromMSK.zip` to the S3 bucket you just created.



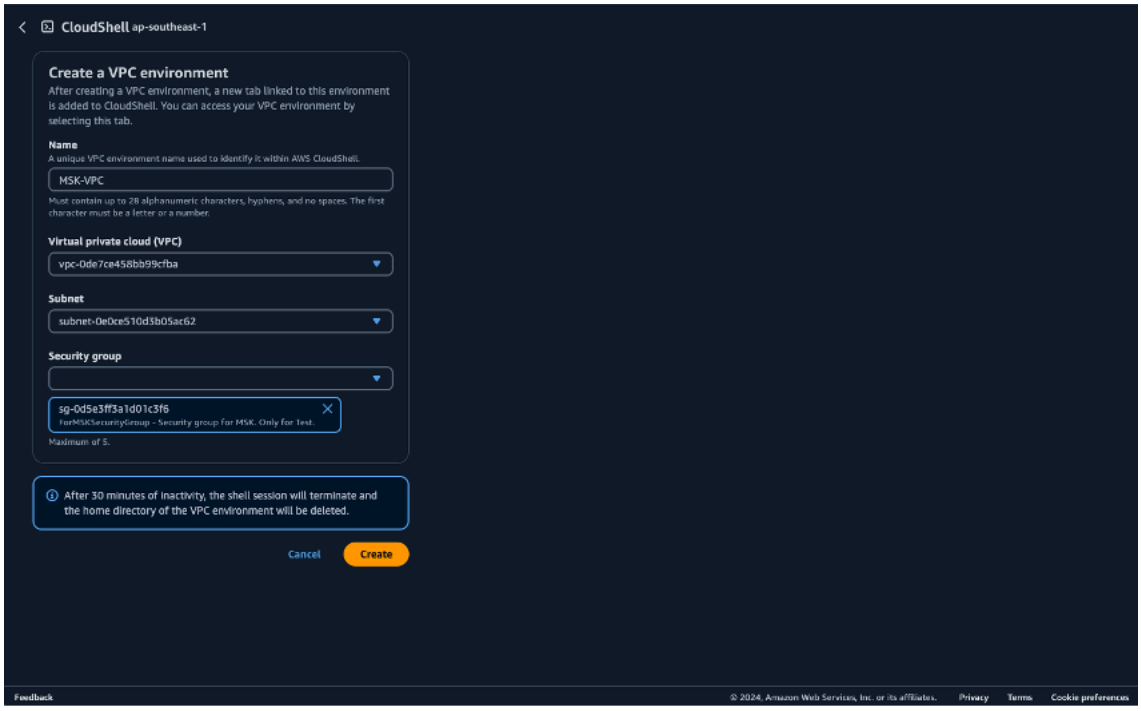
3. Run the CloudFormation template `VPC.yaml` to create a VPC, Amazon MSK cluster, and Lambda function. On the parameter input screen, enter the S3 bucket name you created in Step 1 where it asks for the S3 bucket. Set the CloudFormation stack name to `ForMSKTestVPC`.



4. Prepare the environment for running Python scripts in CloudShell. You can use CloudShell on the AWS Management Console. For more information on using CloudShell, see Getting started with AWS CloudShell. After starting CloudShell, create a CloudShell that belongs to the VPC

you have just created in order to connect to the Amazon MSK Cluster. Create the CloudShell in a private subnet. Fill in the following fields:

1. **Name** - can be set to any name. An example is **MSK-VPC**
2. **VPC** - select **MSKTest**
3. **Subnet** - select **MSKTest Private Subnet (AZ1)**
4. **SecurityGroup** - select **ForMSKSecurityGroup**



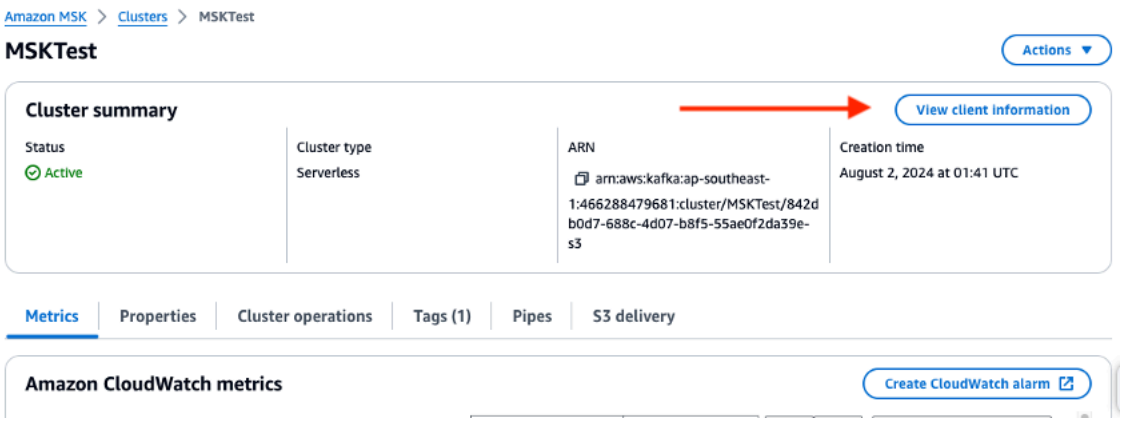
Once the CloudShell belonging to the Private Subnet has started, run the following command:

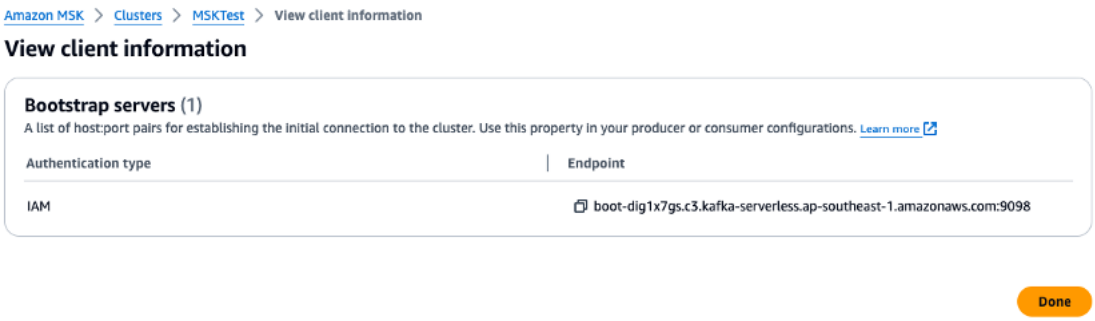
```
pip install boto3 kafka-python aws-msk-iam-sasl-signer-python
```

5. Download Python scripts from the S3 bucket.

```
aws s3 cp s3://[YOUR-BUCKET-NAME]/pythonScripts.zip ./
unzip pythonScripts.zip
```

6. Check the management console and set the environment variables for the broker URL and Region value in the Python scripts. Check the Amazon MSK cluster broker endpoint in the management console.





7. Set the environment variables on the CloudShell. If you are using the US West (Oregon):

```
export AWS_REGION="us-west-2"
export MSK_BROKER="boot-YOURMSKCLUSTER.c3.kafka-serverless.ap-
southeast-1.amazonaws.com:9098"
```

8. Run the following Python scripts.

   Create an Amazon MSK topic:

```
python ./createTopic.py
```

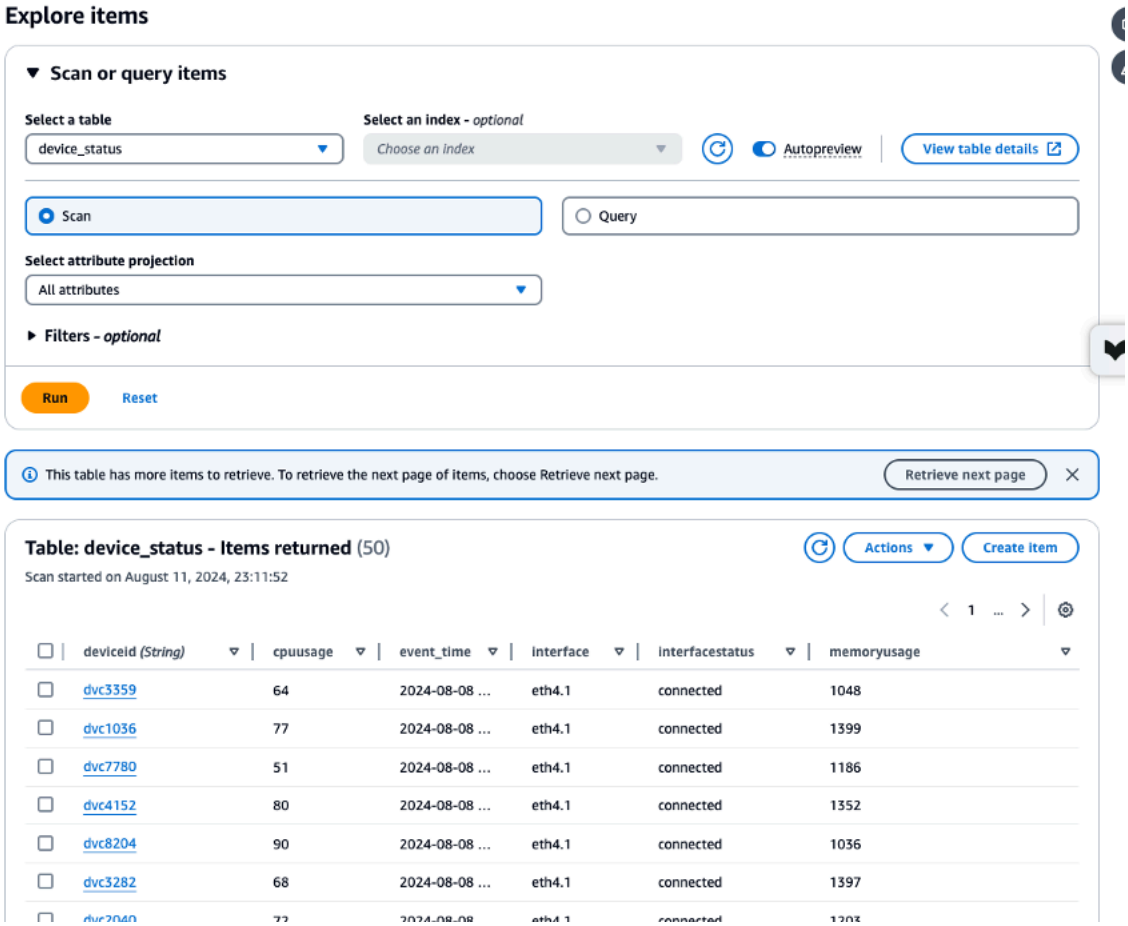
   Create a DynamoDB table:

```
python ./createTable.py
```

   Write test data to the Amazon MSK topic:

```
python ./kafkaDataGen.py
```

9. Check the CloudWatch metrics for the created Amazon MSK, Lambda, and DynamoDB resources, and verify the data stored in the `device_status` table using the DynamoDB Data Explorer to ensure all processes ran correctly. If each process is run without error, you can check that the test data written from CloudShell to Amazon MSK is also written to DynamoDB.



10. When you're done with this example, delete the resources created in this tutorial. Delete the two CloudFormation stacks: `ForMSKTestS3` and `ForMSKTestVPC`. If the stack deletion completes successfully, all resources will be deleted.

Next steps

> **Note**
>
> If you created resources while following along with this example, please remember to delete them to avoid any unexpected charges.

The Integration identified an architecture that links Amazon MSK and DynamoDB to enable stream data to support OLTP workloads. From here, more complex searches can be realized by linking DynamoDB with OpenSearch Service. Consider integrating with EventBridge for more complex event-driven needs, and extensions such as Amazon Managed Service for Apache Flink for higher throughput and lower latency requirements.

Best practices for integrating with DynamoDB

When integrating DynamoDB with other services, you should always follow the best practices for using each individual service. However, there are some best practices specific to integration that you should consider.

Topics

- Creating a snapshot in DynamoDB
- Capturing data change in DynamoDB

Creating a snapshot in DynamoDB

- Generally, we recommend using export to Amazon S3 to create snapshots for initial replication. It is both cost effective, and won't compete with your application's traffic for throughput. You can also consider a backup and restore to a new table followed by a scan operation. This will avoid competing for throughput with your application, but will generally be substantially less cost effective than an export.
- Always set a `StartTime` when doing an export. This makes it easy to determine where you'll start your change data capture (CDC) from.
- When using export to S3, set a lifecycle action on the S3 bucket. Typically, an expiration action set at 7 days is safe, but you should follow any guidelines that your company might have. Even if you explicitly delete your items after ingestion, this action can help catch issues, which helps reduce unnecessary costs and prevents policy violations.

Capturing data change in DynamoDB

- If you need near real-time CDC, use DynamoDB Streams or Amazon Kinesis Data Streams (KDS). When you're deciding which one to use, generally consider which is easiest to use with the downstream service. If you need to provide in-order event processing at a partition-key level, or if you have items that are exceptionally large, use DynamoDB Streams.
- If you don't need near real-time CDC, you can use export to Amazon S3 with incremental exports to export only the changes that have happened between two points in time.

If you used export to S3 for generating a snapshot, this can be especially helpful because you can use similar code to process incremental exports. Typically, export to S3 is slightly cheaper than the previous streaming options, but cost is typically not the main factor for which option to use.

- You can generally only have two simultaneous consumers of a DynamoDB stream. Consider this when planning your integration strategy.
- Don't use scans to detect changes. This might work on a small scale, but becomes impractical fairly quickly.

Using generative AI with DynamoDB

Amazon DynamoDB is a serverless, NoSQL, fully managed database with single-digit millisecond performance at any scale. DynamoDB is optimized for high-throughput workloads and you can extend its capabilities by integrating with generative AI models. Using generative AI models, you can work with data stored in DynamoDB tables in real-time and build applications that are contextually aware and highly personalized. You can also enhance the end user experience by fully leveraging your business, user, and application data to customize your generative AI solutions.

For more information about gen AI and the solutions AWS provides to build gen AI applications, see Transform your business with generative AI.

Topics

- Generative AI use cases for DynamoDB
- Generative AI blogs for DynamoDB
- Leveraging DynamoDB Zero-ETL integration with OpenSearch Service

Generative AI use cases for DynamoDB

DynamoDB is widely used in AI powered conversational applications, such as chatbots and call centers built with a Foundation Model (FM). You can access FMs through Amazon Bedrock, Amazon SageMaker AI, or other model providers. Such applications commonly use DynamoDB to improve personalization and enhance the user experience across three data patterns: application data, business data, and user data. Some examples of these data patterns are as follows:

- Storage of application data, such as chat message history, through integrations with LangChain, LlamaIndex, or a custom code. This context enhances the user experience by allowing the model to *converse* back and forth with the user.
- Creation of a customized user experience by leveraging business data, such as inventory, pricing, and documentation.
- Application of user data, such as web history, past orders, and user preferences, to provide personalized answers.

For instance, an insurance company can build a chatbot using DynamoDB to provide their Retrieval-Augmented Generation (RAG) based gen AI model access to near real-time data. Examples of

such data are real-time mortgage rates, product pricing, compliant/standard contract copy, user web history, and user preferences. Combining DynamoDB with RAG adds in-depth and updated information about insurance products and the user data. This enriches the prompts and answers to provide end users with an accurate, personalized, and near real-time experience.

Similarly, financial services industry customers use DynamoDB, Amazon Bedrock knowledge bases, and Amazon Bedrock agents to build RAG-based gen AI applications. These applications can use open-source earnings reports and call transcripts. They can also use user-specific portfolio and transaction history to generate an on-demand summary of portfolio including an outlook for the future.

Generative AI blogs for DynamoDB

The following articles offer detailed use cases, best practices, and step-by-step guides to help you leverage DynamoDB's capabilities in building advanced AI-powered applications.

- Amazon DynamoDB data models for generative AI chatbots
- Build a scalable, context-aware chatbot with Amazon DynamoDB, Amazon Bedrock, and LangChain

Leveraging DynamoDB Zero-ETL integration with OpenSearch Service

You can use Amazon Bedrock with DynamoDB to provide serverless access to foundational models (FMs), such as Amazon Titan and other third-party models. You can leverage the Zero-ETL integration with Amazon OpenSearch Service to enable vector search capabilities when building generative AI applications. The Generative AI with DynamoDB zero-ETL to OpenSearch integration and Amazon Bedrock workshop provides you hands-on experience in setting up DynamoDB Zero-ETL integration with OpenSearch. This workshop does the following tasks:

- Creates a pipeline from your DynamoDB table to OpenSearch.
- Creates an Amazon Bedrock Connector in OpenSearch.
- Queries Amazon Bedrock leveraging OpenSearch as a vector store.
- Uses the Claude FM in Amazon Bedrock to create a written response in plain English explaining the search results returned by OpenSearch.

This workshop enables you to integrate DynamoDB with OpenSearch to build generative AI applications. It also demonstrates the flexible querying capability across database engines to help you integrate DynamoDB and OpenSearch for traditional use cases. This workshop is one of the seven modules in the Amazon DynamoDB Immersion Day. You can run this workshop in any AWS account.

You can also refer to the following blog post about how to set up a Zero-ETL integration between DynamoDB and OpenSearch Service. This blog post also describes how to set up model connectors in OpenSearch Service to automatically generate embeddings using Amazon Bedrock for incoming data. Vector search for Amazon DynamoDB with zero ETL for Amazon OpenSearch Service.

Quotas and constraints for Amazon DynamoDB

This topic describes current quotas, formerly referred to as limits, within Amazon DynamoDB. This topic also describes how you can perform the quota management tasks, for example, viewing your current quotas and requesting a quota increase.

Topics

- Performing quota management tasks in DynamoDB
- Requesting a quota increase in DynamoDB
- Quotas in Amazon DynamoDB
- Constraints in Amazon DynamoDB

Performing quota management tasks in DynamoDB

Amazon DynamoDB has several service components, such as tables, streams, indexes, and more. When you create your AWS account, there are default *quotas* (formerly referred to as limits) set on these components. Unless otherwise noted, each quota is Region-specific. You can request increases for some of the quotas. After a quota for a resource has been reached, additional requests to create that resource fail with an exception.

Accessing DynamoDB quotas

You can work with DynamoDB Service Quotas in the following ways:

- AWS Management Console

  The Service Quotas console is a browser-based interface that you can use to view and manage your Service Quotas. You can access Service Quotas from any AWS Management Console page by choosing it on the top navigation bar, or by searching for Service Quotas in the AWS Management Console.
- AWS Command Line Interface tools

  When using AWS Command Line Interface tools, you can issue commands at your system's command line to perform Service Quotas tasks. The command line tools are useful if you want to build scripts that perform AWS tasks.
- AWS SDKs

You can use the AWS SDKs for various programming languages and platforms (for example, Java, Python, Ruby, .NET, iOS and Android, and others) to perform Service Quotas tasks.

If an adjustable quota isn't available in the Service Quotas console, use the AWS Support Center Console to create a Service Quotas increase case.

Viewing current quotas in the console

To view your current DynamoDB quotas using the Service Quotas console

1. Open the Service Quotas console at https://console.aws.amazon.com/servicequotas/home/services/dynamodb/quotas/
2. From the navigation bar, at the top of the screen, select a Region.
3. The console displays details about the DynamoDB **Quota name**, **Applied account-level quota value**, **AWS default quota value**, **Utilization**, and the **Adjustability** of the quota at the account-level or resource-level.

   If the applied quota value or utilization is not available, the console displays **Not available**. You can request your applied quota value through the Support Center Console.
4. Choose a specific **Quota name** to view the **Details** page, which displays that quota's **Description**, **Quota code**, **Quota ARN**, **Utilization**, **Applied account-level quota value**, **Adjustability**, and **AWS default quota value**.

   If applicable, the **Details** page also displays any **Monitoring** options, **Alarms**,**request history**, and any of the quota's **Tags**.

Viewing current quotas using the AWS CLI

To view the default values for DynamoDB quotas:

- Call the `ListDefaultServiceQuotas` operation with the DynamoDB service code (dynamodb) to retrieve default values for Amazon DynamoDB Service quotas.

```
$ aws service-quotas list-aws-default-service-quotas \
        --service-code dynamodb

 {
```

```
    "Quotas": [
        {
            "ServiceCode": "dynamodb",
            "ServiceName": "Amazon DynamoDB",
            "QuotaArn": "arn:aws:servicequotas:us-east-1::dynamodb/L-F7858A77",
            "QuotaCode": "L-F7858A77",
            "QuotaName": "Global Secondary Indexes per table",
            "Value": 20.0,
            "Unit": "None",
            "Adjustable": true,
            "GlobalQuota": false
        },
        {
            "ServiceCode": "dynamodb",
            "ServiceName": "Amazon DynamoDB",
            "QuotaArn": "arn:aws:servicequotas:us-east-1::dynamodb/L-AB614373",
            "QuotaCode": "L-AB614373",
            "QuotaName": "Table-level write throughput limit",
            "Value": 40000.0,
            "Unit": "None",
            "Adjustable": true,
            "GlobalQuota": false
        }......
    ]
}
```

To view the applied quota values:

- Call the `ListServiceQuotas` operation with the DynamoDB service code (dynamodb) to retrieve all applied quota values either at the account-level, resource-level, or all levels by passing `ACCOUNT`, `RESOURCE`, or `ALL` respectively as the value for the parameter `QuotaAppliedAtLevel`. The following CLI example retrieves quota values applied at the account-level.

```
$ aws service-quotas list-service-quotas \
        --service-code dynamodb \
        --quota-applied-at-level ACCOUNT

{
    "Quotas": [
```

```
        {
            "ServiceCode": "dynamodb",
            "ServiceName": "Amazon DynamoDB",
            "QuotaArn": "arn:aws:servicequotas:us-east-1:303935678045:dynamodb/L-
F7858A77",
            "QuotaCode": "L-F7858A77",
            "QuotaName": "Global Secondary Indexes per table",
            "Value": 20.0,
{
    "Quotas": [
        {
            "ServiceCode": "dynamodb",
            "ServiceName": "Amazon DynamoDB",
            "QuotaArn": "arn:aws:servicequotas:us-east-1:303935678045:dynamodb/L
-F7858A77",
            "QuotaCode": "L-F7858A77",
            "QuotaName": "Global Secondary Indexes per table",
            "Value": 20.0,
            "Unit": "None",
            "Adjustable": true,
            "GlobalQuota": false,
            "QuotaAppliedAtLevel": "ACCOUNT"
        }.....

        }
    ]
}
```

Requesting a quota increase in DynamoDB

You can request a quota increase for each Region using the Service Quotas console, AWS CLI or a support case. If an adjustable quota isn't available in the Service Quotas console, use the AWS Support Center Console to create a service quota increase case.

Support could approve, deny, or partially approve your quota increase requests. Increases aren't granted immediately, and can take a few days to take effect.

To request an increase using the Service Quotas console

1. Open the Service Quotas console at https://console.aws.amazon.com/servicequotas/home/services/dynamodb/quotas/

2. From the navigation bar, at the top of the screen, select a Region.
3. Filter the list by resource name. For example, enter **On-Demand** to locate the quotas for On-Demand Instances.
4. If the quota is adjustable, choose the quota and then choose **Request quota increase**.
5. For **Change quota value**, enter the new quota value.
6. Choose **Request**.
7. To view any pending or recently resolved requests in the console, choose **Dashboard** from the navigation pane. For pending requests, choose the status of the request to open the request receipt. The initial status of a request is **Pending**. After the status changes to **Quota requested**, you'll see the case number with Support. Choose the case number to open the ticket for your request.

For more information, including how to use the AWS CLI or SDKs to request a quota increase, see Requesting a quota increase in the *Service Quotas User Guide*.

Quotas in Amazon DynamoDB

This section describes current quotas, formerly referred to as limits, within Amazon DynamoDB. Each quota applies on a per-Region basis unless otherwise specified.

Topics

- Read/write throughput
- Reserved Capacity
- Tables
- Global tables
- Secondary indexes
- Projected secondary index attributes
- DynamoDB Streams
- Import from Amazon S3
- Table export to Amazon S3
- Backup and restore
- Contributor Insights

Read/write throughput

Throughput default quotas

AWS places some default quotas on the throughput that your account can provision and consume within a Region.

The account-level read throughput and account-level write throughput quotas apply at the account level. These account-level quotas apply to the sum of the provisioned throughput capacity for all your account's tables and global secondary indexes in a given Region. All the account's available throughput can be provisioned for a single table or across multiple tables. These quotas only apply to tables using the provisioned capacity mode.

The table-level read throughput and table-level write throughput quotas apply differently to tables that use the provisioned capacity mode, and tables that use the on-demand capacity mode.

For provisioned capacity mode tables and GSIs, the quota is the maximum amount of read and write capacity units that can be provisioned for any table or any of its GSIs in the Region. The total of any individual table and all its GSIs must also remain below the account-level read and write throughput quota. This is in addition to the requirement that the total of all provisioned tables and their GSIs must remain below the account-level read and write throughput quota.

For on-demand capacity mode tables and GSIs, the table-level quota is the maximum read and write capacity units that are available for any table, or any individual GSI within that table. No account-level read and write throughput quotas are applied to tables in on-demand mode.

Following are the throughput quotas that apply on your account, by default.

> **Note**
>
> You can request any number of read capacity units (RCU) or write capacity units (WCU) for your DynamoDB tables through a service quota increase. The values listed in the following table represent the initial default quotas. These are not maximum limits for your tables.

Throughput quota name	On-Demand	Provisioned	Adjustable
Per table	40,000 read request units and 40,000 write request units	40,000 read capacity units and 40,000 write capacity units	Yes
Per account	Not applicable	80,000 read capacity units and 80,000 write capacity units	Yes
Minimum throughput for any table or global secondary index	Not applicable	1 read capacity unit and 1 write capacity unit	Yes

Increasing or decreasing throughput (for provisioned tables)

Increasing provisioned throughput

You can increase `ReadCapacityUnits` or `WriteCapacityUnits` as often as necessary, using the AWS Management Console or the `UpdateTable` operation. In a single call, you can increase the provisioned throughput for a table, for any global secondary indexes on that table, or for any combination of these. The new settings do not take effect until the `UpdateTable` operation is complete.

You can't exceed your per-account quotas when you add provisioned capacity, and DynamoDB doesn't allow you to increase provisioned capacity very rapidly. Aside from these restrictions, you can increase the provisioned capacity for your tables as high as you need. For more information about per-account quotas, see the preceding section, Throughput default quotas.

Decreasing provisioned throughput

For every table and global secondary index in an `UpdateTable` operation, you can decrease `ReadCapacityUnits` or `WriteCapacityUnits` (or both). The new settings don't take effect until the `UpdateTable` operation is complete.

There is a default quota on the number of provisioned capacity decreases you can perform on your DynamoDB table per day. A day is defined according to Universal Time Coordinated (UTC).

On a given day, you can start by performing up to four decreases within one hour as long as you have not performed any other decreases yet during that day. Subsequently, you can perform one additional decrease per hour (once every 60 minutes). This effectively brings the maximum number of decreases in a day to 27 times.

> **Important**
>
> Table and global secondary index decrease limits are decoupled, so any global secondary indexes for a particular table have their own decrease limits. However, if a single request decreases the throughput for a table and a global secondary index, it is rejected if either exceeds the current limits. Requests are not partially processed.

Example

In the first 4 hours of a day, a table with a global secondary index can be modified as follows:

- Decrease the table's `WriteCapacityUnits` or `ReadCapacityUnits` (or both) four times.
- Decrease the `WriteCapacityUnits` or `ReadCapacityUnits` (or both) of the global secondary index four times.

At the end of that same day, the table and the global secondary index throughput can potentially be decreased a total of 27 times each.

Reserved Capacity

AWS places a default quota on the amount of active reserved capacity that your account can purchase. The quota limit is a combination of reserved capacity for write capacity units (WCUs) and read capacity units (RCUs).

Reserved capacity quota	Active reserved capacity	Adjustable
Per account	1,000,000 provisioned capacity units (WCUs _ RCUs)	Yes

If you attempt to purchase more than 1,000,000 provisioned capacity units in a single purchase, you will receive an error for this service quota limit. If you have active reserved capacity and

attempt to purchase additional reserved capacity that would result in more than 1,000,000 active provisioned capacity units, you will receive an error for this service quota limit.

Tables

Table size

There is no practical limit on a table's size. Tables are unconstrained in terms of the number of items or the number of bytes.

Maximum number of tables per account per region

For any AWS account, there is an initial quota of 2,500 tables per AWS Region.

If you need more than 2,500 tables for a single account, please reach out to your AWS account team to explore an increase up to a maximum of 10,000 tables. For more than 10,000, the recommended best practice is to setup multiple accounts, each of which can serve up to 10,000 tables.

Global tables

The following default quotas apply when using global tables.

Default global table quotas	On-Demand	Provisioned
Throughput per table	40,000 read request units and 40,000 write request units	40,000 read capacity units and 40,000 write capacity units
Backfilled data for new replicas per account, per Region, per day	10 TB	10 TB

Note

There may be instances where you will need to request a quota limit increase through AWS Support. If any of the following apply to you, please see https://aws.amazon.com/support:

- If you are adding a replica for a table that is configured to use more than 40,000 write capacity units (WCU), you must request a service quota increase for your add replica WCU quota.
- If you are adding a replica or replicas to one destination Region within a 24-hour period with a combined total greater than 10TB, you must request a service quota increase for your add replica data backfill quota.
- If you encounter an error similar to the following:
  - Cannot create a replica of table 'example_table' in region 'example_region_A' because its exceeds your current account limit in region 'example_region_B'.

Secondary indexes

You can define up to 5 local secondary indexes per table.

There is a default quota of 20 global secondary indexes per table.

Projected secondary index attributes

You can project up to 100 attributes combined for all of a table's local and global secondary indexes. This quota only applies to user-specified projected attributes.

For the `CreateTable` operation, if you specify a `ProjectionType` of `INCLUDE`, the total count of attributes specified in `NonKeyAttributes` summed across all secondary indexes must not exceed 100. Projecting the same attribute name into two different indexes counts as two distinct attributes toward the quota.

This quota doesn't apply to secondary indexes with a `ProjectionType` of `KEYS_ONLY` or `ALL`.

DynamoDB Streams

Simultaneous readers of a shard in DynamoDB Streams

For single-Region tables that are not global tables, you can design for up to two simultaneous processes to read from the same DynamoDB Streams shard at the same time. Exceeding this limit can result in request throttling. For global tables, we recommend you limit the number of simultaneous readers to one to avoid request throttling.

Maximum write capacity for a table with DynamoDB Streams enabled

AWS places some default quotas on the write capacity for DynamoDB tables with DynamoDB Streams enabled. These default quotas are applicable only for tables in provisioned read/write capacity mode. amount.

- US East (N. Virginia), US East (Ohio), US West (N. California), US West (Oregon), South America (São Paulo), Europe (Frankfurt), Europe (Ireland), Asia Pacific (Tokyo), Asia Pacific (Seoul), Asia Pacific (Singapore), Asia Pacific (Sydney), China (Beijing) Regions:
  - Per table – 40,000 write capacity units
- All other Regions:
  - Per table – 10,000 write capacity units

Import from Amazon S3

DynamoDB Import from Amazon S3 can support up to 50 concurrent import jobs with a total import source object size of 15TB at a time in us-east-1, us-west-2, and eu-west-1 regions. In all other regions, up to 50 concurrent import tasks with a total size of 1TB is supported. Each import job can take up to 50,000 Amazon S3 objects in all regions. For more information on import and validation, see import format quotas and validation.

Table export to Amazon S3

Full export: up to 300 concurrent export tasks, or up to a total of 100TB from all in-flight table exports, can be exported. Both of these limits are checked before an export is queued.

Incremental export: DynamoDB Incremental Export to Amazon S3 can support up to 300 concurrent export jobs or up to a total of 100TB from all in-flight table exports. The export period window limits are 15 minutes minimum and 24 hours maximum.

Backup and restore

DynamoDB supports up to 50 concurrent restores totaling 50 TB via DynamoDB on-demand or continuous backups. AWS Backup supports up to 50 concurrent restores totaling 25 TB.

Contributor Insights

When you enable Customer Insights on your DynamoDB table, you're still subject to Contributor Insights rules limits. For more information, see CloudWatch service quotas.

Constraints in Amazon DynamoDB

This section describes current constraints, formerly referred to as limits, within Amazon DynamoDB.

Topics

- Read/write capacity mode
- Secondary indexes
- Partition keys and sort keys
- Naming rules
- Data types
- Items
- Attributes
- Expression parameters
- DynamoDB transactions
- DynamoDB Streams
- DynamoDB Accelerator (DAX)
- API-specific constraints
- DynamoDB encryption at rest

Read/write capacity mode

You can switch tables from on-demand mode to provisioned capacity mode at any time. When you do multiple switches between capacity modes, the following conditions apply:

- You can switch a newly created table in on-demand mode to provisioned capacity mode at any time. However, you can only switch it back to on-demand mode 24 hours after the table's creation timestamp.
- You can switch an existing table in on-demand mode to provisioned capacity mode at any time. However, you can only switch it back to on-demand mode 24 hours after the last timestamp indicating a switch to on-demand.

For more information about switching between read and write capacity modes, see Considerations when switching capacity modes in DynamoDB.

Capacity unit sizes (for provisioned tables)

One read capacity unit = one strongly consistent read per second, or two eventually consistent reads per second, for items up to 4 KB in size.

One write capacity unit = one write per second, for items up to 1 KB in size.

Transactional read requests require two read capacity units to perform one read per second for items up to 4 KB.

Transactional write requests require two write capacity units to perform one write per second for items up to 1 KB.

Request unit sizes (for on-demand tables)

One read request unit = one strongly consistent read per second, or two eventually consistent reads per second, for items up to 4 KB in size.

One write request unit = one write per second, for items up to 1 KB in size.

Transactional read requests require two read request units to perform one read per second for items up to 4 KB.

Transactional write requests require two write request units to perform one write per second for items up to 1 KB.

Secondary indexes

Projected Secondary Index attributes per table

You can project a total of up to 100 attributes into all of a table's local and global secondary indexes. This only applies to user-specified projected attributes.

In a `CreateTable` operation, if you specify a `ProjectionType` of `INCLUDE`, the total count of attributes specified in `NonKeyAttributes`, summed across all of the secondary indexes, must not exceed 100. If you project the same attribute name into two different indexes, this counts as two distinct attributes when determining the total.

This limit does not apply for secondary indexes with a `ProjectionType` of `KEYS_ONLY` or `ALL`.

Partition keys and sort keys

Partition key length

The minimum length of a partition key value is 1 byte. The maximum length is 2048 bytes.

Partition key values

There is no practical limit on the number of distinct partition key values, for tables or for secondary indexes.

Sort key length

The minimum length of a sort key value is 1 byte. The maximum length is 1024 bytes.

Sort key values

In general, there is no practical limit on the number of distinct sort key values per partition key value.

The exception is for tables with secondary indexes. An item collection is the set of items which have the same value of partition key attribute. In a global secondary index the item collection is independent of the base table (and can have a different partition key attribute), but in a local secondary index the indexed view is colocated in the same partition as the item in the table and shares the same partition key attribute. As a result of this locality, when a table has one or more LSIs, the item collection cannot be distributed to multiple partitions.

For a table with one or more LSIs, item collections cannot exceed 10GB in size. This includes all base table items and all projected LSI views which have the same value of the partition key attribute. 10GB is the maximum size of a partition. For more detailed information, see Item collection size limit.

Naming rules

Table names and Secondary Index names

Names for tables and secondary indexes must be at least 3 characters long, but no greater than 255 characters long. The following are the allowed characters:

- `A-Z`
- `a-z`

- `0-9`
- _ (underscore)
- - (hyphen)
- . (dot)

Attribute names

In general, an attribute name must be at least one character long, but no greater than 64 KB long.

The following are the exceptions. These attribute names must be no greater than 255 characters long:

- Secondary index partition key names.
- Secondary index sort key names.
- The names of any user-specified projected attributes (applicable only to local secondary indexes). In a `CreateTable` operation, if you specify a `ProjectionType` of `INCLUDE`, the names of the attributes in the `NonKeyAttributes` parameter are length-restricted. The `KEYS_ONLY` and `ALL` projection types are not affected.

These attribute names must be encoded using UTF-8, and the total size of each name (after encoding) cannot exceed 255 bytes.

Data types

String

The length of a String is constrained by the maximum item size of 400 KB.

Strings are Unicode with UTF-8 binary encoding. Because UTF-8 is a variable width encoding, DynamoDB determines the length of a String using its UTF-8 bytes.

Number

A Number can have up to 38 digits of precision, and can be positive, negative, or zero.

- Positive range: `1E-130` to `9.99999999999999999999999999999999999999E+125`
- Negative range: `-9.99999999999999999999999999999999999999E+125` to `-1E-130`

DynamoDB uses JSON strings to represent Number data in requests and replies. For more information, see DynamoDB low-level API.

If number precision is important, you should pass numbers to DynamoDB using strings that you convert from a number type.

Binary

The length of a Binary is constrained by the maximum item size of 400 KB.

Applications that work with Binary attributes must encode the data in base64 format before sending it to DynamoDB. Upon receipt of the data, DynamoDB decodes it into an unsigned byte array and uses that as the length of the attribute.

Items

Item size

The maximum item size in DynamoDB is 400 KB, which includes both attribute name binary length (UTF-8 length) and attribute value lengths (again binary length). The attribute name counts towards the size limit.

For example, consider an item with two attributes: one attribute named "shirt-color" with value "R" and another attribute named "shirt-size" with value "M". The total size of that item is 23 bytes.

Item size for tables with Local Secondary Indexes

For each local secondary index on a table, there is a 400 KB limit on the total of the following:

- The size of an item's data in the table.
- The size of corresponding entries (including key values and projected attributes) in all local secondary indexes.

Attributes

Attribute name-value pairs per item

The cumulative size of attributes per item must fit within the maximum DynamoDB item size (400 KB).

Number of values in list, map, or set

There is no limit on the number of values in a List, a Map, or a Set, as long as the item containing the values fits within the 400 KB item size limit.

Attribute values

Empty String and Binary attribute values are allowed, if the attribute is not used as a key attribute for a table or index. Empty String and Binary values are allowed inside Set, List, and Map types. An attribute value cannot be an an empty Set (String Set, Number Set, or Binary Set). However, empty Lists and Maps are allowed.

Nested attribute depth

DynamoDB supports nested attributes up to 32 levels deep.

Expression parameters

Expression parameters include `ProjectionExpression`, `ConditionExpression`, `UpdateExpression`, and `FilterExpression`.

Lengths

The maximum length of any expression string is 4 KB. For example, the size of the `ConditionExpression a=b` is 3 bytes.

The maximum length of any single expression attribute name or expression attribute value is 255 bytes. For example, `#name` is 5 bytes; `:val` is 4 bytes.

The maximum length of all substitution variables in an expression is 2 MB. This is the sum of the lengths of all `ExpressionAttributeNames` and `ExpressionAttributeValues`.

Operators and operands

The maximum number of operators or functions allowed in an `UpdateExpression` is 300. For example, the *UpdateExpression* `SET a = :val1 + :val2 + :val3` contains two "+" operators.

The maximum number of operands for the `IN` comparator is 100.

Reserved words

DynamoDB does not prevent you from using names that conflict with reserved words. (For a complete list, see Reserved words in DynamoDB.)

However, if you use a reserved word in an expression parameter, you must also specify `ExpressionAttributeNames`. For more information, see Expression attribute names (aliases) in DynamoDB.

DynamoDB transactions

DynamoDB transactional API operations have the following constraints:

- A transaction cannot contain more than 100 unique items.
- A transaction cannot contain more than 4 MB of data.
- No two actions in a transaction can work against the same item in the same table. For example, you cannot both `ConditionCheck` and `Update` the same item in one transaction.
- A transaction cannot operate on tables in more than one AWS account or Region.
- Transactional operations provide atomicity, consistency, isolation, and durability (ACID) guarantees only within the AWS Region where the write is made originally. Transactions are not supported across Regions in global tables. For example, suppose that you have a global table with replicas in the US East (Ohio) and US West (Oregon) Regions and you perform a `TransactWriteItems` operation in the US East (N. Virginia) Region. In this case, you might observe partially completed transactions in the US West (Oregon) Region as changes are replicated. Changes are replicated to other Regions only after they have been committed in the source Region.

DynamoDB Streams

Simultaneous readers of a shard in DynamoDB Streams

For single-Region tables that are not global tables, you can design for up to two processes to read from the same DynamoDB Streams shard at the same time. Exceeding this limit can result in request throttling. For global tables, we recommend you limit the number of simultaneous readers to one to avoid request throttling.

DynamoDB Accelerator (DAX)

AWS Region availability

For a list of AWS Regions in which DAX is available, see DynamoDB Accelerator (DAX) in the *AWS General Reference*.

Nodes

A DAX cluster consists of exactly one primary node, and between zero and ten read replica nodes.

The total number of nodes (per AWS account) cannot exceed 50 in a single AWS Region.

Parameter groups

You can create up to 20 DAX parameter groups per Region.

Subnet groups

You can create up to 50 DAX subnet groups per Region.

Within a subnet group, you can define up to 20 subnets.

> **Important**
>
> A DAX cluster supports a maximum of 500 DynamoDB tables. Once you go beyond 500 DynamoDB tables, your cluster may experience degradation in availability and performance.

API-specific constraints

`CreateTable/UpdateTable/DeleteTable/PutResourcePolicy/DeleteResourcePolicy`

In general, you can have up to 500 CreateTable, UpdateTable, DeleteTable, PutResourcePolicy, and DeleteResourcePolicy requests running simultaneously in any combination. As a result, the total number of tables in the `CREATING`, `UPDATING`, or `DELETING` state cannot exceed 500.

You can submit up to 2,500 requests per second of mutable (`CreateTable`, `DeleteTable`, `UpdateTable`, `PutResourcePolicy`, and `DeleteResourcePolicy`) control plane API requests across a group of tables. However, the `PutResourcePolicy` and `DeleteResourcePolicy` requests have lower individual limits. For more information, see the following quotas details for `PutResourcePolicy` and `DeleteResourcePolicy`.

`CreateTable` and `PutResourcePolicy` requests which include a resource-based policy will count as two additional requests for each KB of the policy. For example, a `CreateTable` or `PutResourcePolicy` request with a policy of size 5 KB will count as 11 requests. 1 for the `CreateTable` request and 10 for the resource-based policy (2 x 5 KB). Similarly, a policy of size

20 KB will count as 41 requests. 1 for the `CreateTable` request and and 40 for the resource-based policy (2 x 20 KB).

`PutResourcePolicy`

You can submit up to 25 `PutResourcePolicy` API requests per second across a group of tables. After a successful request for an individual table, no new `PutResourcePolicy` requests are supported for the following 15 seconds.

The maximum size supported for a resource-based policy document is 20 KB. DynamoDB counts whitespaces when calculating the size of a policy against this limit.

`DeleteResourcePolicy`

You can submit up to 50 `DeleteResourcePolicy` API requests per second across a group of tables. After a successful `PutResourcePolicy` request for an individual table, no `DeleteResourcePolicy` requests are supported for the following 15 seconds.

`BatchGetItem`

A single `BatchGetItem` operation can retrieve a maximum of 100 items. The total size of all the items retrieved cannot exceed 16 MB.

`BatchWriteItem`

A single `BatchWriteItem` operation can contain up to 25 `PutItem` or `DeleteItem` requests. The total size of all the items written cannot exceed 16 MB.

`DescribeStream`

You can call `DescribeStream` at a maximum rate of 10 times per second.

`DescribeTableReplicaAutoScaling`

`DescribeTableReplicaAutoScaling` method supports only 10 requests per second.

`DescribeLimits`

`DescribeLimits` should be called only periodically. You can expect throttling errors if you call it more than once in a minute.

`DescribeContributorInsights/ListContributorInsights/UpdateContributorInsights`

`DescribeContributorInsights`, `ListContributorInsights` and `UpdateContributorInsights` should be called only periodically. DynamoDB supports up to five requests per second for each of these APIs.

`DescribeTable/ListTables/GetResourcePolicy`

You can submit up to 2,500 requests per second of a combination of read-only (`DescribeTable`, `ListTables`, and `GetResourcePolicy`) control plane API requests. The `GetResourcePolicy` API has a lower individual limit of 100 requests per second.

`DescribeTimeToLive`

The `DescribeTimeToLive` operation is throttled at 10 read request units per second. If you exceed this limit, DynamoDB returns a `ThrottlingException` error.

`Query`

The result set from a `Query` is limited to 1 MB per call. You can use the `LastEvaluatedKey` from the query response to retrieve more results.

`Scan`

The result set from a `Scan` is limited to 1 MB per call. You can use the `LastEvaluatedKey` from the scan response to retrieve more results.

`UpdateKinesisStreamingDestination`

When performing `UpdateKinesisStreamingDestination` operations, you can set `ApproximateCreationDateTimePrecision` to a new value a maximum of 3 times in a 24 hour period.

`UpdateTableReplicaAutoScaling`

`UpdateTableReplicaAutoScaling` method supports only ten requests per second.

`UpdateTableTimeToLive`

The `UpdateTableTimeToLive` method supports only one request to enable or disable `Time to Live (TTL)` per specified table per hour. This change can take up to one hour to fully process. Any additional `UpdateTimeToLive` calls for the same table during this one hour duration result in a ValidationException.

DynamoDB encryption at rest

You can switch between an AWS owned key, an AWS managed key, and a customer managed key up to four times, anytime per 24-hour window, on a per table basis, starting from when the table was created. If there was no change in the past six hours, an additional change is allowed. This effectively brings the maximum number of changes in a day to eight (four changes in the first six hours, and one change for each of the subsequent six hour windows in a day).

You can switch encryption keys to use an AWS owned key as often as necessary, even if the above quota has been exhausted.

These are the quotas unless you request a higher amount. To request a service quota increase, see https://aws.amazon.com/support.

DynamoDB API reference

The Amazon DynamoDB API reference contains a complete list of operations supported by:

- DynamoDB
- DynamoDB Streams
- DynamoDB Accelerator (DAX)

Troubleshooting Amazon DynamoDB

The following topics provide troubleshooting advice for errors and issues that you could encounter when using Amazon DynamoDB. If you find an issue that isn't listed here, you can use the feedback button on this page to report it.

For more troubleshooting advice and answers to common support questions, visit the AWS Knowledge Center.

Topics

- Troubleshooting internal server errors in Amazon DynamoDB
- Troubleshooting latency issues in Amazon DynamoDB
- Throttling issues for DynamoDB

Troubleshooting internal server errors in Amazon DynamoDB

In DynamoDB, internal server errors (500 errors) indicate that the service is unable to serve the request. These errors can occur for various reasons, such as transient network issues in the fleet, infrastructure issues, storage node related issues, and more.

You may encounter some internal server errors during the lifecycle of your DynamoDB table. This is expected due to the distributed nature of the service and usually shouldn't be a cause for concern. DynamoDB automatically repairs and heals any transient issues with the service in real time, without requiring any intervention from you. However, if you observe a consistently high number of internal server errors on requests to your table (as seen in the the section called “SystemErrors” metric), you should investigate further.

Topics

- Investigating internal server errors
- Minimizing the impact from internal server errors
- Improving operational awareness

Investigating internal server errors

If you encounter internal server errors in your DynamoDB table, consider these options:

1. **Check the AWS Health Dashboard.**

   To identify the issue, the first step is to check the AWS Service Health Dashboard and your AWS Account Health Dashboard. These dashboards provide valuable information about any service-wide issues, impacted tables, ongoing problems, and the root cause once the issue has been resolved.

   Reviewing the details in these dashboards will give you a better understanding of the current status of the AWS services you're using and any potential problems affecting your account. This information can help you determine the next steps to address the issue and minimize any disruptions to your operations.

2. **Reach out to Support.**

   If you observe prolonged, sustained errors in your requests, it may indicate an issue with the service. As a general rule, if you see an overall failure rate of 1% or more over the last 15 minutes, it's an appropriate time to escalate the issue to the AWS Support team. See, DynamoDB Service Level Agreement to learn more.

   When opening a case with the AWS Support team, provide the following details to help expedite the troubleshooting process:

   - Impacted DDB; tables or secondary indexes
   - Time window when the errors were observed
   - DynamoDB request IDs, such as `4KBNVRGD25RG1KE09UT4V3FQDJVV4KQNSO5AEMVJF66Q9ASUAAJG`, which you can find in your application logs.

   Including these details in the support case will help the AWS team understand the problem and provide a faster resolution. If you don't have the request IDs, you should still log the case with the other available details.

Minimizing the impact from internal server errors

If internal server errors happen when using DynamoDB, minimize the impact of these on your application, consider the following best practices:

- Use backoffs and retries – DynamoDB's default SDK behaviors are designed to find the right balance for most applications in terms of back-off and retry strategy. However, you can

adjust these settings based on your application's tolerance for downtime and performance requirements. Learn more about back-offs and retries to understand how you can fine-tune these retry settings.

- Use eventually consistent reads – If your application doesn't require strongly consistent reads, consider using eventually consistent reads. These reads are lower cost and less likely to experience transient issues due to internal server errors as it would be served from any of the available Storage Nodes. For more information, see DynamoDB read consistency.

Improving operational awareness

Maintaining high availability and reliability of your applications is crucial in today's digital landscape. One key aspect of this is proactively monitoring for internal server errors (ISEs) in your DynamoDB tables and global secondary indexes (GSIs). By creating CloudWatch alarms to monitor these errors, you can gain better operational awareness and be alerted to potential issues before they impact your end-users. This approach aligns with the Operational Excellence pillar of the AWS Well-Architected Framework, ensuring your DynamoDB workload is optimized for performance, security, and reliability.

Creating CloudWatch alarms

You should have CloudWatch alarms set on your DynamoDB tables to receive notifications for consistently high numbers of internal server errors instead of observing the metrics manually. This ties with the operational excellence pillar of the Well-Architected framework for any workload on AWS. See Using the DynamoDB Well-Architected Lens to optimize your DynamoDB workload to learn more about Well-Architecting your DynamoDB tables.

These alarms use custom metric math to calculate the failed request percentage for a 5-minute window. The recommended best practice is to configure the alarm to enter the `ALARM` state when 3 consecutive data points breach the 1% threshold, which means that overall 1% of requests fail within a 15-minute period.

The sample below is a AWS CloudFormation template that can help you create CloudWatch alarms on your table and GSI on the table.

```
AWSTemplateFormatVersion: "2010-09-09"
Description: Sample template for monitoring DynamoDB
Parameters:
 DynamoDBProvisionedTableName:
    Description: Name of DynamoDB Provisioned Table to create
```

```

    Threshold: 1.0
    ComparisonOperator: 'GreaterThanThreshold'
```

Troubleshooting latency issues in Amazon DynamoDB

If your workload appears to experience high latency, you can analyze the CloudWatch `SuccessfulRequestLatency` metric, and check the average latency and median latency through percentile metrics (p50) to see if it's related to DynamoDB. Some variability in the reported `SuccessfulRequestLatency` is normal, and occasional spikes (particularly in the `Maximum` statistic and high percentiles) should not be cause for concern. However, if the `Average` statistic or p50 (median) shows a sharp increase and persists, you should check the AWS Service Health Dashboard and your Personal Health Dashboard for more information. Some possible causes include the size of the item in your table (a 1 KB item and a 400 KB item will vary in latency) or the size of the query (10 items versus 100 items).

The percentile metrics (p99, p90, etc.) can help you better understand your latency distribution. For example:

- p50 (median) shows the typical latency for your workload.
- p90 shows that 90 percent of requests are faster than this value.
- p99 helps identify the worst-case latency affecting 1 percent of requests.

High p99 values with normal p50 values might indicate sporadic issues affecting a small portion of requests, while consistently elevated p50 values might suggest some performance degradation.

> **Note**
>
> To analyze custom percentile values (such as p99.9), you can manually enter the desired percentile (e.g., p99.9) in the CloudWatch metric statistic field. This allows you to evaluate latency distributions beyond the default percentiles listed in the dropdown.

Some variation in latency metrics, particularly in higher percentiles, is expected and can be seen as a result of DynamoDB-driven background operations that help maintain high availability and durability for your data stored in DynamoDB tables or transient infrastructure issues.

If necessary, consider opening a support case with AWS Support, and continue to assess any available fall-back options for your application (such as evacuation of a Region if you have a multi-Region architecture) according to your runbooks. You should log request IDs for slow requests for providing these IDs to AWS Support when you open a support case.

The `SuccessfulRequestLatency` metric only measures latency which is internal to the DynamoDB service — client side activity and network trip times are not included. To learn more about overall latency for calls from your client to the DynamoDB service, you can enable latency metric logging in your AWS SDK.

> **Note**
>
> For most singleton operations (operations which apply to a single item by fully specifying the primary key's value), DynamoDB delivers single-digit millisecond `Average SuccessfulRequestLatency`. This value does not include the transport overhead for the caller code accessing the DynamoDB endpoint. For multi-item data operations, the latency will vary based on factors such as size of the result set, the complexity of the data structures returned, and any condition expressions and filter expressions applied. For repeated multi-item operations to the same data set with the same parameters, DynamoDB will provide highly consistent `Average SuccessfulRequestLatency`.

Consider one or more of the following strategies to reduce latency:

- **Reuse connections:** DynamoDB requests are made via an authenticated session over HTTPS by default. Initiating the connection requires multiple round-trips and takes time so the latency of the first request is higher than following requests that reuse the connection. Requests over an already initialized connection deliver DynamoDB's consistent low latency. To avoid the latency overhead of establishing new connections, you may want to implement a "keep-alive" mechanism by sending a `GetItem` request every 30 seconds if no other requests are made.
- **Use eventually consistent reads:** If your application doesn't require strongly consistent reads, consider using the default eventually consistent reads. Eventually consistent reads have lower cost and can come from multiple availability zones, allowing selection of an availability zone co-located to the requester which decreases latency. For more information, see DynamoDB read consistency.
- **Implement request hedging:** For very low p99 latency requirements, consider implementing request hedging. With request hedging, if the initial request doesn't receive a response quickly enough, send a second equivalent request and let them race, first response wins. This improves tail latency at the cost of some extra requests. You can decide how long to wait before sending the second request. Hedging is easier for reads. For writes, use timestamp-based ordering to ensure hedged requests are treated as occurring at the time of the first attempt, preventing out-

of-order updates. This approach has been discussed in Timestamp writes for write hedging in Amazon DynamoDB.

- **Adjust request timeout and retry behavior:** The path from your client to DynamoDB traverses many components, each designed with redundancy in mind. Consider the following aspects:
  - Network resiliency
  - TCP packet timeouts
  - DynamoDB's distributed architecture

  Default SDK behaviors are optimized for most applications. However, you can implement a fail-fast strategy and adjust timeout settings. Requests taking significantly longer than normal are less likely to ultimately succeed. By failing fast and retrying, you may quickly succeed through a different path. This is similar to request hedging but ends the first request instead of allowing it to proceed.

  Avoid setting timeout values too low. Overly low timeouts can lead to client-induced availability issues. For example, a 50-millisecond socket timeout could cause connection errors during network latency spikes, such as when approaching Amazon EC2 instance bandwidth limits for single-flow traffic. Carefully weigh the benefits of lower timeouts against potential risks to application availability, and prefer hedging to short timeouts.

  For a helpful discussion on this topic, see Tuning AWS Java SDK HTTP request settings for latency-aware Amazon DynamoDB applications.
- **Reduce the distance between the client and DynamoDB endpoint:** If you have globally dispersed users, consider using Global tables - multi-Region replication for DynamoDB. With global tables, you can replicate your table to specified AWS Regions where you want the table to be available. You can place a copy of the data closer to the end user to reduce network latency during read and write operations. For more information about using DynamoDB global tables effectively, see Using Amazon DynamoDB global tables in AWS Prescriptive Guidance.
- **Use caching:** If your traffic is read heavy, consider using one of these caching services:
  - DynamoDB Accelerator (DAX): A fully managed, highly available, in-memory cache for DynamoDB that delivers up to a 10x performance improvement, from milliseconds to microseconds, even at millions of requests per second. For more information about DAX, see In-memory acceleration with DynamoDB Accelerator (DAX):
  - Amazon ElastiCache: A fully managed, in-memory caching service that can be integrated with DynamoDB to improve read performance using the cache-aside pattern. For more information,

see Integrating Amazon DynamoDB and Amazon ElastiCache by using read-through caching in AWS Prescriptive Guidance.

Throttling issues for DynamoDB

Throttling prevents your application from consuming too many capacity units. This topic discusses how to troubleshoot common throttling issues for provisioned and on-demand capacity modes. This topic also describes how to use CloudWatch to investigate where the issues might be coming from.

Topics

- Troubleshooting throttling issues for provisioned mode
- Troubleshooting throttling issues for on-demand mode
- Using CloudWatch metrics to investigate throttling issues

Troubleshooting throttling issues for provisioned mode

If your application exceeds your provisioned throughput capacity on a table or index, it is subject to request throttling. Throttling prevents your application from consuming too many capacity units. When DynamoDB throttles a read or write operation, it returns a `ProvisionedThroughputExceededException` to the caller. The application can then take appropriate action, such as waiting for a short interval before retrying the request.

For troubleshooting issues that appear to be related to throttling, an important first step is to confirm if the throttling is coming from DynamoDB or from the application.

This topic discusses how to troubleshoot common throttling issues for the provisioned capacity mode. The following are some common scenarios, and possible steps to help resolve them.

The DynamoDB table appears to have enough provisioned capacity, but requests are being throttled

This can occur when the throughput is below the average per minute, but it exceeds the amount available per second. DynamoDB only reports minute-level metrics to CloudWatch, which are calculated as the sum for one minute and the averaged. But DynamoDB itself applies rate limits per second. So if too much of that throughput occurs within a small portion of that minute, such as few seconds or less, then requests for the rest of that minute can be throttled.

For example, if we have provisioned 60 WCU on a table, then it can do 3600 write operations in one minute. But if all 3600 WCU requests hit in the same second, then the rest of that minute will be throttled.

One way to resolve this scenario can be to add some jitters and exponential back off to the API calls. For more information see this post about backoff and jitter.

Auto scaling is enabled, but tables are still being throttled

This can occur during sudden spikes in traffic. Auto scaling can be triggered when 2 data points breach the configured target utilization value within a one minute span. Therefore, auto scaling can take place because the consumed capacity is above target utilization for two consistent minutes. But if the spikes are more than one minute apart, auto scaling might not be triggered.

Similarly, a scale down event can be triggered when 15 consecutive data points are lower than the target utilization. In either case, after auto scaling is triggered an `UpdateTable` API operation is invoked. It can then take several minutes to update the provisioned capacity for the table or the index. During this period, any requests that exceed the previous provisioned capacity of the tables will be throttled.

In summary, auto scaling requires consecutive data points where the target utilization value is being breached to scale up a DynamoDB table. For this reason, auto scaling is not recommended as a solution for dealing with spikey workloads. Please refer to the auto scaling cost optimization documentation for more information.

A hot key may be causing throttling issues

In DynamoDB, a partition key that does not have high cardinality can result in many requests which target just a few partitions. If a resulting *hot partition* goes past the partition limits of 3000 RCU or 1000 WCU per second, this can result in throttling. The diagnostic tool CloudWatch Contributor Insights (CCI) can help debug this by providing CCI graphs for each table's item access patterns. You can continuously monitor your DynamoDB tables' most frequently accessed keys and other traffic trends. For more information about CloudWatch Contributor Insights see, CloudWatch Contributor Insights for DynamoDB. For more information, see Designing partition keys to distribute your workload in DynamoDB and Choosing the Right DynamoDB Partition Key.

Your traffic to the table is exceeding the table-level throughput quota.

The table-level read throughput and table-level write throughput quotas apply at the account level in any Region. These quotas apply for tables with both provisioned capacity mode and on-demand capacity mode. By default, the throughput quota placed on your table is 40,000 read requests

units and 40,000 write requests units. If the traffic to your table exceeds this quota, then the table might be throttled. For more information on how to prevent this from happening, see Monitoring DynamoDB for operational awareness.

To resolve this issue, use the Service Quotas console to increase the table-level read or write throughput quota for your account.

Troubleshooting throttling issues for on-demand mode

DynamoDB tables that use on-demand capacity mode automatically adapt to your application's traffic volume. However, tables that use the on-demand mode might still throttle. This topic discusses how to troubleshoot common throttling issues for on-demand tables.

The traffic is more than double the previous peak

If you exceed double your previous traffic's peak within 30 minutes, then you might experience throttling. Before you exceed your previous traffic's peak, we recommend that you spread your traffic growth over at least 30 minutes. To monitor traffic to the table, use the `ConsumedReadCapacityUnits` metric in Amazon CloudWatch. For more information, see DynamoDB Metrics and dimensions.

For new on-demand tables, you can immediately drive up to 4,000 write request units or 12,000 read request units per second.

For an existing table that you switched to on-demand capacity mode, the previous peak is one of the following values:

- Half the previous provisioned throughput for the table
- The setting for a newly created table with on-demand capacity mode

For more information, see Initial throughput for on-demand capacity mode.

The traffic exceeds the per-partition maximum

Each partition of a table or GSI can serve up to 3,000 read request units or 1,000 write request units per second. If traffic to a partition exceeds this limit, the partition might be throttled. To resolve this issue, take the following actions:

1. Use CloudWatch Contributor Insights for DynamoDBto identify the most frequently accessed and throttled keys in your table.

2. Randomize the requests to the table so that the requests to the hot partition keys are distributed over time. For more information, see Using write sharding to distribute workloads evenly in your DynamoDB table.

A hot key may be causing throttling issues

In DynamoDB, a partition key that doesn't have high cardinality can result in many requests which target just a few partitions. If a resulting hot partition goes past the partition limits of 3,000 RCU or 1,000 WCU per second, it can result in throttling.

The diagnostic tool CloudWatch Contributor Insights (CCI) can help you debug this by providing CCI graphs for each table's item access patterns. You can continuously monitor your DynamoDB tables' most frequently accessed keys and other traffic trends. For more information about CloudWatch Contributor Insights see, CloudWatch Contributor Insights for DynamoDB. For more information, see Designing partition keys to distribute your workload in DynamoDB and Choosing the Right DynamoDB Partition Key.

The traffic exceeds the per-table account quota

For on-demand tables, the table-level read throughput and table-level write throughput quotas apply at the account level. By default, the table throughput has a maximum of 40,000 read requests units and a maximum of 40,000 write requests units. If the traffic to a table exceeds the per-table account quotas for throughput, then the table might experience throttling. To resolve this issue, use the Service Quotas console to increase the table-level read throughput and write throughput quotas for your account.

The global secondary index of your table is throttled

If your DynamoDB table has a secondary global index that's being throttled, then the throttling might create back pressure throttles on the base table. For more information, see How does throttling on my global secondary index affect my Amazon DynamoDB table and Using Global Secondary Indexes in DynamoDB.

The traffic exceeds the maximum configured throughput

If your on-demand table's read or write operations exceed the predefined throughput limits, the table will be temporarily restricted, and you'll receive a **ThrottlingException** error message.

Complete the following actions based on your use case:

- To increase or turn off the maximum table throughput setting, use the UpdateTable API.
- Wait and retry the request. See, the section called "Error retries and exponential backoff".
- To monitor the maximum throughput that's configured for a table or global secondary index, use the the section called "OnDemandMaxReadRequestUnits" and the section called "OnDemandMaxWriteRequestUnits" metrics in the CloudWatch console.

Using CloudWatch metrics to investigate throttling issues

Below are some DynamoDB metrics to monitor during throttling events. Use these to help locate which operations are creating throttled requests and identify root issues.

- `ThrottledRequests`
  - One throttled request can contain multiple throttled events, so events can be more relevant to example compared to requests. For example, when you update an item in a table with GSIs, there are multiple events: a write operation to the table and a write operation to each index. Even if one or more of these events are throttled, there will only be one `ThrottledRequest`.
- `ReadThrottleEvents`
  - Watch for requests that exceed the provisioned RCU for a table or GSI.
- `WriteThrottleEvents`
  - Watch for requests that exceed the provisioned WCU for a table or GSI.
- `OnlineIndexConsumedWriteCapacity`
  - Pay attention to the number of WCU consumed when adding a new GSI to a table. Note that `ConsumedWriteCapacityUnits` for a GSI does not include the WCU consumed during index creation.
  - If you've set the WCU for a GSI too low, then incoming write activity during the backfill phase might be throttled.
- `Provisioned Read/Write`
  - View how many provisioned read or write capacity units were consumed over the specified time period, for a table or a specified global secondary index.
  - Note that the `TableName` dimension returns `ProvisionedReadCapacityUnits` for the table only by default. To view the number of provisioned read or write capacity units for a global secondary index, you must specify both `TableName` and `GlobalSecondaryIndexName`.
- `Consumed Read/Write`

- View how many read or write capacity units were consumed over the specified time period.

For more information on DynamoDB CloudWatch metrics, see DynamoDB Metrics and dimensions.

Troubleshooting SSL/TLS connection establishment issues with DynamoDB

Amazon DynamoDB is in the process of moving our endpoints to secure certificates signed by the Amazon Trust Services (ATS) Certificate Authority instead of third-party Certificate Authority. In December 2017, we launched the EU-WEST-3 (Paris) Region with the secure certificates issued by the Amazon Trust Services. All new regions launched after December 2017 have endpoints with the certificates issued by the Amazon Trust Services. This guide shows you how to validate and troubleshoot SSL/TLS connection issues.

Testing your application or service

Most AWS SDKs and Command Line Interfaces (CLIs) support the Amazon Trust Services Certificate Authority. If you are using a version of the AWS SDK for Python or CLI released before October 29, 2013, you must upgrade. The .NET, Java, PHP, Go, JavaScript, and C++ SDKs and CLIs do not bundle any certificates, their certificates come from the underlying operating system. The Ruby SDK has included at least one of the required CAs since June 10, 2015. Before that date, the Ruby V2 SDK did not bundle certificates. If you use an unsupported, custom, or modified version of the AWS SDK, or if you use custom trust store, you might not have the support needed for Amazon Trust Services Certificate Authority.

To validate access to DynamoDB endpoints, you will need to develop a test that accesses DynamoDB API or DynamoDB Streams API in the EU-WEST-3 region and validate that the TLS handshake succeeds. The specific endpoints you will need to access in such test are:

- DynamoDB: https://dynamodb.eu-west-3.amazonaws.com
- DynamoDB Streams: https://streams.dynamodb.eu-west-3.amazonaws.com

If your application does not support Amazon Trust Services Certificate Authority you will see one of the following failures:

- SSL/TLS Negotiation errors
- A long delay before your software receives an error indicating SSL/TLS negotiation failure. The delay time depends on the retry strategy and timeout configuration of your client.

Testing your client browser

To verify that your browser can connect to Amazon DynamoDB, open the following URL: https://dynamodb.eu-west-3.amazonaws.com. If the test is successful, you will see a message like this:

```
healthy: dynamodb.eu-west-3.amazonaws.com
```

If the test is unsuccessful, it will display an error similar to this: https://untrusted-root.badssl.com/.

Updating your software application client

Applications accessing DynamoDB or DynamoDB Streams API endpoints (whether through browsers or programmatically) will need to update the trusted CA list on the client machines if they do not already support any of the following CAs:

- Amazon Root CA 1
- Starfield Services Root Certificate Authority - G2
- Starfield Class 2 Certification Authority

If the clients already trust ANY of the above three CAs then these will trust certificates used by DynamoDB and no action is required. However, if your clients do not already trust any of the above CAs, the HTTPS connections to the DynamoDB or DynamoDB Streams APIs will fail. For more

information, please visit this blog post: https://aws.amazon.com/blogs/security/how-to-prepare-for-aws-move-to-its-own-certificate-authority/.

Updating your client browser

You can update the certificate bundle in your browser simply by updating your browser. Instructions for the most common browsers can be found on the browsers' websites:

- Chrome: https://support.google.com/chrome/answer/95414?hl=en
- Firefox: https://support.mozilla.org/en-US/kb/update-firefox-latest-version
- Safari: https://support.apple.com/en-us/HT204416
- Internet Explorer: https://support.microsoft.com/en-us/help/17295/windows-internet-explorer-which-version#ie=other

Manually updating your certificate bundle

If you can't access the DynamoDB API or DynamoDB Streams API then you need to update your certificate bundle. To do this, you need to import at least one of the required CAs. You can find these at https://www.amazontrust.com/repository/.

The following operating systems and programming languages support Amazon Trust Services certificates:

- Microsoft Windows versions that have January 2005 or later updates installed, Windows Vista, Windows 7, Windows Server 2008, and newer versions.
- MacOS X 10.4 with Java for MacOS X 10.4 Release 5, MacOS X 10.5 and newer versions.
- Red Hat Enterprise Linux 5 (March 2007), Linux 6, and Linux 7 and CentOS 5, CentOS 6, and CentOS 7
- Ubuntu 8.10
- Debian 5.0
- Amazon Linux (all versions)
- Java 1.4.2_12, Java 5 update 2, and all newer versions, including Java 6, Java 7, and Java 8

If you're still unable to connect, consult your software documentation, OS Vendor, or contact with AWS Support https://aws.amazon.com/support for further assistance.

Example tables and data for use in DynamoDB

The *Amazon DynamoDB Developer Guide* uses sample tables to illustrate various aspects of DynamoDB.

Table name	Primary key
ProductCatalog	Simple primary key: • `Id` (Number)
Forum	Simple primary key: • `Name` (String)
Thread	Composite primary key: • `ForumName` (String) • `Subject` (String)
Reply	Composite primary key: • `Id` (String) • `ReplyDateTime` (String)

The *Reply* table has a global secondary index named *PostedBy-Message-Index*. This index will facilitate queries on two non-key attributes of the *Reply* table.

Index name	Primary key
PostedBy-Message-Index	Composite primary key: • `PostedBy` (String) • `Message` (String)

For more information about these tables, see Step 1: Create a table in DynamoDB and Step 2: Write data to a DynamoDB table.

Sample data files

Topics

- ProductCatalog sample data
- Forum sample data
- Thread sample data
- Reply sample data

The following sections show the sample data files that are used for loading the *ProductCatalog*, *Forum*, *Thread* and *Reply* tables.

Each data file contains multiple `PutRequest` elements, each of which contain a single item. These `PutRequest` elements are used as input to the `BatchWriteItem` operation, using the AWS Command Line Interface (AWS CLI).

ProductCatalog sample data

```
{
    "ProductCatalog": [
        {
            "PutRequest": {
                "Item": {
                    "Id": {
                        "N": "101"
                    },
                    "Title": {
                        "S": "Book 101 Title"
                    },
                    "ISBN": {
                        "S": "111-1111111111"
                    },
                    "Authors": {
                        "L": [
                            {
                                "S": "Author1"
                            }
                        ]
                    },
                    "Price": {
                        "N": "2"
```

```
                },
                "Dimensions": {
                    "S": "8.5 x 11.0 x 0.5"
                },
                "PageCount": {
                    "N": "500"
                },
                "InPublication": {
                    "BOOL": true
                },

            "Item": {
                "Id": {
                    "N": "102"
                },
                "Title": {
                    "S": "Book 102 Title"
                },
                "ISBN": {
                    "S": "222-2222222222"
                },
                "Authors": {
                    "L": [
                        {
                            "S": "Author1"
                        },
                        {
                            "S": "Author2"
                        }
                    ]
                },
                "Price": {
                    "N": "20"
                },
                "Dimensions": {
                    "S": "8.5 x 11.0 x 0.8"
                },
```

```
                    "PageCount": {
                        "N": "600"
                    },
                    "InPublication": {
                        "BOOL": true
                    },
                    "ProductCategory": {
                        "S": "Book"
                    }
                }
            }
        },
        {
            "PutRequest": {
                "Item": {
                    "Id": {
                        "N": "103"
                    },
                    "Title": {
                        "S": "Book 103 Title"
                    },
                    "ISBN": {
                        "S": "333-3333333333"
                    },
                    "Authors": {
                        "L": [
                            {
                                "S": "Author1"
                            },
                            {
                                "S": "Author2"
                            }
                        ]
                    },
                    "Price": {
                        "N": "2000"
                    },
                    "Dimensions": {
                        "S": "8.5 x 11.0 x 1.5"
                    },
                    "PageCount": {
                        "N": "600"
                    },
                    "InPublication": {
```

```
                    "BOOL": false
                },
                "ProductCategory": {
                    "S": "Book"
                }
            }
        },
        {
            "PutRequest": {
                "Item": {
                    "Id": {
                        "N": "201"
                    },
                    "Title": {
                        "S": "18-Bike-201"
                    },
                    "Description": {
                        "S": "201 Description"
                    },
                    "BicycleType": {
                        "S": "Road"
                    },
                    "Brand": {
                        "S": "Mountain A"
                    },
                    "Price": {
                        "N": "100"
                    },
                    "Color": {
                        "L": [
                            {
                                "S": "Red"
                            },
                            {
                                "S": "Black"
                            }
                        ]
                    },
                    "ProductCategory": {
                        "S": "Bicycle"
                    }
                }
            }
```

```
        },
        {
            "PutRequest": {
                "Item": {
                    "Id": {
                        "N": "202"
                    },
                    "Title": {

Creating example tables and uploading data in DynamoDB

This appendix provides code to both create the tables and add data programmatically.

Topics

- Creating example tables and uploading data using the AWS SDK for Java
- Creating example tables and uploading data using the AWS SDK for .NET

Creating example tables and uploading data using the AWS SDK for Java

The following Java code example creates tables and uploads data to the tables. For step-by-step instructions to run this code using Eclipse, see Java code examples.

```
package com.amazonaws.codesamples;

import java.text.SimpleDateFormat;
import java.util.ArrayList;
import java.util.Arrays;
import java.util.Date;
import java.util.HashSet;
import java.util.TimeZone;

import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
import com.amazonaws.services.dynamodbv2.document.Item;
import com.amazonaws.services.dynamodbv2.document.Table;
import com.amazonaws.services.dynamodbv2.model.AttributeDefinition;
import com.amazonaws.services.dynamodbv2.model.CreateTableRequest;
import com.amazonaws.services.dynamodbv2.model.KeySchemaElement;
import com.amazonaws.services.dynamodbv2.model.KeyType;
import com.amazonaws.services.dynamodbv2.model.LocalSecondaryIndex;
import com.amazonaws.services.dynamodbv2.model.Projection;

Creating example tables and uploading data using the AWS SDK for .NET

The following C# code example creates tables and uploads data to the tables. For step-by-step instructions to run this code in Visual Studio, see .NET code examples.

```
using System;
using System.Collections.Generic;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.DocumentModel;
using Amazon.DynamoDBv2.Model;
using Amazon.Runtime;
using Amazon.SecurityToken;

namespace com.amazonaws.codesamples
{
    class CreateTablesLoadData
    {
        private static AmazonDynamoDBClient client = new AmazonDynamoDBClient();

        static void Main(string[] args)
        {
            try
            {
                //DeleteAllTables(client);
                DeleteTable("ProductCatalog");
                DeleteTable("Forum");
                DeleteTable("Thread");
                DeleteTable("Reply");

                // Create tables (using the AWS SDK for .NET low-level API).

 attribute.
            thread2Reply2["ReplyDateTime"] = DateTime.UtcNow.Subtract(new TimeSpan(1,
 0, 0, 0)); // Range attribute.
            thread2Reply2["Message"] = "DynamoDB Thread 2 Reply 2 text";
            thread2Reply2["PostedBy"] = "User A";

            replyTable.PutItem(thread2Reply2);
        }
    }
}
```

DynamoDB example application using the AWS SDK for Python (Boto): Tic-tac-toe

The Tic-Tac-Toe game is an example web application built on Amazon DynamoDB. The application uses the AWS SDK for Python (Boto) to make the necessary DynamoDB calls to store game data in a DynamoDB table, and the Python web framework Flask to illustrate end-to-end application development in DynamoDB, including how to model data. It also demonstrates best practices when it comes to modeling data in DynamoDB, including the table you create for the game application, the primary key you define, additional indexes you need based on your query requirements, and the use of concatenated value attributes.

You play the Tic-Tac-Toe application on the web as follows:

1. You log in to the application home page.
2. You then invite another user to play the game as your opponent.

Until another user accepts your invitation, the game status remains as `PENDING`. After an opponent accepts the invite, the game status changes to `IN_PROGRESS`.

3. The game begins after the opponent logs in and accepts the invite.
4. The application stores all game moves and status information in a DynamoDB table.
5. The game ends with a win or a draw, which sets the game status to `FINISHED`.

The end-to-end application building exercise is described in steps:

- **Step 1: Deploy and test locally** – In this section, you download, deploy, and test the application on your local computer. You will create the required tables in the downloadable version of DynamoDB.
- **Step 2: Examine the data model and implementation details** – This section first describes in detail the data model, including the indexes and the use of the concatenated value attribute. Then the section explains how the application works.
- **Step 3: Deploy in production using the DynamoDB service** – This section focuses on deployment considerations in production. In this step, you create a table using the Amazon DynamoDB service and deploy the application using AWS Elastic Beanstalk. When you have the application in production, you also grant appropriate permissions so the application can access the DynamoDB table. The instructions in this section walk you through the end-to-end production deployment.
- **Step 4: Clean up resources** – This section highlights areas that are not covered by this example. The section also provides steps for you to remove the AWS resources you created in the preceding steps so that you avoid incurring any charges.

Step 1: Deploy and test locally

Topics

- 1.1: Download and install the required packages
- 1.2: Test the game application

In this step you download, deploy, and test the Tic-Tac-Toe game application on your local computer. Instead of using the Amazon DynamoDB web service, you will download DynamoDB to your computer, and create the required table there.

1.1: Download and install the required packages

You will need the following to test this application locally:

- Python
- Flask (a microframework for Python)
- AWS SDK for Python (Boto)
- DynamoDB running on your computer
- Git

To get these tools, do the following:

1. Install Python. For step-by-step instructions, see Download Python.

   The Tic-Tac-Toe application has been tested using Python version 2.7.
2. Install Flask and AWS SDK for Python (Boto) using the Python Package Installer (PIP):
   - Install PIP.

     For instructions, see Install PIP. On the installation page, choose the **get-pip.py** link, and then save the file. Then open a command terminal as an administrator, and enter the following at the command prompt.

     ```
     python.exe get-pip.py
     ```

     On Linux, you don't specify the `.exe` extension. You only specify `python get-pip.py`.
   - Using PIP, install the Flask and Boto packages using the following code.

     ```
     pip install Flask
     pip install boto
     pip install configparser
     ```
3. Download DynamoDB to your computer. For instructions on how to run it, see Setting up DynamoDB local (downloadable version) .
4. Download the Tic-Tac-Toe application:
   a. Install Git. For instructions, see git downloads.
   b. Run the following code to download the application.

```
git clone https://github.com/awslabs/dynamodb-tictactoe-example-app.git
```

1.2: Test the game application

To test the Tic-Tac-Toe application, you need to run DynamoDB locally on your computer.

To run the tic-tac-toe application

1. Start DynamoDB.
2. Start the web server for the Tic-Tac-Toe application.

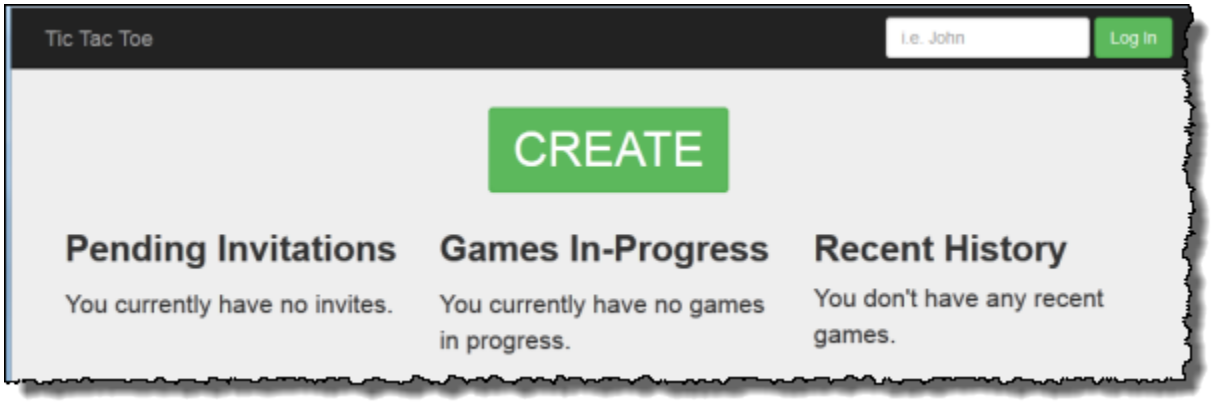
   To do so, open a command terminal, navigate to the folder where you downloaded the Tic-Tac-Toe application, and run the application locally using the following code.

   ```
   python.exe application.py --mode local --serverPort 5000 --port 8000
   ```

   On Linux, you don't specify the `.exe` extension.
3. Open your web browser, and enter the following.

   ```
   http://localhost:5000/
   ```

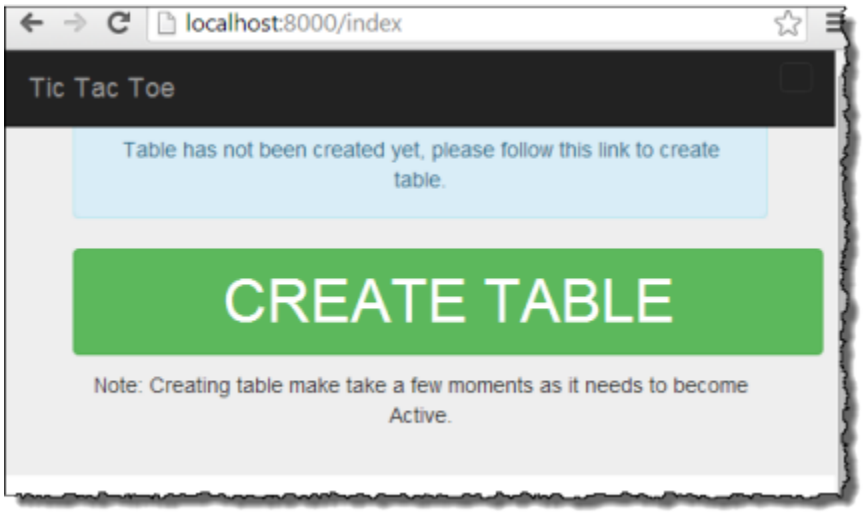
   The browser shows the home page.



4. Enter **`user1`** in the **Log in** box to log in as user1.

> **Note**
>
> This example application does not perform any user authentication. The user ID is only used to identify players. If two players log in with the same alias, the application works as if you are playing in two different browsers.

5. If this is your first time playing the game, a page appears requesting you to create the required table (`Games`) in DynamoDB. Choose **CREATE TABLE**.



6. Choose **CREATE** to create the first tic-tac-toe game.
7. Enter **`user2`** in the **Choose an Opponent** box, and choose **Create Game!**

   Doing this creates the game by adding an item in the `Games` table. It sets the game status to `PENDING`.

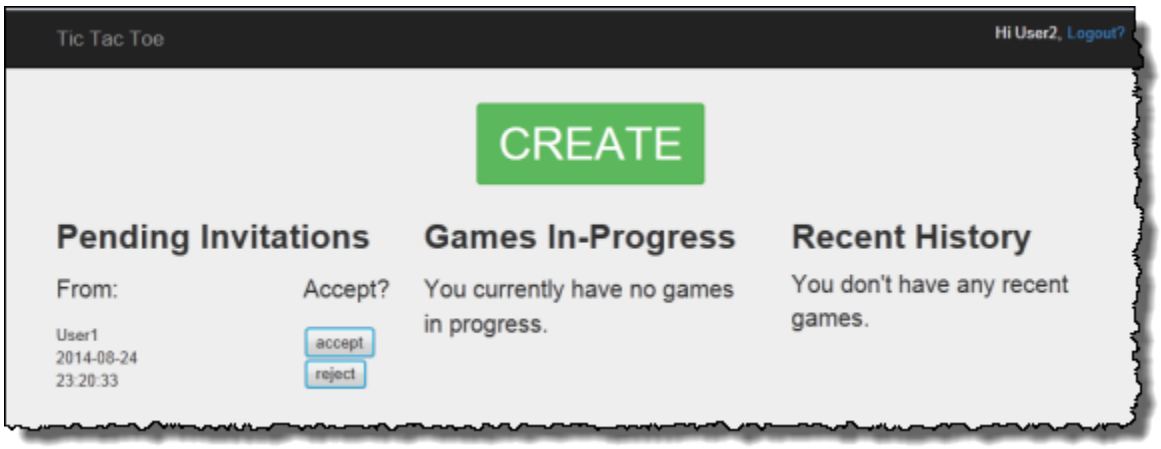
8. Open another browser window, and enter the following.

```
http://localhost:5000/
```

The browser passes information through cookies, so you should use incognito mode or private browsing so that your cookies don't carry over.

9. Log in as user2.

   A page appears that shows a pending invitation from user1.



10. Choose **accept** to accept the invitation.

   The game page appears with an empty tic-tac-toe grid. The page also shows relevant game information such as the game ID, whose turn it is, and game status.

11. Play the game.

For each user move, the web service sends a request to DynamoDB to conditionally update the game item in the `Games` table. For example, the conditions ensure that the move is valid, the square that the user chose is available, and that it was the turn of the user who made the move. For a valid move, the update operation adds a new attribute corresponding to the selection on the board. The update operation also sets the value of the existing attribute to the user who can make the next move.

On the game page, the application makes asynchronous JavaScript calls every second, for up to 5 minutes, to check if the game state in DynamoDB has changed. If it has, the application updates the page with new information. After 5 minutes, the application stops making the requests, and you need to refresh the page to get updated information.

Step 2: Examine the data model and implementation details

Topics

- 2.1: Basic data model
- 2.2: Application in action (code walkthrough)

2.1: Basic data model

This example application highlights the following DynamoDB data model concepts:

- **Table** – In DynamoDB, a table is a collection of items (that is, records), and each item is a collection of name-value pairs called attributes.

  In this Tic-Tac-Toe example, the application stores all game data in a table, `Games`. The application creates one item in the table per game and stores all game data as attributes. A tic-tac-toe game can have up to nine moves. Because DynamoDB tables do not have a schema in cases where only the primary key is the required attribute, the application can store varying number of attributes per game item.

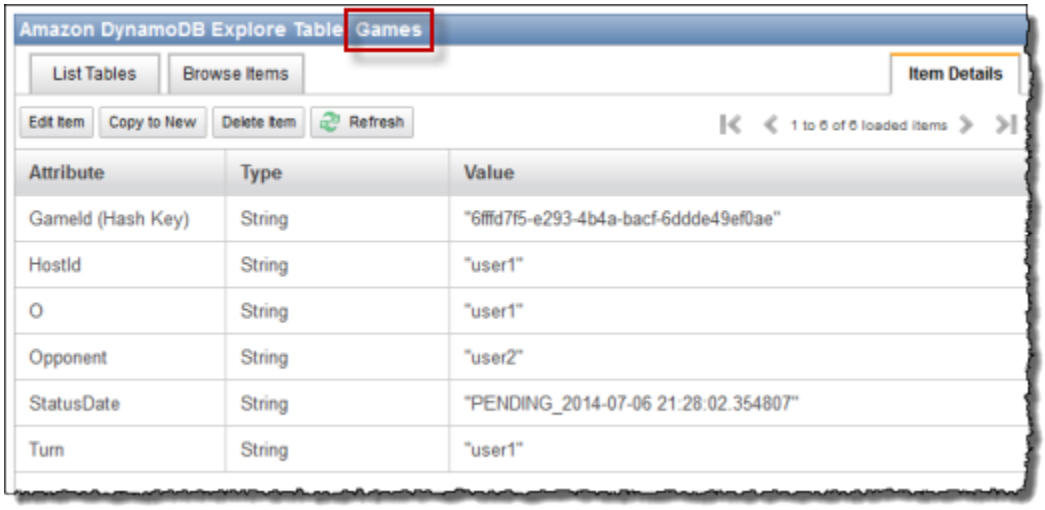
  The `Games` table has a simple primary key made of one attribute, `GameId`, of string type. The application assigns a unique ID to each game. For more information on DynamoDB primary keys, see Primary key.

  When a user initiates a tic-tac-toe game by inviting another user to play, the application creates a new item in the `Games` table with attributes storing game metadata, such as the following:

  - `HostId`, the user who initiated the game.

- `Opponent`, the user who was invited to play.
- The user whose turn it is to play. The user who initiated the game plays first.
- The user who uses the **O** symbol on the board. The user who initiates the games uses the **O** symbol.

In addition, the application creates a `StatusDate` concatenated attribute, marking the initial game state as `PENDING`. The following screenshot shows an example item as it appears in the DynamoDB console:

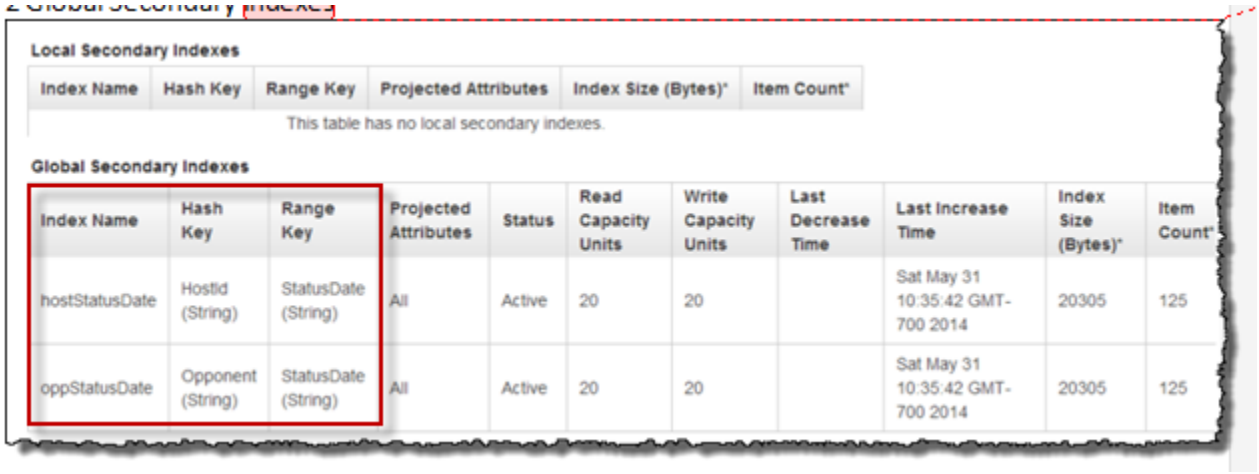


As the game progresses, the application adds one attribute to the table for each game move. The attribute name is the board position, for example `TopLeft` or `BottomRight`. For example, a move might have a `TopLeft` attribute with the value 0, a `TopRight` attribute with the value 0, and a `BottomRight` attribute with the value X. The attribute value is either 0 or X, depending on which user made the move. For example, consider the following board.

- **Concatenated value attributes** – The `StatusDate` attribute illustrates a concatenated value attribute. In this approach, instead of creating separate attributes to store game status (`PENDING`, `IN_PROGRESS`, and `FINISHED`) and date (when the last move was made), you combine them as single attribute, for example `IN_PROGRESS_2014-04-30 10:20:32`.

  The application then uses the `StatusDate` attribute in creating secondary indexes by specifying `StatusDate` as a sort key for the index. The benefit of using the `StatusDate` concatenated value attribute is further illustrated in the indexes discussed next.

- **Global secondary indexes** – You can use the table's primary key, `GameId`, to efficiently query the table to find a game item. To query the table on attributes other than the primary key attributes, DynamoDB supports the creation of secondary indexes. In this example application, you build the following two secondary indexes:



Local Secondary Indexes

Index Name	Hash Key	Range Key	Projected Attributes	Index Size (Bytes)*	Item Count*

This table has no local secondary indexes.

Global Secondary Indexes

Index Name	Hash Key	Range Key	Projected Attributes	Status	Read Capacity Units	Write Capacity Units	Last Decrease Time	Last Increase Time	Index Size (Bytes)*	Item Count*
hostStatusDate	HostId (String)	StatusDate (String)	All	Active	20	20		Sat May 31 10:35:42 GMT-700 2014	20305	125
oppStatusDate	Opponent (String)	StatusDate (String)	All	Active	20	20		Sat May 31 10:35:42 GMT-700 2014	20305	125

  - **HostId-StatusDate-index**. This index has `HostId` as a partition key and `StatusDate` as a sort key. You can use this index to query on `HostId`, for example to find games hosted by a particular user.
  - **OpponentId-StatusDate-index**. This index has `OpponentId` as a partition key and `StatusDate` as a sort key. You can use this index to query on `Opponent`, for example to find games where a particular user is the opponent.

  These indexes are called global secondary indexes because the partition key in these indexes is not the same the partition key (`GameId`), used in the primary key of the table.

  Note that both the indexes specify `StatusDate` as a sort key. Doing this enables the following:

  - You can query using the `BEGINS_WITH` comparison operator. For example, you can find all games with the `IN_PROGRESS` attribute hosted by a particular user. In this case, the `BEGINS_WITH` operator checks for the `StatusDate` value that begins with `IN_PROGRESS`.

- DynamoDB stores the items in the index in sorted order, by sort key value. So if all status prefixes are the same (for example, `IN_PROGRESS`), the ISO format used for the date part will have items sorted from oldest to the newest. This approach enables certain queries to be performed efficiently, for example the following:
  - Retrieve up to 10 of the most recent `IN_PROGRESS` games hosted by the user who is logged in. For this query, you specify the `HostId-StatusDate-index` index.
  - Retrieve up to 10 of the most recent `IN_PROGRESS` games where the user logged in is the opponent. For this query, you specify the `OpponentId-StatusDate-index` index.

For more information about secondary indexes, see Improving data access with secondary indexes in DynamoDB.

2.2: Application in action (code walkthrough)

This application has two main pages:

- **Home page** – This page provides the user a simple login, a **CREATE** button to create a new tic-tac-toe game, a list of games in progress, game history, and any active pending game invitations.

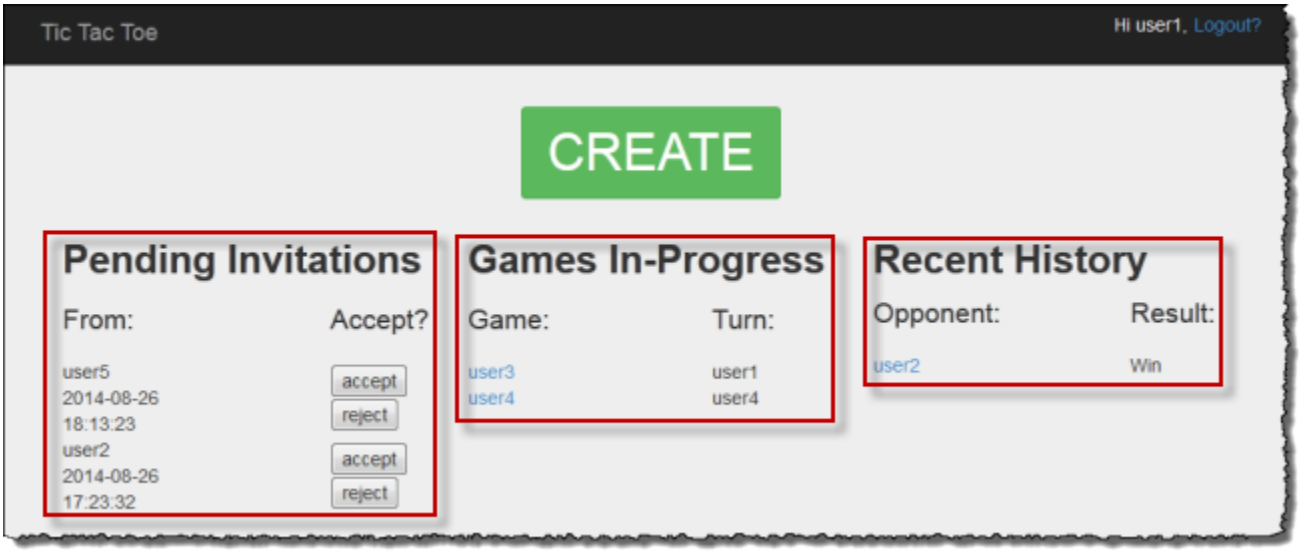
  The home page is not refreshed automatically; you must refresh the page to refresh the lists.
- **Game page** – This page shows the tic-tac-toe grid where users play.

  The application updates the game page automatically every second. The JavaScript in your browser calls the Python web server every second to query the Games table whether the game items in the table have changed. If they have, JavaScript triggers a page refresh so that the user sees the updated board.

Let us see in detail how the application works.

Home page

After the user logs in, the application displays the following three lists of information.



- **Invitations** – This list shows up to the 10 most recent invitations from others that are pending acceptance by the user who is logged in. In the preceding screenshot, user1 has invitations from user5 and user2 pending.
- **Games in-progress** – This list shows up to the 10 most recent games that are in progress. These are games that the user is actively playing, which have the status `IN_PROGRESS`. In the screenshot, user1 is actively playing a tic-tac-toe game with user3 and user4.
- **Recent history** – This list shows up to the 10 most recent games that the user finished, which have the status `FINISHED`. In game shown in the screenshot, user1 has previously played with user2. For each completed game, the list shows the game result.

In the code, the `index` function (in `application.py`) makes the following three calls to retrieve game status information:

```
inviteGames     = controller.getGameInvites(session["username"])
inProgressGames = controller.getGamesWithStatus(session["username"], "IN_PROGRESS")
finishedGames   = controller.getGamesWithStatus(session["username"], "FINISHED")
```

Each of these calls returns a list of items from DynamoDB that are wrapped by the `Game` objects. It is easy to extract data from these objects in the view. The index function passes these object lists to the view to render the HTML.

```
return render_template("index.html",
                       user=session["username"],
                       invites=inviteGames,
```

```
                        inprogress=inProgressGames,
                        finished=finishedGames)
```

The Tic-Tac-Toe application defines the `Game` class primarily to store game data retrieved from DynamoDB. These functions return lists of `Game` objects that enable you to isolate the rest of the application from code related to Amazon DynamoDB items. Thus, these functions help you decouple your application code from the details of the data store layer.

The architectural pattern described here is also referred as the model-view-controller (MVC) UI pattern. In this case, the `Game` object instances (representing data) are the model, and the HTML page is the view. The controller is divided into two files. The `application.py` file has the controller logic for the Flask framework, and the business logic is isolated in the `gameController.py` file. That is, the application stores everything that has to do with DynamoDB SDK in its own separate file in the `dynamodb` folder.

Let us review the three functions and how they query the Games table using global secondary indexes to retrieve relevant data.

Using getGameInvites to get the list of pending game invitations

The `getGameInvites` function retrieves the list of the 10 most recent pending invitations. These games have been created by users, but the opponents have not accepted the game invitations. For these games, the status remains `PENDING` until the opponent accepts the invite. If the opponent declines the invite, the application removes the corresponding item from the table.

The function specifies the query as follows:

- It specifies the `OpponentId-StatusDate-index` index to use with the following index key values and comparison operators:
  - The partition key is `OpponentId` and takes the index key *`user ID`*.
  - The sort key is `StatusDate` and takes the comparison operator and index key value `beginswith="PENDING_"`.

  You use the `OpponentId-StatusDate-index` index to retrieve games to which the logged-in user is invited—that is, where the logged-in user is the opponent.
- The query limits the result to 10 items.

```
gameInvitesIndex = self.cm.getGamesTable().query(
```

```
                                                Opponent__eq=user,
                                                StatusDate__beginswith="PENDING_",
                                                index="OpponentId-StatusDate-index",
                                                limit=10)
```

In the index, for each `OpponentId` (the partition key) DynamoDB keeps items sorted by `StatusDate` (the sort key). Therefore, the games that the query returns will be the 10 most recent games.

Using getGamesWithStatus to get the list of games with a specific status

After an opponent accepts a game invitation, the game status changes to `IN_PROGRESS`. After the game completes, the status changes to `FINISHED`.

Queries to find games that are either in progress or finished are the same except for the different status value. Therefore, the application defines the `getGamesWithStatus` function, which takes the status value as a parameter.

```
inProgressGames = controller.getGamesWithStatus(session["username"], "IN_PROGRESS")
finishedGames   = controller.getGamesWithStatus(session["username"], "FINISHED")
```

The following section discusses in-progress games, but the same description also applies to finished games.

A list of in-progress games for a given user includes both the following:

- In-progress games hosted by the user
- In-progress games where the user is the opponent

The `getGamesWithStatus` function runs the following two queries, each time using the appropriate secondary index.

- The function queries the `Games` table using the `HostId-StatusDate-index` index. For the index, the query specifies primary key values—both the partition key (`HostId`) and sort key (`StatusDate`) values, along with comparison operators.

  ```
  hostGamesInProgress = self.cm.getGamesTable ().query(HostId__eq=user,
                                                       StatusDate__beginswith=status,
                                                       index="HostId-StatusDate-index",
                                                       limit=10)
  ```

Note the Python syntax for comparison operators:

- `HostId__eq=user` specifies the equality comparison operator.
- `StatusDate__beginswith=status` specifies the `BEGINS_WITH` comparison operator.

- The function queries the `Games` table using the `OpponentId-StatusDate-index` index.

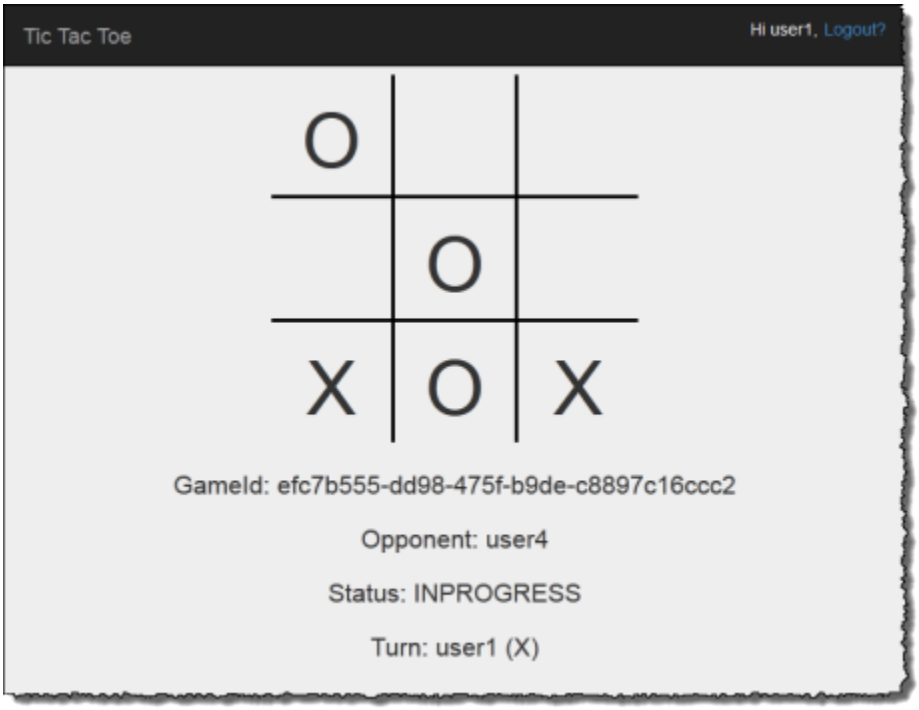
```
oppGamesInProgress = self.cm.getGamesTable().query(Opponent__eq=user,
                                                   StatusDate__beginswith=status,
                                                   index="OpponentId-StatusDate-index",
                                                   limit=10)
```

- The function then combines the two lists, sorts, and for the first 0 to 10 items creates a list of the `Game` objects and returns the list to the calling function (that is, the index).

```
games = self.mergeQueries(hostGamesInProgress,
                          oppGamesInProgress)
return games
```

Game page

The game page is where the user plays tic-tac-toe games. It shows the game grid along with game-relevant information. The following screenshot shows an example game in progress:



The application displays the game page in the following situations:

- The user creates a game inviting another user to play.

  In this case, the page shows the user as host and the game status as `PENDING`, waiting for the opponent to accept.
- The user accepts one of the pending invitations on the home page.

  In this case, the page shows the user as the opponent and game status as `IN_PROGRESS`.

A user selection on the board generates a form `POST` request to the application. That is, Flask calls the `selectSquare` function (in `application.py`) with the HTML form data. This function, in turn, calls the `updateBoardAndTurn` function (in `gameController.py`) to update the game item as follows:

- It adds a new attribute specific to the move.
- It updates the `Turn` attribute value to the user whose turn is next.

```
controller.updateBoardAndTurn(item, value, session["username"])
```

The function returns true if the item update was successful; otherwise, it returns false. Note the following about the `updateBoardAndTurn` function:

- The function calls the `update_item` function of the SDK for Python to make a finite set of updates to an existing item. The function maps to the `UpdateItem` operation in DynamoDB. For more information, see UpdateItem.

  > **Note**
  >
  > The difference between the `UpdateItem` and `PutItem` operations is that `PutItem` replaces the entire item. For more information, see PutItem.

For the `update_item` call, the code identifies the following:

- The primary key of the `Games` table (that is, `ItemId`).

```
key = { "GameId" : { "S" : gameId } }
```

- The new attribute to add, specific to the current user move, and its value (for example, `TopLeft="X"`).

```
attributeUpdates = {
    position : {
        "Action" : "PUT",
        "Value" : { "S" : representation }
    }
}
```

- Conditions that must be true for the update to take place:
  - The game must be in progress. That is, the `StatusDate` attribute value must begin with `IN_PROGRESS`.
  - The current turn must be a valid user turn as specified by the `Turn` attribute.
  - The square that the user chose must be available. That is, the attribute corresponding to the square must not exist.

```
expectations = {"StatusDate" : {"AttributeValueList": [{"S" : "IN_PROGRESS_"}],
    "ComparisonOperator": "BEGINS_WITH"},
    "Turn" : {"Value" : {"S" : current_player}},
    position : {"Exists" : False}}
```

Now the function calls `update_item` to update the item.

```
self.cm.db.update_item("Games", key=key,
    attribute_updates=attributeUpdates,
    expected=expectations)
```

After the function returns, the `selectSquare` function calls redirect, as shown in the following example.

```
redirect("/game="+gameId)
```

This call causes the browser to refresh. As part of this refresh, the application checks to see if the game has ended in a win or draw. If it has, the application updates the game item accordingly.

Step 3: Deploy in production using the DynamoDB service

Topics

- 3.1: Create an IAM role for Amazon EC2
- 3.2: Create the games table in Amazon DynamoDB
- 3.3: Bundle and deploy the tic-tac-toe application code
- 3.4: Set up the AWS Elastic Beanstalk environment

In the preceding sections, you deployed and tested the Tic-Tac-Toe application locally on your computer using DynamoDB local. Now, you deploy the application in production as follows:

- Deploy the application using AWS Elastic Beanstalk, an easy-to-use service for deploying and scaling web applications and services. For more information, see Deploying a flask application to AWS Elastic Beanstalk.

  Elastic Beanstalk launches one or more Amazon Elastic Compute Cloud (Amazon EC2) instances, which you configure through Elastic Beanstalk, on which your Tic-Tac-Toe application will run.
- Using the Amazon DynamoDB service, create a `Games` table that exists on AWS rather than locally on your computer.

In addition, you also have to configure permissions. Any AWS resources you create, such as the `Games` table in DynamoDB, are private by default. Only the resource owner, that is the AWS account that created the `Games` table, can access this table. Thus, by default your Tic-Tac-Toe application cannot update the `Games` table.

To grant necessary permissions, you create an AWS Identity and Access Management (IAM) role and grant this role permissions to access the `Games` table. Your Amazon EC2 instance first assumes this role. In response, AWS returns temporary security credentials that the Amazon EC2 instance can use to update the `Games` table on behalf of the Tic-Tac-Toe application. When you configure your Elastic Beanstalk application, you specify the IAM role that the Amazon EC2 instance or instances can assume. For more information about IAM roles, see IAM roles for amazon EC2 in the *Amazon EC2 User Guide.*

> **Note**
>
> Before you create Amazon EC2 instances for the Tic-Tac-Toe application, you must first decide the AWS Region where you want Elastic Beanstalk to create the instances. After you create the Elastic Beanstalk application, you provide the same Region name and endpoint in a configuration file. The Tic-Tac-Toe application uses information in this file to create the `Games` table and send subsequent requests in a specific AWS Region. Both the DynamoDB `Games` table and the Amazon EC2 instances that Elastic Beanstalk launches must be in the same Region. For a list of available Regions, see Amazon DynamoDB in the *Amazon Web Services General Reference*.

In summary, you do the following to deploy the Tic-Tac-Toe application in production:

1. Create an IAM role using the IAM service. You attach a policy to this role granting permissions for DynamoDB actions to access the `Games` table.
2. Bundle the Tic-Tac-Toe application code and a configuration file, and create a `.zip` file. You use this `.zip` file to give the Tic-Tac-Toe application code to Elastic Beanstalk to put on your servers. For more information about creating a bundle, see Creating an application source bundle in the *AWS Elastic Beanstalk Developer Guide*.

   In the configuration file (`beanstalk.config`), you provide AWS Region and endpoint information. The Tic-Tac-Toe application uses this information to determine which DynamoDB Region to talk to.
3. Set up the Elastic Beanstalk environment. Elastic Beanstalk launches an Amazon EC2 instance or instances and deploys your Tic-Tac-Toe application bundle on them. After the Elastic Beanstalk environment is ready, you provide the configuration file name by adding the `CONFIG_FILE` environment variable.
4. Create the DynamoDB table. Using the Amazon DynamoDB service, you create the `Games` table on AWS, rather than locally on your computer. Remember, this table has a simple primary key made of the `GameId` partition key of string type.
5. Test the game in production.

3.1: Create an IAM role for Amazon EC2

Creating an IAM role of the **Amazon EC2** type allows the Amazon EC2 instance that is running your Tic-Tac-Toe application to assume the correct role and make application requests to access the `Games` table. When creating the role, choose the **Custom Policy** option and copy and paste the following policy.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Action":[
            "dynamodb:ListTables"
         ],
         "Effect":"Allow",
         "Resource":"*"
      },
      {
         "Action":[
            "dynamodb:*"
         ],
         "Effect":"Allow",
         "Resource":[
            "arn:aws:dynamodb:us-west-2:922852403271:table/Games",
            "arn:aws:dynamodb:us-west-2:922852403271:table/Games/index/*"
         ]
      }
   ]
}
```

For further instructions, see Creating a role for an AWS service (AWS Management Console) in the *IAM User Guide.*

3.2: Create the games table in Amazon DynamoDB

The `Games` table in DynamoDB stores game data. If the table does not exist, the application creates the table for you. In this case, let the application create the `Games` table.

3.3: Bundle and deploy the tic-tac-toe application code

If you followed this example's steps, then you already have the downloaded the Tic-Tac-Toe application. If not, download the application and extract all the files to a folder on your local computer. For instructions, see Step 1: Deploy and test locally.

After you extract all files, you will have a `code` folder. To hand off this folder to Elastic Beanstalk, you bundle the contents of this folder as a `.zip` file. First, you add a configuration file to that folder. Your application uses the Region and endpoint information to create a DynamoDB table in the specified Region and make subsequent table operation requests using the specified endpoint.

1. Switch to the folder where you downloaded the Tic-Tac-Toe application.
2. In the root folder of the application, create a text file named `beanstalk.config` with the following content.

   ```
   [dynamodb]
   region=<AWS region>
   endpoint=<DynamoDB endpoint>
   ```

   For example, you might use the following content.

   ```
   [dynamodb]
   region=us-west-2
   endpoint=dynamodb.us-west-2.amazonaws.com
   ```

   For a list of available Regions, see Amazon DynamoDB in the *Amazon Web Services General Reference.*

   > **Important**
   >
   > The Region specified in the configuration file is the location where the Tic-Tac-Toe application creates the `Games` table in DynamoDB. You must create the Elastic Beanstalk application discussed in the next section in the same Region.

Note

When you create your Elastic Beanstalk application, you request to launch an environment where you can choose the environment type. To test the Tic-Tac-Toe example application, you can choose the **Single Instance** environment type, skip the following, and go to the next step.
However, the **Load balancing, autoscaling** environment type provides a highly available and scalable environment, something you should consider when you create and deploy other applications. If you choose this environment type, you also need to generate a UUID and add it to the configuration file, as shown following.

```
[dynamodb]
region=us-west-2
endpoint=dynamodb.us-west-2.amazonaws.com
[flask]
secret_key= 284e784d-1a25-4a19-92bf-8eeb7a9example
```

In client-server communication, when the server sends a response, for security's sake the server sends a signed cookie that the client sends back to the server in the next request. When there is only one server, the server can locally generate an encryption key when it starts. When there are many servers, they all need to know the same encryption key; otherwise, they won't be able to read cookies set by the peer servers. By adding `secret_key` to the configuration file, you tell all servers to use this encryption key.

3. Zip the content of the root folder of the application (which includes the `beanstalk.config` file)—for example, `TicTacToe.zip`.
4. Upload the `.zip` file to an Amazon Simple Storage Service (Amazon S3) bucket. In the next section, you provide this `.zip` file to Elastic Beanstalk to upload on the server or servers.

   For instructions on how to upload to an Amazon S3 bucket, see Create a bucket and Add an object to a bucket in the *Amazon Simple Storage Service User Guide.*

3.4: Set up the AWS Elastic Beanstalk environment

In this step, you create an Elastic Beanstalk application, which is a collection of components including environments. For this example, you launch one Amazon EC2 instance to deploy and run your Tic-Tac-Toe application.

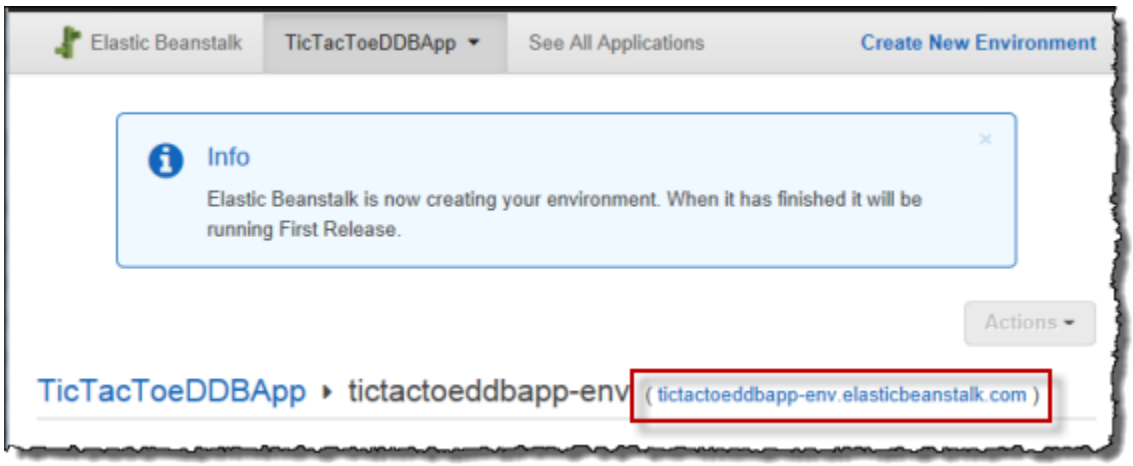
1. Enter the following custom URL to set up an Elastic Beanstalk console to set up the environment.

   ```
   https://console.aws.amazon.com/elasticbeanstalk/?region=<AWS-Region>#/
   newApplication
   ?applicationName=TicTacToeyour-name
   &solutionStackName=Python
   &sourceBundleUrl=https://s3.amazonaws.com/<bucket-name>/TicTacToe.zip
   &environmentType=SingleInstance
   &instanceType=t1.micro
   ```

   For more information about custom URLs, see Constructing a Launch Now URL in the *AWS Elastic Beanstalk Developer Guide.* For the URL, note the following:

   - You must provide an AWS Region name (the same as the one you provided in the configuration file), an Amazon S3 bucket name, and the object name.
   - For testing, the URL requests the **SingleInstance** environment type, and `t1.micro` as the instance type.
   - The application name must be unique. Thus, in the preceding URL, we suggest you prepend your name to the `applicationName`.

   Doing this opens the Elastic Beanstalk console. In some cases, you might need to sign in.
2. In the Elastic Beanstalk console, choose **Review and Launch**, and then choose **Launch**.
3. Note the URL for future reference. This URL opens your Tic-Tac-Toe application home page.



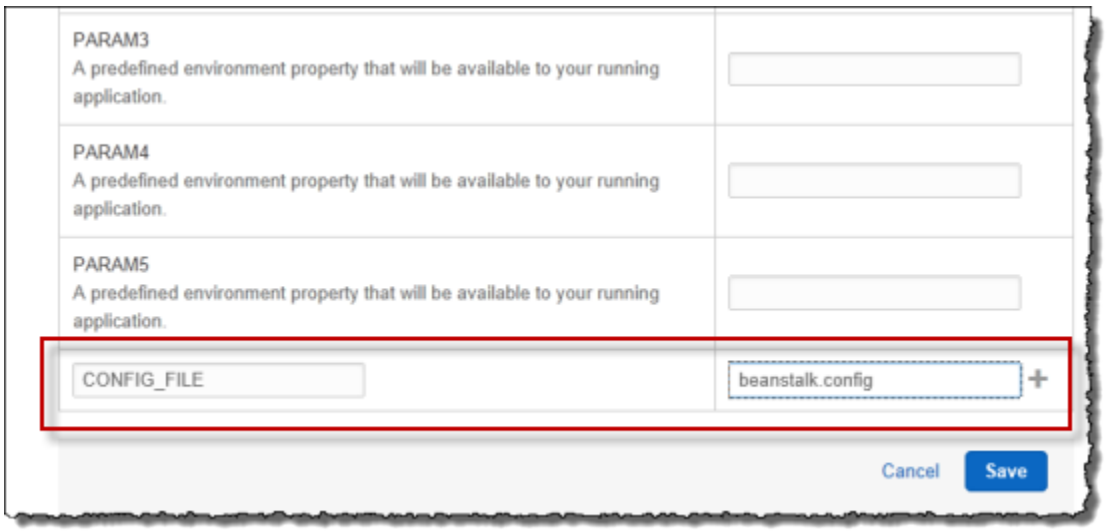
4. Configure the Tic-Tac-Toe application so it knows the location of the configuration file.

   After Elastic Beanstalk creates the application, choose **Configuration**.

   a. Choose the gear icon next to **Software Configuration**, as shown in the following screenshot.

   b. At the end of the **Environment Properties** section, enter **`CONFIG_FILE`** and its value **`beanstalk.config`**, and then choose **Save**.

      It might take a few minutes for this environment update to complete.

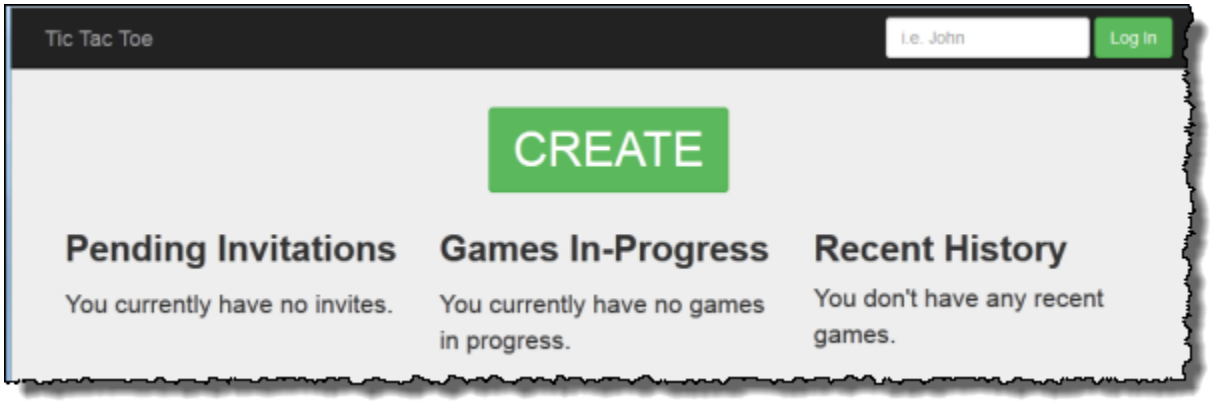


After the update completes, you can play the game.

5. In the browser, enter the URL you copied in the previous step, as shown in the following example.

```
http://<pen-name>.elasticbeanstalk.com
```

Doing this opens the application home page.



6. Log in as testuser1, and choose **CREATE** to start a new tic-tac-toe game.
7. Enter **`testuser2`** in the **Choose an Opponent** box.

8. Open another browser window.

   Make sure that you clear all cookies in your browser window so you won't be logged in as same user.

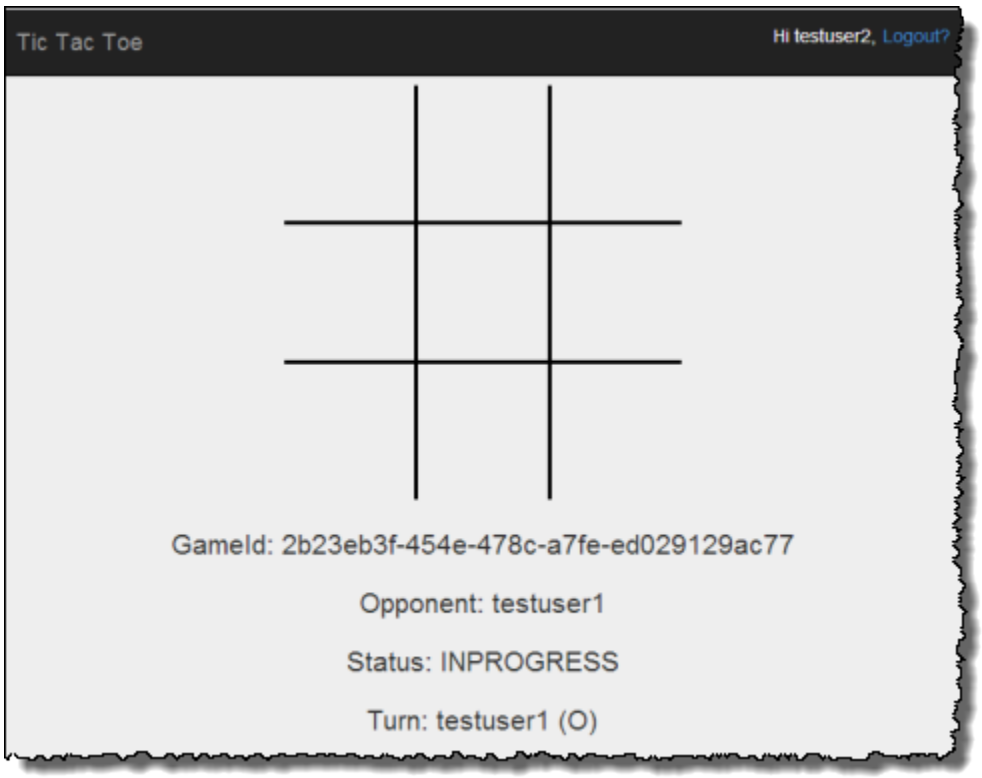
9. Enter the same URL to open the application home page, as shown in the following example.

   ```
   http://<env-name>.elasticbeanstalk.com
   ```

10. Log in as testuser2.

11. For the invitation from testuser1 in the list of pending invitations, choose **accept**.

12. Now the game page appears.



Both testuser1 and testuser2 can play the game. For each move, the application saves the move in the corresponding item in the `Games` table.

Step 4: Clean up resources

Now you have completed the Tic-Tac-Toe application deployment and testing. The application covers end-to-end web application development on Amazon DynamoDB, except for user authentication. The application uses the login information on the home page only to add a player name when creating a game. In a production application, you would add the necessary code to perform user login and authentication.

If you are done testing, you can remove the resources you created to test the Tic-Tac-Toe application to avoid incurring any charges.

To remove the resources you created

1. Remove the `Games` table that you created in DynamoDB.
2. Terminate the Elastic Beanstalk environment to free up the Amazon EC2 instances.
3. Delete the IAM role that you created.

4. Remove the object that you created in Amazon S3.

Reserved words in DynamoDB

The following keywords are reserved for use by DynamoDB. Don't use any of these words as attribute names in expressions. This list isn't case-sensitive.

If you need to write an expression containing an attribute name that conflicts with a DynamoDB reserved word, you can define an expression attribute name to use in the place of the reserved word. For more information, see Expression attribute names (aliases) in DynamoDB.

AWS SDK for Java 1.x examples

This section contains example code for DAX applications using SDK for Java 1.x.

Topics

- Using DAX with AWS SDK for Java 1.x
- Modifying an existing SDK for Java 1.x application to use DAX
- Querying global secondary indexes with SDK for Java 1.x

Using DAX with AWS SDK for Java 1.x

Follow this procedure to run the Java sample for Amazon DynamoDB Accelerator (DAX) on your Amazon EC2 instance.

> **Note**
>
> These instructions are for applications using AWS SDK for Java 1.x. For applications using AWS SDK for Java 2.x, see Java and DAX.

To run the Java sample for DAX

1. Install the Java Development Kit (JDK).

```
sudo yum install -y java-devel
```

2. Download the AWS SDK for Java (`.zip` file), and then extract it.

```
wget http://sdk-for-java.amazonwebservices.com/latest/aws-java-sdk.zip

unzip aws-java-sdk.zip
```

3. Download the latest version of the DAX Java client (`.jar` file).

```
wget http://dax-sdk.s3-website-us-west-2.amazonaws.com/java/DaxJavaClient-
latest.jar
```

> **Note**
>
> The client for the DAX SDK for Java is available on Apache Maven. For more information, see Using the client as an Apache Maven dependency.

4. Set your CLASSPATH variable. In this example, replace *`sdkVersion`* with the actual version number of the AWS SDK for Java (for example, `1.11.112`).

```
export SDKVERSION=sdkVersion

export CLASSPATH=$(pwd)/TryDax/java:$(pwd)/DaxJavaClient-latest.jar:$(pwd)/
aws-java-sdk-$SDKVERSION/lib/aws-java-sdk-$SDKVERSION.jar:$(pwd)/aws-java-sdk-
$SDKVERSION/third-party/lib/*
```

5. Download the sample program source code (`.zip` file).

```
wget http://docs.aws.amazon.com/amazondynamodb/latest/developerguide/samples/
TryDax.zip
```

When the download is complete, extract the source files.

```
unzip TryDax.zip
```

6. Navigate to the Java code directory and compile the code as follows.

```
cd TryDax/java/
```

```
javac TryDax*.java
```

7. Run the program.

```
java TryDax
```

You should see output similar to the following.

```
Creating a DynamoDB client

Attempting to create table; please wait...
Successfully created table.  Table status: ACTIVE
Writing data to the table...
Writing 10 items for partition key: 1
Writing 10 items for partition key: 2

```

```
 Total time: 37.660 ms - Avg time: 7.532 ms
 Total time: 26.781 ms - Avg time: 5.356 ms
 Total time: 46.076 ms - Avg time: 9.215 ms

Attempting to delete table; please wait...
Successfully deleted table.
```

Take note of the timing information—the number of milliseconds required for the `GetItem`, `Query`, and `Scan` tests.

8. In the previous step, you ran the program against the DynamoDB endpoint. Now run the program again, but this time, the `GetItem`, `Query`, and `Scan` operations are processed by your DAX cluster.

   To determine the endpoint for your DAX cluster, choose one of the following:

   - **Using the DynamoDB console** — Choose your DAX cluster. The cluster endpoint is shown on the console, as in the following example.

     ```
     dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com
     ```

   - **Using the AWS CLI** — Enter the following command.

     ```
     aws dax describe-clusters --query "Clusters[*].ClusterDiscoveryEndpoint"
     ```

     The cluster endpoint is shown in the output, as in the following example.

     ```
     {
         "Address": "my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com",
         "Port": 8111,
         "URL": "dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com"
     }
     ```

   Now run the program again, but this time, specify the cluster endpoint as a command line parameter.

   ```
   java TryDax dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com
   ```

Look at the rest of the output, and take note of the timing information. The elapsed times for `GetItem`, `Query`, and `Scan` should be significantly lower with DAX than with DynamoDB.

For more information about this program, see the following sections:

- TryDax.java
- TryDaxHelper.java
- TryDaxTests.java

Using the client as an Apache Maven dependency

Follow these steps to use the client for the DAX SDK for Java in your application as a dependency.

To use the client as a Maven dependency

1. Download and install Apache Maven. For more information, see Downloading Apache Maven and Installing Apache Maven.
2. Add the client Maven dependency to your application's Project Object Model (POM) file. In this example, replace `x.x.x.x` with the actual version number of the client (for example, `1.0.200704.0`).

```
<!--Dependency:-->
<dependencies>
    <dependency>
     <groupId>com.amazonaws</groupId>
     <artifactId>amazon-dax-client</artifactId>
     <version>x.x.x.x</version>
    </dependency>
</dependencies>
```

TryDax.java

The `TryDax.java` file contains the `main` method. If you run the program with no command line parameters, it creates an Amazon DynamoDB client and uses that client for all API operations. If you specify a DynamoDB Accelerator (DAX) cluster endpoint on the command line, the program also creates a DAX client and uses it for `GetItem`, `Query`, and `Scan` operations.

You can modify the program in several ways:

- Use the DAX client instead of the DynamoDB client. For more information, see Java and DAX.
- Choose a different name for the test table.
- Modify the number of items written by changing the `helper.writeData` parameters. The second parameter is the number of partition keys, and the third parameter is the number of sort keys. By default, the program uses 1–10 for partition key values and 1–10 for sort key values, for a total of 100 items written to the table. For more information, see TryDaxHelper.java.
- Modify the number of `GetItem`, `Query`, and `Scan` tests, and modify their parameters.
- Comment out the lines containing `helper.createTable` and `helper.deleteTable` (if you don't want to create and delete the table each time you run the program).

> **Note**
>
> To run this program, you can set up Maven to use the client for the DAX SDK for Java and the AWS SDK for Java as dependencies. For more information, see Using the client as an Apache Maven dependency.
> Alternatively, you can download and include both the DAX Java client and the AWS SDK for Java in your classpath. See Java and DAX for an example of setting your `CLASSPATH` variable.

```
public class TryDax {

    public static void main(String[] args) throws Exception {

        TryDaxHelper helper = new TryDaxHelper();
        TryDaxTests tests = new TryDaxTests();

        DynamoDB ddbClient = helper.getDynamoDBClient();
        DynamoDB daxClient = null;
        if (args.length >= 1) {
            daxClient = helper.getDaxClient(args[0]);
        }

        String tableName = "TryDaxTable";
```

```
        System.out.println("Creating table...");
        helper.createTable(tableName, ddbClient);
        System.out.println("Populating table...");
        helper.writeData(tableName, ddbClient, 10, 10);

        DynamoDB testClient = null;
        if (daxClient != null) {
            testClient = daxClient;
        } else {
            testClient = ddbClient;
        }

        System.out.println("Running GetItem, Scan, and Query tests...");
        System.out.println("First iteration of each test will result in cache misses");
        System.out.println("Next iterations are cache hits\n");

        // GetItem
        tests.getItemTest(tableName, testClient, 1, 10, 5);

        // Query
        tests.queryTest(tableName, testClient, 5, 2, 9, 5);

        // Scan
        tests.scanTest(tableName, testClient, 5);

        helper.deleteTable(tableName, ddbClient);
    }

}
```

TryDaxHelper.java

The `TryDaxHelper.java` file contains utility methods.

The `getDynamoDBClient` and `getDaxClient` methods provide Amazon DynamoDB and DynamoDB Accelerator (DAX) clients. For control plane operations (`CreateTable`, `DeleteTable`) and write operations, the program uses the DynamoDB client. If you specify a DAX cluster endpoint, the main program creates a DAX client for performing read operations (`GetItem`, `Query`, `Scan`).

The other `TryDaxHelper` methods (`createTable`, `writeData`, `deleteTable`) are for setting up and tearing down the DynamoDB table and its data.

You can modify the program in several ways:

- Use different provisioned throughput settings for the table.
- Modify the size of each item written (see the `stringSize` variable in the `writeData` method).
- Modify the number of `GetItem`, `Query`, and `Scan` tests and their parameters.
- Comment out the lines containing `helper.CreateTable` and `helper.DeleteTable` (if you don't want to create and delete the table each time you run the program).

> **Note**
>
> To run this program, you can set up Maven to use the client for the DAX SDK for Java and the AWS SDK for Java as dependencies. For more information, see Using the client as an Apache Maven dependency.
> Or, you can download and include both the DAX Java client and the AWS SDK for Java in your classpath. See Java and DAX for an example of setting your `CLASSPATH` variable.

            e.printStackTrace();
        }
    }

}
```

TryDaxTests.java

The `TryDaxTests.java` file contains methods that perform read operations against a test table in Amazon DynamoDB. These methods are not concerned with how they access the data (using either the DynamoDB client or the DAX client), so there is no need to modify the application logic.

You can modify the program in several ways:

- Modify the `queryTest` method so that it uses a different `KeyConditionExpression`.
- Add a `ScanFilter` to the `scanTest` method so that only some of the items are returned to you.

> **Note**
>
> To run this program, you can set up Maven to use the client for the DAX SDK for Java and the AWS SDK for Java as dependencies. For more information, see Using the client as an Apache Maven dependency.
> Or, you can download and include both the DAX Java client and the AWS SDK for Java in your classpath. See Java and DAX for an example of setting your `CLASSPATH` variable.

```

                }
            } catch (Exception e) {
                System.err.println("Unable to query table:");
                e.printStackTrace();
            }
            endTime = System.nanoTime();
            printTime(startTime, endTime, iterations);
        }
    }
```

```
    void scanTest(String tableName, DynamoDB client, int iterations) {
        long startTime, endTime;
        System.out.println("Scan test - all items in the table");
        Table table = client.getTable(tableName);

        for (int i = 0; i < iterations; i++) {
            startTime = System.nanoTime();
            ItemCollection<ScanOutcome> items = table.scan();
            try {

                Iterator<Item> iter = items.iterator();
                while (iter.hasNext()) {
                    iter.next();
                }
            } catch (Exception e) {
                System.err.println("Unable to scan table:");
                e.printStackTrace();
            }
            endTime = System.nanoTime();
            printTime(startTime, endTime, iterations);
        }
    }

    public void printTime(long startTime, long endTime, int iterations) {
        System.out.format("\tTotal time: %.3f ms - ", (endTime - startTime) /
 (1000000.0));
        System.out.format("Avg time: %.3f ms\n", (endTime - startTime) / (iterations *
 1000000.0));
    }
}
```

Modifying an existing SDK for Java 1.x application to use DAX

If you already have a Java application that uses Amazon DynamoDB, you have to modify it so that it can access your DynamoDB Accelerator (DAX) cluster. You don't have to rewrite the entire application because the DAX Java client is similar to the DynamoDB low-level client included in the AWS SDK for Java.

> **Note**
>
> These instructions are for applications using AWS SDK for Java 1.x. For applications using AWS SDK for Java 2.x, see Modifying an existing application to use DAX.

Suppose that you have a DynamoDB table named `Music`. The partition key for the table is `Artist`, and its sort key is `SongTitle`. The following program reads an item directly from the `Music` table.

```
import java.util.HashMap;

import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.model.AttributeValue;
import com.amazonaws.services.dynamodbv2.model.GetItemRequest;
import com.amazonaws.services.dynamodbv2.model.GetItemResult;

public class GetMusicItem {

    public static void main(String[] args) throws Exception {

        // Create a DynamoDB client
        AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();

        HashMap<String, AttributeValue> key = new HashMap<String, AttributeValue>();
        key.put("Artist", new AttributeValue().withS("No One You Know"));
        key.put("SongTitle", new AttributeValue().withS("Scared of My Shadow"));

        GetItemRequest request = new GetItemRequest()
            .withTableName("Music").withKey(key);

        try {
            System.out.println("Attempting to read the item...");
            GetItemResult result = client.getItem(request);
            System.out.println("GetItem succeeded: " + result);

        } catch (Exception e) {
            System.err.println("Unable to read item");
            System.err.println(e.getMessage());
        }
    }
}
```

To modify the program, replace the DynamoDB client with a DAX client.

```
import java.util.HashMap;

import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazon.dax.client.dynamodbv2.AmazonDaxClientBuilder;
import com.amazonaws.services.dynamodbv2.model.AttributeValue;
import com.amazonaws.services.dynamodbv2.model.GetItemRequest;
import com.amazonaws.services.dynamodbv2.model.GetItemResult;

public class GetMusicItem {

    public static void main(String[] args) throws Exception {

    //Create a DAX client

    AmazonDaxClientBuilder daxClientBuilder = AmazonDaxClientBuilder.standard();
    daxClientBuilder.withRegion("us-
east-1").withEndpointConfiguration("mydaxcluster.2cmrwl.clustercfg.dax.use1.cache.amazonaws.com
    AmazonDynamoDB client = daxClientBuilder.build();

       /*
       ** ...
       ** Remaining code omitted (it is identical)
       ** ...
       */

    }
}
```

Using the DynamoDB document API

The AWS SDK for Java provides a document interface for DynamoDB. The document API acts as a wrapper around the low-level DynamoDB client. For more information, see Document interfaces.

The document interface can also be used with the low-level DAX client, as shown in the following example.

```
import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazon.dax.client.dynamodbv2.AmazonDaxClientBuilder;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
import com.amazonaws.services.dynamodbv2.document.GetItemOutcome;
```

```
import com.amazonaws.services.dynamodbv2.document.Table;

public class GetMusicItemWithDocumentApi {

    public static void main(String[] args) throws Exception {

        //Create a DAX client

        AmazonDaxClientBuilder daxClientBuilder = AmazonDaxClientBuilder.standard();
        daxClientBuilder.withRegion("us-
east-1").withEndpointConfiguration("mydaxcluster.2cmrwl.clustercfg.dax.use1.cache.amazonaws.com
        AmazonDynamoDB client = daxClientBuilder.build();

        // Document client wrapper
        DynamoDB docClient = new DynamoDB(client);

        Table table = docClient.getTable("Music");

        try {
            System.out.println("Attempting to read the item...");
            GetItemOutcome outcome = table.tgetItemOutcome(
                "Artist", "No One You Know",
                "SongTitle", "Scared of My Shadow");
            System.out.println(outcome.getItem());
            System.out.println("GetItem succeeded: " + outcome);
        } catch (Exception e) {
            System.err.println("Unable to read item");
            System.err.println(e.getMessage());
        }

    }
}
```

DAX async client

The `AmazonDaxClient` is synchronous. For a long-running DAX API operation, such as a `Scan` of a large table, this can block program execution until the operation is complete. If your program needs to perform other work while a DAX API operation is in progress, you can use `ClusterDaxAsyncClient` instead.

The following program shows how to use `ClusterDaxAsyncClient`, along with Java `Future`, to implement a non-blocking solution.

```
import java.util.concurrent.ExecutionException;
import java.util.concurrent.Future;

import com.amazon.dax.client.dynamodbv2.ClientConfig;
import com.amazon.dax.client.dynamodbv2.ClusterDaxAsyncClient;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.handlers.AsyncHandler;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBAsync;
import com.amazonaws.services.dynamodbv2.model.AttributeValue;
import com.amazonaws.services.dynamodbv2.model.GetItemRequest;
import com.amazonaws.services.dynamodbv2.model.GetItemResult;

public class DaxAsyncClientDemo {
 public static void main(String[] args) throws Exception {

  ClientConfig daxConfig = new ClientConfig().withCredentialsProvider(new
 ProfileCredentialsProvider())
    .withEndpoints("mydaxcluster.2cmrwl.clustercfg.dax.use1.cache.amazonaws.com:8111");

  AmazonDynamoDBAsync client = new ClusterDaxAsyncClient(daxConfig);

  HashMap<String, AttributeValue> key = new HashMap<String, AttributeValue>();
  key.put("Artist", new AttributeValue().withS("No One You Know"));
  key.put("SongTitle", new AttributeValue().withS("Scared of My Shadow"));

  GetItemRequest request = new GetItemRequest()
    .withTableName("Music").withKey(key);

  // Java Futures
  Future<GetItemResult> call = client.getItemAsync(request);
  while (!call.isDone()) {
   // Do other processing while you're waiting for the response
   System.out.println("Doing something else for a few seconds...");
   Thread.sleep(3000);
  }
  // The results should be ready by now

  try {
   call.get();

  } catch (ExecutionException ee) {
   // Futures always wrap errors as an ExecutionException.
   // The *real* exception is stored as the cause of the
```

```
   // ExecutionException
   Throwable exception = ee.getCause();
   System.out.println("Error getting item: " + exception.getMessage());
  }

  // Async callbacks
  call = client.getItemAsync(request, new AsyncHandler<GetItemRequest, GetItemResult>()
 {

   @Override
   public void onSuccess(GetItemRequest request, GetItemResult getItemResult) {
    System.out.println("Result: " + getItemResult);
   }

   @Override
   public void onError(Exception e) {
    System.out.println("Unable to read item");
    System.err.println(e.getMessage());
    // Callers can also test if exception is an instance of
    // AmazonServiceException or AmazonClientException and cast
    // it to get additional information
   }

  });
  call.get();

 }
}
```

Querying global secondary indexes with SDK for Java 1.x

You can use Amazon DynamoDB Accelerator (DAX) to query global secondary indexes using DynamoDB programmatic interfaces.

The following example demonstrates how to use DAX to query the `CreateDateIndex` global secondary index that is created in Example: Global secondary indexes using the AWS SDK for Java document API.

The `DAXClient` class instantiates the client objects that are needed to interact with the DynamoDB programming interfaces.

```
import com.amazon.dax.client.dynamodbv2.AmazonDaxClientBuilder;
```

```
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBMapper;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
import com.amazonaws.util.EC2MetadataUtils;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;

public class DaxClient {

 private static final String region = EC2MetadataUtils.getEC2InstanceRegion();

 DynamoDB getDaxDocClient(String daxEndpoint) {
  System.out.println("Creating a DAX client with cluster endpoint " + daxEndpoint);
  AmazonDaxClientBuilder daxClientBuilder = AmazonDaxClientBuilder.standard();

  daxClientBuilder.withRegion(region).withEndpointConfiguration(daxEndpoint);
  AmazonDynamoDB client = daxClientBuilder.build();

  return new DynamoDB(client);
 }

 DynamoDBMapper getDaxMapperClient(String daxEndpoint) {
  System.out.println("Creating a DAX client with cluster endpoint " + daxEndpoint);
  AmazonDaxClientBuilder daxClientBuilder = AmazonDaxClientBuilder.standard();

  daxClientBuilder.withRegion(region).withEndpointConfiguration(daxEndpoint);
  AmazonDynamoDB client = daxClientBuilder.build();

  return new DynamoDBMapper(client);
 }
}
```

You can query a global secondary index in the following ways:

- Use the `queryIndex` method on the `QueryIndexDax` class defined in the following example. The `QueryIndexDax` takes as a parameter the client object that is returned by the `getDaxDocClient` method on the `DaxClient` class.
- If you are using the object persistence interface, use the `queryIndexMapper` method on the `QueryIndexDax` class defined in the following example. The `queryIndexMapper` takes as a parameter the client object that is returned by the `getDaxMapperClient` method defined on the `DaxClient` class.

```
import java.util.Iterator;
```

```
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBMapper;
import java.util.List;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBQueryExpression;
import com.amazonaws.services.dynamodbv2.model.AttributeValue;
import java.util.HashMap;
import com.amazonaws.services.dynamodbv2.document.Item;
import com.amazonaws.services.dynamodbv2.document.utils.ValueMap;
import com.amazonaws.services.dynamodbv2.document.spec.QuerySpec;
import com.amazonaws.services.dynamodbv2.document.QueryOutcome;
import com.amazonaws.services.dynamodbv2.document.ItemCollection;
import com.amazonaws.services.dynamodbv2.document.Index;
import com.amazonaws.services.dynamodbv2.document.Table;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;

public class QueryIndexDax {

 //This is used to query Index using the low-level interface.
 public static void queryIndex(DynamoDB client, String tableName, String indexName) {
  Table table = client.getTable(tableName);

  System.out.println("\n***********************************************************
\n");
  System.out.print("Querying index " + indexName + "...");

  Index index = table.getIndex(indexName);

  ItemCollection<QueryOutcome> items = null;

  QuerySpec querySpec = new QuerySpec();

  if (indexName == "CreateDateIndex") {
   System.out.println("Issues filed on 2013-11-01");
   querySpec.withKeyConditionExpression("CreateDate = :v_date and
 begins_with(IssueId, :v_issue)")
     .withValueMap(new ValueMap().withString(":v_date",
 "2013-11-01").withString(":v_issue", "A-"));
   items = index.query(querySpec);
  } else {
   System.out.println("\nNo valid index name provided");
   return;
  }

  Iterator<Item> iterator = items.iterator();
```

```
  System.out.println("Query: printing results...");

  while (iterator.hasNext()) {
   System.out.println(iterator.next().toJSONPretty());
  }

 }

 //This is used to query Index using the high-level mapper interface.
 public static void queryIndexMapper(DynamoDBMapper mapper, String tableName, String
 indexName) {
  HashMap<String, AttributeValue> eav = new HashMap<String, AttributeValue>();
  eav.put(":v_date", new AttributeValue().withS("2013-11-01"));
  eav.put(":v_issue", new AttributeValue().withS("A-"));
  DynamoDBQueryExpression<CreateDate> queryExpression = new
 DynamoDBQueryExpression<CreateDate>()
     .withIndexName("CreateDateIndex").withConsistentRead(false)
     .withKeyConditionExpression("CreateDate = :v_date and
 begins_with(IssueId, :v_issue)")
     .withExpressionAttributeValues(eav);

  List<CreateDate> items = mapper.query(CreateDate.class, queryExpression);
  Iterator<CreateDate> iterator = items.iterator();

  System.out.println("Query: printing results...");

  while (iterator.hasNext()) {
   CreateDate iterObj = iterator.next();
   System.out.println(iterObj.getCreateDate());
   System.out.println(iterObj.getIssueId());
  }
 }
}
```

The class definition below represents the Issues table and is used in the `queryIndexMapper` method.

```
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBTable;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBIndexHashKey;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBIndexRangeKey;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBHashKey;

@DynamoDBTable(tableName = "Issues")
```

```
public class CreateDate {
 private String createDate;
 @DynamoDBHashKey(attributeName = "IssueId")
 private String issueId;

 @DynamoDBIndexHashKey(globalSecondaryIndexName = "CreateDateIndex", attributeName =
 "CreateDate")
 public String getCreateDate() {
  return createDate;
 }

 public void setCreateDate(String createDate) {
  this.createDate = createDate;
 }

 @DynamoDBIndexRangeKey(globalSecondaryIndexName = "CreateDateIndex", attributeName =
 "IssueId")
 public String getIssueId() {
  return issueId;
 }

 public void setIssueId(String issueId) {
  this.issueId = issueId;
 }
}
```

AWS SDK for Go 1.x examples

This section contains example code for DAX applications using Go 1.x.

Topics

- DAX SDK for Go

DAX SDK for Go

Follow this procedure to run the Amazon DynamoDB Accelerator (DAX) SDK for Go sample application on your Amazon EC2 instance.

To run the SDK for Go sample for DAX

1. Set up the SDK for Go on your Amazon EC2 instance:

a. Install the Go programming language (`Golang`).

```
sudo yum install -y golang
```

b. Test that Golang is installed and running correctly.

```
go version
```

A message like this should appear.

```
go version go1.15.5 linux/amd64
```

The remaining instructions rely on module support, which became the default with Go version 1.13.

2. Install the sample Golang application.

```
go get github.com/aws-samples/aws-dax-go-sample
```

3. Run the following Golang programs. The first program creates a DynamoDB table named `TryDaxGoTable`. The second program writes data to the table.

```
go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go -
service dynamodb -command create-table
```

```
go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go -
service dynamodb -command put-item
```

4. Run the following Golang programs.

```
go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go -
service dynamodb -command get-item
```

```
go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go -
service dynamodb -command query
```

```
go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go -
service dynamodb -command scan
```

Take note of the timing information—the number of milliseconds required for the `GetItem`, `Query`, and `Scan` tests.

5. In the previous step, you ran the programs against the DynamoDB endpoint. Now, run the programs again, but this time, the `GetItem`, `Query`, and `Scan` operations are processed by your DAX cluster.

   To determine the endpoint for your DAX cluster, choose one of the following:

   - **Using the DynamoDB console** — Choose your DAX cluster. The cluster endpoint is shown on the console, as in the following example.

     ```
     dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com
     ```

   - **Using the AWS CLI** — Enter the following command.

     ```
     aws dax describe-clusters --query "Clusters[*].ClusterDiscoveryEndpoint"
     ```

     The cluster endpoint is shown in the output, as in the following example.

     ```
     {
         "Address": "my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com",
         "Port": 8111,
         "URL": "dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com"
     }
     ```

   Now run the programs again, but this time, specify the cluster endpoint as a command line parameter.

   ```
   go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go
    -service dax -command get-item -endpoint my-cluster.l6fzcv.dax-clusters.us-
   east-1.amazonaws.com:8111
   ```

   ```
   go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go
    -service dax -command query -endpoint my-cluster.l6fzcv.dax-clusters.us-
   east-1.amazonaws.com:8111
   ```

```
go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go
 -service dax -command scan -endpoint my-cluster.l6fzcv.dax-clusters.us-
east-1.amazonaws.com:8111
```

Look at the rest of the output, and take note of the timing information. The elapsed times for `GetItem`, `Query`, and `Scan` should be significantly lower with DAX than with DynamoDB.

6. Run the following Golang program to delete `TryDaxGoTable`.

```
go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go -
service dynamodb -command delete-table
```

AWS SDK for Node.js 2.x examples

This section contains example code for DAX applications using AWS SDK for Node.js 2.x.

Topics

- Node.js and DAX

Node.js and DAX

Follow these steps to run the Node.js sample application on your Amazon EC2 instance.

To run the Node.js sample for DAX

1. Set up Node.js on your Amazon EC2 instance, as follows:

   a. Install node version manager (nvm).

   ```
   curl -o- https://raw.githubusercontent.com/nvm-sh/nvm/v0.35.3/install.sh | bash
   ```

   b. Use nvm to install Node.js.

   ```
   nvm install 12.16.3
   ```

   c. Test that Node.js is installed and running correctly.

   ```
   node -e "console.log('Running Node.js ' + process.version)"
   ```

This should display the following message.

```
Running Node.js v12.16.3
```

2. Install the DAX Node.js client using the node package manager (`npm`).

```
npm install amazon-dax-client
```

3. Download the sample program source code (`.zip` file).

```
wget http://docs.aws.amazon.com/amazondynamodb/latest/developerguide/samples/
TryDax.zip
```

When the download is complete, extract the source files.

```
unzip TryDax.zip
```

4. Run the following Node.js programs. The first program creates an Amazon DynamoDB table named `TryDaxTable`. The second program writes data to the table.

```
node 01-create-table.js
node 02-write-data.js
```

5. Run the following Node.js programs.

```
node 03-getitem-test.js
node 04-query-test.js
node 05-scan-test.js
```

Take note of the timing information—the number of milliseconds required for the `GetItem`, `Query`, and `Scan` tests.

6. In the previous step, you ran the programs against the DynamoDB endpoint. Run the programs again, but this time, the `GetItem`, `Query` and `Scan` operations are processed by your DAX cluster.

To determine the endpoint for your DAX cluster, choose one of the following.

- **Using the DynamoDB console**—Choose your DAX cluster. The cluster endpoint is shown on the console, as in the following example.

```
dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com
```

- **Using the AWS CLI**—Enter the following command.

```
aws dax describe-clusters --query "Clusters[*].ClusterDiscoveryEndpoint"
```

The cluster endpoint is shown in the output, as in the following example.

```
{
    "Address": "my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com",
    "Port": 8111,
    "URL": "dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com"
}
```

Now run the programs again, but this time, specify the cluster endpoint as a command line parameter.

```
node 03-getitem-test.js dax://my-cluster.l6fzcv.dax-clusters.us-
east-1.amazonaws.com
node 04-query-test.js dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com
node 05-scan-test.js dax://my-cluster.l6fzcv.dax-clusters.us-east-1.amazonaws.com
```

Look at the rest of the output, and take note of the timing information. The elapsed times for `GetItem`, `Query`, and `Scan` should be significantly lower with DAX than with DynamoDB.

7. Run the following Node.js program to delete `TryDaxTable`.

```
node 06-delete-table
```

For more information about these programs, see the following sections:

- 01-create-table.js
- 02-write-data.js
- 03-getitem-test.js
- 04-query-test.js
- 05-scan-test.js

- 06-delete-table.js

01-create-table.js

The `01-create-table.js` program creates a table (`TryDaxTable`). The remaining Node.js programs in this section depend on this table.

```
const AmazonDaxClient = require("amazon-dax-client");
var AWS = require("aws-sdk");

var region = "us-west-2";

AWS.config.update({
  region: region,
});

var dynamodb = new AWS.DynamoDB(); //low-level client

var tableName = "TryDaxTable";

var params = {
  TableName: tableName,
  KeySchema: [
    { AttributeName: "pk", KeyType: "HASH" }, //Partition key
    { AttributeName: "sk", KeyType: "RANGE" }, //Sort key
  ],
  AttributeDefinitions: [
    { AttributeName: "pk", AttributeType: "N" },
    { AttributeName: "sk", AttributeType: "N" },
  ],
  ProvisionedThroughput: {
    ReadCapacityUnits: 10,
    WriteCapacityUnits: 10,
  },
};

dynamodb.createTable(params, function (err, data) {
  if (err) {
    console.error(
      "Unable to create table. Error JSON:",
      JSON.stringify(err, null, 2)
    );
  } else {
```

```
    console.log(
      "Created table. Table description JSON:",
      JSON.stringify(data, null, 2)
    );
  }
});
```

02-write-data.js

The `02-write-data.js` program writes test data to `TryDaxTable`.

```
const AmazonDaxClient = require("amazon-dax-client");
var AWS = require("aws-sdk");

var region = "us-west-2";

AWS.config.update({
  region: region,
});

var ddbClient = new AWS.DynamoDB.DocumentClient();

var tableName = "TryDaxTable";

var someData = "X".repeat(1000);
var pkmax = 10;
var skmax = 10;

for (var ipk = 1; ipk <= pkmax; ipk++) {
  for (var isk = 1; isk <= skmax; isk++) {
    var params = {
      TableName: tableName,
      Item: {
        pk: ipk,
        sk: isk,
        someData: someData,
      },
    };

    //
    //put item
```

```
    ddbClient.put(params, function (err, data) {
      if (err) {
        console.error("Unable to write data: ", JSON.stringify(err, null, 2));
      } else {
        console.log("PutItem succeeded");
      }
    });
  }
}
```

03-getitem-test.js

The `03-getitem-test.js` program performs `GetItem` operations on `TryDaxTable`.

```
const AmazonDaxClient = require("amazon-dax-client");
var AWS = require("aws-sdk");

var region = "us-west-2";

AWS.config.update({
  region: region,
});

var ddbClient = new AWS.DynamoDB.DocumentClient();
var daxClient = null;

if (process.argv.length > 2) {
  var dax = new AmazonDaxClient({
    endpoints: [process.argv[2]],
    region: region,
  });
  daxClient = new AWS.DynamoDB.DocumentClient({ service: dax });
}

var client = daxClient != null ? daxClient : ddbClient;
var tableName = "TryDaxTable";

var pk = 1;
var sk = 10;
var iterations = 5;

for (var i = 0; i < iterations; i++) {
```

```
  var startTime = new Date().getTime();

  for (var ipk = 1; ipk <= pk; ipk++) {
    for (var isk = 1; isk <= sk; isk++) {
      var params = {
        TableName: tableName,
        Key: {
          pk: ipk,
          sk: isk,
        },
      };

      client.get(params, function (err, data) {
        if (err) {
          console.error(
            "Unable to read item. Error JSON:",
            JSON.stringify(err, null, 2)
          );
        } else {
          // GetItem succeeded
        }
      });
    }
  }

  var endTime = new Date().getTime();
  console.log(
    "\tTotal time: ",
    endTime - startTime,
    "ms - Avg time: ",
    (endTime - startTime) / iterations,
    "ms"
  );
}
```

04-query-test.js

The `04-query-test.js` program performs `Query` operations on `TryDaxTable`.

```
const AmazonDaxClient = require("amazon-dax-client");
var AWS = require("aws-sdk");
```

```
var region = "us-west-2";

AWS.config.update({
  region: region,
});

var ddbClient = new AWS.DynamoDB.DocumentClient();
var daxClient = null;

if (process.argv.length > 2) {
  var dax = new AmazonDaxClient({
    endpoints: [process.argv[2]],
    region: region,
  });
  daxClient = new AWS.DynamoDB.DocumentClient({ service: dax });
}

var client = daxClient != null ? daxClient : ddbClient;
var tableName = "TryDaxTable";

var pk = 5;
var sk1 = 2;
var sk2 = 9;
var iterations = 5;

var params = {
  TableName: tableName,
  KeyConditionExpression: "pk = :pkval and sk between :skval1 and :skval2",
  ExpressionAttributeValues: {
    ":pkval": pk,
    ":skval1": sk1,
    ":skval2": sk2,
  },
};

for (var i = 0; i < iterations; i++) {
  var startTime = new Date().getTime();

  client.query(params, function (err, data) {
    if (err) {
      console.error(
        "Unable to read item. Error JSON:",
        JSON.stringify(err, null, 2)
      );
```

```
    } else {
      // Query succeeded
    }
  });

  var endTime = new Date().getTime();
  console.log(
    "\tTotal time: ",
    endTime - startTime,
    "ms - Avg time: ",
    (endTime - startTime) / iterations,
    "ms"
  );
}
```

05-scan-test.js

The `05-scan-test.js` program performs `Scan` operations on `TryDaxTable`.

```
const AmazonDaxClient = require("amazon-dax-client");
var AWS = require("aws-sdk");

var region = "us-west-2";

AWS.config.update({
  region: region,
});

var ddbClient = new AWS.DynamoDB.DocumentClient();
var daxClient = null;

if (process.argv.length > 2) {
  var dax = new AmazonDaxClient({
    endpoints: [process.argv[2]],
    region: region,
  });
  daxClient = new AWS.DynamoDB.DocumentClient({ service: dax });
}

var client = daxClient != null ? daxClient : ddbClient;
var tableName = "TryDaxTable";
```

```
var iterations = 5;

var params = {
  TableName: tableName,
};
var startTime = new Date().getTime();
for (var i = 0; i < iterations; i++) {
  client.scan(params, function (err, data) {
    if (err) {
      console.error(
        "Unable to read item. Error JSON:",
        JSON.stringify(err, null, 2)
      );
    } else {
      // Scan succeeded
    }
  });
}

var endTime = new Date().getTime();
console.log(
  "\tTotal time: ",
  endTime - startTime,
  "ms - Avg time: ",
  (endTime - startTime) / iterations,
  "ms"
);
```

06-delete-table.js

The `06-delete-table.js` program deletes `TryDaxTable`. Run this program after you have finished testing.

```
const AmazonDaxClient = require("amazon-dax-client");
var AWS = require("aws-sdk");

var region = "us-west-2";

AWS.config.update({
  region: region,
});
```

```
var dynamodb = new AWS.DynamoDB(); //low-level client

var tableName = "TryDaxTable";

var params = {
  TableName: tableName,
};

dynamodb.deleteTable(params, function (err, data) {
  if (err) {
    console.error(
      "Unable to delete table. Error JSON:",
      JSON.stringify(err, null, 2)
    );
  } else {
    console.log(
      "Deleted table. Table description JSON:",
      JSON.stringify(data, null, 2)
    );
  }
});
```

Document history for DynamoDB

The following table describes the important changes in each release of the *DynamoDB Developer Guide* from July 3, 2018 onward. For notification about updates to this documentation, you can subscribe to the RSS feed (at the top left corner of this page).

Change	Description	Date
Added support for running DynamoDB local in AWS CloudShell	You can now run DynamoDB local directly in your browser through the AWS Management Console without downloading or installing software. For more information, see Deploying DynamoDB locally on your computer.	May 19, 2025
Added support for r7i instance types in DAX	Expanded instance type options for DAX to provide more flexibility in performance and capacity. For more details about the new r7i instance types and their capabilities, see DAX encryption at rest.	April 29, 2025
New scoped-down full access policy `AmazonDynamoDBFullAccess_v2` replaces `AmazonDynamoDBFullAccess` .	Effective **April 25, 2025**, DynamoDB has deprecated the `AmazonDynamoDBFullAccess` policy and replaced it with a scoped-down policy named `AmazonDynamoDBFullAccess_v2` . For more information, see AWS managed policy:	April 28, 2025

	AmazonDynamoDBFullAccess_v2.	
DynamoDB introduces PrivateLink support for DynamoDB Streams	AWS added PrivateLink support for DynamoDB Streams, enabling customers to invoke DynamoDB Streams APIs from within Amazon Virtual Private Cloud (VPC) using private network connectivity. This feature allows simplified private network access without traversing the public internet, supporting compliance and security requirements for DynamoDB workloads. For more information, see AWS PrivateLink for Amazon DynamoDB Streams.	March 26, 2025
DAX SDK For JS 3.x and Go 2.x is now available	DynamoDB Accelerator (DAX) SDK for JS 3.x is now available and is compatible with the AWS SDK for Java 3.x.	March 17, 2025
NoSQL Workbench 3.13.5 on-demand capacity mode for default table settings release	When you create a table with default settings, DynamoDB creates a table that uses on-demand capacity mode instead of provisioned capacity mode.	February 24, 2025

New best practice for configuring your DAX client	Published a new DAX prescriptive guidance best practices topic for configuri ng your DAX client. For more information, see Configuring your DAX client.	February 17, 2025
New best practices for bulk data operations	Published new best practices topics for working with complex data models in DynamoDB. For more information, see Best practices for using bulk data operations in DynamoDB.	January 9, 2025
Amazon DynamoDB now supports configurable point-in-time recovery (PITR)	DynamoDB now supports configurable recovery periods for PITR. You can now set the PITR period for each table to between 1 and 35 days. For more information, see Point-in-time backups for DynamoDB.	January 7, 2025
Amazon DynamoDB now supports configurable point-in-time recovery (PITR)	DynamoDB now supports configurable recovery periods for PITR. You can now set the PITR period for each table to between 1 and 35 days. For more information, see Point-in-time backups for DynamoDB.	January 7, 2025

Published new topic on integrating Amazon Managed Streaming for Apache Kafka with Amazon DynamoDB	Learn how Amazon Managed Streaming for Apache Kafka integrates with Amazon DynamoDB by reading data from Apache Kafka topics and storing it in DynamoDB. For more information, see Integrating DynamoDB with Amazon Managed Streaming for Apache Kafka.	December 26, 2024
Published new topic on integrating Amazon Managed Streaming for Apache Kafka with Amazon DynamoDB	Learn how Amazon Managed Streaming for Apache Kafka integrates with Amazon DynamoDB by reading data from Apache Kafka topics and storing it in DynamoDB. For more information, see Integrating DynamoDB with Amazon Managed Streaming for Apache Kafka.	December 26, 2024
DynamoDB introduces support for a zero-ETL integration with SageMaker AI Lakehouse	DynamoDB introduces a zero-ETL integration that automates the extracting and loading of data from Amazon DynamoDB into a customer's data lake. For more informati on, see DynamoDB zero-ETL integration with SageMaker AI Lakehouse.	December 3, 2024

DynamoDB introduces support for a zero-ETL integration with Amazon SageMaker Lakehouse	DynamoDB introduces a zero-ETL integration that automates the extracting and loading of data from Amazon DynamoDB into a customer's data lake. For more informati on, see DynamoDB zero-ETL integration with Amazon SageMaker Lakehouse.	December 3, 2024
DynamoDB global tables now supports multi-Region strong consistency	With multi-Region strong consistency, you can build highly available multi-Region applications with a recovery point objective (RPO) of zero, achieving the highest level of resilience. For more informati on, see Global tables with multi-Region strong consisten cy.	December 3, 2024
DynamoDB global tables now supports multi-Region strong consistency	With multi-Region strong consistency, you can build highly available multi-Region applications with a recovery point objective (RPO) of zero, achieving the highest level of resilience. For more informati on, see Global tables with multi-Region strong consisten cy.	December 3, 2024

DynamoDB managed policy update	Added two new permissions to the `AmazonDynamoDBReadOnlyAccess` managed policy: `dynamodb:GetAbacStatus` and `dynamodb:UpdateAbacStatus`. These permissions allow you to view the ABAC status and enable ABAC for your AWS account in the current Region. For more information, see AWS managed policy: AmazonDynamoDBReadOnlyAccess.	November 18, 2024
DynamoDB introduces support for attribute-based access control (ABAC)	ABAC is an authorization strategy that lets you define access permissions based on tags attached to users, roles, and AWS resources. ABAC uses tag-based conditions in your AWS Identity and Access Management (IAM) policies or other policies to allow or deny specific actions on your tables or indexes when IAM principals' tags match the tags for the tables. For more information, see Using attribute-based access control with DynamoDB.	November 18, 2024

DynamoDB introduces warm throughput for on-demand and provisioned tables	DynamoDB now supports warm throughput. Warm throughput provides visibilit y into the number of read and write operations your DynamoDB table can instantaneously support as well as the ability to pre-warm your DynamoDB tables. For more information, see DynamoDB warm throughput.	November 13, 2024
Ability to consume Amazon DynamoDB Streams records with Apache Flink	You can now consume Amazon DynamoDB Streams records with Apache Flink and leverage the Amazon Managed Service for Apache Flink to quickly build and manage end-to-end stream processing applications. For more information, see DynamoDB Streams and Apache Flink.	November 12, 2024
Published new billing topics for global tables and backups	Published two new topics regarding billing for global tables and billing for backups. For more information, see Understanding Amazon DynamoDB billing for global tables and Understanding Amazon DynamoDB billing for backups.	October 16, 2024

Amazon DynamoDB zero-ETL integration with Amazon Redshift	Amazon DynamoDB zero-ETL integration with Amazon Redshift provides a no-code, fully managed ETL pipeline with replication from DynamoDB to Amazon Redshift. For more information, see Amazon DynamoDB zero-ETL integration with Amazon Redshift.	October 15, 2024
Documentation-only update to add a topic about using generative AI with DynamoDB	Published a new topic that provides information about using generative AI with DynamoDB, including examples of gen AI use cases for DynamoDB. For more information, see Using generative AI with DynamoDB.	October 11, 2024
SDK now supports AWS account-based endpoints	Added documentation for account-based endpoints and the `ACCOUNT_ID_ENDPOINT_MODE` setting for SDK clients. For more information, see SDK support of AWS account-based endpoints.	September 3, 2024
Redesigned the getting started experience	Redesigned the getting started experience to consolidate information and get you started with quicker onboarding. For more information, see Getting started with DynamoDB.	August 1, 2024

DAX expansion to new Regions for Spain and Sweden	DAX is now available in Spain and Sweden Regions. For more information, see DAX cluster components.	July 30, 2024
Restructured and consolidated the DynamoDB backup and restore documentation	The DynamoDB Developer Guide has a new structure for backing up and restoring. For more information, see Backup and restore for DynamoDB.	July 2, 2024
What is Amazon DynamoDB? topic rewrite	Published a revised and updated version of the What is Amazon DynamoDB? topic. For more information, see What is Amazon DynamoDB?.	June 21, 2024
Integrate DynamoDB Streams with EventBridge	Published a new topic on integrating DynamoDB Streams with EventBridge. For more information, see Integrating with EventBridge.	June 21, 2024
DAX prescriptive guidance	Published a new best practices topic that provides you comprehensive insights for using DynamoDB Accelerator effectively. This topic covers performan ce optimization, cost management, and operation al best practices. For more information, see DAX prescriptive guidance.	June 3, 2024

Migrating a DynamoDB table from one account to another	Added a new topic on migrating DynamoDB tables from one account to another. For more information, see Migrating a DynamoDB table from one account to another.	May 29, 2024
Restructured and consolidated the DynamoDB monitoring and logging documentation	A new structure for monitoring and logging in DynamoDB includes three concise chapters for metrics, logging operations, and contributor insights.	May 3, 2024

Restructured and consolidated the DynamoDB capacity mode documentation	DynamoDB guide now includes a new chapter that contains all information about the DynamoDB capacity modes – *on-demand* and *provisioned*. With this update, the *Considerations when changing read/write Capacity Mode* topic has been moved inside the Best practices chapter. This topic is now renamed as *Considerations when switching capacity modes* and includes elaborate information about the best practices when switching between the capacity modes. In addition, the guide now features a new chapter that includes all information about DynamoDB reads and writes, and capacity units consumptions for read and write operations. For more information, see DynamoDB throughput capacity, Considerations when switching capacity modes, and DynamoDB reads and writes.	May 1, 2024

Maximum number of on-demand requests	You can now specify the maximum number of on-demand requests that an individual table, index, or both, can perform. Specifying the maximum on-demand throughput will help keep your table-level usage and costs bounded and protect against inadvertent surge in consumed resources. For more information, see Maximum throughput for on-demand tables.	May 1, 2024
NoSQL Workbench operation builder improvements	NoSQL Workbench now includes native support for dark mode. Improved table and item operations in the operations builder. Item results and operation builder request information is available in JSON format. For more information, see NoSQL Workbench operation builder.	April 24, 2024

Resource-based policies for Amazon DynamoDB resources	DynamoDB now supports resource-based policies for tables, indexes, and streams. Resource-based policies let you define access permissions by specifying who has access to each resource, and the actions they are allowed to perform on each resource. For more information, see Using resource-based policies for DynamoDB.	March 20, 2024
DynamoDB managed policy update	Added a new permission `dynamodb:GetResourcePolicy` to the `AmazonDynamoDBReadOnlyAccess` managed policy. This permission provides access to read resource-based policies attached to DynamoDB resources. For more information, see AWS managed policy: AmazonDynamoDBReadOnlyAccess.	March 20, 2024

AWS PrivateLink for Amazon DynamoDB	Amazon DynamoDB now supports AWS PrivateLink. With AWS PrivateLink, you can simplify private network connectivity between virtual private clouds (VPCs), DynamoDB, and your on-premises data centers using interface VPC endpoints and private IP addresses. For more information, see AWS PrivateLink for DynamoDB.	March 19, 2024
Programming with JavaScript guide	Amazon DynamoDB presents a programming guide for AWS SDK for JavaScript. Learn about the AWS SDK for JavaScript, abstraction layers, configuring connection, handling errors, defining retry policies, managing keep-alive, and more. For more information, see Programming with JavaScript.	March 6, 2024

Programming with AWS SDK for Java 2.x guide	Created a new programming guide that goes in depth about high-level, low-level, and document interfaces, HTTP clients and their configuration, error handling, and addresses the most common configuration settings that you should consider when using the SDK for Java 2.x. For more information, see Programming Amazon DynamoDB with AWS SDK for Java 2.x.	March 5, 2024
Clone tables with NoSQL Workbench	Allow developers to use NoSQL Workbench to copy or clone tables between development environments and regions (DynamoDB Local and DynamoDB web). For more information, see Cloning tables with NoSQL Workbench.	February 26, 2024
Programming with Python guide	Created a new guide that goes in depth about both high level and low level libraries and addresses the most common configuration settings that one should consider when using the Python SDK. For more information, see Programming with Python.	January 5, 2024

Time to live (TTL) topic rewrite	Completely rewrote the TTL section of the guide. The new guide helps you get started with TTL by providing ready-to-use code snippets along the way. The current code snippets provided are in Python and Javascript. For more information, see TTL.	December 20, 2023
Best Practices for Understanding your AWS Billing and Usage Reports	Added a new section that clarifies various usage types and the charges for those usage types in DynamoDB. For more information, see Billing and usage reports.	December 15, 2023
Amazon DynamoDB zero-ETL integration with Amazon OpenSearch Service	Amazon DynamoDB now supports zero-ETL integration with Amazon OpenSearch Service, which lets you perform a search on your DynamoDB data by automatically replicating and transforming it without custom code or infrastructure. For more information, see DynamoDB zero-ETL integration with Amazon OpenSearch Service.	November 28, 2023
Migrating to DynamoDB from a relational database	Created a migration guide to help users understsand how to migrate to DynamoDB from a relational database.	November 27, 2023

Generate sample data with NoSQL Workbench	NoSQL Workbench for Amazon DynamoDB now supports creating data models directly from sample data model templates to help you design data schemas for your workloads. You can use this feature to get familiar with NoSQL data modeling best practices when building your applications on DynamoDB.	September 28, 2023
Incremental Export to S3	You can now export data that was inserted, updated or deleted, in small increments. With incremental export, you can export changed data ranging from a few megabytes to terabytes with a few clicks in the AWS Management Console, an API call, or the AWS Command Line Interface.	September 26, 2023
Data modeling for DynamoDB	You can now learn more about data modeling with DynamoDB examples that focus on specific use cases, their access patterns, and step-by-step guidance in realizing those access patterns.	July 14, 2023

Troubleshooting section	You can now find troubleshooting content for latency and throttling issues that might occur in your DynamoDB tables.	March 13, 2023
Deletion protection for Amazon DynamoDB	Deletion protection is now available for Amazon DynamoDB tables in all AWS Regions. DynamoDB now makes it possible for you to protect your tables from accidental deletion when performing regular table management operations.	March 8, 2023
AWS CloudFormation support for KDSD in global tables	Amazon Kinesis Data Streams for DynamoDB now supports AWS CloudFormation for DynamoDB global tables, which means you can enable streaming to an Amazon Kinesis Data Streams on your DynamoDB global tables with CloudFormation templates.	February 15, 2023
DynamoDB local supports 100 actions per transaction	You can now perform up to 100 actions in a single transaction on DynamoDB local.	February 9, 2023

Using the DynamoDB Well-Architected Lens to optimize your DynamoDB workload	You can now use the DynamoDB Well-Architected Lens, a collection of design principles and guidance that you can use for designing well-architected DynamoDB workloads.	February 3, 2023
PartiQL GovGloud availability	PartiQL—a SQL-compatible query language for Amazon DynamoDB is now supported in AWS GovCloud (US-East) and AWS GovCloud (US-West) .	December 21, 2022
Single installation suite for NoSQL Workbench and DynamoDB local	NoSQL Workbench for DynamoDB now includes a guided DynamoDB local installation process to streamline setting up your DynamoDB local development environment.	December 6, 2022
Bulk import from S3	Amazon DynamoDB now makes it easier for you to migrate and load data into new DynamoDB tables by supporting bulk data imports from Amazon S3.	August 18, 2022

Enhanced integration with Service Quotas	Service Quotas now enables you to proactively manage your account and table quotas. You can view current values, set alarms for when your utilization of a quota exceeds a configurable threshold, and more.	June 15, 2022
NoSQL Workbench adds table and GSI support	You can now use NoSQL Workbench for table and global secondary index (GSI) control plane operations such as CreateTable, UpdateTable, and DeleteTable.	June 2, 2022
Standard-infrequent access table class now available in China	Amazon DynamoDB Standard-Infrequent Access table class is available in China Regions. Reduce your DynamoDB costs by up to 60 percent, by using this new table class for tables that store infrequently accessed data.	April 18, 2022
Increase in default service quotas and table management operations	DynamoDB increased the default quota for the number of tables per account and Region from 256 to 2,500 tables, and increased the number of concurrent table management operations from 50 to 500.	March 9, 2022

Optional limiting of items with PartiQL for DynamoDB	DynamoDB can limit the number of items processed in PartiQL for DynamoDB operations as an optional parameter on each request.	March 8, 2022
AWS Backup integration available in China (Beijing and Ningxia) Regions	AWS Backup now integrates with DynamoDB in the China (Beijing and Ningxia) Regions. You can meet complianc e and business continuity requirements more easily through enhanced backup features in AWS Backup, such as cross-account and cross-Region backups.	January 26, 2022
Throughput capacity information through PartiQL API calls	DynamoDB can return the throughput capacity consumed by PartiQL API calls to help you optimize your queries and throughput costs.	January 18, 2022
AWS Backup integration	DynamoDB now helps you meet compliance and business continuity requireme nts more easily through enhanced backup features in AWS Backup, such as cross-account and cross-Region backups.	November 24, 2021

NoSQL Workbench import/export datasets in CSV	NoSQL Workbench for Amazon DynamoDB now enables you to import and automatically populate sample data to help build and visualize your data models.	October 11, 2021
Filter and retrieve Amazon DynamoDB Streams data-plane activity with AWS CloudTrail	Amazon DynamoDB now provides you more granular control of audit logging by enabling you to filter Streams data-plane API activity in AWS CloudTrail.	September 22, 2021
Updated console	The DynamoDB console is now your default console to help you manage data more easily, simplify your common tasks, and give you faster access to resources and features.	August 25, 2021
DAX SDK For Java 2.x is now available	DynamoDB Accelerator (DAX) SDK for Java 2.x is now available and is compatible with the AWS SDK for Java 2.x. You can benefit from the latest features, including non-blocking I/O.	July 29, 2021
NoSQL Workbench feature updates including control plane operations	NoSQL Workbench for Amazon DynamoDB now helps you run frequent operations more easily to modify and access table data.	July 28, 2021

DynamoDB global tables are now available in the Asia Pacific Region	DynamoDB global tables are now available in the Asia Pacific (Osaka) Region. Replicate your DynamoDB tables automatically across your choice of 22 AWS Regions.	July 28, 2021
DAX is now available in China	DynamoDB Accelerator (DAX) is now available in the China (Beijing) Region, operated by Sinnet.	July 28, 2021
DAX encryption in transit	DynamoDB Accelerator (DAX) now supports encryption in transit of data between your applications and DAX clusters, and between the nodes within a DAX cluster.	July 24, 2021
CloudFormation and CloudTrail integration	Integration with AWS CloudFormation and security enhancements with CloudFormation data-plane logging.	June 18, 2021
CloudFormation now supported for global tables	Amazon DynamoDB global tables now support AWS CloudFormation, which means you can create global tables and manage their settings with CloudFormation templates.	May 14, 2021

Amazon DynamoDB local support for Java 2.x	You now can use the AWS SDK for Java 2.x with DynamoDB local, the downloadable version of Amazon DynamoDB. With DynamoDB local, you can develop and test applicati ons by using a version of DynamoDB running in your local development environme nt without incurring any additional costs.	May 3, 2021
NoSQL Workbench now supports AWS CloudForm ation	NoSQL Workbench for Amazon DynamoDB now supports AWS CloudForm ation, so you can manage and modify DynamoDB data models with CloudFormation templates. In addition, you now can configure table capacity settings in NoSQL Workbench.	April 22, 2021
DynamoDB and AWS Amplify now feature integration	AWS Amplify now orchestra tes multiple DynamoDB global secondary index updates in a single deployment.	April 20, 2021
AWS CloudTrail to log Amazon DynamoDB Streams data-plane APIs	You now can use AWS CloudTrail to log Amazon DynamoDB Streams data-plan e API activity, and monitor and investigate item-level changes in your DynamoDB tables.	April 20, 2021

Amazon Kinesis Data Streams for Amazon DynamoDB now supports AWS CloudForm ation	Amazon Kinesis Data Streams for Amazon DynamoDBnow supports AWS CloudForm ation, which means you can enable streaming to an Amazon Kinesis data stream on your DynamoDB tables with CloudFormation templates. By streaming your DynamoDB data changes to a Kinesis data stream, you can build advanced streaming applications with AAmazon Kinesis services.	April 12, 2021
Amazon Keyspaces now offers FIPS 140-2 compliant endpoints	Amazon Keyspaces (for Apache Cassandra) now offers Federal Information Processing Standards (FIPS) 140-2 compliant endpoints to help you run highly regulated workloads more easily. FIPS 140-2 is a US and Canadian government standard that specifies the security requirements for cryptographic modules that protect sensitive information.	April 8, 2021
Amazon EC2 T3 instances for DAX	DAX now supports Amazon EC2 T3 instance types, which provide a baseline level of CPU performance with the ability to burst above the baseline when needed.	February 15, 2021

NoSQL Workbench for Amazon DynamoDB support for PartiQL	You now can use the NoSQL Workbench for DynamoDB to build PartiQL statements for DynamoDB.	December 4, 2020
PartiQL for DynamoDB	You now can use PartiQL for DynamoDB—a SQL-compatible query language—to interact with DynamoDB tables and run ad hoc queries by using the AWS Management Console, AWS Command Line Interface, and DynamoDB APIs for PartiQL.	November 23, 2020
Amazon Kinesis Data Streams for Amazon DynamoDB	You now can use Amazon Kinesis Data Streams for Amazon DynamoDB with your DynamoDB tables to capture item-level changes and replicate them to a Kinesis data stream.	November 23, 2020
DynamoDB table export	You can now export your DynamoDB tables to Amazon S3, enabling you to perform analytics and complex queries on your data with services like Athena, AWS Glue, and Lake Formation.	November 9, 2020

Support for empty values	DynamoDB now supports empty values for non-key String and Binary attributes in DynamoDB tables. Empty value support gives you greater flexibility to use attributes for a broader set of use cases without having to transform such attribute s before sending them to DynamoDB. List, Map, and Set data types also support empty String and Binary values.	May 18, 2020
NoSQL Workbench for Amazon DynamoDB support for Linux	NoSQL Workbench for Amazon DynamoDB is now supported on Linux- Ubuntu , Fedora and Debian.	May 4, 2020
CloudWatch Contributor Insights for DynamoDB – GA	CloudWatch Contributor Insights for DynamoDB is generally available. CloudWatch Contributor Insights for DynamoDB is a diagnostic tool that provides an at-a-glance view of your DynamoDB table's traffic trends and helps you identify your table's most frequently accessed keys (also known as hot keys).	April 2, 2020

Upgrading global tables	You now can update your global tables from version 2017.11.29 to the latest version of global tables (2019.11.21), with a few clicks in the DynamoDB Console. By upgrading the version of your global tables, you can increase the availability of your DynamoDB tables easily by extending your existing tables into additiona l AWS Regions, with no table rebuilds required.	March 16, 2020
NoSQL Workbench for Amazon DynamoDB – GA	NoSQL Workbench for Amazon DynamoDB is generally available. Use the NoSQL Workbench to design, create, query, and manage DynamoDB tables.	March 2, 2020
DAX cache cluster metrics	DAX support for new CloudWatch metrics, that allow you to better understand your DAX cluster's performance.	February 6, 2020
CloudWatch Contributor Insights for DynamoDB – Preview	CloudWatch Contributor Insights for DynamoDB is a diagnostic tool that provides an at-a-glance view of your DynamoDB table's traffic trends and helps you identify your table's most frequently accessed keys (also known as hot keys).	November 26, 2019

Adaptive capacity support for imbalanced workload	Amazon DynamoDB adaptive capacity now handles imbalanced workloads better by isolating frequently accessed items automatic ally. If your application drives disproportionately high traffic to one or more items, DynamoDB will rebalance your partitions such that frequently accessed items do not reside on the same partition.	November 26, 2019
Support for customer managed keys	DynamoDB now supports customer managed keys, which means you can have full control over how you encrypt and manage the security of your DynamoDB data.	November 25, 2019
NoSQL Workbench support for DynamoDB local (Downloadable Version)	The NoSQL Workbench now supports connecting to DynamoDB local (Download able Version) to design, create, query, and manage DynamoDB tables.	November 8, 2019

NoSQL Workbench - Preview	This is the initial release of NoSQL Workbench for DynamoDB. Use NoSQL Workbench to design, create, query, and manage DynamoDB tables. For more information, see NoSQL Workbench for Amazon DynamoDB (Preview).	September 16, 2019
DAX adds support for transactional operations using Python and .NET	DAX supports the `TransactWriteItems` and `TransactGetItems` APIs for applications written in Go, Java, .NET, Node.js, and Python. For more information, see In-Memory Acceleration with DAX.	February 14, 2019
Amazon DynamoDB local (Downloadable Version) Updates	DynamoDB local (Downloadable Version) now supports transactional APIs, on-demand read/write capacity, capacity reporting for read and write operations, and 20 global secondary indexes. For more information, see Differences Between Downloadable DynamoDB and the DynamoDB Web Service.	February 4, 2019

Amazon DynamoDB On-Demand	DynamoDB on-demand is a flexible billing option capable of serving thousands of requests per second without capacity planning. DynamoDB on-demand offers pay-per-request pricing for read and write requests so that you pay only for what you use. For more information, see DynamoDB throughput capacity.	November 28, 2018
Amazon DynamoDB Transactions	DynamoDB transactions make coordinated, all-or-nothing changes to multiple items both within and across tables, providing atomicity, consistency, isolation, and durability (ACID) in DynamoDB. For more information, see Amazon DynamoDB Transactions.	November 27, 2018

Amazon DynamoDB encrypts all customer data at rest	DynamoDB encryption at rest provides an additional layer of data protection by securing your data in the encrypted table, including its primary key, local and global secondary indexes, streams, global tables, backups, and DAX clusters whenever the data is stored in durable media. For more informati on, see Amazon DynamoDB Encryption at Rest.	November 15, 2018
Use Amazon DynamoDB Local More Easily with the New Docker Image	Now, it's easier to use DynamoDB local, the downloadable version of DynamoDB, to help you develop and test your DynamoDB applications by using the new DynamoDB local Docker image. For more information, see DynamoDB (Downloadable Version) and Docker.	August 22, 2018

DynamoDB Accelerator (DAX) Adds Support for Encryption at Rest	DynamoDB Accelerator (DAX) now supports encryption at rest for new DAX clusters to help you accelerate reads from Amazon DynamoDB tables in security-sensitive applications that are subject to strict compliance and regulatory requirements. For more information, see DAX Encryption at Rest.	August 9, 2018
DynamoDB point-in-time recovery (PITR) adds support for restoring deleted tables	If you delete a table with point-in-time recovery enabled, a system backup is automatically created and is retained for 35 days (at no additional cost). For more information, see Before You Begin Using Point In Time Recovery.	August 7, 2018
Updates now available over RSS	You can now subscribe to the RSS feed (at the top left corner of this page) to receive notifications about updates to the Amazon DynamoDB Developer Guide.	July 3, 2018

Earlier updates

The following table describes important changes of the *DynamoDB Developer Guide* before July 3, 2018.

Change	Description	Date Changed
Go support for DAX	Now, you can enable microsecond read performance for Amazon DynamoDB tables in your applications written in the Go programming language by using the new DynamoDB Accelerator (DAX) SDK for Go. For more information, see DAX SDK for Go.	June 26, 2018
DynamoDB announces SLA	DynamoDB has released a public availability SLA. For more information, see Amazon DynamoDB Service Level Agreement.	June 19, 2018
DynamoDB continuous backups and Point-In-Time Recovery (PITR)	Point-in-time recovery helps protect your Amazon DynamoDB tables from accidental write or delete operations. With point in time recovery, you don't have to worry about creating, maintaining, or scheduling on-demand backups. For example, suppose that a test script writes accidentally to a production DynamoDB table. With point-in-time recovery, you can restore that table to any point in time during the last 35 days. DynamoDB maintains incremental backups of your	April 25, 2018

Change	Description	Date Changed
	table. For more information, see Point-in-time backups for DynamoDB.	
Encryption at rest for DynamoDB	DynamoDB encryption at rest, available for new DynamoDB tables, helps you secure your application data in Amazon DynamoDB tables by using AWS-managed encryption keys stored in AWS Key Management Service. For more information, see DynamoDB encryption at rest.	February 8, 2018
DynamoDB Backup and restore	On-Demand Backup allows you to create full backups of your DynamoDB tables data for data archival, helping you meet your corporate and governmental regulatory requirements. You can backup tables from a few megabytes to hundreds of terabytes of data, with no impact on performance and availability to your production applications. For more information, see Backup and restore for DynamoDB.	November 29, 2017

Change	Description	Date Changed
DynamoDB Global tables	Global Tables builds upon DynamoDB's global footprint to provide you with a fully managed, multi-region, and multi-active database that provides fast, local, read and write performance for massively scaled, global applications. Global Tables replicates your Amazon DynamoDB tables automatic ally across your choice of AWS regions. For more information, see Global tables - multi-Region replication for DynamoDB.	November 29, 2017
Node.js support for DAX	Node.js developers can leverage DynamoDB Accelerat or (DAX), using the DAX client for Node.js. For more information, see In-memory acceleration with DynamoDB Accelerator (DAX).	October 5, 2017

Change	Description	Date Changed
VPC Endpoints for DynamoDB	DynamoDB endpoints allow Amazon EC2 instances in your Amazon VPC to access DynamoDB, without exposure to the public Internet. Network traffic between your VPC and DynamoDB does not leave the Amazon network. For more information, see Using Amazon VPC endpoints to access DynamoDB.	August 16, 2017
Auto Scaling for DynamoDB	DynamoDB auto scaling eliminates the need for manually defining or adjust provisioned throughput settings. Instead, DynamoDB auto scaling dynamical ly adjusts read and write capacity in response to actual traffic patterns. This allows a table or a global secondary index to increase its provision ed read and write capacity to handle sudden increases in traffic, without throttling. When the workload decreases , DynamoDB auto scaling decreases the provisioned capacity. For more informati on, see Managing throughpu t capacity automatically with DynamoDB auto scaling.	June 14, 2017

Change	Description	Date Changed
DynamoDB Accelerator (DAX)	DynamoDB Accelerator (DAX) is a fully managed, highly available, in-memory cache for DynamoDB that delivers up to a 10x performance improvement – from milliseconds to microseconds – even at millions of requests per second. For more information, see In-memory acceleration with DynamoDB Accelerator (DAX).	April 19, 2017
DynamoDB now supports automatic item expiration with Time to Live (TTL)	Amazon DynamoDB Time to Live (TTL) enables you to automatically delete expired items from your tables, at no additional cost. For more information, see Using time to live (TTL) in DynamoDB.	Feb 27, 2017
DynamoDB now supports Cost Allocation Tags	You can now add tags to your Amazon DynamoDB tables for improved usage categorization and more granular cost reporting. For more information, see Adding tags and labels to resources in DynamoDB.	Jan 19, 2017

Change	Description	Date Changed
New DynamoDB `DescribeLimits` API	The `DescribeLimits` API returns the current provisioned capacity limits for your AWS account in a region, both for the region as a whole and for any one DynamoDB table that you create there. It lets you determine what your current account-level limits are so that you can compare them to the provisioned capacity that you are currently using, and have plenty of time to apply for an increase before you hit a limit. For more information, see Quotas in Amazon DynamoDB and the DescribeLimits in the *Amazon DynamoDB API Reference*.	March 1, 2016

Change	Description	Date Changed
DynamoDB Console Update and New Terminology for Primary Key Attributes	The DynamoDB management console has been redesigned to be more intuitive and easy to use. As part of this update, we are introducing new terminology for primary key attributes: • **Partition Key—**also known as a *hash attribute*. • **Sort Key—**also known as a *range attribute*. Only the names have changed; the functionality remains the same. When you create a table or a secondary index, you can choose either a simple primary key (partition key only), or a composite primary key (partition key and sort key). The DynamoDB documentation has been updated to reflect these changes.	November 12, 2015

Change	Description	Date Changed
Amazon DynamoDB Storage Backend for Titan	The DynamoDB Storage Backend for Titan is a storage backend for the Titan graph database implemented on top of Amazon DynamoDB. When using the DynamoDB Storage Backend for Titan, your data benefits from the protection of DynamoDB, which runs across Amazon's high-availability data centers. The plugin is available for Titan version 0.4.4 (primarily for compatibility with existing applications) and Titan version 0.5.4 (recommended for new applications). Like other storage backends for Titan, this plugin supports the Tinkerpop stack (versions 2.4 and 2.5), including the Blueprints API and the Gremlin shell.	August 20, 2015

Change	Description	Date Changed
DynamoDB Streams, Cross-Region Replication, and Scan with Strongly Consistent Reads	DynamoDB Streams captures a time-ordered sequence of item-level modifications in any DynamoDB table, and stores this information in a log for up to 24 hours. Applications can access this log and view the data items as they appeared before and after they were modified, in near real time. For more information, see Change data capture for DynamoDB Streams and the DynamoDB Streams API Reference. DynamoDB cross-region replication is a client-side solution for maintaining identical copies of DynamoDB tables across different AWS regions, in near real time. You can use cross region replicati on to back up DynamoDB tables, or to provide low-laten cy access to data where users are geographically distribut ed. The DynamoDB `Scan` operation uses eventuall y consistent reads, by default. You can use strongly consistent reads instead by setting the `Consisten`	July 16, 2015

Change	Description	Date Changed
	`tRead` parameter to true. For more information, see Read consistency for scan and Scan in the Amazon DynamoDB API Reference.	
AWS CloudTrail support for Amazon DynamoDB	DynamoDB is now integrated with CloudTrail. CloudTrail captures API calls made from the DynamoDB console or from the DynamoDB API and tracks them in log files. For more information, see Logging DynamoDB operations by using AWS CloudTrail and the AWS CloudTrail User Guide.	May 28, 2015

Change	Description	Date Changed
Improved support for Query expressions	This release adds a new `KeyConditionExpression` parameter to the `Query` API. A `Query` reads items from a table or an index using primary key values. The `KeyConditionExpression` parameter is a string that identifies primary key names, and conditions to be applied to the key values; the `Query` retrieves only those items that satisfy the expression. The syntax of `KeyConditionExpression` is similar to that of other expression parameters in DynamoDB, and allows you to define substitution variables for names and values within the expression. For more information, see Querying tables in DynamoDB.	April 27, 2015

Change	Description	Date Changed
New comparison functions for conditional writes	In DynamoDB, the `ConditionExpression` parameter determines whether a `PutItem`, `UpdateItem`, or `DeleteItem` succeeds: The item is written only if the condition evaluates to true. This release adds two new functions, `attribute_type` and `size`, for use with `ConditionExpression`. These functions allow you to perform a conditional writes based on the data type or size of an attribute in a table. For more information, see DynamoDB condition expression CLI example.	April 27, 2015

Change	Description	Date Changed
Scan API for secondary indexes	In DynamoDB, a `Scan` operation reads all of the items in a table, applies user-defined filtering criteria, and returns the selected data items to the applicati on. This same capability is now available for secondary indexes too. To scan a local secondary index or a global secondary index, you specify the index name and the name of its parent table. By default, an index `Scan` returns all of the data in the index; you can use a filter expression to narrow the results that are returned to the application. For more information, see Scanning tables in DynamoDB.	February 10, 2015

Change	Description	Date Changed
Online operations for global secondary indexes	Online indexing lets you add or remove global secondary indexes on existing tables. With online indexing, you do not need to define all of a table's indexes when you create a table; instead, you can add a new index at any time. Similarly, if you decide you no longer need an index, you can remove it at any time. Online indexing operation s are non-blocking, so that the table remains available for read and write activity while indexes are being added or removed. For more information, see Managing Global Secondary Indexes in DynamoDB.	January 27, 2015

Change	Description	Date Changed
Document model support with JSON	DynamoDB allows you to store and retrieve documents with full support for document models. New data types are fully compatible with the JSON standard and allow you to nest document elements within one another. You can use document path dereference operators to read and write individual elements, without having to retrieve the entire document. This release also introduces new expressio n parameters for specifying projections, conditions and update actions when reading or writing data items. To learn more about document model support with JSON, see Data types and Using expressions in DynamoDB.	October 7, 2014
Flexible scaling	For tables and global secondary indexes, you can increase provisioned read and write throughput capacity by any amount, provided that you stay within your per-table and per-account limits. For more information, see Quotas in Amazon DynamoDB.	October 7, 2014

Change	Description	Date Changed
Larger item sizes	The maximum item size in DynamoDB has increased from 64 KB to 400 KB. For more information, see Quotas in Amazon DynamoDB.	October 7, 2014
Improved conditional expressions	DynamoDB expands the operators that are available for conditional expressio ns, giving you additional flexibility for conditional puts, updates, and deletes. The newly available operators let you check whether an attribute does or does not exist, is greater than or less than a particular value, is between two values, begins with certain characters, and much more. DynamoDB also provides an optional *OR* operator for evaluatin g multiple conditions. By default, multiple conditions in an expression are *AND*ed together, so the expression is true only if all of its condition s are true. If you specify *OR* instead, the expression is true if one or more one condition s are true. For more informati on, see Working with items and attributes in DynamoDB.	April 24, 2014

Change	Description	Date Changed
Query filter	The DynamoDB `Query` API supports a new `QueryFilter` option. By default, a `Query` finds items that match a specific partition key value and an optional sort key condition. A `Query` filter applies conditional expressions to other, non-key attributes; if a `Query` filter is present, then items that do not match the filter conditions are discarded before the `Query` results are returned to the application. For more information, see Querying tables in DynamoDB.	April 24, 2014

Change	Description	Date Changed
Data export and import using the AWS Management Console	The DynamoDB console has been enhanced to simplify exports and imports of data in DynamoDB tables. With just a few clicks, you can set up an AWS Data Pipeline to orchestrate the workflow, and an Amazon Elastic MapReduce cluster to copy data from DynamoDB tables to an Amazon S3 bucket, or vice-versa. You can perform an export or import one time only, or set up a daily export job. You can even perform cross-region exports and imports, copying DynamoDB data from a table in one AWS region to a table in another AWS region.	March 6, 2014
Reorganized higher-level API documentation	Information about the following APIs is now easier to find: • Java: DynamoDBMappper • .NET: Document model and object-persistence model These higher-level APIs are now documented here: Higher-level programming interfaces for DynamoDB.	January 20, 2014

Change	Description	Date Changed
Global secondary indexes	DynamoDB adds support for global secondary indexes. As with a local secondary index, you define a global secondary index by using an alternate key from a table and then issuing Query requests on the index. Unlike a local secondary index, the partition key for the global secondary index does not have to be the same as that of the table; it can be any scalar attribute from the table. The sort key is optional and can also be any scalar table attribute . A global secondary index also has its own provisioned throughput settings, which are separate from those of the parent table. For more information, see Improving data access with secondary indexes in DynamoDB and Using Global Secondary Indexes in DynamoDB.	December 12, 2013

Change	Description	Date Changed
Fine-grained access control	DynamoDB adds support for fine-grained access control. This feature allows customers to specify which principals (users, groups, or roles) can access individual items and attributes in a DynamoDB table or secondary index. Applications can also leverage web identity federation to offload the task of user authentication to a third-par ty identity provider, such as Facebook, Google, or Login with Amazon. In this way, applications (including mobile apps) can handle very large numbers of users, while ensuring that no one can access DynamoDB data items unless they are authorized to do so. For more informati on, see Using IAM policy conditions for fine-grained access control.	October 29, 2013

Change	Description	Date Changed
4 KB read capacity unit size	The capacity unit size for reads has increased from 1 KB to 4 KB. This enhancement can reduce the number of provisioned read capacity units required for many applications. For example, prior to this release, reading a 10 KB item would consume 10 read capacity units; now that same 10 KB read would consume only 3 units (10 KB / 4 KB, rounded up to the next 4 KB boundary). For more information, see DynamoDB throughput capacity.	May 14, 2013
Parallel scans	DynamoDB adds support for parallel Scan operations. Applications can now divide a table into logical segments and scan all of the segments simultaneously. This feature reduces the time required for a Scan to complete, and fully utilizes a table's provisioned read capacity. For more information, see Scanning tables in DynamoDB.	May 14, 2013

Change	Description	Date Changed
Local secondary indexes	DynamoDB adds support for local secondary indexes. You can define sort key indexes on non-key attributes, and then use these indexes in Query requests. With local secondary indexes, applications can efficiently retrieve data items across multiple dimensions. For more information, see Local Secondary Indexes in DynamoDB.	April 18, 2013
New API version	With this release, DynamoDB introduces a new API version (2012-08-10). The previous API version (2011-12-05) is still supported for backward compatibility with existing applications. New applications should use the new API version 2012-08-10. We recommend that you migrate your existing applications to API version 2012-08-10, since new DynamoDB features (such as local secondary indexes) will not be backported to the previous API version. For more information on API version 2012-08-10, see the Amazon DynamoDB API Reference.	April 18, 2013

Change	Description	Date Changed
IAM policy variable support	The IAM access policy language now supports variables. When a policy is evaluated, any policy variables are replaced with values that are supplied by context-based informati on from the authenticated user's session. You can use policy variables to define general purpose policies without explicitly listing all the components of the policy. For more information about policy variables, go to Policy Variables in the *AWS Identity and Access Management Using IAM* guide. For examples of policy variables in DynamoDB, see Identity and Access Management for Amazon DynamoDB.	April 4, 2013
PHP code examples updated for AWS SDK for PHP version 2	Version 2 of the AWS SDK for PHP is now available . The PHP code examples in the Amazon DynamoDB Developer Guide have been updated to use this new SDK. For more information on Version 2 of the SDK, see AWS SDK for PHP.	January 23, 2013

Change	Description	Date Changed
New endpoint	DynamoDB expands to the AWS GovCloud (US-West) region. For the current list of service endpoints and protocols, see Regions and Endpoints.	December 3, 2012
New endpoint	DynamoDB expands to the South America (São Paulo) region. For the current list of supported endpoints, see Regions and Endpoints.	December 3, 2012
New endpoint	DynamoDB expands to the Asia Pacific (Sydney) region. For the current list of supported endpoints, see Regions and Endpoints.	November 13, 2012

Change	Description	Date Changed
DynamoDB implements support for CRC32 checksums , supports strongly consisten t batch gets, and removes restrictions on concurrent table updates.	• DynamoDB calculates a CRC32 checksum of the HTTP payload and returns this checksum in a new header, `x-amz-crc32` . For more information, see DynamoDB low-level API. • By default, read operation s performed by the `BatchGetItem` API are eventually consistent. A new `ConsistentRead` parameter in `BatchGetI tem` lets you choose strong read consistency instead, for any table(s) in the request. For more information, see Descripti on. • This release removes some restrictions when updating many tables simultane ously. The total number of tables that can be updated at once is still 10; however, these tables can now be any combination of `CREATING`, `UPDATING` or `DELETING` status. Additiona lly, there is no longer any minimum amount for increasing or reducing the *ReadCapacityUnits* or *WriteCapacityUnits* for a	November 2, 2012

	table. For more informati on, see Quotas in Amazon DynamoDB.	
Best practices documentation	The Amazon DynamoDB Developer Guide identifies best practices for working with tables and items, along with recommendations for query and scan operations.	September 28, 2012

Change	Description	Date Changed
Support for binary data type	In addition to the Number and String types, DynamoDB now supports Binary data type. Prior to this release, to store binary data, you converted your binary data into string format and stored it in DynamoDB. In addition to the required conversion work on the client-side, the conversio n often increased the size of the data item requiring more storage and potential ly additional provisioned throughput capacity. With the binary type attribute s you can now store any binary data, for example compressed data, encrypted data, and images. For more information see Data types. For working examples of handling binary type data using the AWS SDKs, see the following sections: • Example: Handling binary type attributes using the AWS SDK for Java document API • Example: Handling binary type attributes using the	August 21, 2012

Change	Description	Date Changed
	AWS SDK for .NET low-level API For the added binary data type support in the AWS SDKs, you will need to download the latest SDKs and you might also need to update any existing applications. For information about downloading the AWS SDKs, see .NET code examples.	
DynamoDB table items can be updated and copied using the DynamoDB console	DynamoDB users can now update and copy table items using the DynamoDB Console, in addition to being able to add and delete items. This new functionality simplifies making changes to individual items through the Console.	August 14, 2012
DynamoDB lowers minimum table throughput requirements	DynamoDB now supports lower minimum table throughput requirements, specifically 1 write capacity unit and 1 read capacity unit. For more information, see the Quotas in Amazon DynamoDB topic in the Amazon DynamoDB Developer Guide.	August 9, 2012

Change	Description	Date Changed
Signature Version 4 support	DynamoDB now supports Signature Version 4 for authenticating requests.	July 5, 2012
Table explorer support in DynamoDB Console	The DynamoDB Console now supports a table explorer that enables you to browse and query the data in your tables. You can also insert new items or delete existing items. The `SampleData` and Using the console sections have been updated for these features.	May 22, 2012
New endpoints	DynamoDB availability expands with new endpoints in the US West (N. Californi a) region, US West (Oregon) region, and the Asia Pacific (Singapore) region. For the current list of supported endpoints, go to Regions and Endpoints.	April 24, 2012

Change	Description	Date Changed
BatchWriteItem API support	DynamoDB now supports a batch write API that enables you to put and delete several items from one or more tables in a single API call. For more information about the DynamoDB batch write API, see BatchWriteItem. For information about working with items and using batch write feature using AWS SDKs, see Working with items and attributes in DynamoDB and .NET code examples.	April 19, 2012
Documented more error codes	For more information, see Error handling with DynamoDB.	April 5, 2012
New endpoint	DynamoDB expands to the Asia Pacific (Tokyo) region. For the current list of supported endpoints, see Regions and Endpoints.	February 29, 2012
`ReturnedItemCount` metric added	A new metric, `ReturnedItemCount` , provides the number of items returned in the response of a Query or Scan operation for DynamoDB is available for monitoring through CloudWatch.	February 24, 2012

Change	Description	Date Changed
Added examples for incrementing values	DynamoDB supports incrementing and decrementing existing numeric values. Examples show adding to existing values in the "Updating an Item" sections at: Working with items: Java. Working with items: .NET.	January 25, 2012
Initial product release	DynamoDB is introduced as a new service in Beta release.	January 18, 2012

Legacy features of DynamoDB

The following topics are legacy features that DynamoDB still supports. No active development is made on these features.

Topics

- Global tables version 2017.11.29 (Legacy)
- Previous low-level DynamoDB API version (2011-12-05)
- Legacy DynamoDB conditional parameters

Global tables version 2017.11.29 (Legacy)

Important

This documentation is for version 2017.11.29 (Legacy) of global tables, which should be avoided for new global tables. Customers should use Global Tables version 2019.11.21 (Current) when possible, as it provides greater flexibility, higher efficiency and consumes less write capacity than 2017.11.29 (Legacy).
To determine which version you are using, see Determining the DynamoDB global table version you are using. To update existing global tables from version 2017.11.29 (Legacy) to version 2019.11.21 (Current), see Upgrading global tables.

Topics

- Global tables: How it works
- Best practices and requirements for managing global tables
- Creating a global table
- Monitoring global tables
- Using IAM with global tables

Global tables: How it works

> **Important**
>
> This documentation is for version 2017.11.29 (Legacy) of global tables, which should be avoided for new global tables. Customers should use Global Tables version 2019.11.21 (Current) when possible, as it provides greater flexibility, higher efficiency and consumes less write capacity than 2017.11.29 (Legacy).
> To determine which version you are using, see Determining the DynamoDB global table version you are using. To update existing global tables from version 2017.11.29 (Legacy) to version 2019.11.21 (Current), see Upgrading global tables.

The following sections help you understand the concepts and behavior of global tables in Amazon DynamoDB.

Global table concepts for Version 2017.11.29 (Legacy)

A *global table* is a collection of one or more replica tables, all owned by a single AWS account.

A *replica table* (or *replica*, for short) is a single DynamoDB table that functions as a part of a global table. Each replica stores the same set of data items. Any given global table can only have one replica table per AWS Region.

The following is a conceptual overview of how a global table is created.

1. Create an ordinary DynamoDB table, with DynamoDB Streams enabled, in an AWS Region.
2. Repeat step 1 for every other Region where you want to replicate your data.
3. Define a DynamoDB global table based on the tables that you have created.

The AWS Management Console automates these tasks, so you can create a global table more quickly and easily. For more information, see Creating a global table.

The resulting DynamoDB global table consists of multiple replica tables, one per Region, that DynamoDB treats as a single unit. Every replica has the same table name and the same primary key schema. When an application writes data to a replica table in one Region, DynamoDB automatically propagates the write to the other replica tables in the other AWS Regions.

Important

To keep your table data in sync, global tables automatically create the following attributes for every item:

- `aws:rep:deleting`
- `aws:rep:updatetime`
- `aws:rep:updateregion`

Do not modify these attributes or create attributes with the same name.

You can add replica tables to the global table so that it can be available in additional Regions. (To do this, the global table must be empty. In other words, none of the replica tables can have any data in them.)

You can also remove a replica table from a global table. If you do this, the table is completely disassociated from the global table. This newly independent table no longer interacts with the global table, and data is no longer propagated to or from the global table.

Warning

Be aware that removing a replica isn't an atomic process. To ensure consistent behavior and known state, you may want to consider diverting your application write traffic away from the replica to be removed ahead of time. After removing it, wait until all replica Region endpoints show the replica as disassociated before making any further writes to it as its own isolated regional table.

Common tasks

Common tasks for global tables work as follows.

You can delete a global table's replica table the same as a regular table. This will stop replication to that Region and delete the table copy kept in that Region. You cannot sever the replication and have copies of the table exist as independent entities.

> **Note**
>
> You won't be able to delete a source table until at least 24 hours after it's used to initiate a new Region. If you try to delete it too soon you will receive an error.

Conflicts can arise if applications update the same item in different Regions at about the same time. To help ensure eventual consistency, DynamoDB global tables use a "last writer wins" method to reconcile between concurrent updates. All the replicas will agree on the latest update and converge toward a state in which they all have identical data.

> **Note**
>
> There are several ways to avoid conflicts, including:
>
> - Using an IAM policy to only allow writes to the table in one Region.
> - Using an IAM policy to route users to only one Region and keeping the other as an idle standby, or alternately routing odd users to one Region and even users to another Region.
> - Avoiding the use of non-idempotent updates such as Bookmark = Bookmark + 1, in favor of static updates such as Bookmark=25.

Monitoring global tables

You can use CloudWatch to observe the metric `ReplicationLatency`. This metric tracks the elapsed time between when an updated item appears in the DynamoDB stream for one replica table, and when that item appears in another replica in the global table. `ReplicationLatency` is expressed in milliseconds and is emitted for every source-Region and destination-Region pair. This is the only CloudWatch metric provided by Global Tables v2.

The latencies you will observe depend on the distance between your chosen Regions, as well as other variables. Latencies in the 0.5 to 2.5 second range for Regions can be common within the same geographic area.

Time To Live (TTL)

You can use Time To Live (TTL) to specify an attribute name whose value indicates the time of expiration for the item. This value is specified as a number in seconds since the start of the Unix epoch.

With global tables legacy version, the TTL deletes are not automatically replicated across other replicas. When an item is deleted via a TTL rule, that work is performed without consuming Write Units.

Be aware that if the source and target table have very low Provisioned write capacity, this may cause throttling as the TTL deletes require write capacity.

Streams and transactions with global tables

Each global table produces an independent stream based on all its writes, regardless of the origination point for those writes. You can choose to consume this DynamoDB stream in one Region or in all Regions independently.

If you want processed local writes but not replicated writes, you can add your own region attribute to each item. Then you can use a Lambda event filter to invoke only the Lambda for writes in the local Region.

Transactional operations provide ACID (Atomicity, Consistency, Isolation, and Durability) guarantees ONLY within the Region where the write is originally made. Transactions aren't supported across Regions in global tables.

For example, if you have a global table with replicas in the US East (Ohio) and US West (Oregon) Regions and perform a TransactWriteItems operation in the US East (Ohio) Region, you may observe partially completed transactions in US West (Oregon) Region as changes are replicated. Changes will only be replicated to other Regions once they have been committed in the source Region.

Note

- Global tables “write around” DynamoDB Accelerator by updating DynamoDB directly. As a result DAX will not be aware it is holding stale data. The DAX cache will only be refreshed when the cache’s TTL expires.
- Tags on global tables do not automatically propagate.

Read and write throughput

Global tables manage read and write throughput in the following ways.

- The write capacity must be the same on all table instances across Regions.
- With Version 2019.11.21 (Current, if the table is set to support auto scaling or is in on-demand mode then the write capacity is automatically kept in sync. The current amount of write capacity provisioned in each Region will rise and fall independently within those synchronized auto scaling settings. If the table is placed in on-demand mode, that mode will sync to the other replicas.
- Read capacity can differ between Regions because reads may not be equal. When adding a global replica to a table, the capacity of the source Region is propagated. After creation you can adjust the read capacity for one replica, and this new setting isn't transferred to the other side.

Consistency and conflict resolution

Any changes made to any item in any replica table are replicated to all the other replicas within the same global table. In a global table, a newly written item is usually propagated to all replica tables within seconds.

With a global table, each replica table stores the same set of data items. DynamoDB does not support partial replication of only some of the items.

An application can read and write data to any replica table. DynamoDB supports eventually consistent reads across Regions, but does not support strongly consistent reads across Regions. If your application only uses eventually consistent reads and only issues reads against one AWS Region, it will work without any modification. However, if your application requires strongly consistent reads then it must perform all the strongly consistent reads and writes in the same Region. Otherwise, if you write to one Region and read from another Region then the read response might include stale data that doesn't reflect the results of recently completed writes in the other Region.

Conflicts can arise if applications update the same item in different Regions at about the same time. To help ensure eventual consistency, DynamoDB global tables use a *last writer wins* reconciliation between concurrent updates, in which DynamoDB makes a best effort to determine the last writer. With this conflict resolution mechanism, all the replicas will agree on the latest update and converge toward a state in which they all have identical data.

Availability and durability

If a single AWS Region becomes isolated or degraded, your application can redirect to a different Region and perform reads and writes against a different replica table. You can apply custom business logic to determine when to redirect requests to other Regions.

If a Region becomes isolated or degraded, DynamoDB keeps track of any writes that have been performed but have not yet been propagated to all of the replica tables. When the Region comes back online, DynamoDB resumes propagating any pending writes from that Region to the replica tables in other Regions. It also resumes propagating writes from other replica tables to the Region that is now back online. All previously successful writes will be propagated eventually no matter how long the Region is isolated.

Best practices and requirements for managing global tables

> **Important**
>
> This documentation is for version 2017.11.29 (Legacy) of global tables, which should be avoided for new global tables. Customers should use Global Tables version 2019.11.21 (Current) when possible, as it provides greater flexibility, higher efficiency and consumes less write capacity than 2017.11.29 (Legacy).
> To determine which version you are using, see Determining the DynamoDB global table version you are using. To update existing global tables from version 2017.11.29 (Legacy) to version 2019.11.21 (Current), see Upgrading global tables.

Using Amazon DynamoDB global tables, you can replicate your table data across AWS Regions. It is important that the replica tables and secondary indexes in your global table have identical write capacity settings to ensure proper replication of data.

Topics

- Global tables version
- Requirements for adding a new replica table
- Best practices and requirements for managing capacity

Global tables version

There are two versions of DynamoDB global tables available: Global Tables version 2019.11.21 (Current) and Global tables version 2017.11.29 (Legacy). Customers should use Global Tables version 2019.11.21 (Current) when possible, as it provides greater flexibility, higher efficiency and consumes less write capacity than 2017.11.29 (Legacy).

To determine which version you are using, see Determining the DynamoDB global table version you are using. To update existing global tables from Version 2017.11.29 (Legacy) to Version 2019.11.21 (Current), see Upgrading global tables.

Requirements for adding a new replica table

If you want to add a new replica table to a global table, each of the following conditions must be true:

- The table must have the same partition key as all of the other replicas.
- The table must have the same write capacity management settings specified.
- The table must have the same name as all of the other replicas.
- The table must have DynamoDB Streams enabled, with the stream containing both the new and the old images of the item.
- None of the new or existing replica tables in the global table can contain any data.

If global secondary indexes are specified, the following conditions must also be met:

- The global secondary indexes must have the same name.
- The global secondary indexes must have the same partition key and sort key (if present).

> **Important**
>
> Write capacity settings should be set consistently across all of your global tables' replica tables and matching secondary indexes. To update write capacity settings for your global table, we strongly recommend using the DynamoDB console or the `UpdateGlobalTableSettings` API operation. `UpdateGlobalTableSettings` applies changes to write capacity settings to all replica tables and matching secondary indexes in a global table automatically. If you use the `UpdateTable`, `RegisterScalableTarget`,

or `PutScalingPolicy` operations, you should apply the change to each replica table and matching secondary index individually. For more information, see UpdateGlobalTableSettings in the Amazon DynamoDB API Reference.
We strongly recommend that you enable auto scaling to manage provisioned write capacity settings. If you prefer to manage write capacity settings manually, you should provision equal replicated write capacity units to all of your replica tables. Also provision equal replicated write capacity units to matching secondary indexes across your global table.
You must also have appropriate AWS Identity and Access Management (IAM) permissions. For more information, see Using IAM with global tables.

Best practices and requirements for managing capacity

Consider the following when managing capacity settings for replica tables in DynamoDB.

Using DynamoDB auto scaling

Using DynamoDB auto scaling is the recommended way to manage throughput capacity settings for replica tables that use the provisioned mode. DynamoDB auto scaling automatically adjusts read capacity units (RCUs) and write capacity units (WCUs) for each replica table based upon your actual application workload. For more information, see Managing throughput capacity automatically with DynamoDB auto scaling.

If you create your replica tables using the AWS Management Console, auto scaling is enabled by default for each replica table, with default auto scaling settings for managing read capacity units and write capacity units.

Changes to auto scaling settings for a replica table or secondary index made through the DynamoDB console or using the `UpdateGlobalTableSettings` call are applied to all of the replica tables and matching secondary indexes in the global table automatically. These changes overwrite any existing auto scaling settings. This ensures that provisioned write capacity settings are consistent across the replica tables and secondary indexes in your global table. If you use the `UpdateTable`, `RegisterScalableTarget`, or `PutScalingPolicy` calls, you should apply the change to each replica table and matching secondary index individually.

Note

If auto scaling doesn't satisfy your application's capacity changes (unpredictable workload), or if you don't want to configure its settings (target settings for minimum, maximum, or

utilization threshold), you can use on-demand mode to manage capacity for your global tables. For more information, see On-demand mode.
If you enable on-demand mode on a global table, your consumption of replicated write request units (rWCUs) will be consistent with how rWCUs are provisioned. For example, if you perform 10 writes to a local table that is replicated in two additional Regions, you will consume 60 write request units (10 + 10 + 10 = 30; 30 x 2 = 60). The consumed 60 write request units include the extra write consumed by global tables Version 2017.11.29 (Legacy) to update the `aws:rep:deleting`, `aws:rep:updatetime`, and `aws:rep:updateregion` attributes.

Managing capacity manually

If you decide not to use DynamoDB auto scaling, you must manually set the read capacity and write capacity settings on each replica table and secondary index.

The provisioned replicated write capacity units (rWCUs) on every replica table should be set to the total number of rWCUs needed for application writes across all Regions multiplied by two. This accommodates application writes that occur in the local Region and replicated application writes coming from other Regions. For example, suppose that you expect 5 writes per second to your replica table in Ohio and 5 writes per second to your replica table in N. Virginia. In this case, you should provision 20 rWCUs to each replica table (5 + 5 = 10; 10 x 2 = 20).

To update write capacity settings for your global table, we strongly recommend using the DynamoDB console or the `UpdateGlobalTableSettings` API operation. `UpdateGlobalTableSettings` applies changes to write capacity settings to all replica tables and matching secondary indexes in a global table automatically. If you use the `UpdateTable`, `RegisterScalableTarget`, or `PutScalingPolicy` operations, you should apply the change to each replica table and matching secondary index individually. For more information, see Amazon DynamoDB API Reference.

Note

To update the settings (`UpdateGlobalTableSettings`) for a global table in DynamoDB, you must have the `dynamodb:UpdateGlobalTable`, `dynamodb:DescribeLimits`, `application-autoscaling:DeleteScalingPolicy`, and `application-autoscaling:DeregisterScalableTarget` permissions. For more information, see Using IAM with global tables.

Creating a global table

> **Important**
>
> This documentation is for version 2017.11.29 (Legacy) of global tables, which should be avoided for new global tables. Customers should use Global Tables version 2019.11.21 (Current) when possible, as it provides greater flexibility, higher efficiency and consumes less write capacity than 2017.11.29 (Legacy).
> To determine which version you are using, see Determining the DynamoDB global table version you are using. To update existing global tables from version 2017.11.29 (Legacy) to version 2019.11.21 (Current), see Upgrading global tables.

This section describes how to create a global table using the Amazon DynamoDB console or the AWS Command Line Interface (AWS CLI).

Topics

- Creating a global table (console)
- Creating a global table (AWS CLI)

Creating a global table (console)

Follow these steps to create a global table using the console. The following example creates a global table with replica tables in United States and Europe.

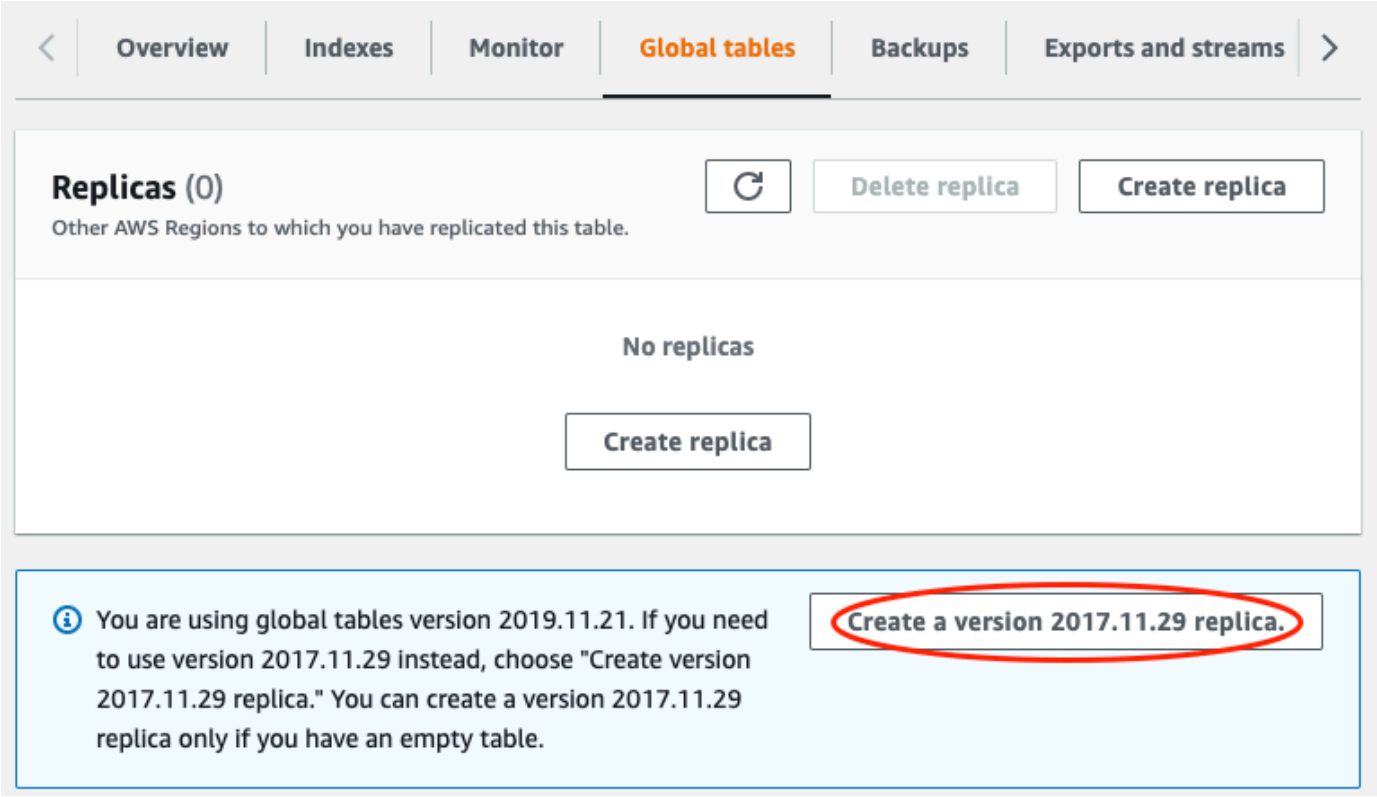
1. Open the DynamoDB console at https://console.aws.amazon.com/dynamodb/home. For this example, choose the us-east-2 (US East Ohio) Region.
2. In the navigation pane on the left side of the console, choose **Tables**.
3. Choose **Create Table**.

   For **Table name**, enter **`Music`**.

   For **Primary key** enter **`Artist`**. Choose **Add sort key**, and enter **`SongTitle`**. (**`Artist`** and **`SongTitle`** should both be strings.)

   To create the table, choose **Create**. This table serves as the first replica table in a new global table. It is the prototype for other replica tables that you add later.

4. Choose the **Global Tables** tab, and then choose **Create a Version 2017.11.29 (Legacy) replica**.



5. From the **Available replication Regions** dropdown, choose **US West (Oregon)**.

   The console checks to ensure that a table with the same name doesn't exist in the selected Region. If a table with the same name does exist, you must delete the existing table before you can create a new replica table in that Region.

6. Choose **Create Replica**. This starts the table creation process in US West (Oregon);.

   The **Global Table** tab for the selected table (and for any other replica tables) shows that the table has been replicated in multiple Regions.

7. Now add another Region so that your global table is replicated and synchronized across the United States and Europe. To do this, repeat step 5, but this time, specify **Europe (Frankfurt)** instead of **US West (Oregon)**.

8. You should still be using the AWS Management Console in the US East (Ohio) Region. Select **Items** in the left navigation menu, select the **Music** table, then choose **Create Item**.

   a. For **Artist**, enter **`item_1`**.

   b. For **SongTitle**, enter **`Song Value 1`**.

   c. To write the item, choose **Create item**.

9. After a short time, the item is replicated across all three Regions of your global table. To verify this, in the console, on the Region selector in the upper-right corner, choose **Europe (Frankfurt)**. The `Music` table in Europe (Frankfurt) should contain the new item.
10. Repeat step 9 and choose **US West (Oregon)** to verify replication in that region.

Creating a global table (AWS CLI)

Follow these steps to create a global table `Music` using the AWS CLI. The following example creates a global table, with replica tables in the United States and in Europe.

1. Create a new table (`Music`) in US East (Ohio), with DynamoDB Streams enabled (`NEW_AND_OLD_IMAGES`).

```
aws dynamodb create-table \
    --table-name Music \
    --attribute-definitions \
        AttributeName=Artist,AttributeType=S \
        AttributeName=SongTitle,AttributeType=S \
    --key-schema \
        AttributeName=Artist,KeyType=HASH \
        AttributeName=SongTitle,KeyType=RANGE \
    --provisioned-throughput \
        ReadCapacityUnits=10,WriteCapacityUnits=5 \
    --stream-specification StreamEnabled=true,StreamViewType=NEW_AND_OLD_IMAGES \
    --region us-east-2
```

2. Create an identical `Music` table in US East (N. Virginia).

```
aws dynamodb create-table \
    --table-name Music \
    --attribute-definitions \
        AttributeName=Artist,AttributeType=S \
        AttributeName=SongTitle,AttributeType=S \
    --key-schema \
        AttributeName=Artist,KeyType=HASH \
        AttributeName=SongTitle,KeyType=RANGE \
    --provisioned-throughput \
        ReadCapacityUnits=10,WriteCapacityUnits=5 \
    --stream-specification StreamEnabled=true,StreamViewType=NEW_AND_OLD_IMAGES \
    --region us-east-1
```

3. Create a global table (`Music`) consisting of replica tables in the `us-east-2` and `us-east-1` Regions.

```
aws dynamodb create-global-table \
    --global-table-name Music \
    --replication-group RegionName=us-east-2 RegionName=us-east-1 \
    --region us-east-2
```

> **Note**
>
> The global table name (`Music`) must match the name of each of the replica tables (`Music`). For more information, see Best practices and requirements for managing global tables.

4. Create another table in Europe (Ireland), with the same settings as those you created in step 1 and step 2.

```
aws dynamodb create-table \
    --table-name Music \
    --attribute-definitions \
        AttributeName=Artist,AttributeType=S \
        AttributeName=SongTitle,AttributeType=S \
    --key-schema \
        AttributeName=Artist,KeyType=HASH \
        AttributeName=SongTitle,KeyType=RANGE \
    --provisioned-throughput \
        ReadCapacityUnits=10,WriteCapacityUnits=5 \
    --stream-specification StreamEnabled=true,StreamViewType=NEW_AND_OLD_IMAGES \
    --region eu-west-1
```

After doing this step, add the new table to the `Music` global table.

```
aws dynamodb update-global-table \
    --global-table-name Music \
    --replica-updates 'Create={RegionName=eu-west-1}' \
    --region us-east-2
```

5. To verify that replication is working, add a new item to the `Music` table in US East (Ohio).

```
aws dynamodb put-item \
```

```
    --table-name Music \
    --item '{"Artist": {"S":"item_1"},"SongTitle": {"S":"Song Value 1"}}' \
    --region us-east-2
```

6. Wait for a few seconds, and then check to see whether the item has been successfully replicated to US East (N. Virginia) and Europe (Ireland).

```
aws dynamodb get-item \
    --table-name Music \
    --key '{"Artist": {"S":"item_1"},"SongTitle": {"S":"Song Value 1"}}' \
    --region us-east-1
```

```
aws dynamodb get-item \
    --table-name Music \
    --key '{"Artist": {"S":"item_1"},"SongTitle": {"S":"Song Value 1"}}' \
    --region eu-west-1
```

Monitoring global tables

> **Important**
>
> This documentation is for version 2017.11.29 (Legacy) of global tables, which should be avoided for new global tables. Customers should use Global Tables version 2019.11.21 (Current) when possible, as it provides greater flexibility, higher efficiency and consumes less write capacity than 2017.11.29 (Legacy).
> To determine which version you are using, see Determining the DynamoDB global table version you are using. To update existing global tables from version 2017.11.29 (Legacy) to version 2019.11.21 (Current), see Upgrading global tables.

You can use Amazon CloudWatch to monitor the behavior and performance of a global table. Amazon DynamoDB publishes `ReplicationLatency` and `PendingReplicationCount` metrics for each replica in the global table.

- **`ReplicationLatency`**—The elapsed time between when an updated item appears in the DynamoDB stream for one replica table, and when that item appears in another replica in the global table. `ReplicationLatency` is expressed in milliseconds and is emitted for every source- and destination-Region pair.

During normal operation, `ReplicationLatency` should be fairly constant. An elevated value for `ReplicationLatency` could indicate that updates from one replica are not propagating to other replica tables in a timely manner. Over time, this could result in other replica tables *falling behind* because they no longer receive updates consistently. In this case, you should verify that the read capacity units (RCUs) and write capacity units (WCUs) are identical for each of the replica tables. In addition, when choosing WCU settings, follow the recommendations in Global tables version.

`ReplicationLatency` can increase if an AWS Region becomes degraded and you have a replica table in that Region. In this case, you can temporarily redirect your application's read and write activity to a different AWS Region.

- **`PendingReplicationCount`**—The number of item updates that are written to one replica table, but that have not yet been written to another replica in the global table. `PendingReplicationCount` is expressed in number of items and is emitted for every source- and destination-Region pair.

  During normal operation, `PendingReplicationCount` should be very low. If `PendingReplicationCount` increases for extended periods, investigate whether your replica tables' provisioned write capacity settings are sufficient for your current workload.

  `PendingReplicationCount` can increase if an AWS Region becomes degraded and you have a replica table in that Region. In this case, you can temporarily redirect your application's read and write activity to a different AWS Region.

For more information, see DynamoDB Metrics and dimensions.

Using IAM with global tables

> **Important**
>
> This documentation is for version 2017.11.29 (Legacy) of global tables, which should be avoided for new global tables. Customers should use Global Tables version 2019.11.21 (Current) when possible, as it provides greater flexibility, higher efficiency and consumes less write capacity than 2017.11.29 (Legacy).

To determine which version you are using, see Determining the DynamoDB global table version you are using. To update existing global tables from version 2017.11.29 (Legacy) to version 2019.11.21 (Current), see Upgrading global tables.

When you create a global table for the first time, Amazon DynamoDB automatically creates an AWS Identity and Access Management (IAM) service-linked role for you. This role is named `AWSServiceRoleForDynamoDBReplication`, and it allows DynamoDB to manage cross-Region replication for global tables on your behalf. Don't delete this service-linked role. If you do, then all of your global tables will no longer function.

For more information about service-linked roles, see Using service-linked roles in the *IAM User Guide*.

To create and maintain global tables in DynamoDB, you must have the `dynamodb:CreateGlobalTable` permission to access each of the following:

- The replica table that you want to add.
- Each existing replica that's already part of the global table.
- The global table itself.

To update the settings (`UpdateGlobalTableSettings`) for a global table in DynamoDB, you must have the `dynamodb:UpdateGlobalTable`, `dynamodb:DescribeLimits`, `application-autoscaling:DeleteScalingPolicy`, and `application-autoscaling:DeregisterScalableTarget` permissions.

The `application-autoscaling:DeleteScalingPolicy` and `application-autoscaling:DeregisterScalableTarget` permissions are required when updating an existing scaling policy. This is so that the global tables service can remove the old scaling policy before attaching the new policy to the table or secondary index.

If you use an IAM policy to manage access to one replica table, you should apply an identical policy to all other replicas within that global table. This practice helps you maintain a consistent permissions model across all of the replica tables.

By using identical IAM policies on all replicas in a global table, you can also avoid granting unintended read and write access to your global table data. For example, consider a user who has access to only one replica in a global table. If that user can write to this replica, DynamoDB

propagates the write to all of the other replica tables. In effect, the user can (indirectly) write to all of the other replicas in the global table. This scenario can be avoided by using consistent IAM policies on all of the replica tables.

Example: Allow the CreateGlobalTable action

Before you can add a replica to a global table, you must have the `dynamodb:CreateGlobalTable` permission for the global table and for each of its replica tables.

The following IAM policy grants permissions to allow the `CreateGlobalTable` action on all tables.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["dynamodb:CreateGlobalTable"],
            "Resource": "*"
        }
    ]
}
```

Example: Allow the UpdateGlobalTable, DescribeLimits, application-autoscaling:DeleteScalingPolicy, and application-autoscaling:DeregisterScalableTarget actions

To update the settings (`UpdateGlobalTableSettings`) for a global table in DynamoDB, you must have the `dynamodb:UpdateGlobalTable`, `dynamodb:DescribeLimits`, `application-autoscaling:DeleteScalingPolicy`, and `application-autoscaling:DeregisterScalableTarget` permissions.

The following IAM policy grants permissions to allow the `UpdateGlobalTableSettings` action on all tables.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
```

```
                "dynamodb:UpdateGlobalTable",
                "dynamodb:DescribeLimits",
                "application-autoscaling:DeleteScalingPolicy",
                "application-autoscaling:DeregisterScalableTarget"
            ],
            "Resource": "*"
        }
    ]
}
```

Example: Allow the CreateGlobalTable action for a specific global table name with replicas allowed in certain regions only

The following IAM policy grants permissions to allow the `CreateGlobalTable` action to create a global table named `Customers` with replicas in two Regions.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "dynamodb:CreateGlobalTable",
            "Resource": [
                "arn:aws:dynamodb::123456789012:global-table/Customers",
                "arn:aws:dynamodb:us-east-1:123456789012:table/Customers",
                "arn:aws:dynamodb:us-west-1:123456789012:table/Customers"
            ]
        }
    ]
}
```

Previous low-level DynamoDB API version (2011-12-05)

This section documents the operations available in the previous DynamoDB low-level API version (2011-12-05). This version of the low-level API is maintained for backward compatibility with existing applications.

New applications should use the current API version (2012-08-10). For more information, see DynamoDB API reference.

Note

We recommend that you migrate your applications to the latest API version (2012-08-10), since new DynamoDB features will not be backported to the previous API version.

BatchGetItem

Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the Amazon DynamoDB API Reference.

Description

The `BatchGetItem` operation returns the attributes for multiple items from multiple tables using their primary keys. The maximum number of items that can be retrieved for a single operation is 100. Also, the number of items retrieved is constrained by a 1 MB size limit. If the response size limit is exceeded or a partial result is returned because the table's provisioned throughput is exceeded, or because of an internal processing failure, DynamoDB returns an `UnprocessedKeys` value so you can retry the operation starting with the next item to get. DynamoDB automatically adjusts the number of items returned per page to enforce this limit. For example, even if you ask to retrieve 100 items, but each individual item is 50 KB in size, the system returns 20 items and an appropriate `UnprocessedKeys` value so you can get the next page of results. If desired, your application can include its own logic to assemble the pages of results into one set.

If no items could be processed because of insufficient provisioned throughput on each of the tables involved in the request, DynamoDB returns a `ProvisionedThroughputExceededException` error.

> **Note**
>
> By default, `BatchGetItem` performs eventually consistent reads on every table in the request. You can set the `ConsistentRead` parameter to `true`, on a per-table basis, if you want consistent reads instead.
> `BatchGetItem` fetches items in parallel to minimize response latencies.
> When designing your application, keep in mind that DynamoDB does not guarantee how attributes are ordered in the returned response. Include the primary key values in the `AttributesToGet` for the items in your request to help parse the response by item.
> If the requested items do not exist, nothing is returned in the response for those items.
> Requests for non-existent items consume the minimum read capacity units according to the type of read. For more information, see DynamoDB item sizes and formats.

Requests

Syntax

```
// This header is abbreviated. For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
```

```
x-amz-target: DynamoDB_20111205.BatchGetItem
content-type: application/x-amz-json-1.0

{"RequestItems":
    {"Table1":
        {"Keys":
            [{"HashKeyElement": {"S":"KeyValue1"}, "RangeKeyElement":
{"N":"KeyValue2"}},
            {"HashKeyElement": {"S":"KeyValue3"}, "RangeKeyElement":{"N":"KeyValue4"}},
            {"HashKeyElement": {"S":"KeyValue5"}, "RangeKeyElement":
{"N":"KeyValue6"}}],
        "AttributesToGet":["AttributeName1", "AttributeName2", "AttributeName3"]},
    "Table2":
        {"Keys":
            [{"HashKeyElement": {"S":"KeyValue4"}},
            {"HashKeyElement": {"S":"KeyValue5"}}],
        "AttributesToGet": ["AttributeName4", "AttributeName5", "AttributeName6"]
        }
    }
}
```

Name	Description	Required
`RequestItems`	A container of the table name and corresponding items to get by primary key. While requesting items, each table name can be invoked only once per operation. Type: String Default: None	Yes
`Table`	The name of the table containing the items to get. The entry is simply a string specifying an existing table with no label. Type: String	Yes

Name	Description	Required
	Default: None	
`Table:Keys`	The primary key values that define the items in the specified table. For more information about primary keys, see Primary key. Type: Keys	Yes
`Table:AttributesToGet`	Array of Attribute names within the specified table. If attribute names are not specified then all attribute s will be returned. If some attributes are not found, they will not appear in the result. Type: Array	No
`Table:ConsistentRead`	If set to `true`, then a consistent read is issued, otherwise eventually consistent is used. Type: Boolean	No

Responses

Syntax

```
HTTP/1.1 200

        "AttributeName2": {"N":"AttributeValue"},
        "AttributeName3": {"SS":["AttributeValue", "AttributeValue", "AttributeValue"]}
        },
        {"AttributeName1": {"S": "AttributeValue"},
        "AttributeName2": {"S": "AttributeValue"},
        "AttributeName3": {"NS": ["AttributeValue", "AttributeValue","AttributeValue"]}
        }],
    "ConsumedCapacityUnits":1}
    },
    "UnprocessedKeys":
        {"Table3":
        {"Keys":
            [{"HashKeyElement": {"S":"KeyValue1"}, "RangeKeyElement":
{"N":"KeyValue2"}},
            {"HashKeyElement": {"S":"KeyValue3"}, "RangeKeyElement":{"N":"KeyValue4"}},
            {"HashKeyElement": {"S":"KeyValue5"}, "RangeKeyElement":
{"N":"KeyValue6"}}],
        "AttributesToGet":["AttributeName1", "AttributeName2", "AttributeName3"]}
        }
}
```

Name	Description
Responses	Table names and the respective item attributes from the tables. Type: Map

Name	Description
`Table`	The name of the table containing the items. The entry is simply a string specifying the table with no label. Type: String
`Items`	Container for the attribute names and values meeting the operation parameters. Type: Map of attribute names to and their data types and values.
`ConsumedCapacityUnits`	The number of read capacity units consumed, for each table. This value shows the number applied toward your provisioned throughput. Requests for non-existent items consume the minimum read capacity units, depending on the type of read. For more information see DynamoDB provisioned capacity mode. Type: Number
`UnprocessedKeys`	Contains an array of tables and their respective keys that were not processed with the current response, possibly due to reaching a limit on the response size. The `UnprocessedKeys` value is in the same form as a `RequestItems` parameter (so the value can be provided directly to a subsequent `BatchGetItem` operation). For more information, see the above `RequestItems` parameter. Type: Array

Name	Description
`UnprocessedKeys : Table: Keys`	The primary key attribute values that define the items and the attributes associated with the items. For more information about primary keys, see Primary key . Type: Array of attribute name-value pairs.
`UnprocessedKeys : Table: AttributesToGet`	Attribute names within the specified table. If attribute names are not specified then all attributes will be returned. If some attributes are not found, they will not appear in the result. Type: Array of attribute names.
`UnprocessedKeys : Table: ConsistentRead`	If set to `true`, then a consistent read is used for the specified table, otherwise an eventually consistent read is used. Type: Boolean.

Special errors

Error	Description
`ProvisionedThroughputExceededException`	Your maximum allowed provisioned throughput has been exceeded.

Examples

The following examples show an HTTP POST request and response using the BatchGetItem operation. For examples using the AWS SDK, see Working with items and attributes in DynamoDB.

Sample request

The following sample requests attributes from two different tables.

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.BatchGetItem
content-type: application/x-amz-json-1.0
content-length: 409

{"RequestItems":
    {"comp1":
        {"Keys":
            [{"HashKeyElement":{"S":"Casey"},"RangeKeyElement":{"N":"1319509152"}},
            {"HashKeyElement":{"S":"Dave"},"RangeKeyElement":{"N":"1319509155"}},
            {"HashKeyElement":{"S":"Riley"},"RangeKeyElement":{"N":"1319509158"}}],
        "AttributesToGet":["user","status"]},
    "comp2":
        {"Keys":
            [{"HashKeyElement":{"S":"Julie"}},{"HashKeyElement":{"S":"Mingus"}}],
        "AttributesToGet":["user","friends"]}
    }
}
```

Sample response

The following sample is the response.

```
HTTP/1.1 200 OK
x-amzn-RequestId: GTPQVRM4VJS792J1UFJTKUBVV4KQNSO5AEMVJF66Q9ASUAAJG
content-type: application/x-amz-json-1.0

BatchWriteItem

> **Important**
>
> ***This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.***
> **For documentation on the current low-level API, see the Amazon DynamoDB API Reference.**

Description

This operation enables you to put or delete several items across multiple tables in a single call.

To upload one item, you can use `PutItem`, and to delete one item, you can use `DeleteItem`. However, when you want to upload or delete large amounts of data, such as uploading large amounts of data from Amazon EMR (Amazon EMR) or migrating data from another database in to DynamoDB, `BatchWriteItem` offers an efficient alternative.

If you use languages such as Java, you can use threads to upload items in parallel. This adds complexity in your application to handle the threads. Other languages don't support threading. For example, if you are using PHP, you must upload or delete items one at a time. In both situations, `BatchWriteItem` provides an alternative where the specified put and delete operations are processed in parallel, giving you the power of the thread pool approach without having to introduce complexity in your application.

Note that each individual put and delete specified in a `BatchWriteItem` operation costs the same in terms of consumed capacity units. However, because `BatchWriteItem` performs the specified operations in parallel, you get lower latency. Delete operations on non-existent items consume 1 write capacity unit. For more information about consumed capacity units, see Working with tables and data in DynamoDB.

When using `BatchWriteItem`, note the following limitations:

- **Maximum operations in a single request**—You can specify a total of up to 25 put or delete operations; however, the total request size cannot exceed 1 MB (the HTTP payload).

- You can use the `BatchWriteItem` operation only to put and delete items. You cannot use it to update existing items.
- **Not an atomic operation—**Individual operations specified in a `BatchWriteItem` are atomic; however `BatchWriteItem` as a whole is a "best-effort" operation and not an atomic operation. That is, in a `BatchWriteItem` request, some operations might succeed and others might fail. The failed operations are returned in an `UnprocessedItems` field in the response. Some of these failures might be because you exceeded the provisioned throughput configured for the table or a transient failure such as a network error. You can investigate and optionally resend the requests. Typically, you call `BatchWriteItem` in a loop and in each iteration check for unprocessed items, and submit a new `BatchWriteItem` request with those unprocessed items.
- **Does not return any items—**The `BatchWriteItem` is designed for uploading large amounts of data efficiently. It does not provide some of the sophistication offered by `PutItem` and `DeleteItem`. For example, `DeleteItem` supports the `ReturnValues` field in your request body to request the deleted item in the response. The `BatchWriteItem` operation does not return any items in the response.
- Unlike `PutItem` and `DeleteItem`, `BatchWriteItem` does not allow you to specify conditions on individual write requests in the operation.
- Attribute values must not be null; string and binary type attributes must have lengths greater than zero; and set type attributes must not be empty. Requests that have empty values will be rejected with a `ValidationException`.

DynamoDB rejects the entire batch write operation if any one of the following is true:

- If one or more tables specified in the `BatchWriteItem` request does not exist.
- If primary key attributes specified on an item in the request does not match the corresponding table's primary key schema.
- If you try to perform multiple operations on the same item in the same `BatchWriteItem` request. For example, you cannot put and delete the same item in the same `BatchWriteItem` request.
- If the total request size exceeds the 1 MB request size (the HTTP payload) limit.
- If any individual item in a batch exceeds the 64 KB item size limit.

Requests

Syntax

```
// This header is abbreviated. For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.BatchGetItem
content-type: application/x-amz-json-1.0

{
  "RequestItems" :  RequestItems
}

RequestItems
{
     "TableName1" :  [ Request, Request, ... ],
     "TableName2" :  [ Request, Request, ... ],
     ...
}

Request ::=
  PutRequest | DeleteRequest

PutRequest ::=
{
  "PutRequest" : {
     "Item" : {
        "Attribute-Name1" : Attribute-Value,
        "Attribute-Name2" : Attribute-Value,
         ...
     }
  }
}

DeleteRequest ::=
{
   "DeleteRequest" : {
      "Key" : PrimaryKey-Value
   }
}

PrimaryKey-Value ::= HashTypePK | HashAndRangeTypePK
```

```
HashTypePK ::=
{
   "HashKeyElement" : Attribute-Value
}

HashAndRangeTypePK
{
   "HashKeyElement" : Attribute-Value,
   "RangeKeyElement" : Attribute-Value,
}

Attribute-Value ::= String | Numeric| Binary | StringSet | NumericSet | BinarySet

Numeric ::=
{
   "N": "Number"
}

String ::=
{
   "S": "String"
}

Binary ::=
{
    "B": "Base64 encoded binary data"
}

StringSet ::=
{
   "SS": [ "String1", "String2", ... ]
}

NumberSet ::=
{
   "NS": [ "Number1", "Number2", ... ]
}

BinarySet ::=
{
   "BS": [ "Binary1", "Binary2", ... ]
}
```

In the request body, the `RequestItems` JSON object describes the operations that you want to perform. The operations are grouped by tables. You can use `BatchWriteItem` to update or delete several items across multiple tables. For each specific write request, you must identify the type of request (`PutItem`, `DeleteItem`) followed by detail information about the operation.

- For a `PutRequest`, you provide the item, that is, a list of attributes and their values.
- For a `DeleteRequest`, you provide the primary key name and value.

Responses

Syntax

The following is the syntax of the JSON body returned in the response.

```
{
  "Responses" :         ConsumedCapacityUnitsByTable
  "UnprocessedItems" :  RequestItems
}

ConsumedCapacityUnitsByTable
{
    "TableName1" : { "ConsumedCapacityUnits", : NumericValue },
    "TableName2" : { "ConsumedCapacityUnits", : NumericValue },
     ...
}

RequestItems
This syntax is identical to the one described in the JSON syntax in the request.
```

Special errors

No errors specific to this operation.

Examples

The following example shows an HTTP POST request and the response of a `BatchWriteItem` operation. The request specifies the following operations on the Reply and the Thread tables:

- Put an item and delete an item from the Reply table
- Put an item into the Thread table

For examples using the AWS SDK, see Working with items and attributes in DynamoDB.

Sample request

```
// This header is abbreviated. For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.BatchGetItem
content-type: application/x-amz-json-1.0

{
  "RequestItems":{
    "Reply":[
      {
        "PutRequest":{
          "Item":{
            "ReplyDateTime":{
              "S":"2012-04-03T11:04:47.034Z"
            },
            "Id":{
              "S":"DynamoDB#DynamoDB Thread 5"
            }
          }
        }
      },
      {
        "DeleteRequest":{
          "Key":{
            "HashKeyElement":{
              "S":"DynamoDB#DynamoDB Thread 4"
            },
            "RangeKeyElement":{
              "S":"oops - accidental row"
            }
          }
        }
      }
    ],
    "Thread":[
      {
        "PutRequest":{
          "Item":{
            "ForumName":{
              "S":"DynamoDB"
```

```
            },
            "Subject":{
              "S":"DynamoDB Thread 5"
            }
          }
        }
      }
    ]
  }
}
```

Sample response

The following example response shows a put operation on both the Thread and Reply tables succeeded and a delete operation on the Reply table failed (for reasons such as throttling that is caused when you exceed the provisioned throughput on the table). Note the following in the JSON response:

- The `Responses` object shows one capacity unit was consumed on both the `Thread` and `Reply` tables as a result of the successful put operation on each of these tables.
- The `UnprocessedItems` object shows the unsuccessful delete operation on the `Reply` table. You can then issue a new `BatchWriteItem` call to address these unprocessed requests.

```
HTTP/1.1 200 OK
x-amzn-RequestId: G8M9ANLOE5QA26AEUHJKJE0ASBVV4KQNSO5AEMVJF66Q9ASUAAJG
Content-Type: application/x-amz-json-1.0
Content-Length: 536
Date: Thu, 05 Apr 2012 18:22:09 GMT

{
   "Responses":{
      "Thread":{
         "ConsumedCapacityUnits":1.0
      },
      "Reply":{
         "ConsumedCapacityUnits":1.0
      }
   },
   "UnprocessedItems":{
      "Reply":[
         {
```

```
            "DeleteRequest":{
               "Key":{
                  "HashKeyElement":{
                     "S":"DynamoDB#DynamoDB Thread 4"
                  },
                  "RangeKeyElement":{
                     "S":"oops - accidental row"
                  }
               }
            }
         }
      ]
   }
}
```

CreateTable

> **Important**
>
> ***This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.***
>
> **For documentation on the current low-level API, see the Amazon DynamoDB API Reference.**

Description

The `CreateTable` operation adds a new table to your account.

The table name must be unique among those associated with the AWS Account issuing the request, and the AWS region that receives the request (such as dynamodb.us-west-2.amazonaws.com). Each DynamoDB endpoint is entirely independent. For example, if you have two tables called "MyTable," one in dynamodb.us-west-2.amazonaws.com and one in dynamodb.us-west-1.amazonaws.com, they are completely independent and do not share any data.

The `CreateTable` operation triggers an asynchronous workflow to begin creating the table. DynamoDB immediately returns the state of the table (`CREATING`) until the table is in the `ACTIVE` state. Once the table is in the `ACTIVE` state, you can perform data plane operations.

Use the DescribeTables operation to check the status of the table.

Requests

Syntax

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.CreateTable
content-type: application/x-amz-json-1.0

{"TableName":"Table1",
    "KeySchema":
        {"HashKeyElement":{"AttributeName":"AttributeName1","AttributeType":"S"},
        "RangeKeyElement":{"AttributeName":"AttributeName2","AttributeType":"N"}},
    "ProvisionedThroughput":{"ReadCapacityUnits":5,"WriteCapacityUnits":10}
}
```

Name	Description	Required
TableName	The name of the table to create. Allowed characters are a-z, A-Z, 0-9, '_' (underscore), '-' (dash), and '.' (dot). Names can be between 3 and 255 characters long. Type: String	Yes
KeySchema	The primary key (simple or composite) structure for the table. A name-value pair for the HashKeyElement is required, and a name-value pair for the RangeKeyElement is optional (only required for composite primary keys). For more info	Yes

Name	Description	Required
	rmation about primary keys, see Primary key. Primary key element names can be between 1 and 255 characters long with no character restrictions. Possible values for the AttributeType are "S" (string), "N" (numeric), or "B" (binary). Type: Map of `HashKeyElement`, or `HashKeyElement` and `RangeKeyElement` for a composite primary key.	
`ProvisionedThroughput`	New throughput for the specified table, consisting of values for `ReadCapacityUnits` and `WriteCapacityUnits`. For details, see DynamoDB provisioned capacity mode. **Note** For current maximum/minimum values, see Quotas in Amazon DynamoDB. Type: Array	Yes

Name	Description	Required
`ProvisionedThroughput : ReadCapacityUnits`	Sets the minimum number of consistent `ReadCapacityUnits` consumed per second for the specified table before DynamoDB balances the load with other operations. Eventually consistent read operations require less effort than a consistent read operation, so a setting of 50 consistent `ReadCapacityUnits` per second provides 100 eventually consistent `ReadCapacityUnits` per second. Type: Number	Yes
`ProvisionedThroughput : WriteCapacityUnits`	Sets the minimum number of `WriteCapacityUnits` consumed per second for the specified table before DynamoDB balances the load with other operations. Type: Number	Yes

Responses

Syntax

    "TableName":"Table1",
    "TableStatus":"CREATING"
    }
}
```

Name	Description
TableDescription	A container for the table properties.
CreationDateTime	Date when the table was created in UNIX epoch time. Type: Number
KeySchema	The primary key (simple or composite) structure for the table. A name-value pair for the HashKeyElement is required, and a name-value pair for the RangeKeyElement is optional (only required for composite primary keys). For more information about primary keys, see Primary key . Type: Map of HashKeyElement , or HashKeyElement and RangeKeyElement for a composite primary key.
ProvisionedThroughput	Throughput for the specified table, consisting of values for ReadCapacityUnits and

Name	Description
	WriteCapacityUnits . See DynamoDB provisioned capacity mode. Type: Array
ProvisionedThroughput :ReadCapacityUnits	The minimum number of ReadCapacityUnits consumed per second before DynamoDB. balances the load with other operations Type: Number
ProvisionedThroughput :WriteCapacityUnits	The minimum number of ReadCapacityUnits consumed per second before WriteCapacityUnits . balances the load with other operations Type: Number
TableName	The name of the created table. Type: String
TableStatus	The current state of the table (CREATING). Once the table is in the ACTIVE state, you can put data in it. Use the DescribeTables API to check the status of the table. Type: String

Special errors

Error	Description
`ResourceInUseException`	Attempt to recreate an already existing table.
`LimitExceededException`	The number of simultaneous table requests (cumulative number of tables in the `CREATING`, `DELETING` or `UPDATING` state) exceeds the maximum allowed. **Note** For current maximum/minimum values, see Quotas in Amazon DynamoDB. .

Examples

The following example creates a table with a composite primary key containing a string and a number. For examples using the AWS SDK, see Working with tables and data in DynamoDB.

Sample request

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.

DeleteItem

> **Important**
>
> ***This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.***
>
> **For documentation on the current low-level API, see the Amazon DynamoDB API Reference.**

Description

Deletes a single item in a table by primary key. You can perform a conditional delete operation that deletes the item if it exists, or if it has an expected attribute value.

Note

If you specify `DeleteItem` without attributes or values, all the attributes for the item are deleted.
Unless you specify conditions, the `DeleteItem` is an idempotent operation; running it multiple times on the same item or attribute does *not* result in an error response.
Conditional deletes are useful for only deleting items and attributes if specific conditions are met. If the conditions are met, DynamoDB performs the delete. Otherwise, the item is not deleted.
You can perform the expected conditional check on one attribute per operation.

Requests

Syntax

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.DeleteItem
content-type: application/x-amz-json-1.0

{"TableName":"Table1",
    "Key":
        {"HashKeyElement":{"S":"AttributeValue1"},"RangeKeyElement":
{"N":"AttributeValue2"}},
    "Expected":{"AttributeName3":{"Value":{"S":"AttributeValue3"}}},
    "ReturnValues":"ALL_OLD"}
}
```

Name	Description	Required
`TableName`	The name of the table containing the item to delete. Type: String	Yes
`Key`	The primary key that defines the item. For more informati	Yes

Name	Description	Required
	on about primary keys, see Primary key. Type: Map of `HashKeyElement` to its value and `RangeKeyElement` to its value.	
`Expected`	Designates an attribute for a conditional delete. The `Expected` parameter allows you to provide an attribute name, and whether or not DynamoDB should check to see if the attribute has a particular value before deleting it. Type: Map of attribute names.	No
`Expected:AttributeName`	The name of the attribute for the conditional put. Type: String	No

Name	Description	Required

`Expected:AttributeName: ExpectedAttributeValue`	Use this parameter to specify whether or not a value already exists for the attribute name-value pair.
	
	The following JSON notation deletes the item if the "Color" attribute doesn't exist for that item:
	
	`"Expected" : {"Color":{"Exists":false}}`
	
	The following JSON notation checks to see if the attribute with name "Color" has an existing value of "Yellow" before deleting the item:
	
	`"Expected" : {"Color":{"Exists":true},{"Value":{"S":"Yellow"}}}`
	
	By default, if you use the `Expected` parameter and provide a `Value`, DynamoDB assumes the attribute exists and has a current value to be replaced. So you don't have to specify `{"Exists":true}`, because it is implied. You can shorten the request to:
	
	`"Expected" :`
		No

Name	Description	Required
	`{"Color":{"Value":{"S":"Yellow"}}}` **Note** If you specify `{"Exists":true}` without an attribute value to check, DynamoDB returns an error.	
`ReturnValues`	Use this parameter if you want to get the attribute name-value pairs before they were deleted. Possible parameter values are `NONE` (default) or `ALL_OLD`. If `ALL_OLD` is specified, the content of the old item is returned. If this parameter is not provided or is `NONE`, nothing is returned. Type: String	No

Responses

Syntax

```
HTTP/1.1 200 OK
x-amzn-RequestId: CSOC7TJPLR0OOKIRLGOHVAICUFVV4KQNSO5AEMVJF66Q9ASUAAJG
content-type: application/x-amz-json-1.0
content-length: 353
Date: Tue, 12 Jul 2011 21:31:03 GMT
```

```
{"Attributes":
    {"AttributeName3":{"SS":["AttributeValue3","AttributeValue4","AttributeValue5"]},
    "AttributeName2":{"S":"AttributeValue2"},
    "AttributeName1":{"N":"AttributeValue1"}
    },
"ConsumedCapacityUnits":1
}
```

Name	Description
`Attributes`	If the `ReturnValues` parameter is provided as `ALL_OLD` in the request, DynamoDB returns an array of attribute name-value pairs (essentially, the deleted item). Otherwise, the response contains an empty set. Type: Array of attribute name-value pairs.
`ConsumedCapacityUnits`	The number of write capacity units consumed by the operation. This value shows the number applied toward your provisioned throughput. Delete requests on non-existent items consume 1 write capacity unit. For more information see DynamoDB provisioned capacity mode. Type: Number

Special errors

Error	Description
`ConditionalCheckFailedException`	Conditional check failed. An expected attribute value was not found.

Examples

Sample request

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.

- PutItem

DeleteTable

Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the Amazon DynamoDB API Reference.

Description

The `DeleteTable` operation deletes a table and all of its items. After a `DeleteTable` request, the specified table is in the `DELETING` state until DynamoDB completes the deletion. If the table is in the `ACTIVE` state, you can delete it. If a table is in `CREATING` or `UPDATING` states, then DynamoDB returns a `ResourceInUseException` error. If the specified table does not exist, DynamoDB returns a `ResourceNotFoundException`. If table is already in the `DELETING` state, no error is returned.

Note

DynamoDB might continue to accept data plane operation requests, such as `GetItem` and `PutItem`, on a table in the `DELETING` state until the table deletion is complete.

Tables are unique among those associated with the AWS Account issuing the request, and the AWS region that receives the request (such as dynamodb.us-west-1.amazonaws.com). Each DynamoDB endpoint is entirely independent. For example, if you have two tables called "MyTable," one in dynamodb.us-west-2.amazonaws.com and one in dynamodb.us-west-1.amazonaws.com, they are completely independent and do not share any data; deleting one does not delete the other.

Use the DescribeTables operation to check the status of the table.

Requests

Syntax

```
// This header is abbreviated.
```

```
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.DeleteTable
content-type: application/x-amz-json-1.0

{"TableName":"Table1"}
```

Name	Description	Required
TableName	The name of the table to delete. Type: String	Yes

Responses

Syntax

```

DescribeTables

> **Important**
>
> ***This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.***
>
> **For documentation on the current low-level API, see the Amazon DynamoDB API Reference.**

Description

Returns information about the table, including the current status of the table, the primary key schema and when the table was created. DescribeTable results are eventually consistent. If you use DescribeTable too early in the process of creating a table, DynamoDB returns a `ResourceNotFoundException`. If you use DescribeTable too early in the process of updating a table, the new values might not be immediately available.

Requests

Syntax

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
```

```
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.DescribeTable
content-type: application/x-amz-json-1.0

{"TableName":"Table1"}
```

Name	Description	Required
TableName	The name of the table to describe. Type: String	Yes

Responses

Syntax

```
HTTP/1.1 200
x-amzn-RequestId: 8966d095-71e9-11e0-a498-71d736f27375
content-type: application/x-amz-json-1.0
Content-Length: 543

{"Table":
    {"CreationDateTime":1.309988345372E9,
    ItemCount:1,
    "KeySchema":
        {"HashKeyElement":{"AttributeName":"AttributeName1","AttributeType":"S"},
        "RangeKeyElement":{"AttributeName":"AttributeName2","AttributeType":"N"}},
    "ProvisionedThroughput":{"LastIncreaseDateTime": Date, "LastDecreaseDateTime":
 Date, "ReadCapacityUnits":10,"WriteCapacityUnits":10},
    "TableName":"Table1",
    "TableSizeBytes":1,
    "TableStatus":"ACTIVE"
    }
}
```

Name	Description
Table	Container for the table being described.

Name	Description
	Type: String
`CreationDateTime`	Date when the table was created in UNIX epoch time.
`ItemCount`	Number of items in the specified table. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value. Type: Number
`KeySchema`	The primary key (simple or composite) structure for the table. A name-value pair for the `HashKeyElement` is required, and a name-value pair for the `RangeKeyElement` is optional (only required for composite primary keys). The maximum hash key size is 2048 bytes. The maximum range key size is 1024 bytes. Both limits are enforced separatel y (i.e. you can have a combined hash + range 2048 + 1024 key). For more information about primary keys, see Primary key .
`ProvisionedThroughput`	Throughput for the specified table, consistin g of values for `LastIncreaseDateTime` (if applicable), `LastDecreaseDateTime` (if applicable), `ReadCapacityUnits` and `WriteCapacityUnits` . If the throughpu t for the table has never been increased or decreased, DynamoDB does not return values for those elements. See DynamoDB provision ed capacity mode. Type: Array

Name	Description
TableName	The name of the requested table. Type: String
TableSizeBytes	Total size of the specified table, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value. Type: Number
TableStatus	The current state of the table (CREATING, ACTIVE, DELETING or UPDATING). Once the table is in the ACTIVE state, you can add data.

Special errors

No errors are specific to this operation.

Examples

The following examples show an HTTP POST request and response using the DescribeTable operation for a table named "comp-table". The table has a composite primary key.

Sample Request

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.DescribeTable
content-type: application/x-amz-json-1.0

{"TableName":"users"}
```

Sample response

```
HTTP/1.1 200
x-amzn-RequestId: 8966d095-71e9-11e0-a498-71d736f27375
```

```
content-type: application/x-amz-json-1.0
content-length: 543

{"Table":
    {"CreationDateTime":1.309988345372E9,
    "ItemCount":23,
    "KeySchema":
        {"HashKeyElement":{"AttributeName":"user","AttributeType":"S"},
        "RangeKeyElement":{"AttributeName":"time","AttributeType":"N"}},
    "ProvisionedThroughput":{"LastIncreaseDateTime": 1.309988345384E9,
 "ReadCapacityUnits":10,"WriteCapacityUnits":10},
    "TableName":"users",
    "TableSizeBytes":949,
    "TableStatus":"ACTIVE"
    }
}
```

GetItem

> **Important**
>
> ***This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.***
>
> **For documentation on the current low-level API, see the Amazon DynamoDB API Reference.**

Description

The `GetItem` operation returns a set of `Attributes` for an item that matches the primary key. If there is no matching item, `GetItem` does not return any data.

The `GetItem` operation provides an eventually consistent read by default. If eventually consistent reads are not acceptable for your application, use `ConsistentRead`. Although this operation

might take longer than a standard read, it always returns the last updated value. For more information, see DynamoDB read consistency.

Requests

Syntax

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.GetItem
content-type: application/x-amz-json-1.0

{"TableName":"Table1",
  "Key":
  {"HashKeyElement": {"S":"AttributeValue1"},
  "RangeKeyElement": {"N":"AttributeValue2"}
 },
 "AttributesToGet":["AttributeName3","AttributeName4"],
 "ConsistentRead":Boolean
}
```

Name	Description	Required
`TableName`	The name of the table containing the requested item. Type: String	Yes
`Key`	The primary key values that define the item. For more information about primary keys, see Primary key. Type: Map of `HashKeyElement` to its value and `RangeKeyElement` to its value.	Yes

Name	Description	Required
AttributesToGet	Array of Attribute names. If attribute names are not specified then all attributes will be returned. If some attributes are not found, they will not appear in the result. Type: Array	No
ConsistentRead	If set to true, then a consistent read is issued, otherwise eventually consistent is used. Type: Boolean	No

Responses

Syntax

```
HTTP/1.1 200
x-amzn-RequestId: 8966d095-71e9-11e0-a498-71d736f27375
content-type: application/x-amz-json-1.0
content-length: 144

{"Item":{
 "AttributeName3":{"S":"AttributeValue3"},
 "AttributeName4":{"N":"AttributeValue4"},
 "AttributeName5":{"B":"dmFsdWU="}
 },
"ConsumedCapacityUnits": 0.5
}
```

Name	Description
Item	Contains the requested attributes.

Name	Description
	Type: Map of attribute name-value pairs.
`ConsumedCapacityUnits`	The number of read capacity units consumed by the operation. This value shows the number applied toward your provisioned throughput. Requests for non-existent items consume the minimum read capacity units, depending on the type of read. For more information see DynamoDB provisioned capacity mode. Type: Number

Special errors

No errors specific to this operation.

Examples

For examples using the AWS SDK, see Working with items and attributes in DynamoDB.

Sample request

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.GetItem
content-type: application/x-amz-json-1.0

{"TableName":"comptable",
 "Key":
  {"HashKeyElement":{"S":"Julie"},
  "RangeKeyElement":{"N":"1307654345"}},
 "AttributesToGet":["status","friends"],
 "ConsistentRead":true
}
```

Sample response

Notice the ConsumedCapacityUnits value is 1, because the optional parameter `ConsistentRead` is set to `true`. If `ConsistentRead` is set to `false` (or not specified) for the same request, the response is eventually consistent and the ConsumedCapacityUnits value would be 0.5.

```
HTTP/1.1 200
x-amzn-RequestId: 8966d095-71e9-11e0-a498-71d736f27375
content-type: application/x-amz-json-1.0
content-length: 72

{"Item":
 {"friends":{"SS":["Lynda, Aaron"]},
 "status":{"S":"online"}
 },
"ConsumedCapacityUnits": 1
}
```

ListTables

> **Important**
>
> ***This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.***
>
> **For documentation on the current low-level API, see the Amazon DynamoDB API Reference.**

Description

Returns an array of all the tables associated with the current account and endpoint.

Each DynamoDB endpoint is entirely independent. For example, if you have two tables called "MyTable," one in dynamodb.us-west-2.amazonaws.com and one in dynamodb.us-east-1.amazonaws.com, they are completely independent and do not share any data. The ListTables operation returns all of the table names associated with the account making the request, for the endpoint that receives the request.

Requests

Syntax

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.ListTables
content-type: application/x-amz-json-1.0

{"ExclusiveStartTableName":"Table1","Limit":3}
```

The ListTables operation, by default, requests all of the table names associated with the account making the request, for the endpoint that receives the request.

Name	Description	Required
`Limit`	A number of maximum table names to return. Type: Integer	No
`ExclusiveStartTableName`	The name of the table that starts the list. If you already ran a ListTables operation and received an `LastEvaluatedTableName` value in the response, use that value here to continue the list. Type: String	No

Responses

Syntax

```
HTTP/1.1 200 OK
x-amzn-RequestId: S1LEK2DPQP8OJNHVHL8OU2M7KRVV4KQNSO5AEMVJF66Q9ASUAAJG
content-type: application/x-amz-json-1.0
```

```
content-length: 81
Date: Fri, 21 Oct 2011 20:35:38 GMT

{"TableNames":["Table1","Table2","Table3"], "LastEvaluatedTableName":"Table3"}
```

Name	Description
`TableNames`	The names of the tables associated with the current account at the current endpoint. Type: Array
`LastEvaluatedTableName`	The name of the last table in the current list, only if some tables for the account and endpoint have not been returned. This value does not exist in a response if all table names are already returned. Use this value as the `ExclusiveStartTableName` in a new request to continue the list until all the table names are returned. Type: String

Special errors

No errors are specific to this operation.

Examples

The following examples show an HTTP POST request and response using the ListTables operation.

Sample request

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.ListTables
content-type: application/x-amz-json-1.0
```

```
{"ExclusiveStartTableName":"comp2","Limit":3}
```

Sample response

```
HTTP/1.1 200 OK
x-amzn-RequestId: S1LEK2DPQP8OJNHVHL8OU2M7KRVV4KQNSO5AEMVJF66Q9ASUAAJG
content-type: application/x-amz-json-1.0
content-length: 81
Date: Fri, 21 Oct 2011 20:35:38 GMT

{"LastEvaluatedTableName":"comp5","TableNames":["comp3","comp4","comp5"]}
```

PutItem

> **Important**
>
> ***This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.***
> **For documentation on the current low-level API, see the Amazon DynamoDB API Reference.**

Description

Creates a new item, or replaces an old item with a new item (including all the attributes). If an item already exists in the specified table with the same primary key, the new item completely replaces the existing item. You can perform a conditional put (insert a new item if one with the specified primary key doesn't exist), or replace an existing item if it has certain attribute values.

Attribute values may not be null; string and binary type attributes must have lengths greater than zero; and set type attributes must not be empty. Requests with empty values will be rejected with a `ValidationException`.

> **Note**
>
> To ensure that a new item does not replace an existing item, use a conditional put operation with `Exists` set to `false` for the primary key attribute, or attributes.

For more information about using `PutItem`, see Working with items and attributes in DynamoDB.

Requests

Syntax

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.PutItem
content-type: application/x-amz-json-1.0

{"TableName":"Table1",
    "Item":{
        "AttributeName1":{"S":"AttributeValue1"},
        "AttributeName2":{"N":"AttributeValue2"},
        "AttributeName5":{"B":"dmFsdWU="}
    },
    "Expected":{"AttributeName3":{"Value": {"S":"AttributeValue"}, "Exists":Boolean}},
    "ReturnValues":"ReturnValuesConstant"}
```

Name	Description	Required
`TableName`	The name of the table to contain the item. Type: String	Yes
`Item`	A map of the attributes for the item, and must include the primary key values that define the item. Other attribute name-value pairs can be provided for the item.	Yes

Name	Description	Required
	For more information about primary keys, see Primary key. Type: Map of attribute names to attribute values.	
`Expected`	Designates an attribute for a conditional put. The `Expected` parameter allows you to provide an attribute name, and whether or not DynamoDB should check to see if the attribute value already exists; or if the attribute value exists and has a particular value before changing it. Type: Map of an attribute names to an attribute value, and whether it exists.	No
`Expected:AttributeName`	The name of the attribute for the conditional put. Type: String	No

Name	Description	Required

`Expected:AttributeName: ExpectedAttributeValue`	Use this parameter to specify whether or not a value already exists for the attribute name-value pair.
	
	The following JSON notation replaces the item if the "Color" attribute doesn't already exist for that item:
	
	`"Expected" : {"Color":{"Exists":false}}`
	
	The following JSON notation checks to see if the attribute with name "Color" has an existing value of "Yellow" before replacing the item:
	
	`"Expected" : {"Color":{"Exists":true,{"Value":{"S":"Yellow"}}}}`
	
	By default, if you use the `Expected` parameter and provide a `Value`, DynamoDB assumes the attribute exists and has a current value to be replaced. So you don't have to specify `{"Exists":true}`, because it is implied. You can shorten the request to:
	
	`"Expected" :`
		No

Name	Description	Required
	`{"Color":{"Value":{"S":"Yellow"}}}` **Note** If you specify `{"Exists":true}` without an attribute value to check, DynamoDB returns an error.	
`ReturnValues`	Use this parameter if you want to get the attribute name-value pairs before they were updated with the `PutItem` request. Possible parameter values are `NONE` (default) or `ALL_OLD`. If `ALL_OLD` is specified, and `PutItem` overwrote an attribute name-value pair, the content of the old item is returned. If this parameter is not provided or is `NONE`, nothing is returned. Type: String	No

Responses

Syntax

The following syntax example assumes the request specified a `ReturnValues` parameter of `ALL_OLD`; otherwise, the response has only the `ConsumedCapacityUnits` element.

```
HTTP/1.1 200
x-amzn-RequestId: 8966d095-71e9-11e0-a498-71d736f27375
content-type: application/x-amz-json-1.0
content-length: 85

{"Attributes":
 {"AttributeName3":{"S":"AttributeValue3"},
 "AttributeName2":{"SS":"AttributeValue2"},
 "AttributeName1":{"SS":"AttributeValue1"},
 },
"ConsumedCapacityUnits":1
}
```

Name	Description
`Attributes`	Attribute values before the put operation, but only if the `ReturnValues` parameter is specified as `ALL_OLD` in the request. Type: Map of attribute name-value pairs.
`ConsumedCapacityUnits`	The number of write capacity units consumed by the operation. This value shows the number applied toward your provision ed throughput. For more information see DynamoDB provisioned capacity mode. Type: Number

Special errors

Error	Description
`ConditionalCheckFailedException`	Conditional check failed. An expected attribute value was not found.
`ResourceNotFoundException`	The specified item or attribute was not found.

Examples

For examples using the AWS SDK, see Working with items and attributes in DynamoDB.

Sample request

```
// This header is abbreviated. For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.PutItem
content-type: application/x-amz-json-1.0

{"TableName":"comp5",
 "Item":
  {"time":{"N":"300"},
  "feeling":{"S":"not surprised"},
  "user":{"S":"Riley"}
  },
 "Expected":
  {"feeling":{"Value":{"S":"surprised"},"Exists":true}}
 "ReturnValues":"ALL_OLD"
}
```

Sample response

```
HTTP/1.1 200
x-amzn-RequestId: 8952fa74-71e9-11e0-a498-71d736f27375
content-type: application/x-amz-json-1.0
content-length: 84

{"Attributes":
 {"feeling":{"S":"surprised"},
 "time":{"N":"300"},
 "user":{"S":"Riley"}},
"ConsumedCapacityUnits":1
}
```

Query

> **Important**
>
> ***This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.***
> **For documentation on the current low-level API, see the Amazon DynamoDB API Reference.**

Description

A `Query` operation gets the values of one or more items and their attributes by primary key (`Query` is only available for hash-and-range primary key tables). You must provide a specific `HashKeyValue`, and can narrow the scope of the query using comparison operators on the `RangeKeyValue` of the primary key. Use the `ScanIndexForward` parameter to get results in forward or reverse order by range key.

Queries that do not return results consume the minimum read capacity units according to the type of read.

> **Note**
>
> If the total number of items meeting the query parameters exceeds the 1MB limit, the query stops and results are returned to the user with a `LastEvaluatedKey` to continue the query in a subsequent operation. Unlike a Scan operation, a Query operation never returns an empty result set *and* a `LastEvaluatedKey`. The `LastEvaluatedKey` is only provided if the results exceed 1MB, or if you have used the `Limit` parameter.
> The result can be set for a consistent read using the `ConsistentRead` parameter.

Requests

Syntax

```
// This header is abbreviated.
```

```
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.Query
content-type: application/x-amz-json-1.0

{"TableName":"Table1",
 "Limit":2,
 "ConsistentRead":true,
 "HashKeyValue":{"S":"AttributeValue1":},
 "RangeKeyCondition": {"AttributeValueList":
[{"N":"AttributeValue2"}],"ComparisonOperator":"GT"}
 "ScanIndexForward":true,
 "ExclusiveStartKey":{
  "HashKeyElement":{"S":"AttributeName1"},
  "RangeKeyElement":{"N":"AttributeName2"}
 },
    "AttributesToGet":["AttributeName1", "AttributeName2", "AttributeName3"]},
}
```

Name	Description	Required
TableName	The name of the table containing the requested items. Type: String	Yes
AttributesToGet	Array of Attribute names. If attribute names are not specified then all attributes will be returned. If some attributes are not found, they will not appear in the result. Type: Array	No
Limit	The maximum number of items to return (not necessarily the number of matching items). If Dynamo	No

Name	Description	Required
	DB processes the number of items up to the limit while querying the table, it stops the query and returns the matching values up to that point, and a `LastEvaluatedKey` to apply in a subsequent operation to continue the query. Also, if the result set size exceeds 1MB before DynamoDB hits this limit, it stops the query and returns the matching values, and a `LastEvaluatedKey` to apply in a subsequent operation to continue the query. Type: Number	
`ConsistentRead`	If set to `true`, then a consistent read is issued, otherwise eventually consistent is used. Type: Boolean	No

Name	Description	Required
`Count`	If set to `true`, DynamoDB returns a total number of items that match the query parameters, instead of a list of the matching items and their attributes. You can apply the `Limit` parameter to count-only queries. Do not set `Count` to `true` while providing a list of `AttributesToGet` ; otherwise, DynamoDB returns a validation error. For more information, see Counting the items in the results. Type: Boolean	No
`HashKeyValue`	Attribute value of the hash component of the composite primary key. Type: String, Number, or Binary	Yes

Name	Description	Required
RangeKeyCondition	A container for the attribute values and comparison operators to use for the query. A query request does not require a RangeKeyCondition. If you provide only the HashKeyValue, DynamoDB returns all items with the specified hash key element value. Type: Map	No
RangeKeyCondition : AttributeValueList	The attribute values to evaluate for the query parameters. The AttributeValueList contains one attribute value, unless a BETWEEN comparison is specified. For the BETWEEN comparison, the AttributeValueList contains two attribute values. Type: A map of AttributeValue to a ComparisonOperator.	No

Name	Description	Required
`RangeKeyCondition : ComparisonOperator`	The criteria for evaluating the provided attributes, such as equals, greater-than, etc. The following are valid comparison operators for a Query operation. **Note** String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, a is greater than A, and aa is greater than B. For a list of code values, see http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters. For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values, for example when evaluating query expressions. Type: String or Binary	No

Name	Description	Required
	EQ : Equal. For EQ, `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set). If an item contains an `AttributeValue` of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}` . Also, `{"N":"6"}` does not equal `{"NS":["6", "2", "1"]}`.	
	LE : Less than or equal. For LE, `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set). If an item contains an `AttributeValue` of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}` . Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.	

Name	Description	Required
	LT : Less than. For LT, `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set). If an item contains an `AttributeValue` of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.	
	GE : Greater than or equal. For GE, `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set). If an item contains an `AttributeValue` of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.	

Name	Description	Required
	GT : Greater than. For GT, `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set). If an item contains an `AttributeValue` of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}` . Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.	
	`BEGINS_WITH` : checks for a prefix. For `BEGINS_WITH` , `AttributeValueList` can contain only one `AttributeValue` of type String or Binary (not a Number or a set). The target attribute of the comparison must be a String or Binary (not a Number or a set).	

Name	Description	Required
	BETWEEN : Greater than, or equal to, the first value and less than, or equal to, the second value. For BETWEEN, AttributeValueList must contain two AttributeValue elements of the same type, either String, Number, or Binary (not a set). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an AttributeValue of a different type than the one specified in the request, the value does not match. For example, {"S":"6"} does not compare to {"N":"6"} . Also, {"N":"6"} does not compare to {"NS":["6", "2", "1"]}.	

Name	Description	Required
ScanIndexForward	Specifies ascending or descending traversal of the index. DynamoDB returns results reflecting the requested order determined by the range key: If the data type is Number, the results are returned in numeric order; otherwise, the traversal is based on ASCII character code values. Type: Boolean Default is true (ascending).	No
ExclusiveStartKey	Primary key of the item from which to continue an earlier query. An earlier query might provide this value as the LastEvaluatedKey if that query operation was interrupted before completing the query; either because of the result set size or the Limit parameter. The LastEvaluatedKey can be passed back in a new query request to continue the operation from that point. Type: HashKeyElement, or HashKeyElement and RangeKeyElement for a composite primary key.	No

Responses

Syntax

```
HTTP/1.1 200
x-amzn-RequestId: 8966d095-71e9-11e0-a498-71d736f27375
content-type: application/x-amz-json-1.0
content-length: 308

{"Count":2,"Items":[{
    "AttributeName1":{"S":"AttributeValue1"},
    "AttributeName2":{"N":"AttributeValue2"},
    "AttributeName3":{"S":"AttributeValue3"}
    },{
    "AttributeName1":{"S":"AttributeValue3"},
    "AttributeName2":{"N":"AttributeValue4"},
    "AttributeName3":{"S":"AttributeValue3"},
    "AttributeName5":{"B":"dmFsdWU="}
}],
    "LastEvaluatedKey":{"HashKeyElement":{"AttributeValue3":"S"},
                        "RangeKeyElement":{"AttributeValue4":"N"}
     },
     "ConsumedCapacityUnits":1
}
```

Name	Description
`Items`	Item attributes meeting the query parameters. Type: Map of attribute names to and their data types and values.
`Count`	Number of items in the response. For more information, see Counting the items in the results. Type: Number
`LastEvaluatedKey`	Primary key of the item where the query operation stopped, inclusive of the previous result set. Use this value to start a new

Name	Description
	operation excluding this value in the new request. The `LastEvaluatedKey` is `null` when the entire query result set is complete (i.e. the operation processed the "last page"). Type: `HashKeyElement`, or `HashKeyElement` and `RangeKeyElement` for a composite primary key.
`ConsumedCapacityUnits`	The number of read capacity units consumed by the operation. This value shows the number applied toward your provisioned throughput. For more information see DynamoDB provisioned capacity mode. Type: Number

Special errors

Error	Description
`ResourceNotFoundException`	The specified table was not found.

Examples

For examples using the AWS SDK, see Querying tables in DynamoDB.

Sample request

```
// This header is abbreviated. For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.Query
content-type: application/x-amz-json-1.0
```

```
{"TableName":"1-hash-rangetable",
 "Limit":2,
 "HashKeyValue":{"S":"John"},
 "ScanIndexForward":false,
 "ExclusiveStartKey":{
  "HashKeyElement":{"S":"John"},
  "RangeKeyElement":{"S":"The Matrix"}
 }
}
```

Sample response

```
HTTP/1.1 200

- Scan

Scan

> **Important**
>
> ***This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.***
>
> **For documentation on the current low-level API, see the Amazon DynamoDB API Reference.**

Description

The `Scan` operation returns one or more items and its attributes by performing a full scan of a table. Provide a `ScanFilter` to get more specific results.

Note

If the total number of scanned items exceeds the 1MB limit, the scan stops and results are returned to the user with a `LastEvaluatedKey` to continue the scan in a subsequent operation. The results also include the number of items exceeding the limit. A scan can result in no table data meeting the filter criteria.
The result set is eventually consistent.

Requests

Syntax

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.Scan
content-type: application/x-amz-json-1.0

{"TableName":"Table1",
    "Limit": 2,
    "ScanFilter":{
        "AttributeName1":{"AttributeValueList":
[{"S":"AttributeValue"}],"ComparisonOperator":"EQ"}
    },
    "ExclusiveStartKey":{
        "HashKeyElement":{"S":"AttributeName1"},
        "RangeKeyElement":{"N":"AttributeName2"}
    },
    "AttributesToGet":["AttributeName1", "AttributeName2", "AttributeName3"]},
}
```

Name	Description	Required
`TableName`	The name of the table containing the requested items. Type: String	Yes

Name	Description	Required
`AttributesToGet`	Array of Attribute names. If attribute names are not specified then all attributes will be returned. If some attributes are not found, they will not appear in the result. Type: Array	No
`Limit`	The maximum number of items to evaluate (not necessarily the number of matching items). If DynamoDB processes the number of items up to the limit while processing the results, it stops and returns the matching values up to that point, and a `LastEvaluatedKey` to apply in a subsequent operation to continue retrieving items. Also, if the scanned data set size exceeds 1MB before DynamoDB reaches this limit, it stops the scan and returns the matching values up to the limit, and a `LastEvaluatedKey` to apply in a subsequent operation to continue the scan. Type: Number	No

Name	Description	Required
`Count`	If set to `true`, DynamoDB returns a total number of items for the Scan operation, even if the operation has no matching items for the assig ned filter. You can apply the Limit parameter to count-onl y scans. Do not set `Count` to `true` while providing a list of `AttributesToGet` , otherwise DynamoDB returns a validation error. For more information, see Counting the items in the results. Type: Boolean	No
`ScanFilter`	Evaluates the scan results and returns only the desired values. Multiple condition s are treated as "AND" operations: all conditions must be met to be included in the results. Type: A map of attribute names to values with comparison operators.	No

Name	Description	Required
`ScanFilter :AttributeValueList`	The values and conditions to evaluate the scan results for the filter. Type: A map of `AttributeValue` to a `Condition` .	No

Name	Description	Required
`ScanFilter : ComparisonOperator`	The criteria for evaluating the provided attributes, such as equals, greater-than, etc. The following are valid comparison operators for a scan operation. **Note** String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, a is greater than A, and aa is greater than B. For a list of code values, see http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters. For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values, for example when evaluating query expressions. Type: String or Binary	No

Name	Description	Required
	EQ : Equal. For EQ, `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set). If an item contains an `AttributeValue` of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS":["6", "2", "1"]}`.	
	NE : Not Equal. For NE, `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set). If an item contains an `AttributeValue` of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS":["6", "2", "1"]}`.	

Name	Description	Required
	LE : Less than or equal. For LE, `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set). If an item contains an `AttributeValue` of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}` . Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.	
	LT : Less than. For LT, `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set). If an item contains an `AttributeValue` of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}` . Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.	

Name	Description	Required
	GE : Greater than or equal. For GE, `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set). If an item contains an `AttributeValue` of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.	
	GT : Greater than. For GT, `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set). If an item contains an `AttributeValue` of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.	

Name	Description	Required
	NOT_NULL : Attribute exists.	
	NULL : Attribute does not exist.	
	CONTAINS : checks for a subsequence, or value in a set. For CONTAINS, AttributeValueList can contain only one AttributeValue of type String, Number, or Binary (not a set). If the target attribute of the comparison is a String, then the operation checks for a substring match. If the target attribute of the comparison is Binary, then the operation looks for a subsequence of the target th at matches the input. If the target attribute of the compa rison is a set ("SS", "NS", or "BS"), then the operation checks for a member of the set (not as a substring).	

Name	Description	Required
	`NOT_CONTAINS` : checks for absence of a subsequence, or absence of a value in a set. For `NOT_CONTAINS` , `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set). If the target attribute of the comparison is a String, then the operation checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operation checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operation checks for the absence of a member of the set (not as a substring).	

Name	Description	Required
	BEGINS_WITH : checks for a prefix. For BEGINS_WITH , AttributeValueList can contain only one AttributeValue of type String or Binary (not a Number or a set). The target attribute of the comparison must be a String or Binary (not a Number or a set).	
	IN : checks for exact matches. For IN, AttributeValueList can contain more than one AttributeValue of type String, Number, or Binary (not a set). The target attribute of the comparison must be of the same type and exact value to match. A String never matches a String set.	

Name	Description	Required
	BETWEEN : Greater than, or equal to, the first value and less than, or equal to, the second value. For BETWEEN, AttributeValueList must contain two AttributeValue elements of the same type, either String, Number, or Binary (not a set). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an AttributeValue of a different type than the one specified in the request, the value does not match. For example, {"S":"6"} does not compare to {"N":"6"} . Also, {"N":"6"} does not compare to {"NS":["6", "2", "1"]}.	

Name	Description	Required
ExclusiveStartKey	Primary key of the item from which to continue an earlier scan. An earlier scan might provide this value if that scan operation was interrupted before scanning the entire table; either because of the result set size or the Limit parameter. The LastEvaluatedKey can be passed back in a new scan request to continue the operation from that point. Type: HashKeyElement , or HashKeyElement and RangeKeyElement for a composite primary key.	No

Responses

Syntax

```
HTTP/1.1 200
x-amzn-RequestId: 8966d095-71e9-11e0-a498-71d736f27375
content-type: application/x-amz-json-1.0
content-length: 229

{"Count":2,"Items":[{
    "AttributeName1":{"S":"AttributeValue1"},
    "AttributeName2":{"S":"AttributeValue2"},
    "AttributeName3":{"S":"AttributeValue3"}
    },{
    "AttributeName1":{"S":"AttributeValue4"},
    "AttributeName2":{"S":"AttributeValue5"},
    "AttributeName3":{"S":"AttributeValue6"},
    "AttributeName5":{"B":"dmFsdWU="}
```

```
    }],
    "LastEvaluatedKey":
        {"HashKeyElement":{"S":"AttributeName1"},
        "RangeKeyElement":{"N":"AttributeName2"},
    "ConsumedCapacityUnits":1,
    "ScannedCount":2}
}
```

Name	Description
`Items`	Container for the attributes meeting the operation parameters. Type: Map of attribute names to and their data types and values.
`Count`	Number of items in the response. For more information, see Counting the items in the results. Type: Number
`ScannedCount`	Number of items in the complete scan before any filters are applied. A high `ScannedCount` value with few, or no, `Count` results indicates an inefficient `Scan` operation. For more information, see Counting the items in the results. Type: Number
`LastEvaluatedKey`	Primary key of the item where the scan operation stopped. Provide this value in a subsequent scan operation to continue the operation from that point. The `LastEvaluatedKey` is `null` when the entire scan result set is complete (i.e. the operation processed the “last page”).

Name	Description
ConsumedCapacityUnits	The number of read capacity units consumed by the operation. This value shows the number applied toward your provision ed throughput. For more information see DynamoDB provisioned capacity mode. Type: Number

Special errors

Error	Description
ResourceNotFoundException	The specified table was not found.

Examples

For examples using the AWS SDK, see Scanning tables in DynamoDB.

UpdateItem

> **Important**
>
> ***This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.***
>
> **For documentation on the current low-level API, see the Amazon DynamoDB API Reference.**

Description

Edits an existing item's attributes. You can perform a conditional update (insert a new attribute name-value pair if it doesn't exist, or replace an existing name-value pair if it has certain expected attribute values).

> **Note**
>
> You cannot update the primary key attributes using UpdateItem. Instead, delete the item and use PutItem to create a new item with new attributes.

The UpdateItem operation includes an `Action` parameter, which defines how to perform the update. You can put, delete, or add attribute values.

Attribute values may not be null; string and binary type attributes must have lengths greater than zero; and set type attributes must not be empty. Requests with empty values will be rejected with a `ValidationException`.

If an existing item has the specified primary key:

- **PUT—** Adds the specified attribute. If the attribute exists, it is replaced by the new value.
- **DELETE—** If no value is specified, this removes the attribute and its value. If a set of values is specified, then the values in the specified set are removed from the old set. So if the attribute value contains [a,b,c] and the delete action contains [a,c], then the final attribute value is [b]. The type of the specified value must match the existing value type. Specifying an empty set is not valid.
- **ADD—** Only use the add action for numbers or if the target attribute is a set (including string sets). ADD does not work if the target attribute is a single string value or a scalar binary value. The specified value is added to a numeric value (incrementing or decrementing the existing numeric value) or added as an additional value in a string set. If a set of values is specified, the values are added to the existing set. For example if the original set is [1,2] and supplied value is [3], then after the add operation the set is [1,2,3], not [4,5]. An error occurs if an Add action is specified for a set attribute and the attribute type specified does not match the existing set type.

  If you use ADD for an attribute that does not exist, the attribute and its values are added to the item.

If no item matches the specified primary key:

- **PUT—** Creates a new item with specified primary key. Then adds the specified attribute.
- **DELETE—** Nothing happens.

- **ADD—** Creates an item with supplied primary key and number (or set of numbers) for the attribute value. Not valid for a string or a binary type.

> **Note**
>
> If you use ADD to increment or decrement a number value for an item that doesn't exist before the update, DynamoDB uses `0` as the initial value. Also, if you update an item using ADD to increment or decrement a number value for an attribute that doesn't exist before the update (but the item does) DynamoDB uses `0` as the initial value. For example, you use ADD to add `+3` to an attribute that did not exist before the update. DynamoDB uses `0` for the initial value, and the value after the update is `3`.

For more information about using this operation, see Working with items and attributes in DynamoDB.

Requests

Syntax

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.UpdateItem
content-type: application/x-amz-json-1.0

{"TableName":"Table1",
    "Key":
        {"HashKeyElement":{"S":"AttributeValue1"},
        "RangeKeyElement":{"N":"AttributeValue2"}},
    "AttributeUpdates":{"AttributeName3":{"Value":
{"S":"AttributeValue3_New"},"Action":"PUT"}},
    "Expected":{"AttributeName3":{"Value":{"S":"AttributeValue3_Current"}}},
    "ReturnValues":"ReturnValuesConstant"
}
```

Name	Description	Required
`TableName`	The name of the table containing the item to update. Type: String	Yes
`Key`	The primary key that defines the item. For more informati on about primary keys, see Primary key. Type: Map of `HashKeyEl ement` to its value and `RangeKeyElement` to its value.	Yes
`AttributeUpdates`	Map of attribute name to the new value and action for the update. The attribute names specify the attributes to modify, and cannot contain any primary key attributes. Type: Map of attribute name, value, and an action for the attribute update.	
`Attribute Updates :Action`	Specifies how to perform the update. Possible values: `PUT` (default), `ADD` or `DELETE`. The semantics are explained in the UpdateItem descripti on. Type: String	No

Name	Description	Required
	Default: PUT	
`Expected`	Designates an attribute for a conditional update. The `Expected` parameter allows you to provide an attribute name, and whether or not DynamoDB should check to see if the attribute value already exists; or if the attribute value exists and has a particular value before changing it. Type: Map of attribute names.	No
`Expected:AttributeName`	The name of the attribute for the conditional put. Type: String	No

Name	Description	Required

`Expected:AttributeName: ExpectedAttributeValue`	Use this parameter to specify whether or not a value already exists for the attribute name-value pair.
	
	The following JSON notation updates the item if the "Color" attribute doesn't already exist for that item:
	
	`"Expected" : {"Color":{"Exists":false}}`
	
	The following JSON notation checks to see if the attribute with name "Color" has an existing value of "Yellow" before updating the item:
	
	`"Expected" : {"Color":{"Exists":true},{"Value":{"S":"Yellow"}}}`
	
	By default, if you use the `Expected` parameter and provide a `Value`, DynamoDB assumes the attribute exists and has a current value to be replaced. So you don't have to specify `{"Exists":true}`, because it is implied. You can shorten the request to:
	
	`"Expected" :`
		No

Name	Description	Required
	`{"Color":{"Value":{"S":"Yellow"}}}` **Note** If you specify `{"Exists":true}` without an attribute value to check, DynamoDB returns an error.	

Name	Description	Required
ReturnValues	Use this parameter if you want to get the attribute name-value pairs before they were updated with the UpdateItem request. Possible parameter values are NONE (default) or ALL_OLD, UPDATED_OLD , ALL_NEW or UPDATED_NEW . If ALL_OLD is specified, and UpdateItem overwrote an attribute name-value pair, the content of the old item is returned. If this parame ter is not provided or is NONE, nothing is returned . If ALL_NEW is specified, then all the attributes of the new version of the item are returned. If UPDATED_NEW is specified, then the new versions of only the updated attributes are returned. Type: String	No

Responses

Syntax

The following syntax example assumes the request specified a ReturnValues parameter of ALL_OLD; otherwise, the response has only the ConsumedCapacityUnits element.

```
HTTP/1.1 200
x-amzn-RequestId: 8966d095-71e9-11e0-a498-71d736f27375
```

```
content-type: application/x-amz-json-1.0
content-length: 140

{"Attributes":{
 "AttributeName1":{"S":"AttributeValue1"},
 "AttributeName2":{"S":"AttributeValue2"},
 "AttributeName3":{"S":"AttributeValue3"},
 "AttributeName5":{"B":"dmFsdWU="}
 },
"ConsumedCapacityUnits":1
}
```

Name	Description
`Attributes`	A map of attribute name-value pairs, but only if the `ReturnValues` parameter is specified as something other than `NONE` in the request. Type: Map of attribute name-value pairs.
`ConsumedCapacityUnits`	The number of write capacity units consumed by the operation. This value shows the number applied toward your provision ed throughput. For more information see DynamoDB provisioned capacity mode. Type: Number

Special errors

Error	Description
`ConditionalCheckFailedException`	Conditional check failed. Attribute ("+ name +") value is ("+ value +") but was expected ("+ expValue +")
`ResourceNotFoundExceptions`	The specified item or attribute was not found.

Examples

For examples using the AWS SDK, see Working with items and attributes in DynamoDB.

UpdateTable

> **Important**
>
> ***This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.***
>
> **For documentation on the current low-level API, see the Amazon DynamoDB API Reference.**

Description

Updates the provisioned throughput for the given table. Setting the throughput for a table helps you manage performance and is part of the provisioned throughput feature of DynamoDB. For more information, see DynamoDB provisioned capacity mode.

The provisioned throughput values can be upgraded or downgraded based on the maximums and minimums listed in Quotas in Amazon DynamoDB.

The table must be in the `ACTIVE` state for this operation to succeed. UpdateTable is an asynchronous operation; while executing the operation, the table is in the `UPDATING` state. While the table is in the `UPDATING` state, the table still has the provisioned throughput from before the call. The new provisioned throughput setting is in effect only when the table returns to the `ACTIVE` state after the UpdateTable operation.

Requests

Syntax

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.UpdateTable
content-type: application/x-amz-json-1.0

{"TableName":"Table1",
    "ProvisionedThroughput":{"ReadCapacityUnits":5,"WriteCapacityUnits":15}
}
```

Name	Description	Required
`TableName`	The name of the table to update. Type: String	Yes
`ProvisionedThroughput`	New throughput for the specified table, consisting of values for `ReadCapacityUnits` and `WriteCapacityUnits`. See DynamoDB provisioned capacity mode. Type: Array	Yes
`ProvisionedThroughput:ReadCapacityUnits`	Sets the minimum number of consistent `ReadCapacityUnits` consumed per second for the specified table before DynamoDB balances the load with other operations. Eventually consistent read operations require less effort than a consistent read operation, so a setting of 50 consistent `ReadCapacityUnits` per second provides 100 eventually consistent `ReadCapacityUnits` per second. Type: Number	Yes

Name	Description	Required
`ProvisionedThroughput :WriteCapacityUnits`	Sets the minimum number of `WriteCapacityUnits` consumed per second for the specified table before DynamoDB balances the load with other operations. Type: Number	Yes

Responses

Syntax

```
HTTP/1.1 200 OK
x-amzn-RequestId: CSOC7TJPLR0OOKIRLGOHVAICUFVV4KQNSO5AEMVJF66Q9ASUAAJG
Content-Type: application/json

    "TableStatus":"UPDATING"}}
```

Name	Description
`CreationDateTime`	Date when the table was created.

Name	Description
	Type: Number
KeySchema	The primary key (simple or composite) structure for the table. A name-value pair for the HashKeyElement is required, and a name-value pair for the RangeKeyElement is optional (only required for composite primary keys). The maximum hash key size is 2048 bytes. The maximum range key size is 1024 bytes. Both limits are enforced separatel y (i.e. you can have a combined hash + range 2048 + 1024 key). For more information about primary keys, see Primary key. Type: Map of HashKeyElement , or HashKeyElement and RangeKeyElement for a composite primary key.
ProvisionedThroughput	Current throughput settings for the specified table, including values for LastIncre aseDateTime (if applicable), LastDecre aseDateTime (if applicable), Type: Array
TableName	The name of the updated table. Type: String
TableStatus	The current state of the table (CREATING, ACTIVE, DELETING or UPDATING), which should be UPDATING. Use the DescribeTables operationto check the status of the table. Type: String

Special errors

Error	Description
ResourceNotFoundException	The specified table was not found.
ResourceInUseException	The table is not in the ACTIVE state.

Legacy DynamoDB conditional parameters

This document provides an overview of legacy conditional parameters in DynamoDB and recommends using the new expression parameters instead. It covers details on parameters like AttributesToGet, AttributeUpdates, ConditionalOperator, Expected, KeyConditions, QueryFilter, and ScanFilter, and provides examples of how to use the new expression parameters as replacements.

> **Important**
>
> We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see Using expressions in DynamoDB. Additionally, DynamoDB does not allow mixing legacy conditional parameters and expression parameters in a single call. For example, calling the `Query` operation with `AttributesToGet` and `ConditionExpression` will result in an error.

The following table shows the DynamoDB API operations that still support these legacy parameters, and which expression parameter to use instead. This table can be helpful if you are considering updating your applications so that they use expression parameters instead.

If you use this API operation ...	With these legacy parameters...	Use this expression parameter instead
`BatchGetItem`	`AttributesToGet`	`ProjectionExpression`
`DeleteItem`	`Expected`	`ConditionExpression`
`GetItem`	`AttributesToGet`	`ProjectionExpression`

If you use this API operation ...	With these legacy parameters...	Use this expression parameter instead
PutItem	Expected	ConditionExpression
Query	AttributesToGet	ProjectionExpression
	KeyConditions	KeyConditionExpression
	QueryFilter	FilterExpression
Scan	AttributesToGet	ProjectionExpression
	ScanFilter	FilterExpression
UpdateItem	AttributeUpdates	UpdateExpression
	Expected	ConditionExpression

The following sections provide more information about legacy conditional parameters.

Topics

- AttributesToGet (legacy)
- AttributeUpdates (legacy)
- ConditionalOperator (legacy)
- Expected (legacy)
- KeyConditions (legacy)
- QueryFilter (legacy)
- ScanFilter (legacy)
- Writing conditions with legacy parameters

AttributesToGet (legacy)

> **Note**
>
> We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see Using expressions in DynamoDB. For specific information on the new parameter replacing this one, Use *ProjectionExpression* instead.

The legacy conditional parameter `AttributesToGet` is an array of one or more attributes to retrieve from DynamoDB. If no attribute names are provided, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result.

`AttributesToGet` allows you to retrieve attributes of type List or Map; however, it cannot retrieve individual elements within a List or a Map.

Note that `AttributesToGet` has no effect on provisioned throughput consumption. DynamoDB determines capacity units consumed based on item size, not on the amount of data that is returned to an application.

Use *ProjectionExpression* instead – Example

Suppose you wanted to retrieve an item from the *Music* table, but that you only wanted to return some of the attributes. You could use a `GetItem` request with an `AttributesToGet` parameter, as in this AWS CLI example:

```
aws dynamodb get-item \
    --table-name Music \
    --attributes-to-get '["Artist", "Genre"]' \
    --key '{
        "Artist": {"S":"No One You Know"},
        "SongTitle": {"S":"Call Me Today"}
    }'
```

You can use a `ProjectionExpression` instead:

```
aws dynamodb get-item \
    --table-name Music \
    --projection-expression "Artist, Genre" \
```

```
    --key '{
        "Artist": {"S":"No One You Know"},
        "SongTitle": {"S":"Call Me Today"}
    }'
```

AttributeUpdates (legacy)

> **Note**
>
> We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see Using expressions in DynamoDB. For specific information on the new parameter replacing this one, use *UpdateExpression* instead..

In an `UpdateItem` operation, the legacy conditional parameter `AttributeUpdates` contains the names of attributes to be modified, the action to perform on each, and the new value for each. If you are updating an attribute that is an index key attribute for any indexes on that table, the attribute type must match the index key type defined in the `AttributesDefinition` of the table description. You can use `UpdateItem` to update any non-key attributes.

Attribute values cannot be null. String and Binary type attributes must have lengths greater than zero. Set type attributes must not be empty. Requests with empty values will be rejected with a `ValidationException` exception.

Each `AttributeUpdates` element consists of an attribute name to modify, along with the following:

- `Value` - The new value, if applicable, for this attribute.
- `Action` - A value that specifies how to perform the update. This action is only valid for an existing attribute whose data type is Number or is a set; do not use ADD for other data types.

  If an item with the specified primary key is found in the table, the following values perform the following actions:

  - PUT - Adds the specified attribute to the item. If the attribute already exists, it is replaced by the new value.
  - `DELETE` - Removes the attribute and its value, if no value is specified for `DELETE`. The data type of the specified value must match the existing value's data type.

If a set of values is specified, then those values are subtracted from the old set. For example, if the attribute value was the set `[a,b,c]` and the `DELETE` action specifies `[a,c]`, then the final attribute value is `[b]`. Specifying an empty set is an error.

- `ADD` - Adds the specified value to the item, if the attribute does not already exist. If the attribute does exist, then the behavior of `ADD` depends on the data type of the attribute:
  - If the existing attribute is a number, and if `Value` is also a number, then `Value` is mathematically added to the existing attribute. If `Value` is a negative number, then it is subtracted from the existing attribute.

    > **Note**
    >
    > If you use `ADD` to increment or decrement a number value for an item that doesn't exist before the update, DynamoDB uses 0 as the initial value.
    > Similarly, if you use `ADD` for an existing item to increment or decrement an attribute value that doesn't exist before the update, DynamoDB uses `0` as the initial value. For example, suppose that the item you want to update doesn't have an attribute named *itemcount*, but you decide to `ADD` the number `3` to this attribute anyway. DynamoDB will create the *itemcount* attribute, set its initial value to `0`, and finally add `3` to it. The result will be a new *itemcount* attribute, with a value of `3`.

  - If the existing data type is a set, and if `Value` is also a set, then `Value` is appended to the existing set. For example, if the attribute value is the set `[1,2]`, and the `ADD` action specified `[3]`, then the final attribute value is `[1,2,3]`. An error occurs if an `ADD` action is specified for a set attribute and the attribute type specified does not match the existing set type.

    Both sets must have the same primitive data type. For example, if the existing data type is a set of strings, `Value` must also be a set of strings.

If no item with the specified key is found in the table, the following values perform the following actions:

- `PUT` - Causes DynamoDB to create a new item with the specified primary key, and then adds the attribute.
- `DELETE` - Nothing happens, because attributes cannot be deleted from a nonexistent item. The operation succeeds, but DynamoDB does not create a new item.
- `ADD` - Causes DynamoDB to create an item with the supplied primary key and number (or set of numbers) for the attribute value. The only data types allowed are Number and Number Set.

If you provide any attributes that are part of an index key, then the data types for those attributes must match those of the schema in the table's attribute definition.

Use *UpdateExpression* instead – Example

Suppose you wanted to modify an item in the *Music* table. You could use an `UpdateItem` request with an `AttributeUpdates` parameter, as in this AWS CLI example:

```
aws dynamodb update-item \
    --table-name Music \
    --key '{
        "SongTitle": {"S":"Call Me Today"},
        "Artist": {"S":"No One You Know"}
    }' \
    --attribute-updates '{
        "Genre": {
            "Action": "PUT",
            "Value": {"S":"Rock"}
        }
    }'
```

You can use a `UpdateExpression` instead:

```
aws dynamodb update-item \
    --table-name Music \
    --key '{
        "SongTitle": {"S":"Call Me Today"},
        "Artist": {"S":"No One You Know"}
    }' \
    --update-expression 'SET Genre = :g' \
    --expression-attribute-values '{
        ":g": {"S":"Rock"}
    }'
```

ConditionalOperator (legacy)

> **Note**
>
> We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see Using expressions in DynamoDB.

The legacy conditional parameter `ConditionalOperator` is a logical operator used to apply to the conditions in a `Expected`, `QueryFilter` or `ScanFilter` map:

- AND - If all of the conditions evaluate to true, then the entire map evaluates to true.
- OR - If at least one of the conditions evaluates to true, then the entire map evaluates to true.

If you omit `ConditionalOperator`, then `AND` is the default.

The operation will succeed only if the entire map evaluates to true.

> **Note**
>
> This parameter does not support attributes of type List or Map.

Expected (legacy)

> **Note**
>
> We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see Using expressions in DynamoDB. For specific information on the new parameter replacing this one, use *ConditionExpression* instead..

The legacy conditional parameter `Expected` is a conditional block for an `UpdateItem` operation. `Expected` is a map of attribute/condition pairs. Each element of the map consists of an attribute name, a comparison operator, and one or more values. DynamoDB compares the attribute with the value(s) you supplied, using the comparison operator. For each `Expected` element, the result of the evaluation is either true or false.

If you specify more than one element in the `Expected` map, then by default all of the conditions must evaluate to true. In other words, the conditions are combined using `AND` operator. (You can use the `ConditionalOperator` parameter to OR the conditions instead. If you do this, then at least one of the conditions must evaluate to true, rather than all of them.)

If the `Expected` map evaluates to true, then the conditional operation succeeds; otherwise, it fails.

`Expected` contains the following:

- `AttributeValueList` - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the `ComparisonOperator` being used.

  For type Number, value comparisons are numeric.

  String value comparisons for greater than, equals, or less than are based on Unicode with UTF-8 binary encoding. For example, `a` is greater than `A`, and `a` is greater than `B`.

  For type Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

- `ComparisonOperator` - A comparator for evaluating attributes in the `AttributeValueList`. When performing the comparison, DynamoDB uses strongly consistent reads.

  The following comparison operators are available:

  `EQ | NE | LE | LT | GE | GT | NOT_NULL | NULL | CONTAINS | NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN`

  The following are descriptions of each comparison operator.

  - `EQ` : Equal. `EQ` is supported for all data types, including lists and maps.

    `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS":["6", "2", "1"]}`.

  - `NE` : Not equal. `NE` is supported for all data types, including lists and maps.

    `AttributeValueList` can contain only one `AttributeValue` of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an `AttributeValue` of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS":["6", "2", "1"]}`.

  - `LE` : Less than or equal.

    `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a

different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

- `LT` : Less than.

  `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

- `GE` : Greater than or equal.

  `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

- `GT` : Greater than.

  `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

- `NOT_NULL` : The attribute exists. `NOT_NULL` is supported for all data types, including lists and maps.

  > **Note**
  >
  > This operator tests for the existence of an attribute, not its data type. If the data type of attribute "a" is null, and you evaluate it using `NOT_NULL`, the result is a Boolean `true`. This result is because the attribute "a" exists; its data type is not relevant to the `NOT_NULL` comparison operator.

- `NULL` : The attribute does not exist. `NULL` is supported for all data types, including lists and maps.

> **Note**
>
> This operator tests for the nonexistence of an attribute, not its data type. If the data type of attribute "a" is null, and you evaluate it using NULL, the result is a Boolean `false`. This is because the attribute "a" exists; its data type is not relevant to the NULL comparison operator.

- `CONTAINS` : Checks for a subsequence, or value in a set.

  `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it finds an exact match with any member of the set.

  CONTAINS is supported for lists: When evaluating "a `CONTAINS` b", " a" can be a list; however, "b" cannot be a set, a map, or a list.

- `NOT_CONTAINS` : Checks for absence of a subsequence, or absence of a value in a set.

  `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it `does not` find an exact match with any member of the set.

  NOT_CONTAINS is supported for lists: When evaluating "a `NOT CONTAINS` b", " a" can be a list; however, "b" cannot be a set, a map, or a list.

- `BEGINS_WITH` : Checks for a prefix.

  `AttributeValueList` can contain only one `AttributeValue` of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

- `IN` : Checks for matching elements within two sets.

`AttributeValueList` can contain one or more `AttributeValue` elements of type String, Number, or Binary (not a set type). These attributes are compared against an existing set type attribute of an item. If any elements of the input set are present in the item attribute, the expression evaluates to true.

- `BETWEEN` : Greater than or equal to the first value, and less than or equal to the second value.

  `AttributeValueList` must contain two `AttributeValue` elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not compare to `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`

The following parameters can be used instead of `AttributeValueList` and `ComparisonOperator`:

- `Value` - A value for DynamoDB to compare with an attribute.
- `Exists` - A Boolean value that causes DynamoDB to evaluate the value before attempting the conditional operation:
  - If `Exists` is `true`, DynamoDB will check to see if that attribute value already exists in the table. If it is found, then the condition evaluates to true; otherwise the condition evaluates to false.
  - If `Exists` is `false`, DynamoDB assumes that the attribute value does not exist in the table. If in fact the value does not exist, then the assumption is valid and the condition evaluates to true. If the value is found, despite the assumption that it does not exist, the condition evaluates to false.

  Note that the default value for `Exists` is `true`.

The `Value` and `Exists` parameters are incompatible with `AttributeValueList` and `ComparisonOperator`. Note that if you use both sets of parameters at once, DynamoDB will return a `ValidationException` exception.

> **Note**
>
> This parameter does not support attributes of type List or Map.

Use *ConditionExpression* instead – Example

Suppose you wanted to modify an item in the *Music* table, but only if a certain condition was true. You could use an `UpdateItem` request with an `Expected` parameter, as in this AWS CLI example:

```
aws dynamodb update-item \
    --table-name Music \
    --key '{
        "Artist": {"S":"No One You Know"},
        "SongTitle": {"S":"Call Me Today"}
    }' \
    --attribute-updates '{
        "Price": {
            "Action": "PUT",
            "Value": {"N":"1.98"}
        }
    }' \
    --expected '{
        "Price": {
            "ComparisonOperator": "LE",
            "AttributeValueList": [ {"N":"2.00"} ]
        }
    }'
```

You can use a `ConditionExpression` instead:

```
aws dynamodb update-item \
    --table-name Music \
    --key '{
        "Artist": {"S":"No One You Know"},
        "SongTitle": {"S":"Call Me Today"}
    }' \
    --update-expression 'SET Price = :p1' \
    --condition-expression 'Price <= :p2' \
    --expression-attribute-values '{
        ":p1": {"N":"1.98"},
        ":p2": {"N":"2.00"}
```

```
    }'
```

KeyConditions (legacy)

> **Note**
>
> We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see Using expressions in DynamoDB. For specific information on the new parameter replacing this one, use *KeyConditionExpression* instead..

The legacy conditional parameter `KeyConditions` contains selection criteria for a `Query` operation. For a query on a table, you can have conditions only on the table primary key attributes. You must provide the partition key name and value as an `EQ` condition. You can optionally provide a second condition, referring to the sort key.

> **Note**
>
> If you don't provide a sort key condition, all of the items that match the partition key will be retrieved. If a `FilterExpression` or `QueryFilter` is present, it will be applied after the items are retrieved.

For a query on an index, you can have conditions only on the index key attributes. You must provide the index partition key name and value as an `EQ` condition. You can optionally provide a second condition, referring to the index sort key.

Each `KeyConditions` element consists of an attribute name to compare, along with the following:

- `AttributeValueList` - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the `ComparisonOperator` being used.

  For type Number, value comparisons are numeric.

  String value comparisons for greater than, equals, or less than are based on Unicode with UTF-8 binary encoding. For example, a is greater than A, and a is greater than B.

For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

- `ComparisonOperator` - A comparator for evaluating attributes. For example: equals, greater than, and less than.

  For `KeyConditions`, only the following comparison operators are supported:

  `EQ | LE | LT | GE | GT | BEGINS_WITH | BETWEEN`

  The following are descriptions of these comparison operators.

  - `EQ` : Equal.

    `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one specified in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS":["6", "2", "1"]}`.

  - `LE` : Less than or equal.

    `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

  - `LT` : Less than.

    `AttributeValueList` can contain only one `AttributeValue` of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

  - `GE` : Greater than or equal.

    `AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

  - `GT` : Greater than.

`AttributeValueList` can contain only one `AttributeValue` element of type String, Number, or Binary (not a set type). If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

- `BEGINS_WITH` : Checks for a prefix.

  `AttributeValueList` can contain only one `AttributeValue` of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

- `BETWEEN` : Greater than or equal to the first value, and less than or equal to the second value.

  `AttributeValueList` must contain two `AttributeValue` elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an `AttributeValue` element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not compare to `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

Use *KeyConditionExpression* instead – Example

Suppose you wanted to retrieve several items with the same partition key from the *Music* table. You could use a `Query` request with a `KeyConditions` parameter, as in this AWS CLI example:

```
aws dynamodb query \
    --table-name Music \
    --key-conditions '{
        "Artist":{
            "ComparisonOperator":"EQ",
            "AttributeValueList": [ {"S": "No One You Know"} ]
        },
        "SongTitle":{
            "ComparisonOperator":"BETWEEN",
            "AttributeValueList": [ {"S": "A"}, {"S": "M"} ]
        }
    }'
```

You can use a `KeyConditionExpression` instead:

```
aws dynamodb query \
    --table-name Music \
    --key-condition-expression 'Artist = :a AND SongTitle BETWEEN :t1 AND :t2' \
    --expression-attribute-values '{
        ":a": {"S": "No One You Know"},
        ":t1": {"S": "A"},
        ":t2": {"S": "M"}
    }'
```

QueryFilter (legacy)

> **Note**
>
> We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see Using expressions in DynamoDB. For specific information on the new parameter replacing this one, use *FilterExpression* instead..

In a `Query` operation, the legacy conditional parameter `QueryFilter` is a condition that evaluates the query results after the items are read and returns only the desired values.

This parameter does not support attributes of type List or Map.

> **Note**
>
> A `QueryFilter` is applied after the items have already been read; the process of filtering does not consume any additional read capacity units.

If you provide more than one condition in the `QueryFilter` map, then by default all of the conditions must evaluate to true. In other words, the conditions are combined using the `AND` operator. (You can use the ConditionalOperator (legacy) parameter to OR the conditions instead. If you do this, then at least one of the conditions must evaluate to true, rather than all of them.)

Note that `QueryFilter` does not allow key attributes. You cannot define a filter condition on a partition key or a sort key.

Each `QueryFilter` element consists of an attribute name to compare, along with the following:

- `AttributeValueList` - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the operator specified in `ComparisonOperator`.

  For type Number, value comparisons are numeric.

  String value comparisons for greater than, equals, or less than are based on UTF-8 binary encoding. For example, a is greater than A, and a is greater than B.

  For type Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

  For information on specifying data types in JSON, see DynamoDB low-level API.
- `ComparisonOperator` - A comparator for evaluating attributes. For example: equals, greater than, and less than.

  The following comparison operators are available:

  `EQ | NE | LE | LT | GE | GT | NOT_NULL | NULL | CONTAINS | NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN`

Use *FilterExpression* instead – Example

Suppose you wanted to query the *Music* table and apply a condition to the matching items. You could use a `Query` request with a `QueryFilter` parameter, as in this AWS CLI example:

```
aws dynamodb query \
    --table-name Music \
    --key-conditions '{
        "Artist": {
            "ComparisonOperator": "EQ",
            "AttributeValueList": [ {"S": "No One You Know"} ]
        }
    }' \
    --query-filter '{
        "Price": {
            "ComparisonOperator": "GT",
            "AttributeValueList": [ {"N": "1.00"} ]
        }
    }'
```

You can use a `FilterExpression` instead:

```
aws dynamodb query \
    --table-name Music \
    --key-condition-expression 'Artist = :a' \
    --filter-expression 'Price > :p' \
    --expression-attribute-values '{
        ":p": {"N":"1.00"},
        ":a": {"S":"No One You Know"}
    }'
```

ScanFilter (legacy)

> **Note**
>
> We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see Using expressions in DynamoDB. For specific information on the new parameter replacing this one, use *FilterExpression* instead..

In a `Scan` operation, the legacy conditional parameter `ScanFilter` is a condition that evaluates the scan results and returns only the desired values.

> **Note**
>
> This parameter does not support attributes of type List or Map.

If you specify more than one condition in the `ScanFilter` map, then by default all of the conditions must evaluate to true. In other words, the conditions are ANDed together. (You can use the ConditionalOperator (legacy) parameter to OR the conditions instead. If you do this, then at least one of the conditions must evaluate to true, rather than all of them.)

Each `ScanFilter` element consists of an attribute name to compare, along with the following:

- `AttributeValueList` - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the operator specified in `ComparisonOperator` .

  For type Number, value comparisons are numeric.

String value comparisons for greater than, equals, or less than are based on UTF-8 binary encoding. For example, a is greater than A, and a is greater than B.

For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

For information on specifying data types in JSON, see DynamoDB low-level API.

- `ComparisonOperator` - A comparator for evaluating attributes. For example: equals, greater than, and less than.

  The following comparison operators are available:

  `EQ | NE | LE | LT | GE | GT | NOT_NULL | NULL | CONTAINS | NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN`

Use *FilterExpression* instead – Example

Suppose you wanted to scan the *Music* table and apply a condition to the matching items. You could use a `Scan` request with a `ScanFilter` parameter, as in this AWS CLI example:

```
aws dynamodb scan \
    --table-name Music \
    --scan-filter '{
        "Genre":{
            "AttributeValueList":[ {"S":"Rock"} ],
            "ComparisonOperator": "EQ"
        }
    }'
```

You can use a `FilterExpression` instead:

```
aws dynamodb scan \
    --table-name Music \
    --filter-expression 'Genre = :g' \
    --expression-attribute-values '{
        ":g": {"S":"Rock"}
    }'
```

Writing conditions with legacy parameters

> **Note**
>
> We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see Using expressions in DynamoDB.

The following section describes how to write conditions for use with legacy parameters, such as `Expected`, `QueryFilter`, and `ScanFilter`.

> **Note**
>
> New applications should use expression parameters instead. For more information, see Using expressions in DynamoDB.

Simple conditions

With attribute values, you can write conditions for comparisons against table attributes. A condition always evaluates to true or false, and consists of:

- `ComparisonOperator` — greater than, less than, equal to, and so on.
- `AttributeValueList` (optional) — attribute value(s) to compare against. Depending on the `ComparisonOperator` being used, the `AttributeValueList` might contain one, two, or more values; or it might not be present at all.

The following sections describe the various comparison operators, along with examples of how to use them in conditions.

Comparison operators with no attribute values

- `NOT_NULL` - true if an attribute exists.
- `NULL` - true if an attribute does not exist.

Use these operators to check whether an attribute exists, or doesn't exist. Because there is no value to compare against, do not specify `AttributeValueList`.

Example

The following expression evaluates to true if the *Dimensions* attribute exists.

```
...
    "Dimensions": {
         ComparisonOperator: "NOT_NULL"
    }
...
```

Comparison operators with one attribute value

- `EQ` - true if an attribute is equal to a value.

  `AttributeValueList` can contain only one value of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains a value of a different type than the one specified in the request, the value does not match. For example, the string `"3"` is not equal to the number `3`. Also, the number `3` is not equal to the number set `[3, 2, 1]`.
- `NE` - true if an attribute is not equal to a value.

  `AttributeValueList` can contain only one value of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains a value of a different type than the one specified in the request, the value does not match.
- `LE` - true if an attribute is less than or equal to a value.

  `AttributeValueList` can contain only one value of type String, Number, or Binary (not a set). If an item contains an `AttributeValue` of a different type than the one specified in the request, the value does not match.
- `LT` - true if an attribute is less than a value.

  `AttributeValueList` can contain only one value of type String, Number, or Binary (not a set). If an item contains a value of a different type than the one specified in the request, the value does not match.
- `GE` - true if an attribute is greater than or equal to a value.

  `AttributeValueList` can contain only one value of type String, Number, or Binary (not a set). If an item contains a value of a different type than the one specified in the request, the value does not match.
- `GT` - true if an attribute is greater than a value.

`AttributeValueList` can contain only one value of type String, Number, or Binary (not a set). If an item contains a value of a different type than the one specified in the request, the value does not match.

- `CONTAINS` - true if a value is present within a set, or if one value contains another.

  `AttributeValueList` can contain only one value of type String, Number, or Binary (not a set). If the target attribute of the comparison is a String, then the operator checks for a substring match. If the target attribute of the comparison is Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set, then the operator evaluates to true if it finds an exact match with any member of the set.

- `NOT_CONTAINS` - true if a value is *not* present within a set, or if one value does not contain another value.

  `AttributeValueList` can contain only one value of type String, Number, or Binary (not a set). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set, then the operator evaluates to true if it *does not* find an exact match with any member of the set.

- `BEGINS_WITH` - true if the first few characters of an attribute match the provided value. Do not use this operator for comparing numbers.

  `AttributeValueList` can contain only one value of type String or Binary (not a Number or a set). The target attribute of the comparison must be a String or Binary (not a Number or a set).

Use these operators to compare an attribute with a value. You must specify an `AttributeValueList` consisting of a single value. For most of the operators, this value must be a scalar; however, the `EQ` and `NE` operators also support sets.

Examples

The following expressions evaluate to true if:

- A product's price is greater than 100.

```
...
    "Price": {
```

```
        ComparisonOperator: "GT",
        AttributeValueList: [ {"N":"100"} ]
    }
...
```

- A product category begins with "Bo".

```
...
    "ProductCategory": {
        ComparisonOperator: "BEGINS_WITH",
        AttributeValueList: [ {"S":"Bo"} ]
    }
...
```

- A product is available in either red, green, or black:

```
...
    "Color": {
        ComparisonOperator: "EQ",
        AttributeValueList: [
            [ {"S":"Black"}, {"S":"Red"}, {"S":"Green"} ]
        ]
    }
...
```

> **Note**
>
> When comparing set data types, the order of the elements does not matter. DynamoDB will return only the items with the same set of values, regardless of the order in which you specify them in your request.

Comparison operators with two attribute values

- `BETWEEN` - true if a value is between a lower bound and an upper bound, endpoints inclusive.

  `AttributeValueList` must contain two elements of the same type, either String, Number, or Binary (not a set). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains a value of a different type than the one specified in the request, the value does not match.

Use this operator to determine if an attribute value is within a range. The `AttributeValueList` must contain two scalar elements of the same type - String, Number, or Binary.

Example

The following expression evaluates to true if a product's price is between 100 and 200.

```
...
    "Price": {
        ComparisonOperator: "BETWEEN",
        AttributeValueList: [ {"N":"100"}, {"N":"200"} ]
    }
...
```

Comparison operators with *n* attribute values

- `IN` - true if a value is equal to any of the values in an enumerated list. Only scalar values are supported in the list, not sets. The target attribute must be of the same type and exact value in order to match.

  `AttributeValueList` can contain one or more elements of type String, Number, or Binary (not a set). These attributes are compared against an existing non-set type attribute of an item. If *any* elements of the input set are present in the item attribute, the expression evaluates to true.

  `AttributeValueList` can contain one or more values of type String, Number, or Binary (not a set). The target attribute of the comparison must be of the same type and exact value to match. A String never matches a String set.

Use this operator to determine whether the supplied value is within an enumerated list. You can specify any number of scalar values in `AttributeValueList`, but they all must be of the same data type.

Example

The following expression evaluates to true if the value for *Id* is 201, 203, or 205.

```
...
    "Id": {
        ComparisonOperator: "IN",
        AttributeValueList: [ {"N":"201"}, {"N":"203"}, {"N":"205"} ]
```

```
    }
...
```

Using multiple conditions

DynamoDB lets you combine multiple conditions to form complex expressions. You do this by providing at least two expressions, with an optional ConditionalOperator (legacy).

By default, when you specify more than one condition, *all* of the conditions must evaluate to true in order for the entire expression to evaluate to true. In other words, an implicit *AND* operation takes place.

Example

The following expression evaluates to true if a product is a book that has at least 600 pages. Both of the conditions must evaluate to true, since they are implicitly *AND*ed together.

```
...
    "ProductCategory": {
        ComparisonOperator: "EQ",
        AttributeValueList: [ {"S":"Book"} ]
    },
    "PageCount": {
        ComparisonOperator: "GE",
        AttributeValueList: [ {"N":600} ]
    }
...
```

You can use ConditionalOperator (legacy) to clarify that an *AND* operation will take place. The following example behaves in the same manner as the previous one.

```
...
    "ConditionalOperator" : "AND",
    "ProductCategory": {
        "ComparisonOperator": "EQ",
        "AttributeValueList": [ {"N":"Book"} ]
    },
    "PageCount": {
        "ComparisonOperator": "GE",
        "AttributeValueList": [ {"N":600} ]
    }
```

```
...
```

You can also set `ConditionalOperator` to *OR*, which means that *at least one* of the conditions must evaluate to true.

Example

The following expression evaluates to true if a product is a mountain bike, if it is a particular brand name, or if its price is greater than 100.

```
...
    ConditionalOperator : "OR",
    "BicycleType": {
        "ComparisonOperator": "EQ",
        "AttributeValueList": [ {"S":"Mountain" ]
    },
    "Brand": {
        "ComparisonOperator": "EQ",
        "AttributeValueList": [ {"S":"Brand-Company A" ]
    },
    "Price": {
        "ComparisonOperator": "GT",
        "AttributeValueList": [ {"N":"100"} ]
    }
...
```

Note

In a complex expression, the conditions are processed in order, from the first condition to the last.
You cannot use both AND and OR in a single expression.

Other conditional operators

In previous releases of DynamoDB, the `Expected` parameter behaved differently for conditional writes. Each item in the `Expected` map represented an attribute name for DynamoDB to check, along with the following:

- `Value` — a value to compare against the attribute.
- `Exists` — determine whether the value exists prior to attempting the operation.

The `Value` and `Exists` options continue to be supported in DynamoDB; however, they only let you test for an equality condition, or whether an attribute exists. We recommend that you use `ComparisonOperator` and `AttributeValueList` instead, because these options let you construct a much wider range of conditions.

Example

A `DeleteItem` can check to see whether a book is no longer in publication, and only delete it if this condition is true. Here is an AWS CLI example using a legacy condition:

```
aws dynamodb delete-item \
    --table-name ProductCatalog \
    --key '{
        "Id": {"N":"600"}
    }' \
    --expected '{
        "InPublication": {
            "Exists": true,
            "Value": {"BOOL":false}
        }
    }'
```

The following example does the same thing, but does not use a legacy condition:

```
aws dynamodb delete-item \
    --table-name ProductCatalog \
    --key '{
        "Id": {"N":"600"}
    }' \
    --expected '{
        "InPublication": {
            "ComparisonOperator": "EQ",
            "AttributeValueList": [ {"BOOL":false} ]
        }
    }'
```

Example

A `PutItem` operation can protect against overwriting an existing item with the same primary key attributes. Here is an example using a legacy condition:

```
aws dynamodb put-item \
    --table-name ProductCatalog \
    --item '{
      "Id": {"N":"500"},
        "Title": {"S":"Book 500 Title"}
    }' \
    --expected '{
        "Id": { "Exists": false }
    }'
```

The following example does the same thing, but does not use a legacy condition:

```
aws dynamodb put-item \
    --table-name ProductCatalog \
    --item '{
      "Id": {"N":"500"},
        "Title": {"S":"Book 500 Title"}
    }' \
    --expected '{
        "Id": { "ComparisonOperator": "NULL" }
    }'
```

Note

For conditions in the `Expected` map, do not use the legacy `Value` and `Exists` options together with `ComparisonOperator` and `AttributeValueList`. If you do this, your conditional write will fail.

Preview features

The following topics are preview features for DynamoDB. Preview features are subject to change.

Topics

- Multi-Region strong consistency

Multi-Region strong consistency

> **Note**
>
> Multi-Region strong consistency (MRSC) is available in preview and is subject to change.

Multi-Region strong consistency (MRSC) is a new DynamoDB global tables capability available in preview. A global table configured for MRSC provides the ability to perform a strongly consistent read with multi-Region scope. Performing a strongly consistent read on an MRSC table ensures you're always reading the latest version of an item, irrespective of the Region in which you're performing the read.

You can use multi-Region strongly consistent global tables to build applications with a recovery point objective (RPO) of zero. An RPO of zero ensures your applications can always read the latest version of DynamoDB data, even if an application interruption causes you to shift traffic to a different AWS Region.

MRSC preview is *only* supported for global tables version 2019.11.21 (Current).

Topics

- Consistency modes for global tables
- Region availability for MRSC preview
- MRSC preview considerations
- Managing MRSC global tables

Consistency modes for global tables

When you create a global table, you can configure its consistency mode. Global tables offer the following multi-Region consistency modes: Eventual consistency and Strong consistency (preview).

If you don't specify a consistency mode when creating a global table, the global table defaults to multi-Region eventual consistency (MREC). A global table can't contain replicas configured with different consistency modes. You can't change a global table's consistency mode.

Multi-Region eventual consistency (MREC)

Multi-Region eventually consistent (MREC) is the default consistency mode for global tables. Changes that you make to an item in an MREC global table replica are replicated to all other replicas, typically within a second or less. This means read operations made with the ConsistentRead parameter set to `true` (a strongly consistent read) will always return the latest version of an item if the item was updated in the Region where the read occurred, but might return stale data if the item was updated in a different Region.

Conflicts that occur because of the same item being modified in multiple Regions simultaneously are resolved with a *last writer wins* approach.

MREC global tables will have lower write and strongly-consistent read latencies compared to MRSC global tables.

You should use the MREC mode when:

- Your application can tolerate stale data returned from strongly consistent read operations if that data was updated in another Region.
- You prioritize lower write and strongly consistent read latencies over multi-Region read consistency.
- Your multi-Region high availability strategy can tolerate an RPO greater than zero.

Multi-Region strong consistency (preview)

> **Note**
>
> Multi-Region strong consistency (MRSC) is available in preview and is subject to change.

Changes that you make to an item in an MRSC global table replica can immediately be read in any other replica table in the global table with a strongly consistent read. This means read operations made with the `ConsistentRead` parameter set to `true` (a strongly consistent read) will always return the latest version of an item from any replica table.

If a write operation would modify an item that is already being modified in another Region, that write operation will fail with a `ReplicatedWriteConflictException`. Writes that fail with the `ReplicatedWriteConflictException` can be retried, and will succeed if the conflicting update has been resolved and no other conflicting updates are in progress.

MRSC global tables will have higher write and strongly-consistent read latencies compared to MREC global tables.

You should use the MRSC mode when:

- You need strongly consistent read guarantees with a multi-Region scope.
- You prioritize global read consistency over lower write latency.
- Your multi-Region high availability strategy requires an RPO of zero.

Region availability for MRSC preview

The MRSC preview is available in the following AWS Regions:

- US East (N. Virginia) – us-east-1
- US East (Ohio) – us-east-2
- US West (Oregon) – us-west-2

MRSC preview considerations

When you use global tables with MRSC, the following considerations apply for the preview:

Workload considerations

- Global tables with MRSC are available in preview only. You shouldn't use them for production workloads.
- The performance and throughput characteristics of MRSC tables might change throughout the preview.

Feature support

- Only Amazon owned keys are supported for the preview.
- AWS managed keys aren't supported in preview.
- Customer managed keys aren't supported in preview.
- Resource-based policies can't be used to interrupt replication between Regions.
- CloudWatch Contributor Insights information is only reported for the Region in which operations occurred for MRSC global tables in preview.
- Time to Live (TTL) isn't supported for MRSC global tables in preview.
- Local secondary indexes (LSIs) aren't supported for MRSC global tables in preview.
- Transaction APIs aren't supported in preview.

Behavior differences from MREC global tables

- The MRSC preview is available in a limited set of Regions.
- An MRSC global table must contain exactly three replica tables.
- You must create an MRSC global table by adding two replica tables to an existing single-Region table that doesn't contain any data.
- You can't delete a single replica table from an MRSC global table. To delete an MRSC global table, you must delete two replica tables in a single action, resulting in a single-Region table. You can then delete the remaining single-Region table.
- Global secondary index key violations might occur beyond the initial backfilling period.

Quotas

- An AWS account can have a maximum of three global tables with MRSC.
- Write throughput in provisioned capacity mode is limited to 10,000 replicated Write Capacity Units (rWCUs).
- Read throughput in provisioned capacity mode is limited to 10,000 Read Capacity Units (RCUs).
- Write throughput in on-demand capacity mode is limited to 10,000 replicated Write Request Units (rWRUs).
- Read throughput in on-demand capacity mode is limited to 10,000 Read Request Units (RRUs).

Managing MRSC global tables

> **Note**
>
> Multi-Region strong consistency (MRSC) is available in preview and is subject to change.

You can manage multi-Region strongly consistent global tables in a supported Region using one of the following ways:

- AWS Management Console
- AWS APIs for DynamoDB
- AWS Command Line Interface (AWS CLI)
- AWS SDK

The following tutorials explain how to create and delete MRSC global tables using the AWS Management Console and AWS CLI.

Topics

- Tutorial: Creating MRSC global tables in DynamoDB
- Tutorial: Deleting MRSC global tables in DynamoDB

Tutorial: Creating MRSC global tables in DynamoDB

> **Note**
>
> Multi-Region strong consistency (MRSC) is available in preview and is subject to change.

In preview, a global table with MRSC must contain exactly three replicas in the supported Regions. You create an MRSC global table by adding two replica tables to a single-Region DynamoDB table that doesn't contain any data, and doesn't have any unsupported features configured.

Using the AWS Management Console

This console procedure creates an MRSC global table by creating a new single-Region table. This procedure also adds two replica tables in the remaining supported preview Regions.

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. From the top navigation pane, choose the Region where global tables with MRSC is supported. For example, choose **`us-east-2`**.
3. Create a new on-demand, single-Region table. For information about creating a table, see AWS Management Console in Step 1: Create a table in DynamoDB.

   > **Note**
   >
   > It might take a few minutes for the newly created table to change to the ACTIVE state.

4. On the **Tables** page, choose your newly created table.
5. Choose the **Global tables** tab, then choose **Create replica**.
6. On the **Create replica** page, do the following:

   a. Under **Multi-Region Consistency**, choose **Strong consistency**.

   b. Choose **Create replicas**.

   > **Note**
   >
   > It might take a few minutes for the new replica tables to appear and change to the ACTIVE state.

Using the AWS CLI

This AWS CLI procedure creates an MRSC global table by creating a new single-Region table, and then adding two replica tables.

1. Create a new on-demand, single-Region table named `MusicTable` in the us-east-2 Region.

```
aws dynamodb create-table \
    --table-name MusicTable \
    --attribute-definitions \
        AttributeName=Artist,AttributeType=S \
        AttributeName=SongTitle,AttributeType=S \
    --key-schema \
```

```
        AttributeName=Artist,KeyType=HASH \
        AttributeName=SongTitle,KeyType=RANGE \
    --billing-mode PAY_PER_REQUEST \
    --region us-east-2
```

2. Verify that the new table has been created and is in the ACTIVE state.

> **Note**
>
> It might take a few minutes for the table to change to the ACTIVE state.

```
aws dynamodb describe-table \
    --table-name MusicTable \
    --region us-east-2

    {
    "Table": {
        ...
        "TableStatus": "ACTIVE",
       ...
}
```

3. Add two new replica tables to the single-Region table in the remaining supported Regions for preview by specifying the `multi-region-consistency` parameter to `STRONG`.

```
aws dynamodb update-table \
    --table-name MusicTable \
    --replica-updates '[{"Create": {"RegionName": "us-east-1"}}, {"Create":
 {"RegionName": "us-west-2"}}]' \
    --multi-region-consistency STRONG \
    --region us-east-2
```

4. Use the describe-table command to verify that the two new replicas have been created and are in the ACTIVE state, and that the global table is configured for multi-Region strong consistency.

```
aws dynamodb describe-table \
    --table-name MusicTable \
    --region us-east-1
```

```
    {
    "Table": {
        ...

Tutorial: Deleting MRSC global tables in DynamoDB

> **Note**
>
> Multi-Region strong consistency (MRSC) is available in preview and is subject to change.

In preview, to delete an MRSC global table, you must delete two replica tables in one action, leaving a single-Region table. Then, you can optionally delete the remaining single-Region table. You can't delete only one replica table from an MRSC global table and you can't delete all three replica tables from an MRSC global table in one action.

Using the AWS Management Console

This console procedure deletes an MRSC global table by deleting two replica tables, resulting in a single-Region table.

1. Sign in to the AWS Management Console and open the DynamoDB console at https://console.aws.amazon.com/dynamodb/.
2. From the top navigation pane, choose a Region containing an MRSC global table. For example, choose **`us-east-2`**.
3. On the **Tables** page, choose the MRSC global table.

4. Choose the **Global tables** tab, then choose **Delete replicas**.
5. On the confirmation dialog that appears, type **`confirm`**.

> **Note**
>
> The Region you selected in the console will contain the remaining single-Region table after two replicas are deleted from the MRSC global table.

6. Choose **Delete**.

Using the AWS CLI

This AWS CLI procedure deletes an MRSC global table by deleting two replica tables, resulting in a single-Region table.

1. Delete two replica tables from the MRSC global table.

```
aws dynamodb update-table \
    --table-name MusicTable \
    --replica-updates '[{"Delete": {"RegionName": "us-east-1"}}, {"Delete":
 {"RegionName": "us-west-2"}}]' \
    --region us-east-2
```

2. Verify that the remaining single-Region table is in the ACTIVE state, and doesn't have any associated replica tables.

```
aws dynamodb describe-table \
    --table-name MusicTable \
    --region us-east-2

    {
    "Table": {
        "AttributeDefinitions": [
            {
                "AttributeName": "Artist",
                "AttributeType": "S"
            },
            {
                "AttributeName": "SongTitle",
                "AttributeType": "S"
            }
```

```
        ],
        "TableName": "MusicTable",
        "TableStatus": "ACTIVE",
        ...
    }
}
```
