5. On the **Edit basic settings** page, for **SnapStart**, choose **Published versions**.
6. Choose **Save**.
7. [Publish a function version](#). Lambda initializes your code, creates a snapshot of the initialized execution environment, and then caches the snapshot for low-latency access.
8. [Invoke the function version](#).

Activating SnapStart (AWS CLI)

To activate SnapStart for an existing function

1. Update the function configuration by running the [update-function-configuration](#) command with the **--snap-start** option.

```
aws lambda update-function-configuration \  
  --function-name my-function \  
  --snap-start ApplyOn=PublishedVersions
```

2. Publish a function version with the [publish-version](#) command.

```
aws lambda publish-version \  
  --function-name my-function
```

3. Confirm that SnapStart is activated for the function version by running the [get-function-configuration](#) command and specifying the version number. The following example specifies version 1.

```
aws lambda get-function-configuration \  
  --function-name my-function:1
```

If the response shows that [OptimizationStatus](#) is On and [State](#) is Active, then SnapStart is activated and a snapshot is available for the specified function version.

```
"SnapStart": {  
  "ApplyOn": "PublishedVersions",  
  "OptimizationStatus": "On"  
},  
"State": "Active",
```

4. Invoke the function version by running the [invoke](#) command and specifying the version. The following example invokes version 1.

```
aws lambda invoke \  
  --cli-binary-format raw-in-base64-out \  
  --function-name my-function:1 \  
  --payload '{ "name": "Bob" }' \  
  response.json
```

The **cli-binary-format** option is required if you're using AWS CLI version 2. To make this the default setting, run `aws configure set cli-binary-format raw-in-base64-out`. For more information, see [AWS CLI supported global command line options](#) in the *AWS Command Line Interface User Guide for Version 2*.

To activate SnapStart when you create a new function

1. Create a function by running the [create-function](#) command with the **--snap-start** option. For **--role**, specify the Amazon Resource Name (ARN) of your [execution role](#).

```
aws lambda create-function \  
  --function-name my-function \  
  --runtime "java25" \  
  --zip-file fileb://my-function.zip \  
  --handler my-function.handler \  
  --role arn:aws:iam::111122223333:role/lambda-ex \  
  --snap-start ApplyOn=PublishedVersions
```

2. Create a version with the [publish-version](#) command.

```
aws lambda publish-version \  
  --function-name my-function
```

3. Confirm that SnapStart is activated for the function version by running the [get-function-configuration](#) command and specifying the version number. The following example specifies version 1.

```
aws lambda get-function-configuration \  
  --function-name my-function:1
```

If the response shows that [OptimizationStatus](#) is On and [State](#) is Active, then SnapStart is activated and a snapshot is available for the specified function version.

```
"SnapStart": {  
  "ApplyOn": "PublishedVersions",  
  "OptimizationStatus": "On"  
},  
"State": "Active",
```

4. Invoke the function version by running the [invoke](#) command and specifying the version. The following example invokes version 1.

```
aws lambda invoke \  
  --cli-binary-format raw-in-base64-out \  
  --function-name my-function:1 \  
  --payload '{ "name": "Bob" }' \  
  response.json
```

The **cli-binary-format** option is required if you're using AWS CLI version 2. To make this the default setting, run `aws configure set cli-binary-format raw-in-base64-out`. For more information, see [AWS CLI supported global command line options](#) in the *AWS Command Line Interface User Guide for Version 2*.

Activating SnapStart (API)

To activate SnapStart

1. Do one of the following:
 - Create a new function with SnapStart activated by using the [CreateFunction](#) API action with the [SnapStart](#) parameter.
 - Activate SnapStart for an existing function by using the [UpdateFunctionConfiguration](#) action with the [SnapStart](#) parameter.
2. Publish a function version with the [PublishVersion](#) action. Lambda initializes your code, creates a snapshot of the initialized execution environment, and then caches the snapshot for low-latency access.
3. Confirm that SnapStart is activated for the function version by using the [GetFunctionConfiguration](#) action. Specify a version number to confirm that SnapStart is activated for that version. If the response shows that [OptimizationStatus](#) is On and [State](#) is Active, then SnapStart is activated and a snapshot is available for the specified function version.

```
"SnapStart": {  
  "ApplyOn": "PublishedVersions",  
  "OptimizationStatus": "On"  
},  
"State": "Active",
```

4. Invoke the function version with the [Invoke](#) action.

Lambda SnapStart and function states

The following function states can occur when you use SnapStart.

Pending

Lambda is initializing your code and taking a snapshot of the initialized execution environment. Any invocations or other API actions that operate on the function version will fail.

Active

Snapshot creation is complete and you can invoke the function. To use SnapStart, you must invoke the published function version, not the unpublished version (\$LATEST).

Inactive

The `Inactive` state can occur when Lambda periodically regenerates function snapshots to apply software updates. In this instance, if your function fails to initialize, the function can enter an `Inactive` state.

For functions using a Java runtime, Lambda deletes snapshots after 14 days without an invocation. If you invoke the function version after 14 days, Lambda returns a `SnapStartNotReadyException` response and begins initializing a new snapshot. Wait until the function version reaches the `Active` state, and then invoke it again.

Failed

Lambda encountered an error when running the initialization code or creating the snapshot.

Updating a snapshot

Lambda creates a snapshot for each published function version. To update a snapshot, publish a new function version.

Using SnapStart with AWS SDKs

To make AWS SDK calls from your function, Lambda generates an ephemeral set of credentials by assuming your function's execution role. These credentials are available as environment variables during your function's invocation. You don't need to provide credentials for the SDK

directly in code. By default, the credential provider chain sequentially checks each place where you can set credentials and chooses the first available—usually the environment variables (`AWS_ACCESS_KEY_ID`, `AWS_SECRET_ACCESS_KEY`, and `AWS_SESSION_TOKEN`).

Note

When SnapStart is activated, the Lambda runtime automatically uses the container credentials (`AWS_CONTAINER_CREDENTIALS_FULL_URI` and `AWS_CONTAINER_AUTHORIZATION_TOKEN`) instead of the access key environment variables. This prevents credentials from expiring before the function is restored.

Using SnapStart with CloudFormation, AWS SAM, and AWS CDK

- **AWS CloudFormation:** Declare the [SnapStart](#) entity in your template.
- **AWS Serverless Application Model (AWS SAM):** Declare the [SnapStart](#) property in your template.
- **AWS Cloud Development Kit (AWS CDK):** Use the [SnapStartProperty](#) type.

Deleting snapshots

Lambda deletes snapshots when:

- You delete the function or function version.
- **Java runtimes only** — You don't invoke the function version for 14 days. After 14 days without an invocation, the function version transitions to the [Inactive](#) state. If you invoke the function version after 14 days, Lambda returns a `SnapStartNotReadyException` response and begins initializing a new snapshot. Wait until the function version reaches the [Active](#) state, and then invoke it again.

Lambda removes all resources associated with deleted snapshots in compliance with the General Data Protection Regulation (GDPR).

Handling uniqueness with Lambda SnapStart

When invocations scale up on a SnapStart function, Lambda uses a single initialized snapshot to resume multiple execution environments. If your initialization code generates unique content that is included in the snapshot, then the content might not be unique when it is reused across execution environments. To maintain uniqueness when using SnapStart, you must generate unique content after initialization. This includes unique IDs, unique secrets, and entropy that's used to generate pseudorandomness.

We recommend the following best practices to help you maintain uniqueness in your code. For Java functions, Lambda also provides an open-source [SnapStart scanning tool](#) to help check for code that assumes uniqueness. If you generate unique data during the initialization phase, then you can use a [runtime hook](#) to restore uniqueness. With runtime hooks, you can run specific code immediately before Lambda takes a snapshot or immediately after Lambda resumes a function from a snapshot.

Avoid saving state that depends on uniqueness during initialization

During the [initialization phase](#) of your function, avoid caching data that's intended to be unique, such as generating a unique ID for logging or setting seeds for random functions. Instead, we recommend that you generate unique data or set seeds for random functions inside your function handler—or use a [runtime hook](#).

The following examples demonstrate how to generate a UUID in the function handler.

Java

Example – Generating a unique ID in function handler

```
import java.util.UUID;

public class Handler implements RequestHandler<String, String> {
    private static UUID uniqueSandboxId = null;
    @Override
    public String handleRequest(String event, Context context) {
        if (uniqueSandboxId == null)
            uniqueSandboxId = UUID.randomUUID();
        System.out.println("Unique Sandbox Id: " + uniqueSandboxId);
        return "Hello, World!";
    }
}
```

Python

Example – Generating a unique ID in function handler

```
import json
import random
import time

unique_number = None

def lambda_handler(event, context):
    seed = int(time.time() * 1000)
    random.seed(seed)
    global unique_number
    if not unique_number:
        unique_number = random.randint(1, 10000)

    print("Unique number: ", unique_number)

    return "Hello, World!"
```

.NET

Example – Generating a unique ID in function handler

```
namespace Example;
public class SnapstartExample
{
    private Guid _myExecutionEnvironmentGuid;
    public SnapstartExample()
    {
        // This GUID is set for non-restore use cases, such as testing or if
        // SnapStart is turned off
        _myExecutionEnvironmentGuid = new Guid();
        // Register the method which will run after each restore. You may need to
        // update Amazon.Lambda.Core to see this
        Amazon.Lambda.Core.SnapshotRestore.RegisterAfterRestore(MyAfterRestore);
    }

    private ValueTask MyAfterRestore()
    {
        // After restoring this snapshot to a new execution environment, update the
        // GUID
    }
}
```

```
        _myExecutionEnvironmentGuid = new Guid();
        return ValueTask.CompletedTask;
    }

    public string Handler()
    {
        return $"Hello World! My Execution Environment GUID is
{_myExecutionEnvironmentGuid}";
    }
}
```

Use cryptographically secure pseudorandom number generators (CSPRNGs)

If your application depends on randomness, we recommend that you use cryptographically secure random number generators (CSPRNGs). In addition to OpenSSL 1.0.2, the Lambda managed runtimes also include the following built-in CSPRNGs:

- **Java:** `java.security.SecureRandom`
- **Python:** `random.SystemRandom`
- **.NET:** `System.Security.Cryptography.RandomNumberGenerator`

Software that always gets random numbers from `/dev/random` or `/dev/urandom` also maintains randomness with SnapStart.

AWS cryptography libraries automatically maintain randomness with SnapStart beginning with the minimum versions specified in the following table. If you use these libraries with your Lambda functions, make sure that you use the following minimum versions or later versions:

Library	Minimum supported version (x86)	Minimum supported version (ARM)
AWS libcrypto (AWS-LC)	1.16.0	1.30.0
AWS libcrypto FIPS	2.0.13	2.0.13

If you package the preceding cryptographic libraries with your Lambda functions as transitive dependencies through the following libraries, make sure that you use the following minimum versions or later versions:

Library	Minimum supported version (x86)	Minimum supported version (ARM)
AWS SDK for Java 2.x	2.23.20	2.26.12
AWS Common Runtime for Java	0.29.8	0.29.25
Amazon Corretto Crypto Provider	2.4.1	2.4.1
Amazon Corretto Crypto Provider FIPS	2.4.1	2.4.1

The following examples demonstrate how to use CSPRNGs to guarantee unique number sequences even when the function is restored from a snapshot.

Java

Example – `java.security.SecureRandom`

```
import java.security.SecureRandom;

public class Handler implements RequestHandler<String, String> {
    private static SecureRandom rng = new SecureRandom();
    @Override
    public String handleRequest(String event, Context context) {
        for (int i = 0; i < 10; i++) {
            System.out.println(rng.next());
        }
        return "Hello, World!";
    }
}
```

Python

Example – random.SystemRandom

```
import json
import random

secure_rng = random.SystemRandom()

def lambda_handler(event, context):
    random_numbers = [secure_rng.random() for _ in range(10)]

    for number in random_numbers:
        print(number)

    return "Hello, World!"
```

.NET

Example – RandomNumberGenerator

```
using Amazon.Lambda.Core;
using System.Security.Cryptography;
[assembly: LambdaSerializer(typeof(Amazon.Lambda.Serialization.SystemTextJson.DefaultLambdaJsonSerializer))]

namespace DotnetSecureRandom;

public class Function
{
    public string FunctionHandler()
    {
        using (RandomNumberGenerator rng = RandomNumberGenerator.Create())
        {
            byte[] randomUnsignedInteger32Bytes = new byte[4];
            for (int i = 0; i < 10; i++)
            {
                rng.GetBytes(randomUnsignedInteger32Bytes);
                int randomInt32 = BitConverter.ToInt32(randomUnsignedInteger32Bytes,
0);

                Console.WriteLine("{0:G}", randomInt32);
            }
        }
    }
}
```

```
        return "Hello World!";  
    }  
}
```

SnapStart scanning tool (Java only)

Lambda provides a scanning tool for Java to help you check for code that assumes uniqueness. The SnapStart scanning tool is an open-source [SpotBugs](#) plugin that runs a static analysis against a set of rules. The scanning tool helps identify potential code implementations that might break assumptions regarding uniqueness. For installation instructions and a list of checks that the scanning tool performs, see the [aws-lambda-snapstart-java-rules](#) repository on GitHub.

To learn more about handling uniqueness with SnapStart, see [Starting up faster with AWS Lambda SnapStart](#) on the AWS Compute Blog.

Implement code before or after Lambda function snapshots

You can use runtime hooks to implement code before Lambda creates a snapshot or after Lambda resumes a function from a snapshot. Runtime hooks are useful for a variety of purposes, such as:

- **Cleanup and initialization:** Before a snapshot is created, you can use a runtime hook to perform cleanup or resource release operations. After a snapshot is restored, you can use a runtime hook to re-initialize any resources or state that were not captured in the snapshot.
- **Dynamic configuration:** You can use runtime hooks to dynamically update configuration or other metadata before a snapshot is created or after it is restored. This can be useful if your function needs to adapt to changes in the runtime environment.
- **External integrations:** You can use runtime hooks to integrate with external services or systems, such as sending notifications or updating external state, as part of the checkpointing and restoration process.
- **Performance tuning:** You can use runtime hooks to fine-tune your function's startup sequence, such as by preloading dependencies. For more information, see [Performance tuning](#).

The following pages explain how to implement runtime hooks for your preferred runtime.

Topics

- [Lambda SnapStart runtime hooks for Java](#)
- [Lambda SnapStart runtime hooks for Python](#)
- [Lambda SnapStart runtime hooks for .NET](#)

Lambda SnapStart runtime hooks for Java

You can use runtime hooks to implement code before Lambda creates a snapshot or after Lambda resumes a function from a snapshot. Runtime hooks are available as part of the open-source Coordinated Restore at Checkpoint (CRaC) project. CRaC is in development for the [Open Java Development Kit \(OpenJDK\)](#). For an example of how to use CRaC with a reference application, see the [CRaC](#) repository on GitHub. CRaC uses three main elements:

- **Resource** – An interface with two methods, `beforeCheckpoint()` and `afterRestore()`. Use these methods to implement the code that you want to run before a snapshot and after a restore.

- `Context <R extends Resource>` – To receive notifications for checkpoints and restores, a `Resource` must be registered with a `Context`.
- `Core` – The coordination service, which provides the default global `Context` via the static method `Core.getGlobalContext()`.

For more information about `Context` and `Resource`, see [Package org.crac](#) in the CRaC documentation.

Use the following steps to implement runtime hooks with the [org.crac package](#). The Lambda runtime contains a customized CRaC context implementation that calls your runtime hooks before checkpointing and after restoring.

Runtime hook registration and execution

The order that Lambda executes your runtime hooks is determined by the order of registration. Registration order follows the order of import, definition, or execution in your code.

- `beforeCheckpoint()`: Executed in the reverse order of registration
- `afterRestore()`: Executed in the order of registration

Make sure that all registered hooks are properly imported and included in your function's code. If you register runtime hooks in a separate file or module, you must ensure that the module is imported, either directly or as part of a larger package, in your function's handler file. If the file or module is not imported in the function handler, Lambda ignores the runtime hooks.

Note

When Lambda creates a snapshot, your initialization code can run for up to 15 minutes. The time limit is 130 seconds or the [configured function timeout](#) (maximum 900 seconds), whichever is higher. Your `beforeCheckpoint()` runtime hooks count towards the initialization code time limit. When Lambda restores a snapshot, the runtime must load and `afterRestore()` runtime hooks must complete within the timeout limit (10 seconds). Otherwise, you'll get a `SnapStartTimeoutException`.

Step 1: Update the build configuration

Add the `org.crac` dependency to the build configuration. The following example uses Gradle. For examples for other build systems, see the [Apache Maven documentation](#).

```
dependencies {  
    compile group: 'com.amazonaws', name: 'aws-lambda-java-core', version: '1.2.1'  
    # All other project dependencies go here:  
    # ...  
    # Then, add the org.crac dependency:  
    implementation group: 'org.crac', name: 'crac', version: '1.4.0'  
}
```

Step 2: Update the Lambda handler

The Lambda function *handler* is the method in your function code that processes events. When your function is invoked, Lambda runs the handler method. Your function runs until the handler returns a response, exits, or times out.

For more information, see [Define Lambda function handler in Java](#).

The following example handler shows how to run code before checkpointing (`beforeCheckpoint()`) and after restoring (`afterRestore()`). This handler also registers the `Resource` to the runtime-managed global `Context`.

Note

When Lambda creates a snapshot, your initialization code can run for up to 15 minutes. The time limit is 130 seconds or the [configured function timeout](#) (maximum 900 seconds), whichever is higher. Your `beforeCheckpoint()` runtime hooks count towards the initialization code time limit. When Lambda restores a snapshot, the runtime (JVM) must load and `afterRestore()` runtime hooks must complete within the timeout limit (10 seconds). Otherwise, you'll get a `SnapStartTimeoutException`.

```
...  
import org.crac.Resource;  
import org.crac.Core;  
...
```

```
public class CRaCDemo implements RequestStreamHandler, Resource {
    public CRaCDemo() {
        Core.getGlobalContext().register(this);
    }
    public String handleRequest(String name, Context context) throws IOException {
        System.out.println("Handler execution");
        return "Hello " + name;
    }
    @Override
    public void beforeCheckpoint(org.crac.Context<? extends Resource> context)
        throws Exception {
        System.out.println("Before checkpoint");
    }
    @Override
    public void afterRestore(org.crac.Context<? extends Resource> context)
        throws Exception {
        System.out.println("After restore");
    }
}
```

Context maintains only a [WeakReference](#) to the registered object. If a [Resource](#) is garbage collected, runtime hooks do not run. Your code must maintain a strong reference to the Resource to guarantee that the runtime hook runs.

Here are two examples of patterns to avoid:

Example – Object without a strong reference

```
Core.getGlobalContext().register( new MyResource() );
```

Example – Objects of anonymous classes

```
Core.getGlobalContext().register( new Resource() {

    @Override
    public void afterRestore(Context<? extends Resource> context) throws Exception {
        // ...
    }

    @Override
    public void beforeCheckpoint(Context<? extends Resource> context) throws Exception {
        // ...
    }
}
```

```
} );
```

Instead, maintain a strong reference. In the following example, the registered resource isn't garbage collected and runtime hooks run consistently.

Example – Object with a strong reference

```
Resource myResource = new MyResource(); // This reference must be maintained to prevent  
the registered resource from being garbage collected  
Core.getGlobalContext().register( myResource );
```

Lambda SnapStart runtime hooks for Python

You can use runtime hooks to implement code before Lambda creates a snapshot or after Lambda resumes a function from a snapshot. Python runtime hooks are available as part of the open-source [Snapshot Restore for Python library](#), which is included in Python managed runtimes. This library provides two decorators that you can use to define your runtime hooks:

- `@register_before_snapshot`: For functions you want to run before Lambda creates a snapshot.
- `@register_after_restore`: For functions you want to run when Lambda resumes a function from a snapshot.

Alternatively, you can use the following methods to register callables for runtime hooks:

- `register_before_snapshot(func, *args, **kwargs)`
- `register_after_restore(func, *args, **kwargs)`

Runtime hook registration and execution

The order that Lambda executes your runtime hooks is determined by the order of registration:

- Before snapshot: Executed in the reverse order of registration
- After snapshot: Executed in the order of registration

The order of runtime hook registration depends on how you define the hooks. When using decorators (`@register_before_snapshot` and `@register_after_restore`), the

registration order follows the order of import, definition, or execution in your code. If you need more control over the registration order, use the `register_before_snapshot()` and `register_after_restore()` methods instead of decorators.

Make sure that all registered hooks are properly imported and included in your function's code. If you register runtime hooks in a separate file or module, you must ensure that the module is imported, either directly or as part of a larger package, in your function's handler file. If the file or module is not imported in the function handler, Lambda ignores the runtime hooks.

Note

When Lambda creates a snapshot, your initialization code can run for up to 15 minutes. The time limit is 130 seconds or the [configured function timeout](#) (maximum 900 seconds), whichever is higher. Your `@register_before_snapshot` runtime hooks count towards the initialization code time limit. When Lambda restores a snapshot, the runtime must load and `@register_after_restore` runtime hooks must complete within the timeout limit (10 seconds). Otherwise, you'll get a `SnapStartTimeoutException`.

Example

The following example handler shows how to run code before checkpointing (`@register_before_snapshot`) and after restoring (`@register_after_restore`).

```
from snapshot_restore_py import register_before_snapshot, register_after_restore

def lambda_handler(event, context):
    # Handler code

@register_before_snapshot
def before_checkpoint():
    # Logic to be executed before taking snapshots

@register_after_restore
def after_restore():
    # Logic to be executed after restore
```

For more examples, see [Snapshot Restore for Python](#) in the AWS GitHub repository.

Lambda SnapStart runtime hooks for .NET

You can use runtime hooks to implement code before Lambda creates a snapshot or after Lambda resumes a function from a snapshot. .NET runtime hooks are available as part of the [Amazon.Lambda.Core](#) package (version 2.5.0 or later). This library provides two methods that you can use to define your runtime hooks:

- `RegisterBeforeSnapshot()`: Code to run before snapshot creation
- `RegisterAfterSnapshot()`: Code to run after resuming a function from a snapshot

Note

If you're using the [Lambda Annotations framework for .NET](#), upgrade to [Amazon.Lambda.Annotations](#) version 1.6.0 or later to ensure compatibility with SnapStart.

Runtime hook registration and execution

Register your hooks in your initialization code. Consider the following guidelines based on your Lambda function's [execution model](#):

- For the [executable assembly approach](#), register your hooks before you start the Lambda bootstrap with `RunAsync`.
- For the [class library approach](#), register your hooks in the handler class constructor.
- For [ASP.NET Core applications](#), register your hooks before calling the `WebApplications.Run` method.

To register runtime hooks for SnapStart in .NET, use the following methods:

```
Amazon.Lambda.Core.SnapshotRestore.RegisterBeforeSnapshot(BeforeCheckpoint);  
Amazon.Lambda.Core.SnapshotRestore.RegisterAfterRestore(AfterCheckpoint);
```

When multiple hook types are registered, the order that Lambda executes your runtime hooks is determined by the order of registration:

- `RegisterBeforeSnapshot()`: Executed in the reverse order of registration

- `RegisterAfterSnapshot()`: Executed in the order of registration

Note

When Lambda creates a snapshot, your initialization code can run for up to 15 minutes. The time limit is 130 seconds or the [configured function timeout](#) (maximum 900 seconds), whichever is higher. Your `RegisterBeforeSnapshot()` runtime hooks count towards the initialization code time limit. When Lambda restores a snapshot, the runtime must load and `RegisterAfterSnapshot()` runtime hooks must complete within the timeout limit (10 seconds). Otherwise, you'll get a `SnapStartTimeoutException`.

Example

The following example function shows how to run code before checkpointing (`RegisterBeforeSnapshot`) and after restoring (`RegisterAfterRestore`).

```
public class SampleClass
{
    public SampleClass()
    {
        Amazon.Lambda.Core.SnapshotRestore.RegisterBeforeSnapshot(BeforeCheckpoint);
        Amazon.Lambda.Core.SnapshotRestore.RegisterAfterRestore(AfterCheckpoint);
    }

    private ValueTask BeforeCheckpoint()
    {
        // Add logic to be executed before taking the snapshot
        return ValueTask.CompletedTask;
    }

    private ValueTask AfterCheckpoint()
    {
        // Add logic to be executed after restoring the snapshot
        return ValueTask.CompletedTask;
    }

    public APIGatewayProxyResponse FunctionHandler(APIGatewayProxyRequest request,
        ILambdaContext context)
    {
        // Add business logic
    }
}
```

```
        return new APIGatewayProxyResponse
        {
            StatusCode = 200
        };
    }
}
```

Monitoring for Lambda SnapStart

You can monitor your Lambda SnapStart functions using Amazon CloudWatch, AWS X-Ray, and the [Accessing real-time telemetry data for extensions using the Telemetry API](#).

Note

The `AWS_LAMBDA_LOG_GROUP_NAME` and `AWS_LAMBDA_LOG_STREAM_NAME` [environment variables](#) are not available in Lambda SnapStart functions.

Understanding logging and billing behavior with SnapStart

There are a few differences with the [CloudWatch log stream](#) format for SnapStart functions:

- **Initialization logs** – When a new execution environment is created, the REPORT doesn't include the `Init Duration` field. That's because Lambda initializes SnapStart functions when you create a version instead of during function invocation. For SnapStart functions, the `Init Duration` field is in the `INIT_REPORT` record. This record shows duration details for the [Init phase](#), including the duration of any beforeCheckpoint [runtime hooks](#).
- **Invocation logs** – When a new execution environment is created, the REPORT includes the `Restore Duration` and `Billed Restore Duration` fields:
 - **Restore Duration**: The time it takes for Lambda to restore a snapshot, load the runtime, and run any after-restore [runtime hooks](#). The process of restoring snapshots can include time spent on activities outside the MicroVM. This time is reported in `Restore Duration`.
 - **Billed Restore Duration**: The time it takes for Lambda to load the runtime and run any after-restore [runtime hooks](#).

Note

As with all Lambda functions, duration charges apply to code that runs in the function handler. For SnapStart functions, duration charges also apply to initialization code that's declared outside of the handler, the time it takes for the runtime to load, and any code that runs in a [runtime hook](#).

The cold start duration is the sum of `Restore Duration` + `Duration`.

The following example is a Lambda Insights query that returns the latency percentiles for SnapStart functions. For more information about Lambda Insights queries, see [Example workflow using queries to troubleshoot a function](#).

```
filter @type = "REPORT"
  | parse @log /\d+:\aws\lambda\(?<function>.*)/
  | parse @message /Restore Duration: (?<restoreDuration>.*?) ms/
  | stats

X-Ray active tracing for SnapStart

You can use [X-Ray](#) to trace requests to Lambda SnapStart functions. There are a few differences with the X-Ray subsegments for SnapStart functions:

- There is no Initialization subsegment for SnapStart functions.
- The Restore subsegment shows the time it takes for Lambda to restore a snapshot, load the runtime, and run any after-restore [runtime hooks](#). The process of restoring snapshots can include time spent on activities outside the MicroVM. This time is reported in the Restore subsegment. You aren't charged for the time spent outside the microVM to restore a snapshot.

Telemetry API events for SnapStart

Lambda sends the following SnapStart events to the [Telemetry API](#):

- [platform.restoreStart](#) – Shows the time when the [Restore phase](#) started.
- [platform.restoreRuntimeDone](#) – Shows whether the Restore phase was successful. Lambda sends this message when the runtime sends a restore/next runtime API request. There are three possible statuses: success, failure, and timeout.
- [platform.restoreReport](#) – Shows how long the Restore phase lasted and how many milliseconds you were billed for during this phase.

Amazon API Gateway and function URL metrics

If you create a web API [using API Gateway](#), then you can use the [IntegrationLatency](#) metric to measure end-to-end latency (the time between when API Gateway relays a request to the backend and when it receives a response from the backend).

If you're using a [Lambda function URL](#), then you can use the [UrlRequestLatency](#) metric to measure end-to-end latency (the time between when the function URL receives a request and when the function URL returns a response).

Security model for Lambda SnapStart

Lambda SnapStart supports encryption at rest. Lambda encrypts snapshots with an AWS KMS key. By default, Lambda uses an AWS managed key. If this default behavior suits your workflow, then you don't need to set up anything else. Otherwise, you can use the `--kms-key-arn` option in the [create-function](#) or [update-function-configuration](#) command to provide an AWS KMS customer managed key. You might do this to control rotation of the KMS key or to meet the requirements of your organization for managing KMS keys. Customer managed keys incur standard AWS KMS charges. For more information, see [AWS Key Management Service pricing](#).

When you delete a SnapStart function or function version, all Invoke requests to that function or function version fail. Lambda removes all resources associated with deleted snapshots in compliance with the General Data Protection Regulation (GDPR).

Maximize Lambda SnapStart performance

Topics

- [Performance tuning](#)
- [Networking best practices](#)

Performance tuning

To maximize the benefits of SnapStart, consider the following code optimization recommendations for your runtime.

Note

SnapStart works best when used with function invocations at scale. Functions that are invoked infrequently might not experience the same performance improvements.

Java

To maximize the benefits of SnapStart, we recommend that you preload dependencies and initialize resources that contribute to startup latency in your initialization code instead of in the function handler. This moves the latency associated with heavy class loading out of the invocation path, optimizing startup performance with SnapStart.

If you can't preload dependencies or resources during initialization, then we recommend that you preload them with dummy invocations. To do this, update the function handler code, as shown in the following example from the [pet store function](#) on the AWS Labs GitHub repository.

```
private static SpringLambdaContainerHandler<AwsProxyRequest, AwsProxyResponse> handler;
static {
    try {
        handler =
            SpringLambdaContainerHandler.getAwsProxyHandler(PetStoreSpringAppConfig.class);

        // Use the onStartup method of the handler to register the custom filter
        handler.onStartup(servletContext -> {
            FilterRegistration.Dynamic registration =
                servletContext.addFilter("CognitoIdentityFilter", CognitoIdentityFilter.class);
```

```

        registration.addMappingForUrlPatterns(EnumSet.of(DispatcherType.REQUEST),
false, "/*");
    });

    // Send a fake Amazon API Gateway request to the handler to load classes
ahead of time
    ApiGatewayRequestIdentity identity = new ApiGatewayRequestIdentity();
    identity.setApiKey("foo");
    identity.setAccountId("foo");
    identity.setAccessKey("foo");

    AwsProxyRequestContext reqCtx = new AwsProxyRequestContext();
    reqCtx.setPath("/pets");
    reqCtx.setStage("default");
    reqCtx.setAuthorizer(null);
    reqCtx.setIdentity(identity);

    AwsProxyRequest req = new AwsProxyRequest();
    req.setHttpMethod("GET");
    req.setPath("/pets");
    req.setBody("");
    req.setRequestContext(reqCtx);

    Context ctx = new TestContext();
    handler.proxy(req, ctx);

} catch (ContainerInitializationException e) {
    // if we fail here. We re-throw the exception to force another cold start
    e.printStackTrace();
    throw new RuntimeException("Could not initialize Spring framework", e);
}
}

```

Python

To maximize the benefits of SnapStart, focus on efficient code organization and resource management within your Python functions. As a general guideline, perform heavy computational tasks during the [initialization phase](#). This approach moves time-consuming operations out of the invocation path, improving overall function performance. To implement this strategy effectively, we recommend the following best practices:

- Import dependencies outside of the function handler.

- Create boto3 instances outside of the handler.
- Initialize static resources or configurations before the handler is invoked.
- Consider using a before-snapshot [runtime hook](#) for resource-intensive tasks such as downloading external files, pre-loading frameworks like Django, or loading machine learning models.

Example — Optimize Python function for SnapStart

```
# Import all dependencies outside of Lambda handler
from snapshot_restore_py import register_before_snapshot
import boto3
import pandas
import pydantic

# Create S3 and SSM clients outside of Lambda handler
s3_client = boto3.client("s3")

# Register the function to be called before snapshot
@register_before_snapshot
def download_llm_models():
    # Download an object from S3 and save to tmp
    # This files will persist in this snapshot
    with open('/tmp/FILE_NAME', 'wb') as f:
        s3_client.download_fileobj('amzn-s3-demo-bucket', 'OBJECT_NAME', f)
    ...

def lambda_handler(event, context):
    ...
```

.NET

To reduce just-in-time (JIT) compilation and assembly loading time, consider invoking your function handler from a `RegisterBeforeCheckpoint` [runtime hook](#). Because of how .NET tiered compilation works, you'll get optimal results by invoking the handler multiple times, as shown in the following example.

Important

Make sure that your dummy function invocation does not produce unintended side effects, such as initiating business transactions.

Example

```
public class Function
{
    public Function()
    {
        Amazon.Lambda.Core.SnapshotRestore.RegisterBeforeSnapshot(FunctionWarmup);
    }

    // Warmup method that calls the function handler before snapshot to warm up
    the .NET code and runtime.
    // This speeds up future cold starts after restoring from a snapshot.

    private async ValueTask FunctionWarmup()
    {
        var request = new APIGatewayProxyRequest
        {
            Path = "/healthcheck",
            HttpMethod = "GET"
        };

        for (var i = 0; i < 10; i++)
        {
            await FunctionHandler(request, null);
        }
    }

    public async Task<APIGatewayProxyResponse> FunctionHandler(APIGatewayProxyRequest
request, ILambdaContext context)
    {
        //
        // Process HTTP request
        //

        var response = new APIGatewayProxyResponse
        {
            StatusCode = 200
        };

        return await Task.FromResult(response);
    }
}
```

Networking best practices

The state of connections that your function establishes during the initialization phase isn't guaranteed when Lambda resumes your function from a snapshot. In most cases, network connections that an AWS SDK establishes automatically resume. For other connections, we recommend the following best practices.

Re-establish network connections

Always re-establish your network connections when your function resumes from a snapshot. We recommend that you re-establish network connections in the function handler. Alternatively, you can use an after-restore [runtime hook](#).

Don't use hostname as a unique execution environment identifier

We recommend against using `hostname` to identify your execution environment as a unique node or container in your applications. With SnapStart, a single snapshot is used as the initial state for multiple execution environments. All execution environments return the same `hostname` value for `InetAddress.getLocalHost()` (Java), `socket.gethostname()` (Python), and `Dns.GetHostName()` (.NET). For applications that require a unique execution environment identity or `hostname` value, we recommend that you generate a unique ID in the function handler. Or, use an after-restore [runtime hook](#) to generate a unique ID, and then use the unique ID as the identifier for the execution environment.

Avoid binding connections to fixed source ports

We recommend that you avoid binding network connections to fixed source ports. Connections are re-established when a function resumes from a snapshot, and network connections that are bound to a fixed source port might fail.

Avoid using Java DNS cache

Lambda functions already cache DNS responses. If you use another DNS cache with SnapStart, then you might experience connection timeouts when the function resumes from a snapshot.

The `java.util.logging.Logger` class can indirectly enable the JVM DNS cache. To override the default settings, set [networkaddress.cache.ttl](#) to 0 before initializing `logger`. Example:

```
public class MyHandler {  
    // first set TTL property
```

```
static{
    java.security.Security.setProperty("networkaddress.cache.ttl" , "0");
}
// then instantiate logger
var logger = org.apache.logging.log4j.LogManager.getLogger(MyHandler.class);
}
```

To prevent `UnknownHostException` failures in the Java 11 runtime, we recommend setting `networkaddress.cache.negative.ttl` to 0. In Java 17 and later runtimes, this step isn't necessary. You can set this property for a Lambda function with the `AWS_LAMBDA_JAVA_NETWORKADDRESS_CACHE_NEGATIVE_TTL=0` environment variable.

Disabling the JVM DNS cache does not disable Lambda's managed DNS caching.

Troubleshooting SnapStart errors for Lambda functions

This page addresses common issues that occur when using Lambda SnapStart, including snapshot creation errors, timeout errors, and internal service errors.

SnapStartNotReadyException

Error: An error occurred (SnapStartNotReadyException) when calling the Invoke20150331 operation: Lambda is initializing your function. It will be ready to invoke once your function state becomes ACTIVE.

Common causes

This error occurs when you try to invoke a function version that is in the Inactive [state](#). Your function version becomes Inactive when it hasn't been invoked for 14 days or when Lambda periodically recycles the execution environment

Resolution

Wait until the function version reaches the Active state, and then invoke it again.

SnapStartTimeoutException

Issue: You receive a SnapStartTimeoutException when you try to invoke a SnapStart function version.

Common cause

During the [Restore](#) phase, Lambda restores the Java runtime and runs any after-restore [runtime hooks](#). If an after-restore runtime hook runs for longer than 10 seconds, the Restore phase times out and you get an error when you try to invoke the function. Network connection and credentials issues can also cause Restore phase timeouts.

Resolution

Check the function's CloudWatch logs for timeout errors that happened during the [Restore](#) phase. Make sure that all after-restore hooks complete in less than 10 seconds.

Example CloudWatch log

```
{ "cause": "Lambda couldn't restore the snapshot within the timeout limit. (Service: Lambda, Status Code: 408, Request ID: 11a222c3-410f-427c-ab22-931d6bcbf4f2)", "error": "Lambda.SnapStartTimeoutException" }
```

500 Internal Service Error

Error: Lambda was unable to create a new snapshot because you have reached your concurrent snapshot creation limit.

Common cause

A 500 error is an internal error within the Lambda service itself, rather than an issue with your function or code. These errors are often intermittent.

Resolution

Try to publish the function version again.

401 Unauthorized

Error: Bad session token or header key

Common cause

This error occurs when using the [AWS Systems Manager Parameter Store and AWS Secrets Manager extension](#) with Lambda SnapStart.

Resolution

The AWS Systems Manager Parameter Store and AWS Secrets Manager extension isn't compatible with SnapStart. The extension generates credentials for communicating with AWS Secrets Manager during function initialization, which causes expired credential errors when used with SnapStart.

UnknownHostException (Java)

Error: Unable to execute HTTP request: Certificate for abc.us-east-1.amazonaws.com doesn't match any of the subject alternative names.

Common cause

Lambda functions already cache DNS responses. If you use another DNS cache with SnapStart, then you might experience connection timeouts when the function resumes from a snapshot.

Resolution

To prevent `UnknownHostException` failures in the Java 11 runtime, we recommend setting `networkaddress.cache.negative.ttl` to 0. In Java 17 and later runtimes, this step isn't necessary. You can set this property for a Lambda function with the `AWS_LAMBDA_JAVA_NETWORKADDRESS_CACHE_NEGATIVE_TTL=0` environment variable.

Snapshot creation failures

Error: AWS Lambda could not invoke your SnapStart function. If this error persists, check your function's CloudWatch logs for initialization errors.

Resolution

Review your function's Amazon CloudWatch logs for before-checkpoint [runtime hook](#) timeouts. You can also try publishing a new function version, which can sometimes resolve the issue.

Snapshot creation latency

Issue: When you publish a new function version, the function stays in the Pending [state](#) for a long time.

Common cause

When Lambda creates a snapshot, your initialization code can run for up to 15 minutes. The time limit is 130 seconds or the [configured function timeout](#) (maximum 900 seconds), whichever is higher.

If your function is [attached to a VPC](#), Lambda might also need to create network interfaces before the function becomes `Active`. If you try to invoke the function version while the function is `Pending`, you might get a `409 ResourceConflictException`. If the function is invoked using an Amazon API Gateway endpoint, you might get a 500 error in API Gateway.

Resolution

Wait at least 15 minutes for the function version to initialize before invoking it.

Tenant isolation

Use tenant isolation mode when you need isolated request processing for individual end-users or tenants invoking a Lambda function. This capability simplifies building multi-tenant applications that process tenant-specific code or data, such as SaaS platforms for workflow automation or code execution, by removing the need to manage tenant-specific function resources and request routing logic.

Multi-tenant applications have strict isolation requirements when running code or processing data for individual tenants or end-users. With tenant isolation mode, Lambda uses a customer-specified tenant identifier to route requests to underlying function execution environments, ensuring that a function's execution environments are only used to serve invocations from the specified end-user or tenant. Lambda's function execution environments leverage [Firecracker virtualization](#) to provide workload isolation.

When a function using tenant isolation mode receives an invoke with a tenant identifier, Lambda first attempts to locate an available execution environment associated with that tenant identifier. If no execution environments exist, Lambda creates and assigns a new execution environment to that tenant. As function invocations with the specified tenant identifier scale up, Lambda locates or creates new execution environments as necessary.

Topics

- [When to use tenant isolation mode](#)
- [Supported features and limitations](#)
- [Supported AWS Regions](#)
- [Considerations](#)
- [Pricing](#)
- [Isolation mode](#)
- [Enabling tenant isolation for Lambda functions](#)
- [Invoking Lambda functions with tenant isolation](#)
- [Accessing tenant identifier in Lambda function code](#)
- [Monitoring Lambda functions with tenant isolation](#)
- [Troubleshooting tenant isolation for Lambda functions](#)

When to use tenant isolation mode

Use tenant isolation mode when you need to serve multiple end-users or tenants using a single Lambda function, while ensuring that the execution environments used to process invocations for individual tenants remain isolated from one another. This strict isolation of execution environments is required for multi-tenant applications that:

- **Execute end-user supplied code:** Maintaining separate execution environments for individual tenants can limit the impact of executing user-supplied code that may be incorrect or malicious.
- **Process tenant-specific data:** Maintaining separate execution environments for individual tenants can prevent exposure of sensitive tenant-specific data to other tenants.

Multiple invocation requests from the same tenant can re-use the same function execution environment, reducing cold-starts and improving response times for latency sensitive applications.

Supported features and limitations

Tenant isolation mode is not supported with functions that use [function URLs](#), [provisioned concurrency](#), or [SnapStart](#). You can send requests to a tenant-isolated function using [synchronous invocations](#), [asynchronous invocations](#), or by using [Amazon API Gateway as an event-trigger](#).

Supported AWS Regions

Tenant isolation mode is supported in all [commercial Regions](#) except Asia Pacific (New Zealand).

Considerations

When using tenant isolation with your Lambda functions, keep the following in mind:

- **Immutable configuration:** Tenant isolation is an immutable function property. It can only be enabled when creating a function.
- **Required tenant-id parameter:** Functions using tenant isolation mode must be invoked with a `tenant-id` parameter. Omitting this parameter will cause function invocations to fail.
- **Execution role applies to all tenants:** Invocations from all tenants use the permissions defined in your Lambda function's [execution role](#).

- **Concurrency:** There are no changes to your function's [concurrency](#) or [scaling behavior](#) when using tenant isolation. Lambda imposes a limit of 2,500 tenant-isolated execution environments (active or idle) for every 1,000 [concurrent executions](#) configured for your Lambda function.

Pricing

You are charged when Lambda creates a new tenant-isolated execution environment. The price depends on the amount of [memory](#) that you allocate to your function and the [CPU architecture](#) that you use. For more information, see [AWS Lambda pricing](#).

Isolation mode

The following table outlines differences between Lambda functions with and without tenant isolation.

Feature	With tenant isolation	Without tenant isolation
Isolation type	Tenant-level isolation	Function-level isolation
Environment reuse	Execution environments are never reused across different tenants	Execution environments might be reused across invocations of the same function
Data isolation	Data from other tenants is not accessible	Data from previous invocations of the same function version may be accessible
Cold starts	More cold starts due to tenant-specific environments	Fewer cold starts due to environment reuse
Pricing	Additional charge besides the standard Lambda pricing	Standard Lambda pricing

Enabling tenant isolation for Lambda functions

To activate tenant isolation mode, create a new Lambda function. You cannot enable tenant isolation on existing functions.

Topics

- [Enabling tenant isolation \(console\)](#)
- [Enabling tenant isolation \(AWS CLI\)](#)
- [Enabling tenant isolation \(API\)](#)
- [Enabling tenant isolation \(CloudFormation\)](#)

Enabling tenant isolation (console)

To create a Lambda function using the console

1. Open the [Functions page](#) of the Lambda console.
2. Choose **Create function**.
3. Select **Author from scratch**.
4. In the **Basic information** pane, for **Function name**, enter **image-analysis**.
5. For **Runtime**, choose any of the [supported Lambda runtimes](#).
6. Under additional configurations, **Tenant isolation mode**, select **Enable**.
7. Review your settings, and choose **Create function**.

Enabling tenant isolation (AWS CLI)

Create function with tenant isolation

When creating a new function using the CLI, add the `--tenancy-config '{"TenantIsolationMode": "PER_TENANT"}'` option to your [create-function](#) request.

Example:

```
aws lambda create-function \
  --function-name image-analysis \
  --runtime nodejs24.x \
  --zip-file fileb://image-analysis-function.zip \
  --handler image-analysis-function.handler \
  --tenancy-config '{"TenantIsolationMode": "PER_TENANT"}'
```

```
--role arn:aws:iam:123456789012:role/execution-role \  
--tenancy-config '{"TenantIsolationMode": "PER_TENANT"}'
```

Enabling tenant isolation (API)

To enable tenant isolation using the Lambda API

1. Create a new function with tenant isolation enabled by using the [CreateFunction](#) API action with the `TenancyConfig` parameter.
2. Confirm that tenant isolation is enabled for the function by using the [GetFunctionConfiguration](#) action. If the response shows that `TenantIsolationMode` is `PER_TENANT`, then tenant isolation is enabled for the function:

```
"TenancyConfig": {  
    "TenantIsolationMode": "PER_TENANT"  
}
```

Invoke the function version with the [Invoke](#) action. For more information, see [Invoking Lambda functions with tenant isolation](#).

Enabling tenant isolation (CloudFormation)

The following CloudFormation template creates a new Lambda function with tenant isolation enabled:

```
MyLambdaFunction:  
  Type: AWS::Lambda::Function  
  Properties:  
    FunctionName: my-sample-python-lambda  
    Runtime: python3.14  
    Role: !GetAtt LambdaExecutionRole.Arn  
    Handler: index.lambda_handler  
    TenancyConfig:  
      TenantIsolationMode: PER_TENANT  
    Code:  
      ZipFile: |  
        import json  
  
        def lambda_handler(event, context):  
          return {
```

```
        'statusCode': 200,  
        'body': json.dumps(f'Hello from Lambda! Tenant-ID:  
{context.tenant_id}')  
    }  
    Timeout: 10  
    MemorySize: 128
```

Invoking Lambda functions with tenant isolation

When invoking a function that has tenant isolation enabled, you must provide a `tenant-id` parameter. This parameter ensures that your function invocation is processed in an execution environment dedicated to that specific tenant.

Invoking functions with tenant isolation (AWS CLI)

Synchronous invocation

For synchronous invocations, add the `--tenant-id` parameter to your [Invoke](#) command:

```
aws lambda invoke \  
  --function-name image-analysis \  
  --tenant-id blue \  
  response.json
```

Asynchronous invocation

For asynchronous invocations, include both the `--tenant-id` and `--invocation-type Event` parameters:

```
aws lambda invoke \  
  --function-name image-analysis \  
  --tenant-id blue \  
  --invocation-type Event \  
  response.json
```

Invoking functions with tenant isolation (API)

When using the [Invoke](#) API action directly, include the tenant identifier using the `X-Amzn-Tenant-Id` parameter in your request.

Example API request

```
POST /2015-03-31/functions/image-analysis/invocations HTTP/1.1  
Host: lambda.us-east-1.amazonaws.com  
Content-Type: application/json  
Authorization: AWS4-HMAC-SHA256 Credential=...  
X-Amz-Tenant-Id: blue
```

```
{
  "key1": "value1",
  "key2": "value2"
}
```

Invoking functions with tenant isolation (API Gateway)

When using API Gateway REST APIs to trigger tenant-isolated Lambda functions, you must configure API Gateway to map client request properties to the `X-Amz-Tenant-Id` header that Lambda expects. API Gateway uses Lambda's [Invoke](#) API action, which requires the tenant ID to be passed using the `X-Amz-Tenant-Id` HTTP header. You can configure API Gateway to inject this HTTP header into the Lambda invocation request with a value obtained from client request properties such as HTTP headers, query parameters, or path parameters. You must first map the client request property before you can override the `X-Amz-Tenant-Id` header.

Note

You cannot use HTTP APIs to invoke tenant-isolated Lambda functions because it is not possible to override the `X-Amz-Tenant-Id` header.

Using request headers

Configure your API Gateway integration to map a custom header from the client request to the `X-Amz-Tenant-Id` header. The following example shows a client request with an `x-tenant-id` header:

```
POST /api/process HTTP/1.1
Host: your-api-id.execute-api.us-east-1.amazonaws.com
Content-Type: application/json
x-tenant-id: blue

{
  "data": "sample payload"
}
```

In your API Gateway method configuration, you must:

1. Enable the client request header parameter (for example, `method.request.header.x-tenant-id`)

2. Map the client header to the Lambda integration header using `integration.request.header.X-Amz-Tenant-Id`

Using query parameters

Similarly, you can map query parameters to the X-Amz-Tenant-Id header:

```
GET /api/process?tenant-id=blue&data=sample HTTP/1.1
Host: your-api-id.execute-api.us-east-1.amazonaws.com
```

Configure the method to enable the query parameter and map it to the integration header.

Invoking functions with tenant isolation (SDK)

When using AWS SDKs to invoke tenant-isolated functions, include the tenant identifier in your invocation request.

Python

```
import boto3
import json

lambda_client = boto3.client('lambda')

response = lambda_client.invoke(
    FunctionName='image-analysis',
    TenantId='blue',
    Payload=json.dumps({
        'key1': 'value1',
        'key2': 'value2'
    })
)

result = json.loads(response['Payload'].read())
```

Node.js

```
const AWS = require('aws-sdk');
const lambda = new AWS.Lambda();

const params = {
```

```
    FunctionName: 'image-analysis',
    TenantId: 'blue',
    Payload: JSON.stringify({
      key1: 'value1',
      key2: 'value2'
    })
  });

lambda.invoke(params, (err, data) => {
  if (err) {
    console.error(err);
  } else {
    const result = JSON.parse(data.Payload);
    console.log(result);
  }
});
```

Java

```
import software.amazon.awssdk.services.lambda.LambdaClient;
import software.amazon.awssdk.services.lambda.model.InvokeRequest;
import software.amazon.awssdk.services.lambda.model.InvokeResponse;
import software.amazon.awssdk.core.SdkBytes;

public class TenantIsolationExample {

    public static void main(String[] args) {
        LambdaClient lambdaClient = LambdaClient.create();

        String payload = "{\"key1\": \"value1\", \"key2\": \"value2\"}";

        InvokeRequest request = InvokeRequest.builder()
            .functionName("image-analysis")
            .tenantId("blue")
            .payload(SdkBytes.fromUtf8String(payload))
            .build();

        InvokeResponse response = lambdaClient.invoke(request);
    }
}
```

Accessing tenant identifier in Lambda function code

When your Lambda function has tenant isolation enabled, the tenant identifier used to invoke your function is made available within the context object passed to your function handler. You can use this identifier to implement tenant-specific logic, monitoring, and debugging capabilities.

Topics

- [Accessing the tenant identifier](#)
- [Common usage patterns](#)
- [Monitoring and debugging](#)

Accessing the tenant identifier

The tenant identifier is available through the `tenantId` property of the context object. Note that this property is available during the [invocation phase](#), not during the [initialization phase](#).

Python

```
def lambda_handler(event, context):
    tenant_id = context.tenant_id
    print(f"Processing request for tenant: {tenant_id}")

    # Implement tenant-specific logic
    if tenant_id == "blue":
        return process_blue_tenant(event)
    elif tenant_id == "green":
        return process_green_tenant(event)
    else:
        return process_default_tenant(event)
```

Node.js

```
exports.handler = async (event, context) => {
    const tenantId = context.tenantId;
    console.log(`Processing request for tenant: ${tenantId}`);

    // Implement tenant-specific logic
    switch (tenantId) {
        case 'blue':
```

```
        return processBlueTenant(event);
    case 'green':
        return processGreenTenant(event);
    default:
        return processDefaultTenant(event);
    }
};
```

Java

```
public class TenantHandler implements RequestHandler<Map<String, Object>, String> {

    @Override
    public String handleRequest(Map<String, Object> event, Context context) {
        String tenantId = context.getTenantId();
        System.out.println("Processing request for tenant: " + tenantId);

        // Implement tenant-specific logic
        switch (tenantId) {
            case "blue":
                return processBlueTenant(event);
            case "green":
                return processGreenTenant(event);
            default:
                return processDefaultTenant(event);
        }
    }
}
```

Common usage patterns

Here are common ways to use the tenant identifier in your function code:

Tenant-specific configuration

Use the tenant ID to load tenant-specific configuration or settings:

```
def lambda_handler(event, context):
    tenant_id = context.tenant_id

    # Load tenant-specific configuration
    config = load_tenant_config(tenant_id)
```

```
database_url = config['database_url']
api_key = config['api_key']

# Process with tenant-specific settings
return process_request(event, database_url, api_key)
```

Tenant-specific data access

Use the tenant ID to ensure data isolation and access control:

```
import boto3

def lambda_handler(event, context):
    tenant_id = context.tenant_id

    # Ensure data access is scoped to the tenant
    dynamodb = boto3.resource('dynamodb')
    table = dynamodb.Table('user_data')

    user_id = event.get('userId')

    response = table.get_item(
        Key={
            'tenant_id': tenant_id,
            'user_id': user_id
        }
    )

    return process_results(response.get('Item'), tenant_id)
```

Monitoring and debugging

The tenant identifier is automatically included in Lambda logs when you have [JSON logging enabled](#), making it easier to monitor and debug tenant-specific issues. You can also use the tenant ID for custom metrics and tracing.

Example Custom metrics with tenant ID

The following example demonstrates how to use the tenant ID to create tenant-specific CloudWatch metrics for monitoring usage patterns and performance by tenant:

```
import boto3
```

```
def lambda_handler(event, context):
    tenant_id = context.tenant_id
    cloudwatch = boto3.client('cloudwatch')

    # Record tenant-specific metrics
    cloudwatch.put_metric_data(
        Namespace='MyApp/TenantMetrics',
        MetricData=[
            {
                'MetricName': 'RequestCount',
                'Dimensions': [
                    {
                        'Name': 'TenantId',
                        'Value': tenant_id
                    }
                ],
                'Value': 1,
                'Unit': 'Count'
            }
        ]
    )

    return process_request(event, tenant_id)
```

Monitoring Lambda functions with tenant isolation

You can monitor your tenant-isolated Lambda functions using Amazon CloudWatch, AWS X-Ray, and by accessing real-time telemetry data for extensions [using the Telemetry API](#).

Understanding logging for tenant isolated mode

For functions using tenant isolation, Lambda automatically includes the tenant identifier in [function logs](#) when you have [JSON logging enabled](#), making it easier to monitor and debug tenant-specific issues. Lambda creates a separate [CloudWatch log stream](#) for each execution environment. You can use CloudWatch Logs Insights to find log streams that belong to a particular tenant by filtering by tenant identifier:

```
fields @logStream, @message
| filter tenantId=='BlueTenant' or record.tenantId=='BlueTenant'
| stats count() as logCount by @logStream
| sort @timestamp desc
```

You can also use this parameter to retrieve tenant-specific logs across all log streams:

```
fields @message
| filter tenantId=='BlueTenant' or record.tenantId=='BlueTenant'
| limit 1000
```

The `tenantId` property is included for platform events (like `platform.start` and `platform.report`) and custom logs you print in your function code, as shown below:

```
{
  "time": "2025-10-13T19:48:06.990Z",
  "type": "platform.start",
  "record": {
    "requestId": "a0f40320-b43c-44b3-91bf-d5b5240a1bed",
    "functionArn": "arn:aws:lambda:us-east-1:xxxxxx:function:multitenant-
function-1",
    "version": "$LATEST",
    "tenantId": "BlueTenant"
  }
}
{
  "timestamp": "2025-10-13T19:48:06.992Z",
```

```
"level": "INFO",  
"requestId": "a0f40320-b43c-44b3-91bf-d5b5240a1bed",  
"tenantId": "BlueTenant",  
"message": "custom log line1"  
}  
{  
  "timestamp": "2025-10-13T19:48:07.022Z",  
  "level": "WARN",  
  "requestId": "a0f40320-b43c-44b3-91bf-d5b5240a1bed",  
  "tenantId": "BlueTenant",  
  "message": "custom log line2"  
}
```

Troubleshooting tenant isolation for Lambda functions

This page addresses common issues that occur when using tenant isolation for AWS Lambda.

InvalidParameterValueException

Error : Tenant ID configuration not specified or passed to a function when tenant isolation is not enabled.

Common causes

This error occurs when invoking a tenant-isolated function without a tenant ID, or invoking a non-tenant-isolated function with a tenant ID.

Resolution

Add a tenant ID if the function has tenant isolation enabled, or remove the tenant ID if the function doesn't have tenant isolation enabled.

TooManyRequestsException

Error: Rate exceeded

Common causes

In addition to rate limiting based on [maximum concurrent executions](#) and [function scaling rate](#), Lambda limits the maximum number of tenant-aware execution environments (active or idle) that can exist at a time to 2,500 for every 1,000 concurrent executions of your function.

Resolution

To fix this issue, you can either lower the rate at which invocation requests with unique tenant identifiers are made, [implement retries with backoff and jitter](#), or [request a function concurrency limit increase](#).

Invoking Lambda with events from other AWS services

Some AWS services can directly invoke Lambda functions using *triggers*. These services push events to Lambda, and the function is invoked immediately when the specified event occurs. Triggers are suitable for discrete events and real-time processing. When you [create a trigger using the Lambda console](#), the console interacts with the corresponding AWS service to configure the event notification on that service. The trigger is actually stored and managed by the service that generates the events, not by Lambda.

The events are data structured in JSON format. The JSON structure varies depending on the service that generates it and the event type, but they all contain the data that the function needs to process the event.

A function can have multiple triggers. Each trigger acts as a client invoking your function independently, and each event that Lambda passes to your function has data from only one trigger. Lambda converts the event document into an object and passes it to your function handler.

Depending on the service, the event-driven invocation can be [synchronous](#) or [asynchronous](#).

- For synchronous invocation, the service that generates the event waits for the response from your function. That service defines the data that the function needs to return in the response. The service controls the error strategy, such as whether to retry on errors.
- For asynchronous invocation, Lambda queues the event before passing it to your function. When Lambda queues the event, it immediately sends a success response to the service that generated the event. After the function processes the event, Lambda doesn't return a response to the event-generating service.

Creating a trigger

The easiest way to create a trigger is to use the Lambda console. When you create a trigger using the console, Lambda automatically adds the required permissions to the function's [resource-based policy](#).

To create a trigger using the Lambda console

1. Open the [Functions page](#) of the Lambda console.
2. Select the function you want to create a trigger for.

3. In the **Function overview** pane, choose **Add trigger**.
4. Select the AWS service you want to invoke your function.
5. Fill out the options in the **Trigger configuration** pane and choose **Add**. Depending on the AWS service you choose to invoke your function, the trigger configuration options will be different.

Services that can invoke Lambda functions

The following table lists services that can invoke Lambda functions.

Service	Method of invocation
Amazon Managed Streaming for Apache Kafka	Event source mapping
Self-managed Apache Kafka	Event source mapping
Amazon API Gateway	Event-driven; synchronous invocation
AWS CloudFormation	Event-driven; asynchronous invocation
Amazon CloudWatch Logs	Event-driven; asynchronous invocation
AWS CodeCommit	Event-driven; asynchronous invocation
AWS CodePipeline	Event-driven; asynchronous invocation
Amazon Cognito	Event-driven; synchronous invocation
AWS Config	Event-driven; asynchronous invocation
Amazon Connect	Event-driven; synchronous invocation
Amazon DocumentDB	Event source mapping
Amazon DynamoDB	Event source mapping
Elastic Load Balancing (Application Load Balancer)	Event-driven; synchronous invocation

Service	Method of invocation
Amazon EventBridge (CloudWatch Events)	Event-driven; asynchronous invocation (event buses), synchronous or asynchronous invocation (pipes and schedules)
AWS IoT	Event-driven; asynchronous invocation
Amazon Kinesis	Event source mapping
Amazon Data Firehose	Event-driven; synchronous invocation
Amazon Lex	Event-driven; synchronous invocation
Amazon MQ	Event source mapping
Amazon Simple Email Service	Event-driven; asynchronous invocation
Amazon Simple Notification Service	Event-driven; asynchronous invocation
Amazon Simple Queue Service	Event source mapping
Amazon Simple Storage Service (Amazon S3)	Event-driven; asynchronous invocation
Amazon Simple Storage Service Batch	Event-driven; synchronous invocation
Secrets Manager	Secret rotation
AWS Step Functions	Event-driven; synchronous or asynchronous invocation
Amazon VPC Lattice	Event-driven; synchronous invocation

Using Lambda with Apache Kafka

Lambda supports [Apache Kafka](#) as an [event source](#). Apache Kafka is an open-source event streaming platform designed to handle high-throughput, real-time data pipelines and streaming applications. There are two main ways to use Lambda with Apache Kafka:

- [the section called “MSK”](#) – Amazon Managed Streaming for Apache Kafka (Amazon MSK) is a fully-managed service by AWS. Amazon MSK helps automate management of your Kafka infrastructure, including provisioning, patching, and scaling.
- [the section called “Self-managed Apache Kafka”](#) – In AWS terminology, a self-managed cluster includes non-AWS hosted Kafka clusters. For example, you can still use Lambda with a Kafka cluster hosted with a non-AWS cloud provider such as [Confluent Cloud](#) or [Redpanda](#).

When deciding between Amazon MSK and self-managed Apache Kafka, consider your operational needs and control requirements. Amazon MSK is a better choice if you want AWS to quickly help you manage a scalable, production-ready Kafka setup with minimal operational overhead. It simplifies security, monitoring, and high availability, helping you focus on application development rather than infrastructure management. On the other hand, self-managed Apache Kafka is better suited for use cases running on non-AWS hosted environments, including on-premises clusters.

Using Lambda with Amazon MSK

[Amazon Managed Streaming for Apache Kafka \(Amazon MSK\)](#) is a fully-managed service that you can use to build and run applications that use Apache Kafka to process streaming data. Amazon MSK simplifies the setup, scaling, and management of Kafka clusters. Amazon MSK also makes it easier to configure your application for multiple Availability Zones and for security with AWS Identity and Access Management (IAM).

This chapter explains how to use an Amazon MSK cluster as an event source for your Lambda function. The general process for integrating Amazon MSK with Lambda involves the following steps:

1. **[Cluster and network setup](#)** – First, set up your [Amazon MSK cluster](#). This includes the correct networking configuration to allow Lambda to access your cluster.
2. **[Event source mapping setup](#)** – Then, create the [event source mapping](#) resource that Lambda needs to securely connect your Amazon MSK cluster to your function.
3. **[Function and permissions setup](#)** – Finally, ensure that your function is correctly set up, and has the necessary permissions in its [execution role](#).

Note

You can now create and manage your Amazon MSK event source mappings directly from either the Lambda or the Amazon MSK console. Both consoles offer the option to automatically handle the setup of the necessary Lambda execution role permissions for a more streamlined configuration process.

For examples on how to set up a Lambda integration with an Amazon MSK cluster, see [the section called “Tutorial”, Using Amazon MSK as an event source for AWS Lambda](#) on the AWS Compute Blog, and [Amazon MSK Lambda Integration](#) in the Amazon MSK Labs.

- [Configuring Amazon MSK event sources for Lambda](#)

- [Tutorial: Using an Amazon MSK event source mapping to invoke a Lambda function](#)

Example event

Lambda sends the batch of messages in the event parameter when it invokes your function. The event payload contains an array of messages. Each array item contains details of the Amazon MSK topic and partition identifier, together with a timestamp and a base64-encoded message.

```
{
  "eventSource": "aws:kafka",
  "eventSourceArn": "arn:aws:kafka:us-east-1:123456789012:cluster/
vpc-2priv-2pub/751d2973-a626-431c-9d4e-d7975eb44dd7-2",
  "bootstrapServers": "b-2.demo-cluster-1.a1bcde.c1.kafka.us-
east-1.amazonaws.com:9092,b-1.demo-cluster-1.a1bcde.c1.kafka.us-
east-1.amazonaws.com:9092",
  "records": {
    "mytopic-0": [
      {
        "topic": "mytopic",
        "partition": 0,
        "offset": 15,
        "timestamp": 1545084650987,
        "timestampType": "CREATE_TIME",
        "key": "abcDEFghiJkLmnoPQRstuVWXyz1234==",
        "value": "SGVsbG8sIHRoaXMgaXMgYSB0ZXN0Lg==",
        "headers": [
          {
            "headerKey": [
              104,
              101,
              97,
              100,
              101,
              114,
              86,
              97,
              108,
              117,
              101
            ]
          }
        ]
      }
    ]
  }
}
```

```
}  
  ]  
}  
}
```

Configuring your Amazon MSK cluster and Amazon VPC network for Lambda

To connect your AWS Lambda function to your Amazon MSK cluster, you need to correctly configure your cluster and the [Amazon Virtual Private Cloud \(VPC\)](#) it resides in. This page describes how to configure your cluster and VPC. If your cluster and VPC are already configured properly, see [the section called “Configure event source”](#) to configure the event source mapping.

Topics

- [Overview of network configuration requirements for Lambda and MSK integrations](#)
- [Configuring a NAT gateway for an MSK event source](#)
- [Configuring AWS PrivateLink endpoints for an MSK event source](#)

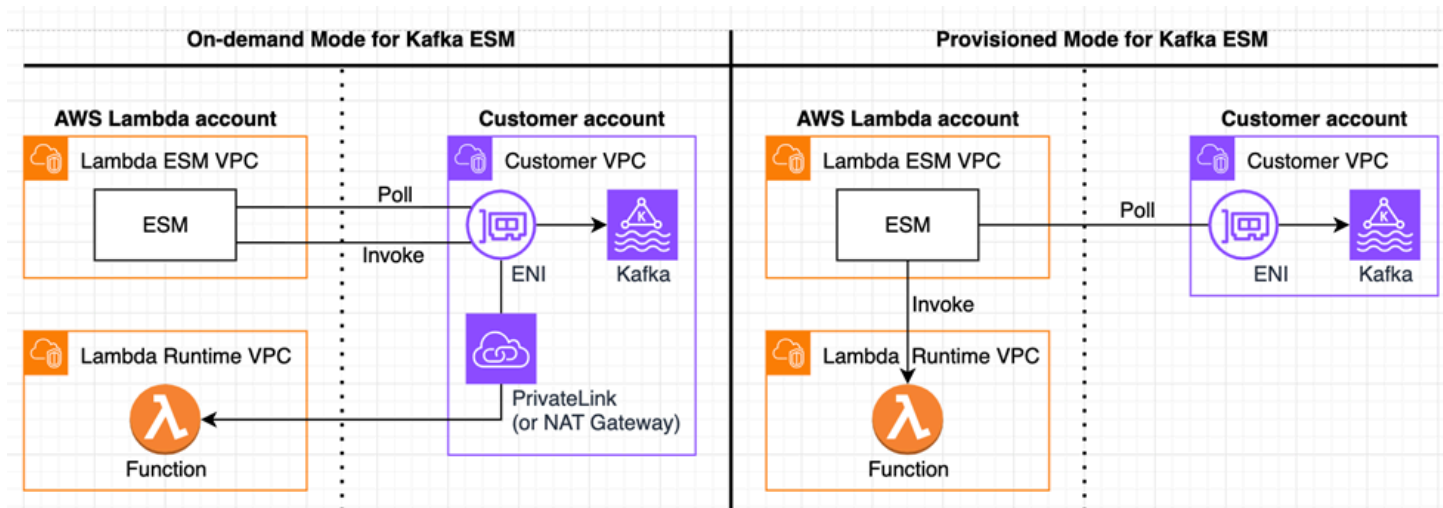

Overview of network configuration requirements for Lambda and MSK integrations

The networking configuration required for a Lambda and MSK integration depends on the network architecture of your application. There are three main resources involved in this integration: the Amazon MSK cluster, the Lambda function, and the Lambda event source mapping. Each of these resources resides in a different VPC:

- Your Amazon MSK cluster typically resides in a private subnet of a VPC that you manage.
- Your Lambda function resides in an AWS-managed VPC owned by Lambda.
- Your Lambda event source mapping resides in another AWS-managed VPC owned by Lambda, separate from the VPC that contains your function.

The [event source mapping](#) is the intermediary resource between the MSK cluster and the Lambda function. The event source mapping has two primary jobs. First, it polls your MSK cluster for new messages. Then, it invokes your Lambda function with those messages. Since these three resources are in different VPCs, both the poll and invoke operations require cross-VPC network calls.

The network configuration requirements for your event source mapping depends on whether it uses [provisioned mode](#) or on-demand mode, as shown in the following diagram:

The way that the Lambda event source mapping polls your MSK cluster for new messages is the same in both modes. To establish a connection between your event source mapping and your MSK cluster, Lambda creates a [hyperplane ENI](#) (or reuses an existing one, if available) in your private subnet to establish a secure connection. As illustrated in the diagram, this hyperplane ENI uses the subnet and security group configuration of your MSK cluster, not your Lambda function.

After polling the message from the cluster, the way Lambda invokes your function is different in each mode:

- In provisioned mode, Lambda automatically handles the connection between the event source mapping VPC and the function VPC. So, you don't need any additional networking components to successfully invoke your function.
- In on-demand mode, your Lambda event source mapping invokes your function via a path through your customer-managed VPC. Because of this, you need to configure either a [NAT gateway](#) in the public subnet of your VPC, or [AWS PrivateLink](#) endpoints in the private subnet of the VPC that provide access to Lambda, [AWS Security Token Service \(STS\)](#), and optionally, [AWS Secrets Manager](#). Correctly configuring either one of these options allows a connection between your VPC and the Lambda-managed runtime VPC, which is necessary to invoke your function.

A NAT gateway allows resources in your private subnet to access the public internet. Using this configuration means your traffic traverses the internet before invoking the Lambda function. AWS PrivateLink endpoints allow private subnets to securely connect to AWS services or other private VPC resources without traversing the public internet. See [the section called "Configuring a NAT gateway for an MSK event source"](#) or [the section called "Configuring AWS PrivateLink endpoints for an MSK event source"](#) for details on how to configure these resources.

So far, we've assumed that your MSK cluster resides in a private subnet within your VPC, which is the more common case. However, even if your MSK cluster is in a public subnet within your VPC, you must configure AWS PrivateLink endpoints to enable a secure connection. The following table summarizes the networking configuration requirements based on how you configure your MSK cluster and Lambda event source mapping:

MSK cluster location (in customer-managed VPC)	Lambda event source mapping scaling mode	Required networking configuration
Private subnet	On-demand mode	NAT gateway (in your VPC's public subnet), or AWS PrivateLink endpoints (in your VPC's private subnet) to enable access to Lambda, AWS STS, and optionally, Secrets Manager.
Public subnet	On-demand mode	AWS PrivateLink endpoints (in your VPC's public subnet) to enable access to Lambda, AWS STS, and optionally, Secrets Manager.
Private subnet	Provisioned mode	None
Public subnet	Provisioned mode	None

In addition, the security groups associated with your MSK cluster must allow traffic over the correct ports. Ensure that you have the following security group rules configured:

- **Inbound rules** – Allow all traffic on the default broker port. The port that MSK uses depends on the type of authentication on the cluster: 9098 for IAM authentication, 9096 for SASL/SCRAM, and 9094 for TLS. Alternatively, you can use a self-referencing security group rule to allow access from instances within the same security group.
- **Outbound rules** – Allow all traffic on port 443 for external destinations if your function needs to communicate with other AWS services. Alternatively, you can use a self-referencing security

group rule to limit access to the broker if you don't need to communicate with other AWS services.

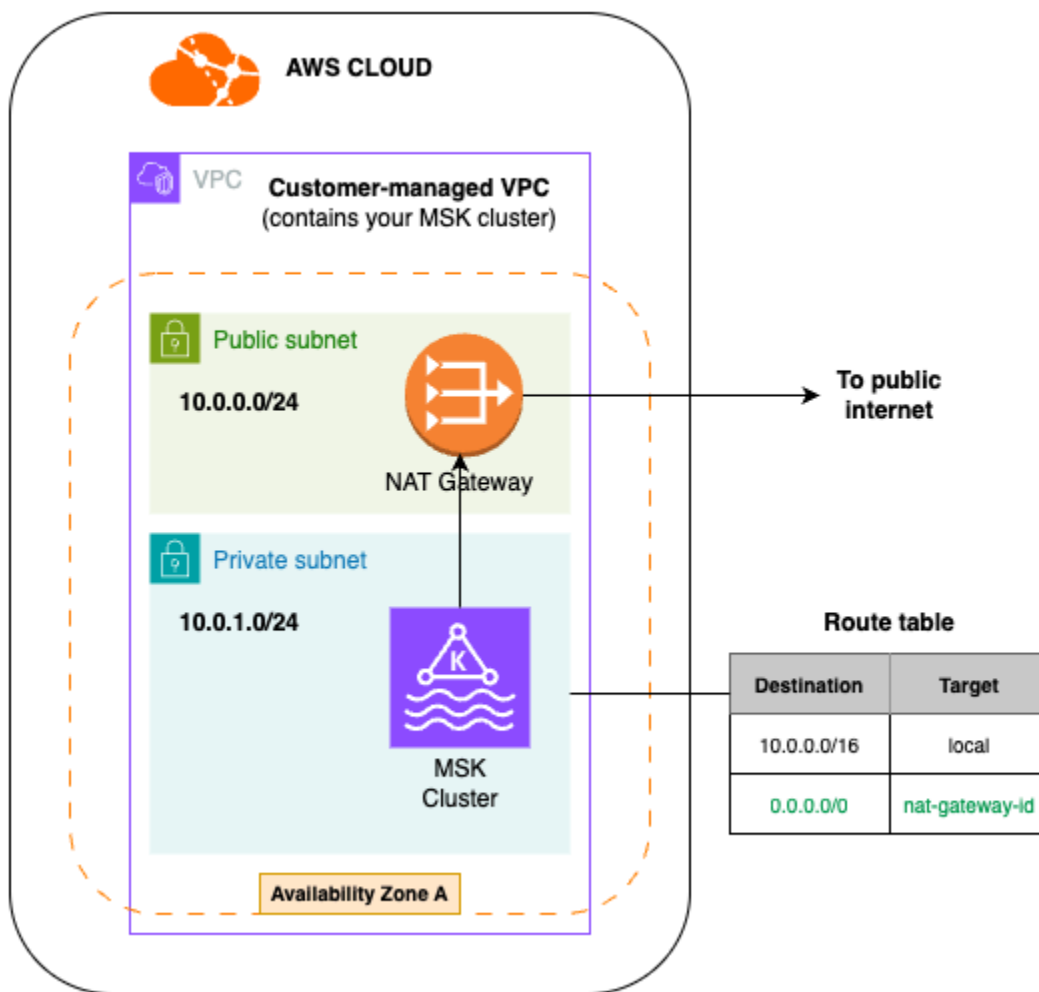

- **Amazon VPC endpoint inbound rules** – If you're using an Amazon VPC endpoint, the security group associated with the endpoint must allow inbound traffic on port 443 from the cluster's security group.

Configuring a NAT gateway for an MSK event source

You can configure a NAT gateway to allow your event source mapping to poll messages from your cluster, and invoke the function via a path through your VPC. This is required only if your event source mapping uses on-demand mode, and your cluster resides within a private subnet of your VPC. If your cluster resides in a public subnet of your VPC, or your event source mapping uses provisioned mode, you don't need to configure a NAT gateway.

A [NAT gateway](#) allows resources in a private subnet to access the public internet. If you need private connectivity to Lambda, see [the section called "Configuring AWS PrivateLink endpoints for an MSK event source"](#) instead.

After you configure your NAT gateway, you must configure the appropriate route tables. This allows traffic from your private subnet to route to the public internet via the NAT gateway.

The following steps guide you through configuring a NAT gateway using the console. Repeat these steps as necessary for each Availability Zone (AZ).

To configure a NAT gateway and proper routing (console)

- Follow the steps in [Create a NAT gateway](#), noting the following:
 - NAT gateways should always reside in a public subnet. Create NAT gateways with [public connectivity](#).
 - If your MSK cluster is replicated across multiple AZs, create one NAT gateway per AZ. For example, in each AZ, your VPC should have one private subnet containing your cluster, and one public subnet containing your NAT gateway. For a setup with three AZs, you'll have three private subnets, three public subnets, and three NAT gateways.
- After you create your NAT gateway, open the [Amazon VPC console](#) and choose **Route tables** in the left menu.

3. Choose **Create route table**.
4. Associate this route table with the VPC that contains your MSK cluster. Optionally, enter a name for your route table.
5. Choose **Create route table**.
6. Choose the route table you just created.
7. Under the **Subnet associations** tab, choose **Edit subnet associations**.
 - Associate this route table with the private subnet that contains your MSK cluster.
8. Choose **Edit routes**.
9. Choose **Add route**:
 1. For **Destination**, choose `0.0.0.0/0`.
 2. For **Target**, choose **NAT gateway**.
 3. In the search box, choose the NAT gateway you created in step 1. This should be the NAT gateway in the same AZ as the private subnet that contains your MSK cluster (the private subnet that you associated with this route table in step 6).
10. Choose **Save changes**.

Configuring AWS PrivateLink endpoints for an MSK event source

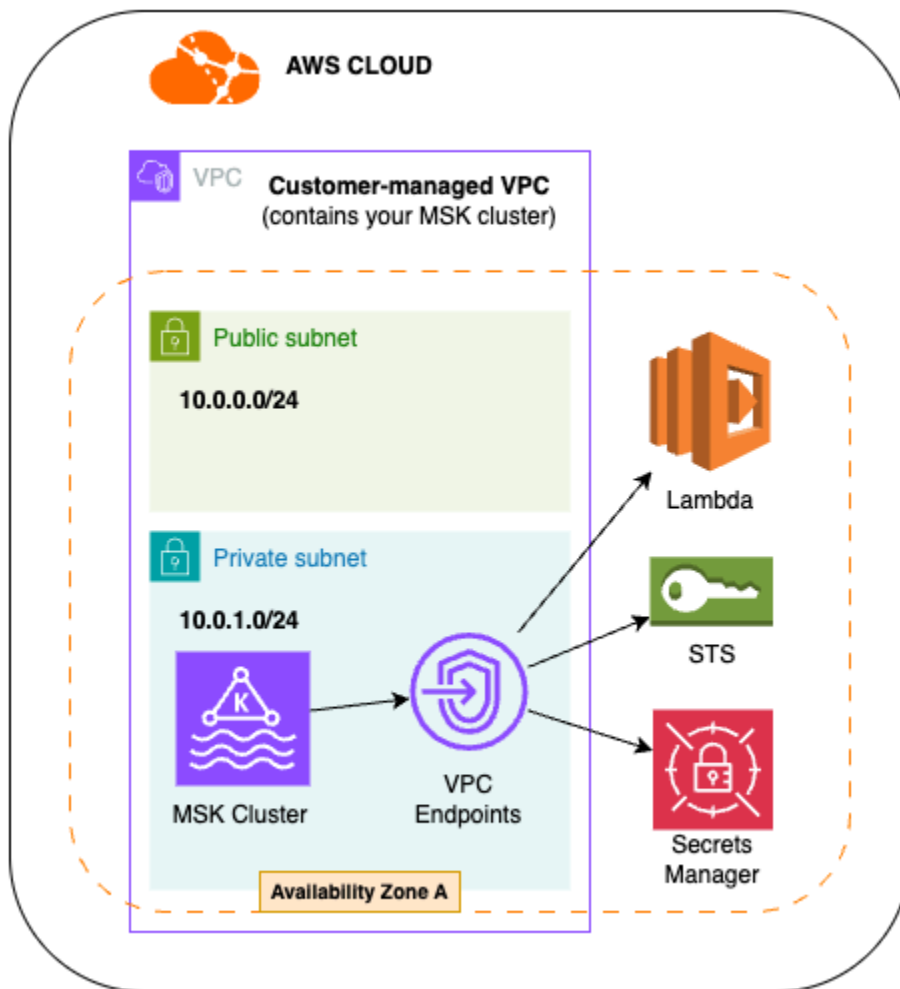

You can configure AWS PrivateLink endpoints to poll messages from your cluster, and invoke the function via a path through your VPC. These endpoints should allow your MSK cluster to access the following:

- The Lambda service
- The [AWS Security Token Service \(STS\)](#)
- Optionally, the [AWS Secrets Manager](#) service. This is required if the secret required for cluster authentication is stored in Secrets Manager.

Configuring PrivateLink endpoints is required only if your event source mapping uses on-demand mode. If your event source mapping uses provisioned mode, Lambda establishes the required connections for you.

PrivateLink endpoints allow secure, private access to AWS services over AWS PrivateLink. Alternatively, to configure a NAT gateway to give your MSK cluster access to the public internet, see [the section called “Configuring a NAT gateway for an MSK event source”](#).

After you configure your VPC endpoints, your MSK cluster should have direct and private access to Lambda, STS, and optionally, Secrets Manager.

The following steps guide you through configuring a PrivateLink endpoint using the console. Repeat these steps as necessary for each endpoint (Lambda, STS, Secrets Manager).

To configure VPC PrivateLink endpoints (console)

1. Open the [Amazon VPC console](#) and choose **Endpoints** in the left menu.
2. Choose **Create endpoint**.
3. Optionally, enter a name for your endpoint.
4. For **Type**, choose **AWS services**.
5. Under **Services**, start typing the name of the service. For example, to create an endpoint to connect to Lambda, type `lambda` in the search box.

6. In the results, you should see the service endpoint in the current region. For example, in the US East (N. Virginia) region, you should see `com.amazonaws.us-east-2.lambda`. Select this service.
7. Under **Network settings**, select the VPC that contains your MSK cluster.
8. Under **Subnets**, select the AZs that your MSK cluster is in.
 - For each AZ, under **Subnet ID**, choose the private subnet that contains your MSK cluster.
9. Under **Security groups**, select the security groups associated with your MSK cluster.
10. Choose **Create endpoint**.

By default, Amazon VPC endpoints have open IAM policies that allow broad access to resources. Best practice is to restrict these policies to perform the needed actions using that endpoint. For example, for your Secrets Manager endpoint, you can modify its policy such that it allows only your function's execution role to access the secret.

Example VPC endpoint policy – Secrets Manager endpoint

```
{
  "Statement": [
    {
      "Action": "secretsmanager:GetSecretValue",
      "Effect": "Allow",
      "Principal": {
        "AWS": [
          "arn:aws::iam::123456789012:role/my-role"
        ]
      },
      "Resource": "arn:aws::secretsmanager:us-west-2:123456789012:secret:my-secret"
    }
  ]
}
```

For the AWS STS and Lambda endpoints, you can restrict the calling principal to the Lambda service principal. However, ensure that you use `"Resource": "*" in these policies.`

Example VPC endpoint policy – AWS STS endpoint

```
{
  "Statement": [
```

```

    {
      "Action": "sts:AssumeRole",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "lambda.amazonaws.com"
        ]
      },
      "Resource": "*"
    }
  ]
}

```

Example VPC endpoint policy – Lambda endpoint

```

{
  "Statement": [
    {
      "Action": "lambda:InvokeFunction",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "lambda.amazonaws.com"
        ]
      },
      "Resource": "*"
    }
  ]
}

```

Configuring Lambda permissions for Amazon MSK event source mappings

To access the Amazon MSK cluster, your function and event source mapping need permissions to perform various Amazon MSK API actions. Add these permissions to the function's [execution role](#). If your users need access, add the required permissions to the identity policy for the user or role.

The [AWSLambdaMSKExecutionRole](#) managed policy contains the minimum required permissions for Amazon MSK Lambda event source mappings. To simplify the permissions process, you can:

- Attach the [AWSLambdaMSKExecutionRole](#) managed policy to your execution role.
- Let the Lambda console generate the permissions for you. When you [create an Amazon MSK event source mapping in the console](#), Lambda evaluates your execution role and alerts you if any

permissions are missing. Choose **Generate permissions** to automatically update your execution role. This doesn't work if you manually created or modified your execution role policies, or if the policies are attached to multiple roles. Note that additional permissions may still be required in your execution role when using advanced features such as [On-Failure Destination](#) or [AWS Glue Schema Registry](#).

Topics

- [Required permissions](#)
- [Optional permissions](#)

Required permissions

Your Lambda function execution role must have the following required permissions for Amazon MSK event source mappings. These permissions are included in the [AWSLambdaMSKExecutionRole](#) managed policy.

CloudWatch Logs permissions

The following permissions allow Lambda to create and store logs in Amazon CloudWatch Logs.

- [logs:CreateLogGroup](#)
- [logs:CreateLogStream](#)
- [logs:PutLogEvents](#)

MSK cluster permissions

The following permissions allow Lambda to access your Amazon MSK cluster on your behalf:

- [kafka:DescribeCluster](#)
- [kafka:DescribeClusterV2](#)
- [kafka:GetBootstrapBrokers](#)

We recommend using [kafka:DescribeClusterV2](#) instead of [kafka:DescribeCluster](#). The v2 permission works with both provisioned and serverless Amazon MSK clusters. You only need one of these permissions in your policy.

VPC permissions

The following permissions allow Lambda to create and manage network interfaces when connecting to your Amazon MSK cluster:

- [ec2:CreateNetworkInterface](#)
- [ec2:DescribeNetworkInterfaces](#)
- [ec2:DescribeVpcs](#)
- [ec2>DeleteNetworkInterface](#)
- [ec2:DescribeSubnets](#)
- [ec2:DescribeSecurityGroups](#)

Optional permissions

Your Lambda function might also need permissions to:

- Access cross-account Amazon MSK clusters. For cross-account event source mappings, you need [kafka:DescribeVpcConnection](#) in the execution role. An IAM principal creating a cross-account event source mapping needs [kafka:ListVpcConnections](#).
- Access your SCRAM secret, if you're using [SASL/SCRAM authentication](#). This lets your function use a username and password to connect to Kafka.
- Describe your Secrets Manager secret, if you're using SASL/SCRAM or [mTLS authentication](#). This allows your function to retrieve the credentials or certificates needed for secure connections.
- Access your AWS KMS customer managed key, if your AWS Secrets Manager secret is encrypted with an AWS KMS customer managed key.
- Access your schema registry secrets, if you're using a schema registry with authentication:
 - For AWS Glue Schema Registry: Your function needs `glue:GetRegistry` and `glue:GetSchemaVersion` permissions. These allow your function to look up and use the message format rules stored in AWS Glue.
 - For [Confluent Schema Registry](#) with BASIC_AUTH or CLIENT_CERTIFICATE_TLS_AUTH: Your function needs `secretsmanager:GetSecretValue` permission for the secret containing the authentication credentials. This lets your function retrieve the username/password or certificates needed to access the Confluent Schema Registry.

- For private CA certificates: Your function needs `secretsmanager:GetSecretValue` permission for the secret containing the certificate. This allows your function to verify the identity of schema registries that use custom certificates.
- Access Kafka cluster consumer groups and poll messages from the topic, if you're using IAM authentication for the event source mapping.

These correspond to the following required permissions:

- [kafka:ListScramSecrets](#) - Allows listing of SCRAM secrets for Kafka authentication
- [secretsmanager:GetSecretValue](#) - Enables retrieval of secrets from Secrets Manager
- [kms:Decrypt](#) - Permits decryption of encrypted data using AWS KMS
- [glue:GetRegistry](#) - Allows access to AWS Glue Schema Registry
- [glue:GetSchemaVersion](#) - Enables retrieval of specific schema versions from AWS Glue Schema Registry
- [kafka-cluster:Connect](#) - Grants permission to connect and authenticate to the cluster
- [kafka-cluster:AlterGroup](#) - Grants permission to join groups on a cluster, equivalent to Apache Kafka's READ GROUP ACL
- [kafka-cluster:DescribeGroup](#) - Grants permission to describe groups on a cluster, equivalent to Apache Kafka's DESCRIBE GROUP ACL
- [kafka-cluster:DescribeTopic](#) - Grants permission to describe topics on a cluster, equivalent to Apache Kafka's DESCRIBE TOPIC ACL
- [kafka-cluster:ReadData](#) - Grants permission to read data from topics on a cluster, equivalent to Apache Kafka's READ TOPIC ACL

Additionally, if you want to send records of failed invocations to an on-failure destination, you'll need the following permissions depending on the destination type:

- For Amazon SQS destinations: [sqs:SendMessage](#) - Allows sending messages to an Amazon SQS queue
- For Amazon SNS destinations: [sns:Publish](#) - Permits publishing messages to an Amazon SNS topic
- For Amazon S3 bucket destinations: [s3:PutObject](#) and [s3:ListBucket](#) - Enables writing and listing objects in an Amazon S3 bucket

For troubleshooting authentication and authorization errors, see [the section called “Troubleshooting”](#).

Configuring Amazon MSK event sources for Lambda

To use an Amazon MSK cluster as an event source for your Lambda function, you create an [event source mapping](#) that connects the two resources. This page describes how to create an event source mapping for Amazon MSK.

This page assumes that you've already properly configured your MSK cluster and the [Amazon Virtual Private Cloud \(VPC\)](#) it resides in. If you need to set up your cluster or VPC, see [the section called “Cluster and network setup”](#). To configure retry behavior for error handling, see [the section called “Retry configurations”](#).

Topics

- [Using an Amazon MSK cluster as an event source](#)
- [Configuring Amazon MSK cluster authentication methods in Lambda](#)
- [Creating a Lambda event source mapping for an Amazon MSK event source](#)
- [Creating cross-account event source mappings in Lambda](#)
- [All Amazon MSK event source configuration parameters in Lambda](#)

Using an Amazon MSK cluster as an event source

When you add your Apache Kafka or Amazon MSK cluster as a trigger for your Lambda function, the cluster is used as an [event source](#).

Lambda reads event data from the Kafka topics that you specify as `Topics` in a [CreateEventSourceMapping](#) request, based on the [starting position](#) that you specify. After successful processing, your Kafka topic is committed to your Kafka cluster.

Lambda reads messages sequentially for each Kafka topic partition. A single Lambda payload can contain messages from multiple partitions. When more records are available, Lambda continues processing records in batches, based on the `BatchSize` value that you specify in a [CreateEventSourceMapping](#) request, until your function catches up with the topic.

After Lambda processes each batch, it commits the offsets of the messages in that batch. If your function returns an error for any of the messages in a batch, Lambda retries the whole batch of

messages until processing succeeds or the messages expire. You can send records that fail all retry attempts to an on-failure destination for later processing.

 **Note**

While Lambda functions typically have a maximum timeout limit of 15 minutes, event source mappings for Amazon MSK, self-managed Apache Kafka, Amazon DocumentDB, and Amazon MQ for ActiveMQ and RabbitMQ only support functions with maximum timeout limits of 14 minutes.

Configuring Amazon MSK cluster authentication methods in Lambda

Lambda needs permission to access your Amazon MSK cluster, retrieve records, and perform other tasks. Amazon MSK supports several ways to authenticate with your MSK cluster.

Cluster authentication methods

- [Unauthenticated access](#)
- [SASL/SCRAM authentication](#)
- [Mutual TLS authentication](#)
- [IAM authentication](#)
- [How Lambda chooses a bootstrap broker](#)

Unauthenticated access

If no clients access the cluster over the internet, you can use unauthenticated access.

SASL/SCRAM authentication

Lambda supports [Simple Authentication and Security Layer/Salted Challenge Response Authentication Mechanism \(SASL/SCRAM\)](#) authentication, with the SHA-512 hash function and Transport Layer Security (TLS) encryption. For Lambda to connect to the cluster, store the authentication credentials (username and password) in a Secrets Manager secret, and reference this secret when configuring your event source mapping.

For more information about using Secrets Manager, see [Sign-in credentials authentication with Secrets Manager](#) in the *Amazon Managed Streaming for Apache Kafka Developer Guide*.

Note

Amazon MSK doesn't support SASL/PLAIN authentication.

Mutual TLS authentication

Mutual TLS (mTLS) provides two-way authentication between the client and the server. The client sends a certificate to the server for the server to verify the client. The server also sends a certificate to the client for the client to verify the server.

For Amazon MSK integrations with Lambda, your MSK cluster acts as the server, and Lambda acts as the client.

- For Lambda to verify your MSK cluster, you configure a client certificate as a secret in Secrets Manager, and reference this certificate in your event source mapping configuration. The client certificate must be signed by a certificate authority (CA) in the server's trust store.
- The MSK cluster also sends a server certificate to Lambda. The server certificate must be signed by a certificate authority (CA) in the AWS trust store.

Amazon MSK doesn't support self-signed server certificates. All brokers in Amazon MSK use [public certificates](#) signed by [Amazon Trust Services CAs](#), which Lambda trusts by default.

Configuring the mTLS secret

The CLIENT_CERTIFICATE_TLS_AUTH secret requires a certificate field and a private key field. For an encrypted private key, the secret requires a private key password. Both the certificate and private key must be in PEM format.

Note

Lambda supports the [PBES1](#) (but not PBES2) private key encryption algorithms.

The certificate field must contain a list of certificates, beginning with the client certificate, followed by any intermediate certificates, and ending with the root certificate. Each certificate must start on a new line with the following structure:

```
-----BEGIN CERTIFICATE-----
```

```
<certificate contents>
-----END CERTIFICATE-----
```

Secrets Manager supports secrets up to 65,536 bytes, which is enough space for long certificate chains.

The private key must be in [PKCS #8](#) format, with the following structure:

```
-----BEGIN PRIVATE KEY-----
    <private key contents>
-----END PRIVATE KEY-----
```

For an encrypted private key, use the following structure:

```
-----BEGIN ENCRYPTED PRIVATE KEY-----
    <private key contents>
-----END ENCRYPTED PRIVATE KEY-----
```

The following example shows the contents of a secret for mTLS authentication using an encrypted private key. For an encrypted private key, you include the private key password in the secret.

```
{
  "privateKeyPassword": "testpassword",
  "certificate": "-----BEGIN CERTIFICATE-----
MIIE5DCCAsygAwIBAgIRAPJdwaFaNRrytHBto0j5BA0wDQYJKoZIhvcNAQELBQAw
...
j0Lh4/+1HfgyE2KlmII36dg4IMzNjAFEBZiCRoPim040s1cRqtFHxoa10QQbIlxk
cmUuiAii9R0=
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----

-----END ENCRYPTED PRIVATE KEY-----"
```

```
}
```

For more information about mTLS for Amazon MSK, and instructions on how to generate a client certificate, see [Mutual TLS client authentication for Amazon MSK](#) in the *Amazon Managed Streaming for Apache Kafka Developer Guide*.

IAM authentication

You can use AWS Identity and Access Management (IAM) to authenticate the identity of clients that connect to the MSK cluster. With IAM auth, Lambda relies on the permissions in your function's [execution role](#) to connect to the cluster, retrieve records, and perform other required actions. For a sample policy that contains the necessary permissions, see [Create authorization policies for the IAM role](#) in the *Amazon Managed Streaming for Apache Kafka Developer Guide*.

If IAM auth is active on your MSK cluster, and you don't provide a secret, Lambda automatically defaults to using IAM auth.

For more information about IAM authentication in Amazon MSK, see [IAM access control](#).

How Lambda chooses a bootstrap broker

Lambda chooses a [bootstrap broker](#) based on the authentication methods available on your cluster, and whether you provide a secret for authentication. If you provide a secret for mTLS or SASL/SCRAM, Lambda automatically chooses that auth method. If you don't provide a secret, Lambda selects the strongest auth method that's active on your cluster. The following is the order of priority in which Lambda selects a broker, from strongest to weakest auth:

- mTLS (secret provided for mTLS)
- SASL/SCRAM (secret provided for SASL/SCRAM)
- SASL IAM (no secret provided, and IAM auth active)
- Unauthenticated TLS (no secret provided, and IAM auth not active)
- Plaintext (no secret provided, and both IAM auth and unauthenticated TLS are not active)

Note

If Lambda can't connect to the most secure broker type, Lambda doesn't attempt to connect to a different (weaker) broker type. If you want Lambda to choose a weaker broker type, deactivate all stronger auth methods on your cluster.

Creating a Lambda event source mapping for an Amazon MSK event source

To create an event source mapping, you can use the Lambda console, the [AWS Command Line Interface \(CLI\)](#), or an [AWS SDK](#).

Note

When you create the event source mapping, Lambda creates a [hyperplane ENI](#) in the private subnet that contains your MSK cluster, allowing Lambda to establish a secure connection. This hyperplane ENI allows uses the subnet and security group configuration of your MSK cluster, not your Lambda function.

The following console steps add an Amazon MSK cluster as a trigger for your Lambda function. Under the hood, this creates an event source mapping resource.

To add an Amazon MSK trigger to your Lambda function (console)

1. Open the [Function page](#) of the Lambda console.
2. Choose the name of the Lambda function you want to add an Amazon MSK trigger to.
3. Under **Function overview**, choose **Add trigger**.
4. Under **Trigger configuration**, choose **MSK**.
5. To specify your Kafka cluster details, do the following:
 1. For **MSK cluster**, select your cluster.
 2. For **Topic name**, enter the name of the Kafka topic to consume messages from.
 3. For **Consumer group ID**, enter the ID of a Kafka consumer group to join, if applicable. For more information, see [the section called "Consumer group ID"](#).
6. For **Cluster authentication**, make the necessary configurations. For more information about cluster authentication, see [the section called "Cluster authentication"](#).
 - Toggle on **Use authentication** if you want Lambda to perform authentication with your MSK cluster when establishing a connection. Authentication is recommended.
 - If you use authentication, for **Authentication method**, choose the authentication method to use.
 - If you use authentication, for **Secrets Manager key**, choose the Secrets Manager key that contains the authentication credentials needed to access your cluster.

7. Under **Event poller configuration**, make the necessary configurations.
 - Choose **Activate trigger** to enable the trigger immediately after creation.
 - Choose whether you want to **Configure provisioned mode** for your event source mapping. For more information, see [the section called “Event poller scaling”](#).
 - If you configure provisioned mode, enter a value for **Minimum event pollers**, a value for **Maximum event pollers**, and an optional value for `PollerGroupName` to specify grouping of multiple ESMs within the same event source VPC.
 - For **Starting position**, choose how you want Lambda to start reading from your stream. For more information, see [the section called “Polling and stream positions”](#).
8. Under **Batching**, make the necessary configurations. For more information about batching, see [the section called “Batching behavior”](#).
 1. For **Batch size**, enter the maximum number of messages to receive in a single batch.
 2. For **Batch window**, enter the maximum number of seconds that Lambda spends gathering records before invoking the function.
9. Under **Filtering**, make the necessary configurations. For more information about filtering, see [the section called “Event filtering”](#).
 - For **Filter criteria**, add filter criteria definitions to determine whether or not to process an event.
10. Under **Failure handling**, make the necessary configurations. For more information about failure handling, see [the section called “Retain failed invocations”](#).
 - For **On-failure destination**, specify the ARN of your on-failure destination.
11. For **Tags**, enter the tags to associate with this event source mapping.
12. To create the trigger, choose **Add**.

You can also create the event source mapping using the AWS CLI with the [create-event-source-mapping](#) command. The following example creates an event source mapping to map the Lambda function `my-msk-function` to the `AWSKafkaTopic` topic, starting from the LATEST message. This command also uses the [SourceAccessConfiguration](#) object to instruct Lambda to use [SASL/SCRAM](#) authentication when connecting to the cluster.

```
aws lambda create-event-source-mapping \
```

```
--event-source-arn arn:aws:kafka:us-east-1:111122223333:cluster/my-cluster/fc2f5bdf-  
fd1b-45ad-85dd-15b4a5a6247e-2 \  
--topics AWSKafkaTopic \  
--starting-position LATEST \  
--function-name my-kafka-function  
--source-access-configurations '["Type": "SASL_SCRAM_512_AUTH", "URI":  
"arn:aws:secretsmanager:us-east-1:111122223333:secret:my-secret"]]'
```

If the cluster uses [mTLS authentication](#), include a [SourceAccessConfiguration](#) object that specifies `CLIENT_CERTIFICATE_TLS_AUTH` and a Secrets Manager key ARN. This is shown in the following command:

```
aws lambda create-event-source-mapping \  
--event-source-arn arn:aws:kafka:us-east-1:111122223333:cluster/my-cluster/fc2f5bdf-  
fd1b-45ad-85dd-15b4a5a6247e-2 \  
--topics AWSKafkaTopic \  
--starting-position LATEST \  
--function-name my-kafka-function  
--source-access-configurations '["Type": "CLIENT_CERTIFICATE_TLS_AUTH", "URI":  
"arn:aws:secretsmanager:us-east-1:111122223333:secret:my-secret"]]'
```

When the cluster uses [IAM authentication](#), you don't need a [SourceAccessConfiguration](#) object. This is shown in the following command:

```
aws lambda create-event-source-mapping \  
--event-source-arn arn:aws:kafka:us-east-1:111122223333:cluster/my-cluster/fc2f5bdf-  
fd1b-45ad-85dd-15b4a5a6247e-2 \  
--topics AWSKafkaTopic \  
--starting-position LATEST \  
--function-name my-kafka-function
```

Creating cross-account event source mappings in Lambda

You can use [multi-VPC private connectivity](#) to connect a Lambda function to a provisioned MSK cluster in a different AWS account. Multi-VPC connectivity uses AWS PrivateLink, which keeps all traffic within the AWS network.

Note

You can't create cross-account event source mappings for serverless MSK clusters.

To create a cross-account event source mapping, you must first [configure multi-VPC connectivity for the MSK cluster](#). When you create the event source mapping, use the managed VPC connection ARN instead of the cluster ARN, as shown in the following examples. The [CreateEventSourceMapping](#) operation also differs depending on which authentication type the MSK cluster uses.

Example— Create cross-account event source mapping for cluster that uses IAM authentication

When the cluster uses [IAM role-based authentication](#), you don't need a [SourceAccessConfiguration](#) object. Example:

```
aws lambda create-event-source-mapping \  
  --event-source-arn arn:aws:kafka:us-east-1:111122223333:vpc-connection/444455556666/  
  my-cluster-name/51jn98b4-0a61-46cc-b0a6-61g9a3d797d5-7 \  
  --topics AWSKafkaTopic \  
  --starting-position LATEST \  
  --function-name my-kafka-function
```

Example— Create cross-account event source mapping for cluster that uses SASL/SCRAM authentication

If the cluster uses [SASL/SCRAM authentication](#), you must include a [SourceAccessConfiguration](#) object that specifies SASL_SCRAM_512_AUTH and a Secrets Manager secret ARN.

There are two ways to use secrets for cross-account Amazon MSK event source mappings with SASL/SCRAM authentication:

- Create a secret in the Lambda function account and sync it with the cluster secret. [Create a rotation](#) to keep the two secrets in sync. This option allows you to control the secret from the function account.
- Use the secret that's associated with the MSK cluster. This secret must allow cross-account access to the Lambda function account. For more information, see [Permissions to AWS Secrets Manager secrets for users in a different account](#).

```
aws lambda create-event-source-mapping \  
  --event-source-arn arn:aws:kafka:us-east-1:111122223333:vpc-connection/444455556666/  
  my-cluster-name/51jn98b4-0a61-46cc-b0a6-61g9a3d797d5-7 \  
  --topics AWSKafkaTopic \  
  --starting-position LATEST \  
  --source-access-configuration arn:aws:secretsmanager:us-east-1:111122223333:secret/my-secret
```

```
--function-name my-kafka-function \
--source-access-configurations '["Type": "SASL_SCRAM_512_AUTH", "URI":
"arn:aws:secretsmanager:us-east-1:444455556666:secret:my-secret"]]'
```

Example— Create cross-account event source mapping for cluster that uses mTLS authentication

If the cluster uses [mTLS authentication](#), you must include a [SourceAccessConfiguration](#) object that specifies CLIENT_CERTIFICATE_TLS_AUTH and a Secrets Manager secret ARN. The secret can be stored in the cluster account or the Lambda function account.

```
aws lambda create-event-source-mapping \
--event-source-arn arn:aws:kafka:us-east-1:111122223333:vpc-connection/444455556666/
my-cluster-name/51jn98b4-0a61-46cc-b0a6-61g9a3d797d5-7 \
--topics AWSKafkaTopic \
--starting-position LATEST \
--function-name my-kafka-function \
--source-access-configurations '["Type": "CLIENT_CERTIFICATE_TLS_AUTH", "URI":
"arn:aws:secretsmanager:us-east-1:444455556666:secret:my-secret"]]'
```

All Amazon MSK event source configuration parameters in Lambda

All Lambda event source types share the same [CreateEventSourceMapping](#) and [UpdateEventSourceMapping](#) API operations. However, only some of the parameters apply to Amazon MSK, as shown in the following table.

Parameter	Required	Default	Notes
AmazonManagedKafkaEventSourceConfig	N	Contains the ConsumerGroupId field, which defaults to a unique value.	Can set only on Create
BatchSize	N	100	Maximum: 10,000
DestinationConfig	N	N/A	the section called "Retain failed invocations"
Enabled	N	True	

Parameter	Required	Default	Notes
BisectBatchOnFunctionError	N	False	the section called “Retry configurations”
FunctionResponseTypes	N	N/A	the section called “Retry configurations”
MaximumRecordAgeInSeconds	N	-1 (infinite)	the section called “Retry configurations”
MaximumRetryAttempts	N	-1 (infinite)	the section called “Retry configurations”
EventSourceArn	Y	N/A	Can set only on Create
FilterCriteria	N	N/A	Control which events Lambda sends to your function
FunctionName	Y	N/A	
KMSKeyArn	N	N/A	the section called “Encryption of filter criteria”
MaximumBatchingWindowInSeconds	N	500 ms	Batching behavior

Parameter	Required	Default	Notes
ProvisionedPollers Config	N	MinimumPollers : default value of 1 if not specified MaximumPollers : default value of 200 if not specified PollerGroupName : N/A	the section called “Provisioned mode”
SourceAccessConfig urations	N	No credentials	SASL/SCRAM or CLIENT_C RTIFICATE_TLS_AUTH (MutualTLS) authentication credentials for your event source
StartingPosition	Y	N/A	AT_TIMESTAMP, TRIM_HORIZON, or LATEST Can set only on Create
StartingPositionTi mestamp	N	N/A	Required if StartingP osition is set to AT_TIMESTAMP
Tags	N	N/A	the section called “Event source mapping tags”

Parameter	Required	Default	Notes
Topics	Y	N/A	Kafka topic name Can set only on Create

Note

When you specify a `PollerGroupName`, multiple ESMs within the same Amazon VPC can share Event Poller Unit (EPU) capacity. You can use this option to optimize Provisioned mode costs for your ESMs. Requirements for ESM grouping:

- ESMs must be within the same Amazon VPC
- Maximum of 100 ESMs per poller group
- Aggregate maximum pollers across all ESMs in a group cannot exceed 2000

You can update the `PollerGroupName` to move an ESM to a different group, or remove an ESM from a group by setting `PollerGroupName` to an empty string ("").

Tutorial: Using an Amazon MSK event source mapping to invoke a Lambda function

In this tutorial, you will perform the following:

- Create a Lambda function in the same AWS account as an existing Amazon MSK cluster.
- Configure networking and authentication for Lambda to communicate with Amazon MSK.
- Set up a Lambda Amazon MSK event source mapping, which runs your Lambda function when events show up in the topic.

After you are finished with these steps, when events are sent to Amazon MSK, you will be able to set up a Lambda function to process those events automatically with your own custom Lambda code.

What can you do with this feature?

Example solution: Use an MSK event source mapping to deliver live scores to your customers.

Consider the following scenario: Your company hosts a web application where your customers can view information about live events, such as sports games. Information updates from the game are provided to your team through a Kafka topic on Amazon MSK. You want to design a solution that consumes updates from the MSK topic to provide an updated view of the live event to customers inside an application you develop. You have decided on the following design approach: Your client applications will communicate with a serverless backend hosted in AWS. Clients will connect over websocket sessions using the Amazon API Gateway WebSocket API.

In this solution, you need a component that reads MSK events, performs some custom logic to prepare those events for the application layer and then forwards that information to the API Gateway API. You can implement this component with AWS Lambda, by providing your custom logic in a Lambda function, then calling it with a AWS Lambda Amazon MSK event source mapping.

For more information about implementing solutions using the Amazon API Gateway WebSocket API, see [WebSocket API tutorials](#) in the API Gateway documentation.

Prerequisites

An AWS account with the following preconfigured resources:

To fulfill these prerequisites, we recommend following [Getting started using Amazon MSK in the Amazon MSK documentation](#).

- An Amazon MSK cluster. See [Create an Amazon MSK cluster](#) in *Getting started using Amazon MSK*.
- The following configuration:
 - Ensure **IAM role-based authentication** is **Enabled** in your cluster security settings. This improves your security by limiting your Lambda function to only access the Amazon MSK resources needed. This is enabled by default on new Amazon MSK clusters.
 - Ensure **Public access** is off in your cluster networking settings. Restricting your Amazon MSK cluster's access to the internet improves your security by limiting how many intermediaries handle your data. This is enabled by default on new Amazon MSK clusters.
- A Kafka topic in your Amazon MSK cluster to use for this solution. See [Create a topic](#) in *Getting started using Amazon MSK*.
- A Kafka admin host set up to retrieve information from your Kafka cluster and send Kafka events to your topic for testing, such as an Amazon EC2 instance with the Kafka admin CLI and Amazon MSK IAM library installed. See [Create a client machine](#) in *Getting started using Amazon MSK*.

Once you have set up these resources, gather the following information from your AWS account to confirm that you are ready to continue.

- The name of your Amazon MSK cluster. You can find this information in the Amazon MSK console.
- The cluster UUID, part of the ARN for your Amazon MSK cluster, which you can find in the Amazon MSK console. Follow the procedures in [Listing clusters](#) in the Amazon MSK documentation to find this information.
- The security groups associated with your Amazon MSK cluster. You can find this information in the Amazon MSK console. In the following steps, refer to these as your *clusterSecurityGroups*.
- The id of the Amazon VPC containing your Amazon MSK cluster. You can find this information by identifying subnets associated with your Amazon MSK cluster in the Amazon MSK console, then identifying the Amazon VPC associated with the subnet in the Amazon VPC Console.
- The name of the Kafka topic used in your solution. You can find this information by calling your Amazon MSK cluster with the Kafka topics CLI from your Kafka admin host. For more information about the topics CLI, see [Adding and removing topics](#) in the Kafka documentation.
- The name of a consumer group for your Kafka topic, suitable for use by your Lambda function. This group can be created automatically by Lambda, so you don't need to create it with the Kafka CLI. If you do need to manage your consumer groups, to learn more about the consumer-groups CLI, see [Managing Consumer Groups](#) in the Kafka documentation.

The following permissions in your AWS account:

- Permission to create and manage a Lambda function.
- Permission to create IAM policies and associate them with your Lambda function.
- Permission to create Amazon VPC endpoints and alter networking configuration in the Amazon VPC hosting your Amazon MSK cluster.

Install the AWS Command Line Interface

If you have not yet installed the AWS Command Line Interface, follow the steps at [Installing or updating the latest version of the AWS CLI](#) to install it.

The tutorial requires a command line terminal or shell to run commands. In Linux and macOS, use your preferred shell and package manager.

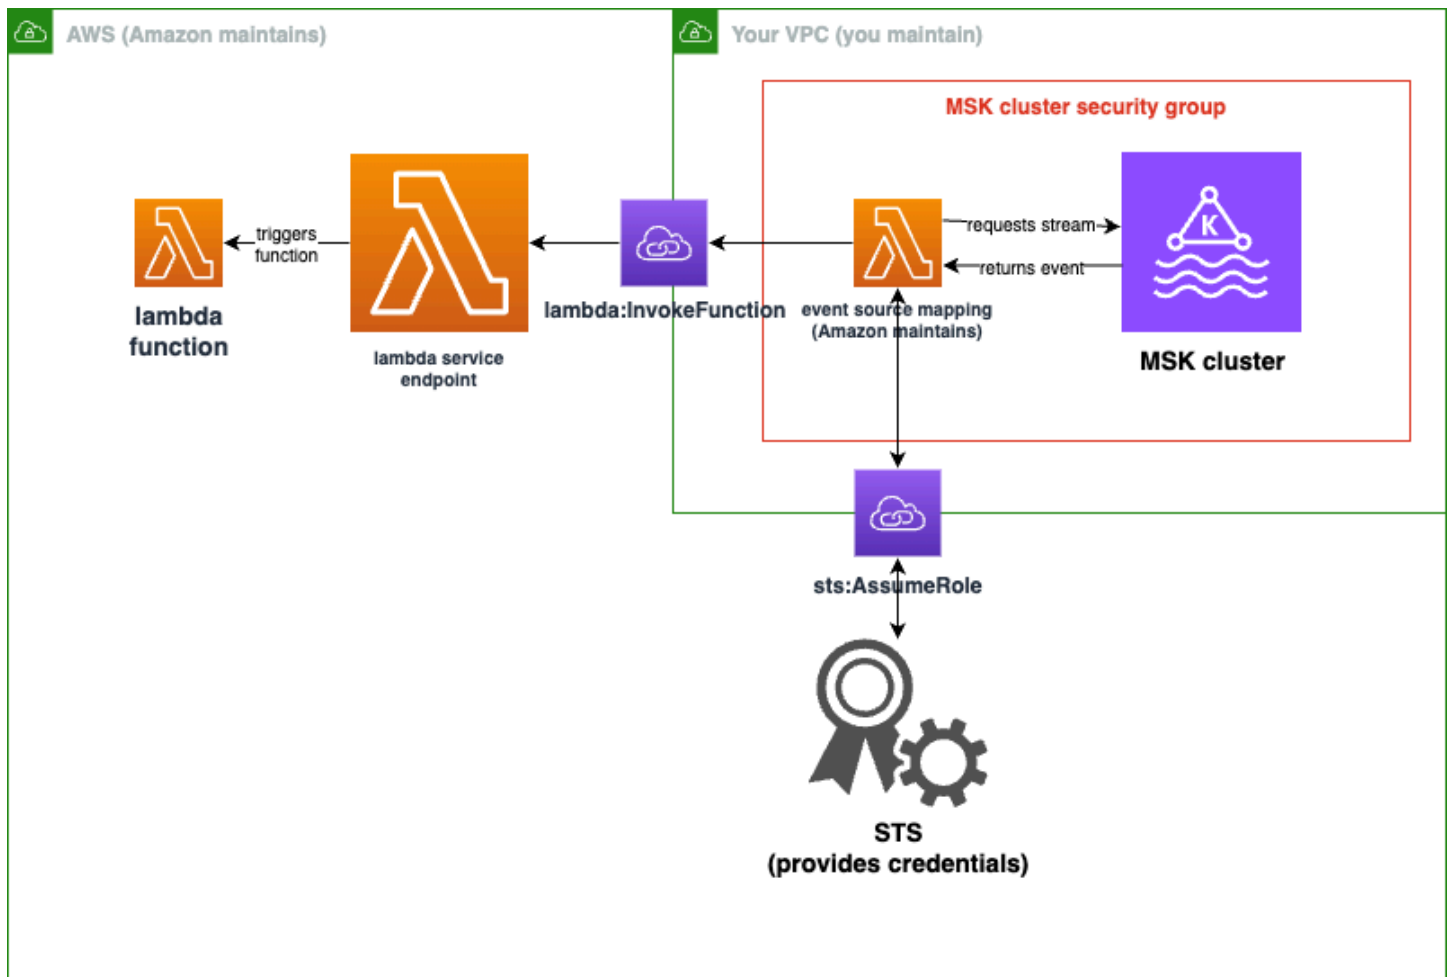

Note

In Windows, some Bash CLI commands that you commonly use with Lambda (such as `zip`) are not supported by the operating system's built-in terminals. To get a Windows-integrated version of Ubuntu and Bash, [install the Windows Subsystem for Linux](#).

Configure network connectivity for Lambda to communicate with Amazon MSK

Use AWS PrivateLink to connect Lambda and Amazon MSK. You can do so by creating interface Amazon VPC endpoints in the Amazon VPC console. For more information about networking configuration, see [the section called “Cluster and network setup”](#).

When a Amazon MSK event source mapping runs on the behalf of a Lambda function, it assumes the Lambda function's execution role. This IAM role authorizes the mapping to access resources secured by IAM, such as your Amazon MSK cluster. Although the components share an execution role, the Amazon MSK mapping and your Lambda function have separate connectivity requirements for their respective tasks, as shown in the following diagram.

Your event source mapping belongs to your Amazon MSK cluster security group. In this networking step, create Amazon VPC endpoints from your Amazon MSK cluster VPC to connect the event source mapping to the Lambda and STS services. Secure these endpoints to accept traffic from your Amazon MSK cluster security group. Then, adjust the Amazon MSK cluster security groups to allow the event source mapping to communicate with the Amazon MSK cluster.

You can configure the following steps using the AWS Management Console.

To configure interface Amazon VPC endpoints to connect Lambda and Amazon MSK

1. Create a security group for your interface Amazon VPC endpoints, *endpointSecurityGroup*, that allows inbound TCP traffic on 443 from *clusterSecurityGroups*. Follow the procedure in [Create a security group](#) in the Amazon EC2 documentation to create a security group. Then, follow the procedure in [Add rules to a security group](#) in the Amazon EC2 documentation to add appropriate rules.

Create a security group with the following information:

When adding your inbound rules, create a rule for each security group in *clusterSecurityGroups*. For each rule:

- For **Type**, select **HTTPS**.
 - For **Source**, select one of *clusterSecurityGroups*.
2. Create an endpoint connecting the Lambda service to the Amazon VPC containing your Amazon MSK cluster. Follow the procedure in [Create an interface endpoint](#).

Create an interface endpoint with the following information:

- For **Service name**, select `com.amazonaws.regionName.lambda`, where *regionName* hosts your Lambda function.
- For **VPC**, select the Amazon VPC containing your Amazon MSK cluster.
- For **Security groups**, select *endpointSecurityGroup*, which you created earlier.
- For **Subnets**, select the subnets that host your Amazon MSK cluster.
- For **Policy**, provide the following policy document, which secures the endpoint for use by the Lambda service principal for the `lambda:InvokeFunction` action.

```
{
  "Statement": [
    {
      "Action": "lambda:InvokeFunction",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "lambda.amazonaws.com"
        ]
      },
      "Resource": "*"
    }
  ]
}
```

- Ensure **Enable DNS name** remains set.
3. Create an endpoint connecting the AWS STS service to the Amazon VPC containing your Amazon MSK cluster. Follow the procedure in [Create an interface endpoint](#).

Create an interface endpoint with the following information:

- For **Service name**, select AWS STS.
- For **VPC**, select the Amazon VPC containing your Amazon MSK cluster.
- For **Security groups**, select *endpointSecurityGroup*.
- For **Subnets**, select the subnets that host your Amazon MSK cluster.
- For **Policy**, provide the following policy document, which secures the endpoint for use by the Lambda service principal for the `sts:AssumeRole` action.

```
{
  "Statement": [
    {
      "Action": "sts:AssumeRole",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "lambda.amazonaws.com"
        ]
      },
      "Resource": "*"
    }
  ]
}
```

- Ensure **Enable DNS name** remains set.
4. For each security group associated with your Amazon MSK cluster, that is, in *clusterSecurityGroups*, allow the following:
- Allow all inbound and outbound TCP traffic on 9098 to all of *clusterSecurityGroups*, including within itself.
 - Allow all outbound TCP traffic on 443.

Some of this traffic is allowed by default security group rules, so if your cluster is attached to a single security group, and that group has default rules, additional rules are not necessary. To adjust security group rules, follow the procedures in [Add rules to a security group](#) in the Amazon EC2 documentation.

Add rules to your security groups with the following information:

- For each inbound rule or outbound rule for port 9098, provide

- For **Type**, select **Custom TCP**.
- For **Port range**, provide 9098.
- For **Source**, provide one of *clusterSecurityGroups*.
- For each inbound rule for port 443, for **Type**, select **HTTPS**.

Create an IAM role for Lambda to read from your Amazon MSK topic

Identify the auth requirements for Lambda to read from your Amazon MSK topic, then define them in a policy. Create a role, *lambdaAuthRole*, that authorizes Lambda to use those permissions. Authorize actions on your Amazon MSK cluster using `kafka-cluster` IAM actions. Then, authorize Lambda to perform Amazon MSK `kafka` and Amazon EC2 actions needed to discover and connect to your Amazon MSK cluster, as well as CloudWatch actions so Lambda can log what it has done.

To describe the auth requirements for Lambda to read from Amazon MSK

1. Write an IAM policy document (a JSON document), *clusterAuthPolicy*, that allows Lambda to read from your Kafka topic in your Amazon MSK cluster using your Kafka consumer group. Lambda requires a Kafka consumer group to be set when reading.

Alter the following template to align with your prerequisites:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "kafka-cluster:Connect",
        "kafka-cluster:DescribeGroup",
        "kafka-cluster:AlterGroup",
        "kafka-cluster:DescribeTopic",
        "kafka-cluster:ReadData",
        "kafka-cluster:DescribeClusterDynamicConfiguration"
      ],
      "Resource": [
```

```

        "arn:aws:kafka:us-
east-1:111122223333:cluster/mskClusterName/cluster-uuid",
        "arn:aws:kafka:us-
east-1:111122223333:topic/mskClusterName/cluster-uuid/mskTopicName",
        "arn:aws:kafka:us-
east-1:111122223333:group/mskClusterName/cluster-uuid/mskGroupName"
    ]
}
]
}

```

For more information, consult [the section called “Configure permissions”](#). When writing your policy:

- Replace *us-east-1* and *111122223333* with the AWS Region and AWS account of your Amazon MSK cluster.
 - For *mskClusterName*, provide the name of your Amazon MSK cluster.
 - For *cluster-uuid*, provide the UUID in the ARN for your Amazon MSK cluster.
 - For *mskTopicName*, provide the name of your Kafka topic.
 - For *mskGroupName*, provide the name of your Kafka consumer group.
2. Identify the Amazon MSK, Amazon EC2 and CloudWatch permissions required for Lambda to discover and connect your Amazon MSK cluster, and log those events.

The `AWSLambdaMSKExecutionRole` managed policy permissively defines the required permissions. Use it in the following steps.

In a production environment, assess `AWSLambdaMSKExecutionRole` to restrict your execution role policy based on the principle of least privilege, then write a policy for your role that replaces this managed policy.

For details about the IAM policy language, see the [IAM documentation](#).

Now that you have written your policy document, create an IAM policy so you can attach it to your role. You can do this using the console with the following procedure.

To create an IAM policy from your policy document

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane on the left, choose **Policies**.
3. Choose **Create policy**.
4. In the **Policy editor** section, choose the **JSON** option.
5. Paste *clusterAuthPolicy*.
6. When you are finished adding permissions to the policy, choose **Next**.
7. On the **Review and create** page, type a **Policy Name** and a **Description** (optional) for the policy that you are creating. Review **Permissions defined in this policy** to see the permissions that are granted by your policy.
8. Choose **Create policy** to save your new policy.

For more information, see [Creating IAM policies](#) in the IAM documentation.

Now that you have appropriate IAM policies, create a role and attach them to it. You can do this using the console with the following procedure.

To create an execution role in the IAM console

1. Open the [Roles page](#) in the IAM console.
2. Choose **Create role**.
3. Under **Trusted entity type**, choose **AWS service**.
4. Under **Use case**, choose **Lambda**.
5. Choose **Next**.
6. Select the following policies:
 - *clusterAuthPolicy*
 - `AWSLambdaMSKExecutionRole`
7. Choose **Next**.
8. For **Role name**, enter *lambdaAuthRole* and then choose **Create role**.

For more information, see [the section called “Execution role \(permissions for functions to access other resources\)”](#).

Create a Lambda function to read from your Amazon MSK topic

Create a Lambda function configured to use your IAM role. You can create your Lambda function using the console.

To create a Lambda function using your auth configuration

1. Open the Lambda console and select **Create function** from the header.
2. Select **Author from scratch**.
3. For **Function name**, provide an appropriate name of your choice.
4. For **Runtime**, choose the **Latest supported** version of Node . js to use the code provided in this tutorial.
5. Choose **Change default execution role**.
6. Select **Use an existing role**.
7. For **Existing role**, select *lambdaAuthRole*.

In a production environment, you usually need to add further policies to the execution role for your Lambda function to meaningfully process your Amazon MSK events. For more information on adding policies to your role, see [Add or remove identity permissions](#) in the IAM documentation.

Create an event source mapping to your Lambda function

Your Amazon MSK event source mapping provides the Lambda service the information necessary to invoke your Lambda when appropriate Amazon MSK events occur. You can create a Amazon MSK mapping using the console. Create a Lambda trigger, then the event source mapping is automatically set up.

To create a Lambda trigger (and event source mapping)

1. Navigate to your Lambda function's overview page.
2. In the function overview section, choose **Add trigger** on the bottom left.
3. In the **Select a source** dropdown, select **Amazon MSK**.
4. Don't set **authentication**.
5. For **MSK cluster**, select your cluster's name.
6. For **Batch size**, enter 1. This step makes this feature easier to test, and is not an ideal value in production.

7. For **Topic name**, provide the name of your Kafka topic.
8. For **Consumer group ID**, provide the id of your Kafka consumer group.

Update your Lambda function to read your streaming data

Lambda provides information about Kafka events through the event method parameter. For an example structure of a Amazon MSK event, see [the section called " Example event"](#). After you understand how to interpret Lambda forwarded Amazon MSK events, you can alter your Lambda function code to use the information they provide.

Provide the following code to your Lambda function to log the contents of a Lambda Amazon MSK event for testing purposes:

.NET

SDK for .NET

Note

Consuming an Amazon MSK event with Lambda using .NET.

```
using System.Text;
using Amazon.Lambda.Core;
using Amazon.Lambda.KafkaEvents;

// Assembly attribute to enable the Lambda function's JSON input to be converted
// into a .NET class.
[assembly:
    LambdaSerializer(typeof(Amazon.Lambda.Serialization.SystemTextJson.DefaultLambdaJsonSerializer))]

namespace MSKLambda;

public class Function
{
```

```

    /// <param name="input">The event for the Lambda function handler to
    process.</param>
    /// <param name="context">The ILambdaContext that provides methods for
    logging and describing the Lambda environment.</param>
    /// <returns></returns>
    public void FunctionHandler(KafkaEvent evnt, ILambdaContext context)
    {

        foreach (var record in evnt.Records)
        {
            Console.WriteLine("Key:" + record.Key);
            foreach (var eventRecord in record.Value)
            {
                var valueBytes = eventRecord.Value.ToArray();
                var valueText = Encoding.UTF8.GetString(valueBytes);

                Console.WriteLine("Message:" + valueText);
            }
        }
    }
}

Consuming an Amazon MSK event with Lambda using Rust.

```

use aws_lambda_events::event::kafka::KafkaEvent;
use lambda_runtime::{run, service_fn, tracing, Error, LambdaEvent};
use base64::prelude::*;
use serde_json::{Value};
use tracing::{info};

/// Pre-Requisites:
/// 1. Install Cargo Lambda - see https://www.cargo-lambda.info/guide/getting-
started.html
/// 2. Add packages tracing, tracing-subscriber, serde_json, base64
///
/// This is the main body for the function.
/// Write your code inside it.
/// There are some code example in the following URLs:
/// - https://github.com/aws-labs/aws-lambda-rust-runtime/tree/main/examples
/// - https://github.com/aws-samples/serverless-rust-demo/

async fn function_handler(event: LambdaEvent<KafkaEvent>) -> Result<Value, Error>
{
    let payload = event.payload.records;

    for (_name, records) in payload.iter() {

        for record in records {

```

```

        let record_text = record.value.as_ref().ok_or("Value is None"?);
        info!("Record: {}", &record_text);

        // perform Base64 decoding
        let record_bytes = BASE64_STANDARD.decode(record_text)?;
        let message = std::str::from_utf8(&record_bytes)?;

        info!("Message: {}", message);
    }

}

Ok(()).into())
}

#[tokio::main]
async fn main() -> Result<(), Error> {

    // required to enable CloudWatch error logging by the runtime
    tracing::init_default_subscriber();
    info!("Setup CW subscriber!");

    run(service_fn(function_handler)).await
}

```

You can provide function code to your Lambda using the console.

To update function code using the console code editor

1. Open the [Functions page](#) of the Lambda console and select your function.
2. Select the **Code** tab.
3. In the **Code source** pane, select your source code file and edit it in the integrated code editor.
4. In the **DEPLOY** section, choose **Deploy** to update your function's code:

Test your Lambda function to verify it is connected to your Amazon MSK topic

You can now verify whether or not your Lambda is being invoked by the event source by inspecting CloudWatch event logs.

To verify whether your Lambda function is being invoked

1. Use your Kafka admin host to generate Kafka events using the `kafka-console-producer` CLI. For more information, see [Write some events into the topic](#) in the Kafka documentation. Send enough events to fill up the batch defined by batch size for your event source mapping defined in the previous step, or Lambda will wait for more information to invoke.
2. If your function runs, Lambda writes what happened to CloudWatch. In the console, navigate to your Lambda function's detail page.
3. Select the **Configuration** tab.
4. From the sidebar, select **Monitoring and operations tools**.
5. Identify the **CloudWatch log group** under **Logging configuration**. The log group should start with `/aws/lambda`. Choose the link to the log group.
6. In the CloudWatch console, inspect the **Log events** for the log events Lambda has sent to the log stream. Identify if there are log events containing the message from your Kafka event, as in the following image. If there are, you have successfully connected a Lambda function to Amazon MSK with a Lambda event source mapping.

Using Lambda with self-managed Apache Kafka

This topic describes how to use Lambda with a self-managed Kafka cluster. In AWS terminology, a self-managed cluster includes non-AWS hosted Kafka clusters. For example, you can host your Kafka cluster with a cloud provider such as [Confluent Cloud](#) or [Redpanda](#).

This chapter explains how to use a self-managed Apache Kafka cluster as an event source for your Lambda function. The general process for integrating self-managed Apache Kafka with Lambda involves the following steps:

1. [Cluster and network setup](#) – First, set up your self-managed Apache Kafka cluster with the correct networking configuration to allow Lambda to access your cluster.
2. [Event source mapping setup](#) – Then, create the [event source mapping](#) resource that Lambda needs to securely connect your Apache Kafka cluster to your function.
3. [Function and permissions setup](#) – Finally, ensure that your function is correctly set up, and has the necessary permissions in its [execution role](#).

Apache Kafka as an event source operates similarly to using Amazon Simple Queue Service (Amazon SQS) or Amazon Kinesis. Lambda internally polls for new messages from the event source and then synchronously invokes the target Lambda function. Lambda reads the messages in batches and provides these to your function as an event payload. The maximum batch size is configurable (the default is 100 messages). For more information, see [the section called “Batching behavior”](#).

To optimize the throughput of your self-managed Apache Kafka event source mapping, configure provisioned mode. In provisioned mode, you can define the minimum and maximum number of event pollers allocated to your event source mapping. This can improve the ability of your event source mapping to handle unexpected message spikes. For more information, see [provisioned mode](#).

Warning

Lambda event source mappings process each event at least once, and duplicate processing of records can occur. To avoid potential issues related to duplicate events, we strongly recommend that you make your function code idempotent. To learn more, see [How do I make my Lambda function idempotent](#) in the AWS Knowledge Center.

For Kafka-based event sources, Lambda supports processing control parameters, such as batching windows and batch size. For more information, see [Batching behavior](#).

For an example of how to use self-managed Kafka as an event source, see [Using self-hosted Apache Kafka as an event source for AWS Lambda](#) on the AWS Compute Blog.

Topics

Example event

Lambda sends the batch of messages in the event parameter when it invokes your Lambda function. The event payload contains an array of messages. Each array item contains details of the Kafka topic and Kafka partition identifier, together with a timestamp and a base64-encoded message.

```
{
  "eventSource": "SelfManagedKafka",
  "bootstrapServers": "b-2.demo-cluster-1.a1bcde.c1.kafka.us-east-1.amazonaws.com:9092,b-1.demo-cluster-1.a1bcde.c1.kafka.us-east-1.amazonaws.com:9092",
  "records": {

}
}
}
}

```

Configuring your self-managed Apache Kafka cluster and network for Lambda

To connect your Lambda function to your self-managed Apache Kafka cluster, you need to correctly configure your cluster and the network it resides in. This page describes how to configure your cluster and network. If your cluster and network are already configured properly, see [the section called “Configure event source”](#) to configure the event source mapping.

Topics

- [Self-managed Apache Kafka cluster setup](#)
- [Configure network security](#)

Self-managed Apache Kafka cluster setup

You can host your self-managed Apache Kafka cluster with cloud providers such as [Confluent Cloud](#) or [Redpanda](#), or run it on your own infrastructure. Ensure that your cluster is properly configured and accessible from the network where your Lambda event source mapping will connect.

Configure network security

To give Lambda full access to self-managed Apache Kafka through your event source mapping, either your cluster must use a public endpoint (public IP address), or you must provide access to the Amazon VPC you created the cluster in.

When you use self-managed Apache Kafka with Lambda, create [AWS PrivateLink VPC endpoints](#) that provide your function access to the resources in your Amazon VPC.

Note

AWS PrivateLink VPC endpoints are required for functions with event source mappings that use the default (on-demand) mode for event pollers. If your event source mapping uses [provisioned mode](#), you don't need to configure AWS PrivateLink VPC endpoints.

Create an endpoint to provide access to the following resources:

- Lambda — Create an endpoint for the Lambda service principal.
- AWS STS — Create an endpoint for the AWS STS in order for a service principal to assume a role on your behalf.
- Secrets Manager — If your cluster uses Secrets Manager to store credentials, create an endpoint for Secrets Manager.

Alternatively, configure a NAT gateway on each public subnet in the Amazon VPC. For more information, see [the section called “Internet access for VPC functions”](#).

When you create an event source mapping for self-managed Apache Kafka, Lambda checks whether Elastic Network Interfaces (ENIs) are already present for the subnets and security groups configured for your Amazon VPC. If Lambda finds existing ENIs, it attempts to re-use them. Otherwise, Lambda creates new ENIs to connect to the event source and invoke your function.

Note

Lambda functions always run inside VPCs owned by the Lambda service. Your function's VPC configuration does not affect the event source mapping. Only the networking configuration of the event source's determines how Lambda connects to your event source.

Configure the security groups for the Amazon VPC containing your cluster. By default, self-managed Apache Kafka uses the following ports: 9092.

- Inbound rules – Allow all traffic on the default broker port for the security group associated with your event source. Alternatively, you can use a self-referencing security group rule to allow access from instances within the same security group.

- Outbound rules – Allow all traffic on port 443 for external destinations if your function needs to communicate with AWS services. Alternatively, you can also use a self-referencing security group rule to limit access to the broker if you don't need to communicate with other AWS services.
- Amazon VPC endpoint inbound rules — If you are using an Amazon VPC endpoint, the security group associated with your Amazon VPC endpoint must allow inbound traffic on port 443 from the cluster security group.

If your cluster uses authentication, you can also restrict the endpoint policy for the Secrets Manager endpoint. To call the Secrets Manager API, Lambda uses your function role, not the Lambda service principal.

Example VPC endpoint policy — Secrets Manager endpoint

```
{
  "Statement": [
    {
      "Action": "secretsmanager:GetSecretValue",
      "Effect": "Allow",
      "Principal": {
        "AWS": [
          "arn:aws::iam::123456789012:role/my-role"
        ]
      },
      "Resource": "arn:aws::secretsmanager:us-west-2:123456789012:secret:my-secret"
    }
  ]
}
```

When you use Amazon VPC endpoints, AWS routes your API calls to invoke your function using the endpoint's Elastic Network Interface (ENI). The Lambda service principal needs to call `lambda:InvokeFunction` on any roles and functions that use those ENIs.

By default, Amazon VPC endpoints have open IAM policies that allow broad access to resources. Best practice is to restrict these policies to perform the needed actions using that endpoint. To ensure that your event source mapping is able to invoke your Lambda function, the VPC endpoint policy must allow the Lambda service principal to call `sts:AssumeRole` and `lambda:InvokeFunction`. Restricting your VPC endpoint policies to allow only API calls

originating within your organization prevents the event source mapping from functioning properly, so "Resource": "*" is required in these policies.

The following example VPC endpoint policies show how to grant the required access to the Lambda service principal for the AWS STS and Lambda endpoints.

Example VPC Endpoint policy — AWS STS endpoint

```
{
  "Statement": [
    {
      "Action": "sts:AssumeRole",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "lambda.amazonaws.com"
        ]
      },
      "Resource": "*"
    }
  ]
}
```

Example VPC Endpoint policy — Lambda endpoint

```
{
  "Statement": [
    {
      "Action": "lambda:InvokeFunction",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "lambda.amazonaws.com"
        ]
      },
      "Resource": "*"
    }
  ]
}
```

Configuring Lambda execution role permissions

In addition to [accessing your self-managed Kafka cluster](#), your Lambda function needs permissions to perform various API actions. You add these permissions to the function's [execution role](#). If your users need access to any API actions, add the required permissions to the identity policy for the AWS Identity and Access Management (IAM) user or role.

Topics

- [Required Lambda function permissions](#)
- [Optional Lambda function permissions](#)
- [Adding permissions to your execution role](#)
- [Granting users access with an IAM policy](#)

Required Lambda function permissions

To create and store logs in a log group in Amazon CloudWatch Logs, your Lambda function must have the following permissions in its execution role:

- [logs:CreateLogGroup](#)
- [logs:CreateLogStream](#)
- [logs:PutLogEvents](#)

Optional Lambda function permissions

Your Lambda function might also need permissions to:

- Describe your Secrets Manager secret.
- Access your AWS Key Management Service (AWS KMS) customer managed key.
- Access your Amazon VPC.
- Send records of failed invocations to a destination.

Secrets Manager and AWS KMS permissions

Depending on the type of access control that you're configuring for your Kafka brokers, your Lambda function might need permission to access your Secrets Manager secret or to decrypt your

AWS KMS customer managed key. To access these resources, your function's execution role must have the following permissions:

- [secretsmanager:GetSecretValue](#)
- [kms:Decrypt](#)

VPC permissions

If only users within a VPC can access your self-managed Apache Kafka cluster, your Lambda function must have permission to access your Amazon VPC resources. These resources include your VPC, subnets, security groups, and network interfaces. To access these resources, your function's execution role must have the following permissions:

- [ec2:CreateNetworkInterface](#)
- [ec2:DescribeNetworkInterfaces](#)
- [ec2:DescribeVpcs](#)
- [ec2>DeleteNetworkInterface](#)
- [ec2:DescribeSubnets](#)
- [ec2:DescribeSecurityGroups](#)

Adding permissions to your execution role

To access other AWS services that your self-managed Apache Kafka cluster uses, Lambda uses the permissions policies that you define in your Lambda function's [execution role](#).

By default, Lambda is not permitted to perform the required or optional actions for a self-managed Apache Kafka cluster. You must create and define these actions in an [IAM trust policy](#) for your execution role. This example shows how you might create a policy that allows Lambda to access your Amazon VPC resources.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
```

```
        "Action": [
            "ec2:CreateNetworkInterface",
            "ec2:DescribeNetworkInterfaces",
            "ec2:DescribeVpcs",
            "ec2>DeleteNetworkInterface",
            "ec2:DescribeSubnets",
            "ec2:DescribeSecurityGroups"
        ],
        "Resource": "*"
    }
}
```

Granting users access with an IAM policy

By default, users and roles don't have permission to perform [event source API operations](#). To grant access to users in your organization or account, you create or update an identity-based policy. For more information, see [Controlling access to AWS resources using policies](#) in the *IAM User Guide*.

For troubleshooting authentication and authorization errors, see [the section called "Troubleshooting"](#).

Configuring self-managed Apache Kafka event sources for Lambda

To use a self-managed Apache Kafka cluster as an event source for your Lambda function, you create an [event source mapping](#) that connects the two resources. This page describes how to create an event source mapping for self-managed Apache Kafka.

This page assumes that you've already properly configured your Kafka cluster and the network it resides in. If you need to set up your cluster or network, see [the section called "Cluster and network setup"](#).

Topics

- [Using a self-managed Apache Kafka cluster as an event source](#)
- [Configuring cluster authentication methods in Lambda](#)
- [Creating a Lambda event source mapping for a self-managed Apache Kafka event source](#)
- [All self-managed Apache Kafka event source configuration parameters in Lambda](#)

Using a self-managed Apache Kafka cluster as an event source

When you add your Apache Kafka or Amazon MSK cluster as a trigger for your Lambda function, the cluster is used as an [event source](#).

Lambda reads event data from the Kafka topics that you specify as Topics in a [CreateEventSourceMapping](#) request, based on the [starting position](#) that you specify. After successful processing, your Kafka topic is committed to your Kafka cluster.

Lambda reads messages sequentially for each Kafka topic partition. A single Lambda payload can contain messages from multiple partitions. When more records are available, Lambda continues processing records in batches, based on the BatchSize value that you specify in a [CreateEventSourceMapping](#) request, until your function catches up with the topic.

After Lambda processes each batch, it commits the offsets of the messages in that batch. If your function returns an error for any of the messages in a batch, Lambda retries the whole batch of messages until processing succeeds or the messages expire. You can send records that fail all retry attempts to an on-failure destination for later processing.

Note

While Lambda functions typically have a maximum timeout limit of 15 minutes, event source mappings for Amazon MSK, self-managed Apache Kafka, Amazon DocumentDB, and Amazon MQ for ActiveMQ and RabbitMQ only support functions with maximum timeout limits of 14 minutes.

Configuring cluster authentication methods in Lambda

Lambda supports several methods to authenticate with your self-managed Apache Kafka cluster. Make sure that you configure the Kafka cluster to use one of these supported authentication methods. For more information about Kafka security, see the [Security](#) section of the Kafka documentation.

SASL/SCRAM authentication

Lambda supports Simple Authentication and Security Layer/Salted Challenge Response Authentication Mechanism (SASL/SCRAM) authentication with Transport Layer Security (TLS) encryption (SASL_SSL). Lambda sends the encrypted credentials to authenticate with the cluster.

Lambda doesn't support SASL/SCRAM with plaintext (SASL_PLAINTEXT). For more information about SASL/SCRAM authentication, see [RFC 5802](#).

Lambda also supports SASL/PLAIN authentication. Because this mechanism uses clear text credentials, the connection to the server must use TLS encryption to ensure that the credentials are protected.

For SASL authentication, you store the sign-in credentials as a secret in AWS Secrets Manager. For more information about using Secrets Manager, see [Create an AWS Secrets Manager secret](#) in the *AWS Secrets Manager User Guide*.

 **Important**

To use Secrets Manager for authentication, secrets must be stored in the same AWS region as your Lambda function.

Mutual TLS authentication

Mutual TLS (mTLS) provides two-way authentication between the client and server. The client sends a certificate to the server for the server to verify the client, and the server sends a certificate to the client for the client to verify the server.

In self-managed Apache Kafka, Lambda acts as the client. You configure a client certificate (as a secret in Secrets Manager) to authenticate Lambda with your Kafka brokers. The client certificate must be signed by a CA in the server's trust store.

The Kafka cluster sends a server certificate to Lambda to authenticate the Kafka brokers with Lambda. The server certificate can be a public CA certificate or a private CA/self-signed certificate. The public CA certificate must be signed by a certificate authority (CA) that's in the Lambda trust store. For a private CA/self-signed certificate, you configure the server root CA certificate (as a secret in Secrets Manager). Lambda uses the root certificate to verify the Kafka brokers.

For more information about mTLS, see [Introducing mutual TLS authentication for Amazon MSK as an event source](#).

Configuring the client certificate secret

The CLIENT_CERTIFICATE_TLS_AUTH secret requires a certificate field and a private key field. For an encrypted private key, the secret requires a private key password. Both the certificate and private key must be in PEM format.

Note

Lambda supports the [PBES1](#) (but not PBES2) private key encryption algorithms.

The certificate field must contain a list of certificates, beginning with the client certificate, followed by any intermediate certificates, and ending with the root certificate. Each certificate must start on a new line with the following structure:

```
-----BEGIN CERTIFICATE-----
        <certificate contents>
-----END CERTIFICATE-----
```

Secrets Manager supports secrets up to 65,536 bytes, which is enough space for long certificate chains.

The private key must be in [PKCS #8](#) format, with the following structure:

```
-----BEGIN PRIVATE KEY-----
        <private key contents>
-----END PRIVATE KEY-----
```

For an encrypted private key, use the following structure:

```
-----BEGIN ENCRYPTED PRIVATE KEY-----
        <private key contents>
-----END ENCRYPTED PRIVATE KEY-----
```

The following example shows the contents of a secret for mTLS authentication using an encrypted private key. For an encrypted private key, include the private key password in the secret.

```
{"privateKeyPassword":"testpassword",
"certificate":"-----BEGIN CERTIFICATE-----
MIIE5DCCAsygAwIBAgIRAPJdwaFaNRrytHBto0j5BA0wDQYJKoZIhvcNAQELBQAw
...
j0Lh4/+1HfgyE2KlmII36dg4IMzNjAFEBZiCRoPim040s1cRqtFHxoa10QQbIlxk
cmUuiAii9R0=
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
MIIFgjCCA2qgAwIBAgIQdjNZd6uFf9hbNC5RdfmHrzANBgkqhkiG9w0BAQsFADBb
```

```

...
rQoiowbbk5wXCheYSANQIfTZ6weQTgiCHCCbuuMKNVS95FkXm0vqVD/YpXKwA/no
c8PH3PSoAaRwMMg0SA2ALJvbRz8mpg==
-----END CERTIFICATE-----",
"privateKey":"-----BEGIN ENCRYPTED PRIVATE KEY-----
MIIFKzBVBGkqhkiG9w0BBQ0wSDANBgkqhkiG9w0BBQwwGgQUiAFcK5hT/X7Kjmgp
...
QrSekqF+kWzmB6nAfSzg09IaoAaytLvNgGTckWeUkWn/V0Ck+LdGUXzAC4RxZnoQ
zp2mwJn2NYB7AZ7+imp0azDZb+8YG2aUCiyqb6PnnA==
-----END ENCRYPTED PRIVATE KEY-----"
}

```

Configuring the server root CA certificate secret

You create this secret if your Kafka brokers use TLS encryption with certificates signed by a private CA. You can use TLS encryption for VPC, SASL/SCRAM, SASL/PLAIN, or mTLS authentication.

The server root CA certificate secret requires a field that contains the Kafka broker's root CA certificate in PEM format. The following example shows the structure of the secret.

```

{"certificate":"-----BEGIN CERTIFICATE-----
MIID7zCCAtagAwIBAgIBADANBgkqhkiG9w0BAQsFADCBmDELMakGA1UEBhMCVVMx
EDA0BgNVBAGTB0FyaXpvbmExEzARBgNVBAcTC1Njb3R0c2RhbGUxJTAjBgNVBAoT
HFN0YXJmaWVsZCBUZWNobm9sb2dpZXMsIEluYy4xOzA5BgNVBAMTM1N0YXJmaWVs
ZCBTZXJ2aWNlcyBSb290IENlcnRpZmljYXR1IEF1dG...
-----END CERTIFICATE-----"
}

```

Creating a Lambda event source mapping for a self-managed Apache Kafka event source

To create an event source mapping, you can use the Lambda console, the [AWS Command Line Interface \(CLI\)](#), or an [AWS SDK](#).

The following console steps add a self-managed Apache Kafka cluster as a trigger for your Lambda function. Under the hood, this creates an event source mapping resource.

Prerequisites

- A self-managed Apache Kafka cluster. Lambda supports Apache Kafka version 0.10.1.0 and later.
- An [execution role](#) with permission to access the AWS resources that your self-managed Kafka cluster uses.

Adding a self-managed Kafka cluster (console)

Follow these steps to add your self-managed Apache Kafka cluster and a Kafka topic as a trigger for your Lambda function.

To add an Apache Kafka trigger to your Lambda function (console)

1. Open the [Functions page](#) of the Lambda console.
2. Choose the name of your Lambda function.
3. Under **Function overview**, choose **Add trigger**.
4. Under **Trigger configuration**, do the following:
 - a. Choose the **Apache Kafka** trigger type.
 - b. For **Bootstrap servers**, enter the host and port pair address of a Kafka broker in your cluster, and then choose **Add**. Repeat for each Kafka broker in the cluster.
 - c. For **Topic name**, enter the name of the Kafka topic used to store records in the cluster.
 - d. If you configure provisioned mode, enter a value for **Minimum event pollers**, a value for **Maximum event pollers**, and an optional value for **PollerGroupName** to specify grouping of multiple ESMs within the same event source VPC.
 - e. (Optional) For **Batch size**, enter the maximum number of records to receive in a single batch.
 - f. For **Batch window**, enter the maximum amount of seconds that Lambda spends gathering records before invoking the function.
 - g. (Optional) For **Consumer group ID**, enter the ID of a Kafka consumer group to join.
 - h. (Optional) For **Starting position**, choose **Latest** to start reading the stream from the latest record, **Trim horizon** to start at the earliest available record, or **At timestamp** to specify a timestamp to start reading from.
 - i. (Optional) For **VPC**, choose the Amazon VPC for your Kafka cluster. Then, choose the **VPC subnets** and **VPC security groups**.

This setting is required if only users within your VPC access your brokers.

- j. (Optional) For **Authentication**, choose **Add**, and then do the following:
 - i. Choose the access or authentication protocol of the Kafka brokers in your cluster.

- ~~If your Kafka broker uses SASL/PLAIN authentication, choose **BASIC_AUTH**.~~

- If your broker uses SASL/SCRAM authentication, choose one of the **SASL_SCRAM** protocols.
 - If you're configuring mTLS authentication, choose the **CLIENT_CERTIFICATE_TLS_AUTH** protocol.
- ii. For SASL/SCRAM or mTLS authentication, choose the Secrets Manager secret key that contains the credentials for your Kafka cluster.
 - k. (Optional) For **Encryption**, choose the Secrets Manager secret containing the root CA certificate that your Kafka brokers use for TLS encryption, if your Kafka brokers use certificates signed by a private CA.

This setting applies to TLS encryption for SASL/SCRAM or SASL/PLAIN, and to mTLS authentication.

- l. To create the trigger in a disabled state for testing (recommended), clear **Enable trigger**. Or, to enable the trigger immediately, select **Enable trigger**.

5. To create the trigger, choose **Add**.

Adding a self-managed Kafka cluster (AWS CLI)

Use the following example AWS CLI commands to create and view a self-managed Apache Kafka trigger for your Lambda function.

Using SASL/SCRAM

If Kafka users access your Kafka brokers over the internet, specify the Secrets Manager secret that you created for SASL/SCRAM authentication. The following example uses the [create-event-source-mapping](#) AWS CLI command to map a Lambda function named `my-kafka-function` to a Kafka topic named `AWSKafkaTopic`.

```
aws lambda create-event-source-mapping \
  --topics AWSKafkaTopic \
  --source-access-configuration Type=SASL_SCRAM_512_AUTH,URI=arn:aws:secretsmanager:us-east-1:111122223333:secret:MyBrokerSecretName \
  --function-name arn:aws:lambda:us-east-1:111122223333:function:my-kafka-function \
  --self-managed-event-source '{"Endpoints":{"KAFKA_BOOTSTRAP_SERVERS":  
["abc3.xyz.com:9092", "abc2.xyz.com:9092"]}}'
```

Using a VPC

If only Kafka users within your VPC access your Kafka brokers, you must specify your VPC, subnets, and VPC security group. The following example uses the [create-event-source-mapping](#) AWS CLI command to map a Lambda function named `my-kafka-function` to a Kafka topic named `AWSKafkaTopic`.

```
aws lambda create-event-source-mapping \
  --topics AWSKafkaTopic \
  --source-access-configuration '[{"Type": "VPC_SUBNET", "URI":
"subnet:subnet-0011001100"}, {"Type": "VPC_SUBNET", "URI":
"subnet:subnet-0022002200"}, {"Type": "VPC_SECURITY_GROUP", "URI":
"security_group:sg-0123456789"}]' \
  --function-name arn:aws:lambda:us-east-1:111122223333:function:my-kafka-function \
  --self-managed-event-source '{"Endpoints":{"KAFKA_BOOTSTRAP_SERVERS":
["abc3.xyz.com:9092", "abc2.xyz.com:9092"]}}'
```

Viewing the status using the AWS CLI

The following example uses the [get-event-source-mapping](#) AWS CLI command to describe the status of the event source mapping that you created.

```
aws lambda get-event-source-mapping
  --uuid dh38738e-992b-343a-1077-3478934hjkfd7
```

All self-managed Apache Kafka event source configuration parameters in Lambda

All Lambda event source types share the same [CreateEventSourceMapping](#) and [UpdateEventSourceMapping](#) API operations. However, only some of the parameters apply to self-managed Apache Kafka, as shown in the following table.

Parameter	Required	Default	Notes
BatchSize	N	100	Maximum: 10,000
DestinationConfig	N	N/A	the section called "Retain failed invocations"
Enabled	N	True	

Parameter	Required	Default	Notes
FilterCriteria	N	N/A	Control which events Lambda sends to your function
FunctionName	Y	N/A	
KMSKeyArn	N	N/A	the section called "Encryption of filter criteria"
MaximumBatchingWindowInSeconds	N	500 ms	Batching behavior
ProvisionedPollersConfig	N	MinimumPollers : default value of 1 if not specified MaximumPollers : default value of 200 if not specified PollerGroupName : N/A	the section called "Provisioned mode"
SelfManagedEventSource	Y	N/A	List of Kafka Brokers. Can set only on Create
SelfManagedKafkaEventSourceConfig	N	Contains the ConsumerGroupId field which defaults to a unique value.	Can set only on Create

Parameter	Required	Default	Notes
SourceAccessConfigurations	N	No credentials	VPC information or authentication credentials for the cluster For SASL_PLAIN, set to BASIC_AUTH
StartingPosition	Y	N/A	AT_TIMESTAMP, TRIM_HORIZON, or LATEST Can set only on Create
StartingPositionTimestamp	N	N/A	Required if StartingPosition is set to AT_TIMESTAMP
Tags	N	N/A	the section called “Event source mapping tags”
Topics	Y	N/A	Topic name Can set only on Create

Note

When you specify a `PollerGroupName`, multiple ESMs within the same Amazon VPC can share Event Poller Unit (EPU) capacity. You can use this option to optimize Provisioned mode costs for your ESMs. Requirements for ESM grouping:

- ESMs must be within the same Amazon VPC
- Maximum of 100 ESMs per poller group

- Aggregate maximum pollers across all ESMs in a group cannot exceed 2000

You can update the `PollerGroupName` to move an ESM to a different group, or remove an ESM from a group by setting `PollerGroupName` to an empty string (`""`).

Apache Kafka event poller scaling modes in Lambda

You can choose between two modes of event poller scaling for Amazon MSK and self-managed Apache Kafka event source mappings:

- [On-demand mode \(default\)](#)
- [Provisioned mode](#)

On-demand mode (default)

When you initially create the Kafka event source, Lambda allocates a default number of event pollers to process all partitions in the Kafka topic. Lambda automatically scales up or down the number of [event pollers](#) based on message load.

In one-minute intervals, Lambda evaluates the offset lag of all the partitions in the topic. If the offset lag is too high, the partition is receiving messages faster than Lambda can process them. If necessary, Lambda adds or removes event pollers from the topic. This autoscaling process of adding or removing event pollers occurs within three minutes of evaluation.

If your target Lambda function is throttled, Lambda reduces the number of event pollers. This action reduces the workload on the function by reducing the number of messages that event pollers can retrieve and send to the function.

Provisioned mode

For workloads where you need to fine-tune the throughput of your event source mapping, you can use provisioned mode. In provisioned mode, you define minimum and maximum limits for the amount of provisioned event pollers. These provisioned event pollers are dedicated to your event source mapping, and can handle unexpected message spikes through responsive autoscaling. We recommend that you use provisioned mode for Kafka workloads that have strict performance requirements.

In Lambda, an event poller is a compute unit with throughput capabilities that vary by event source type. For Amazon MSK and self-managed Apache Kafka, each event poller can handle up to 5 MB/sec of throughput or up to 5 concurrent invocations. For example, if your event source produces an average payload of 1 MB and the average duration of your function is 1 second, a single Kafka event poller can support 5 MB/sec throughput and 5 concurrent Lambda invocations (assuming no payload transformation). For Amazon SQS, each event poller can handle up to 1 MB/sec of

throughput or up to 10 concurrent invocations. Using provisioned mode incurs additional costs based on your event poller usage. For pricing details, see [AWS Lambda pricing](#).

 **Note**

When using provisioned mode, you don't need to create AWS PrivateLink VPC endpoints or grant the associated permissions as part of your network configuration.

In provisioned mode, the range of accepted values for the minimum number of event pollers (`MinimumPollers`) is between 1 and 200, inclusive. The range of accepted values for the maximum number of event pollers (`MaximumPollers`) is between 1 and 2,000, inclusive. `MaximumPollers` must be greater than or equal to `MinimumPollers`. In addition, to maintain ordered processing within partitions, Lambda caps the `MaximumPollers` to the number of partitions in the topic.

For more details about choosing appropriate values for minimum and maximum event pollers, see [Best practices](#).

You can configure provisioned mode for your Kafka event source mapping using the console or the Lambda API.

To configure provisioned mode for an existing event source mapping (console)

1. Open the [Functions page](#) of the Lambda console.
2. Choose the function with the event source mapping you want to configure provisioned mode for.
3. Choose **Configuration**, then choose **Triggers**.
4. Choose the event source mapping that you want to configure provisioned mode for, then choose **Edit**.
5. Under **Provisioned mode**, select **Configure**.
 - For **Minimum event pollers**, enter a value between 1 and 200. If you don't specify a value, Lambda chooses a default value of 1.
 - For **Maximum event pollers**, enter a value between 1 and 2,000. This value must be greater than or equal to your value for **Minimum event pollers**. If you don't specify a value, Lambda chooses a default value of 200.
6. Choose **Save**.

You can configure provisioned mode programmatically using the [ProvisionedPollerConfig](#) object in your [EventSourceMappingConfiguration](#). For example, the following [UpdateEventSourceMapping](#) CLI command configures a `MinimumPollers` value of 5, and a `MaximumPollers` value of 100.

```
aws lambda update-event-source-mapping \  
  --uuid a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 \  
  --provisioned-poller-config '{"MinimumPollers": 5, "MaximumPollers": 100}'
```

After configuring provisioned mode, you can observe the usage of event pollers for your workload by monitoring the `ProvisionedPollers` metric. For more information, see [the section called “Event source mapping metrics”](#).

To disable provisioned mode and return to default (on-demand) mode, you can use the following [UpdateEventSourceMapping](#) CLI command:

```
aws lambda update-event-source-mapping \  
  --uuid a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 \  
  --provisioned-poller-config '{}'
```

Advanced error handling and performance features

For Kafka event source mappings with provisioned mode enabled, you can configure additional features to improve error handling and performance:

- [Retry configurations](#) – Control how Lambda handles failed records with maximum retry attempts, record age limits, batch splitting, and partial batch responses.
- [Kafka on-failure destinations](#) – Send failed records to a Kafka topic for later processing or analysis.

Best practices and considerations when using provisioned mode

The optimal configuration of minimum and maximum event pollers for your event source mapping depends on your application's performance requirements. We recommend that you start with the default minimum event pollers to baseline the performance profile. Adjust your configuration based on observed message processing patterns and your desired performance profile.

For workloads with spiky traffic and strict performance needs, increase the minimum event pollers to handle sudden surges in messages. To determine the minimum event pollers required, consider

your workload's messages per second and average payload size, and use the throughput capacity of a single event poller (up to 5 MBps) as a reference.

To maintain ordered processing within a partition, Lambda limits the maximum event pollers to the number of partitions in the topic. Additionally, the maximum event pollers your event source mapping can scale to depends on the function's concurrency settings.

When activating provisioned mode, update your network settings to remove AWS PrivateLink VPC endpoints and associated permissions.

Cost Optimization for Provisioned mode

Provisioned mode pricing

Provisioned mode is charged based on the provisioned minimum event pollers, and the event pollers consumed during autoscaling. Charges are calculated using a billing unit called Event Poller Unit (EPU). You pay for the number and duration of EPUs used, measured in Event-Poller-Unit-hours. You can use Provisioned mode with either a single ESM for performance-sensitive applications or you can group multiple ESMs within the same VPC to share EPU capacity and costs. We will deep dive on two capabilities that help you optimize your Provisioned mode costs. For pricing details, see [AWS Lambda pricing](#).

Enhanced EPU Utilization

Each EPU supports up to 20 MB/s throughput capacity for event polling and supports a default of 10 event pollers. When you create a Provisioned mode for Kafka ESM by setting minimum and maximum pollers, it uses minimum poller number to provision EPUs based on default of 10 event pollers per EPU. However, each event poller can independently scale to support up to 5 MB/s of throughput capacity, which may require lower density of event pollers on a specific EPU and can trigger scaling of EPUs. The number of event pollers allocated on an EPU depends on the compute capacity consumed by each event poller. This approach of enhanced EPU utilization allows event pollers with varying throughput requirements to utilize EPU capacity effectively, reducing costs for all ESMs.

ESM grouping

To optimize your Provisioned mode costs further, you can group multiple Kafka ESMs to share EPU capacity. With ESM grouping and enhanced EPU Utilization, you can reduce your Provisioned mode costs up to 90% for low-throughput workloads compared to running in single ESM mode. All ESMs that require less than 1 EPU capacity will benefit from ESM grouping. Such ESMs typically require few minimum event pollers to support their throughput needs. This capability will allow

you to adopt Provisioned mode for all your Kafka workloads, and benefit from features like schema validation, filtering of Avro/Protobuf events, low-latency invocations, and enhanced error handling that only available in Provisioned mode.

When you configure the `PollerGroupName` parameter with the same value for multiple ESMs within the same Amazon VPC, those ESMs share EPU resources instead of each requiring dedicated EPU capacity. You can group up to 100 ESMs per poller group and aggregate maximum pollers across all ESMs in a group cannot exceed 2000.

To configure ESM grouping (console)

1. Open the [Functions page](#) of the Lambda console.
2. Choose your function.
3. Choose **Configuration**, and then choose **Triggers**.
4. When creating a new Kafka event source mapping, or editing an existing one, select **Configure** under **Provisioned mode**.
5. For **Minimum event pollers**, enter a value between 1 and 200.
6. For **Maximum event pollers**, enter a value between 1 and 2,000.
7. For **Poller group name**, enter an identifier for the group. Use the same name for other ESMs you want to group together.
8. Choose **Save**.

To configure ESM grouping (AWS CLI)

The following example creates an ESM with a poller group named `production-app-group`:

```
aws lambda create-event-source-mapping \  
  --function-name myFunction1 \  
  --event-source-arn arn:aws:kafka:us-east-1:123456789012:cluster/MyCluster/abcd1234 \  
  --topics topic1 \  
  --starting-position LATEST \  
  --provisioned-poller-config '{  
    "MinimumPollers": 1,  
    "MaximumPollers": 10,  
    "PollerGroupName": "production-app-group"  
  }'
```

To add another ESM to the same group (sharing EPU capacity), use the same `PollerGroupName`:

```
aws lambda create-event-source-mapping \  
  --function-name myFunction2 \  
  --event-source-arn arn:aws:kafka:us-east-1:123456789012:cluster/MyCluster/abcd1234 \  
  --topics topic2 \  
  --starting-position LATEST \  
  --provisioned-poller-config '{  
    "MinimumPollers": 1,  
    "MaximumPollers": 10,  
    "PollerGroupName": "production-app-group"  
  }'
```

Note

You can update the `PollerGroupName` to move an ESM to a different group, or remove an ESM from a group by passing an empty string ("") for `PollerGroupName`:

```
# Move ESM to a different group  
aws lambda update-event-source-mapping \  
  --uuid a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 \  
  --provisioned-poller-config '{  
    "MinimumPollers": 1,  
    "MaximumPollers": 10,  
    "PollerGroupName": "new-group-name"  
  }'  
  
# Remove ESM from group (use dedicated resources)  
aws lambda update-event-source-mapping \  
  --uuid a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 \  
  --provisioned-poller-config '{  
    "MinimumPollers": 1,  
    "MaximumPollers": 10,  
    "PollerGroupName": ""  
  }'
```

Grouping strategy considerations

- **Application boundary** – Group ESMs that belong to the same applications or services for better cost allocation and management. Consider using naming conventions like `app-name-environment` (e.g., `order-processor-prod`).

- **Traffic pattern** – Avoid grouping ESMs with high throughput and spiky traffic pattern, as this may lead to resource contention.
- **Blast radius** – Consider the impact if the shared infrastructure experiences issues. All ESMs in the same group are affected by shared resource limitations. For mission-critical workloads, you may want to use separate groups or dedicated ESMs.

Cost optimization example

Consider a scenario where you have 10 ESMs, each configured with 1 event poller and throughput under 2 MB/s:

Without grouping:

- Each ESM requires its own EPU
- Total EPUs needed: 10
- Cost per EPU: \$0.185/hour in US East (N. Virginia)
- Monthly EPU cost (720 hours): $10 \times 720 \times \$0.185 = \$1,332$

With grouping:

- All 10 ESMs share EPU capacity
- 10 event pollers fit in 1 EPU (with new 10 poller per EPU support)
- Total EPUs needed: 1
- Monthly EPU cost (720 hours): $1 \times 720 \times \$0.185 = \133.20
- **Cost savings: 90%** (\$1,198.80 savings per month)

Apache Kafka polling and stream starting positions in Lambda

The [StartingPosition parameter](#) tells Lambda when to start reading messages from your Amazon MSK or self-managed Apache Kafka stream. There are three options to choose from:

- **Latest** – Lambda starts reading just after the most recent record in the Kafka topic.
- **Trim horizon** – Lambda starts reading from the last untrimmed record in the Kafka topic. This is also the oldest record in the topic.
- **At timestamp** – Lambda starts reading from a position defined by a timestamp, in Unix time seconds. Use the [StartingPositionTimestamp parameter](#) to specify the timestamp.

Stream polling during an event source mapping create or update is eventually consistent:

- During event source mapping creation, it may take several minutes to start polling events from the stream.
- During event source mapping updates, it may take up to 90 seconds to stop and restart polling events from the stream.

This behavior means that if you specify LATEST as the starting position for the stream, the event source mapping could miss events during a create or update. To ensure that no events are missed, specify either TRIM_HORIZON or AT_TIMESTAMP.

Customizable consumer group ID in Lambda

When setting up Amazon MSK or self-managed Apache Kafka as an event source, you can specify a [consumer group](#) ID. This consumer group ID is an existing identifier for the Kafka consumer group that you want your Lambda function to join. You can use this feature to seamlessly migrate any ongoing Kafka record processing setups from other consumers to Lambda.

Kafka distributes messages across all consumers in a consumer group. If you specify a consumer group ID that has other active consumers, Lambda receives only a portion of the messages from the Kafka topic. If you want Lambda to handle all messages in the topic, turn off any other consumers in that consumer group.

Additionally, if you specify a consumer group ID, and Kafka finds a valid existing consumer group with the same ID, Lambda ignores the [StartingPosition](#) for your event source mapping. Instead, Lambda begins processing records according to the committed offset of the consumer group. If you specify a consumer group ID, and Kafka cannot find an existing consumer group, then Lambda configures your event source with the specified `StartingPosition`.

The consumer group ID that you specify must be unique among all your Kafka event sources. After creating a Kafka event source mapping with the consumer group ID specified, you cannot update this value.

Filtering events from Amazon MSK and self-managed Apache Kafka event sources

You can use event filtering to control which records from a stream or queue Lambda sends to your function. For general information about how event filtering works, see [the section called “Event filtering”](#).

Note

Amazon MSK and self-managed Apache Kafka event source mappings only support filtering on the `value` key.

Topics

- [Kafka event filtering basics](#)

Kafka event filtering basics

Suppose a producer is writing messages to a topic in your Kafka cluster, either in valid JSON format or as plain strings. An example record would look like the following, with the message converted to a Base64 encoded string in the `value` field.

```
{
  "mytopic-0": [
    {
      "topic": "mytopic",
      "partition": 0,
      "offset": 15,
      "timestamp": 1545084650987,
      "timestampType": "CREATE_TIME",
      "value": "SGVsbG8sIHRoaXMgaXMgYSB0ZXN0Lg==",
      "headers": []
    }
  ]
}
```

Suppose your Apache Kafka producer is writing messages to your topic in the following JSON format.

```
{
  "device_ID": "AB1234",
  "session":{
    "start_time": "yyyy-mm-ddThh:mm:ss",
    "duration": 162
  }
}
```

You can use the `value` key to filter records. Suppose you wanted to filter only those records where `device_ID` begins with the letters AB. The `FilterCriteria` object would be as follows.

```
{
  "Filters": [
    {
      "Pattern": "{ \"value\" : { \"device_ID\" : [ { \"prefix\": \"AB\" } ] } }"
    }
  ]
}
```

For added clarity, here is the value of the filter's `Pattern` expanded in plain JSON.

```
{
  "value": {
    "device_ID": [ { "prefix": "AB" } ]
  }
}
```

You can add your filter using the console, AWS CLI or an AWS SAM template.

Console

To add this filter using the console, follow the instructions in [Attaching filter criteria to an event source mapping \(console\)](#) and enter the following string for the **Filter criteria**.

```
{ "value" : { "device_ID" : [ { "prefix": "AB" } ] } }
```

AWS CLI

To create a new event source mapping with these filter criteria using the AWS Command Line Interface (AWS CLI), run the following command.

```
aws lambda create-event-source-mapping \
  --function-name my-function \
  --event-source-arn arn:aws:kafka:us-east-2:123456789012:cluster/my-cluster/  
b-8ac7cc01-5898-482d-be2f-a6b596050ea8 \
  --filter-criteria '{"Filters": [{"Pattern": "{ \"value\" : { \"device_ID\" :  
[ { \"prefix\": \"AB\" } ] } }"]}'
```

To add these filter criteria to an existing event source mapping, run the following command.

```
aws lambda update-event-source-mapping \
  --uuid "a1b2c3d4-5678-90ab-cdef-1111EXAMPLE" \
  --filter-criteria '{"Filters": [{"Pattern": "{ \"value\" : { \"device_ID\" :  
[ { \"prefix\": \"AB\" } ] } }"]}'
```

AWS SAM

To add this filter using AWS SAM, add the following snippet to the YAML template for your event source.

```
FilterCriteria:
  Filters:
    - Pattern: '{ "value" : { "device_ID" : [ { "prefix": "AB" } ] } }'
```

With Kafka, you can also filter records where the message is a plain string. Suppose you want to ignore those messages where the string is "error". The `FilterCriteria` object would look as follows.

```
{
  "Filters": [
    {
      "Pattern": "{ \"value\" : [ { \"anything-but\": [ \"error\" ] } ] }"
    }
  ]
}
```

For added clarity, here is the value of the filter's `Pattern` expanded in plain JSON.

```
{
  "value": [
```

```

    {
      "anything-but": [ "error" ]
    }
  ]
}

```

You can add your filter using the console, AWS CLI or an AWS SAM template.

Console

To add this filter using the console, follow the instructions in [Attaching filter criteria to an event source mapping \(console\)](#) and enter the following string for the **Filter criteria**.

```
{ "value" : [ { "anything-but": [ "error" ] } ] }
```

AWS CLI

To create a new event source mapping with these filter criteria using the AWS Command Line Interface (AWS CLI), run the following command.

```
aws lambda create-event-source-mapping \
  --function-name my-function \
  --event-source-arn arn:aws:kafka:us-east-2:123456789012:cluster/my-cluster/  
b-8ac7cc01-5898-482d-be2f-a6b596050ea8 \
  --filter-criteria '{"Filters": [{"Pattern": "{ \"value\" : [ { \"anything-but\":  
[ \"error\" ] } ] }"]}]'
```

To add these filter criteria to an existing event source mapping, run the following command.

```
aws lambda update-event-source-mapping \
  --uuid "a1b2c3d4-5678-90ab-cdef-1111EXAMPLE" \
  --filter-criteria '{"Filters": [{"Pattern": "{ \"value\" : [ { \"anything-but\":  
[ \"error\" ] } ] }"]}]'
```

AWS SAM

To add this filter using AWS SAM, add the following snippet to the YAML template for your event source.

```
FilterCriteria:
  Filters:
```

```
- Pattern: '{ "value" : [ { "anything-but": [ "error" ] } ] }'
```

Kafka messages must be UTF-8 encoded strings, either plain strings or in JSON format. That's because Lambda decodes Kafka byte arrays into UTF-8 before applying filter criteria. If your messages use another encoding, such as UTF-16 or ASCII, or if the message format doesn't match the `FilterCriteria` format, Lambda processes metadata filters only. The following table summarizes the specific behavior:

Incoming message format	Filter pattern format for message properties	Resulting action
Plain string	Plain string	Lambda filters based on your filter criteria.
Plain string	No filter pattern for data properties	Lambda filters (on the other metadata properties only) based on your filter criteria.
Plain string	Valid JSON	Lambda filters (on the other metadata properties only) based on your filter criteria.
Valid JSON	Plain string	Lambda filters (on the other metadata properties only) based on your filter criteria.
Valid JSON	No filter pattern for data properties	Lambda filters (on the other metadata properties only) based on your filter criteria.
Valid JSON	Valid JSON	Lambda filters based on your filter criteria.
Non-UTF-8 encoded string	JSON, plain string, or no pattern	Lambda filters (on the other metadata properties only) based on your filter criteria.

Using schema registries with Kafka event sources in Lambda

Schema registries help you define and manage data stream schemas. A schema defines the structure and format of a data record. In the context of Kafka event source mappings, you can configure a schema registry to validate the structure and format of Kafka messages against predefined schemas before they reach your Lambda function. This adds a layer of data governance to your application and allows you to efficiently manage data formats, ensure schema compliance, and optimize costs through event filtering.

This feature works with all programming languages, but consider these important points:

- Powertools for Lambda provides specific support for Java, Python, and TypeScript, maintaining consistency with existing Kafka development patterns and allowing direct access to business objects without custom deserialization code
- This feature is only available for event source mappings using provisioned mode. Schema registry doesn't support event source mappings in on-demand mode. If you're using provisioned mode and you have a schema registry configured, you can't change to on-demand mode unless you remove your schema registry configuration first. For more information, see [the section called "Provisioned mode"](#)
- You can configure only one schema registry per event source mapping (ESM). Using a schema registry with your Kafka event source may increase your Lambda Event Poller Unit (EPU) usage, which is a pricing dimension for Provisioned mode.

- [Error handling and troubleshooting for schema registry issues](#)

Schema registry options

Lambda supports the following schema registry options:

- [AWS Glue Schema Registry](#)
- [Confluent Cloud Schema Registry](#)
- [Self-managed Confluent Schema Registry](#)

Your schema registry supports validating messages in the following data formats:

- Apache Avro
- Protocol Buffers (Protobuf)
- JSON Schema (JSON-SE)

To use a schema registry, first ensure that your event source mapping is in provisioned mode. When you use a schema registry, Lambda adds metadata about the schema to the payload. For more information, see [Payload formats and deserialization behavior](#).

How Lambda performs schema validation for Kafka messages

When you configure a schema registry, Lambda performs the following steps for each Kafka message:

1. Lambda polls the Kafka record from your cluster.
2. Lambda validates selected message attributes in the record against a specific schema in your schema registry.
 - If the schema associated with the message is not found in the registry, Lambda sends the message to a DLQ with reason code `SCHEMA_NOT_FOUND`.
3. Lambda deserializes the message according to the schema registry configuration to validate the message. If event filtering is configured, Lambda then performs filtering based on the configured filter criteria.
 - If deserialization fails, Lambda sends the message to a DLQ with reason code `DESERIALIZATION_ERROR`. If no DLQ is configured, Lambda drops the message.
4. If the message is validated by the schema registry, and isn't filtered out by your filter criteria, Lambda invokes your function with the message.

This feature is intended to validate messages that are already produced using Kafka clients integrated with a schema registry. We recommend configuring your Kafka producers to work with your schema registry to create properly formatted messages.

Configuring a Kafka schema registry

The following console steps add a Kafka schema registry configuration to your event source mapping.

To add a Kafka schema registry configuration to your event source mapping (console)

1. Open the [Function page](#) of the Lambda console.
2. Choose **Configuration**.
3. Choose **Triggers**.
4. Select the Kafka event source mapping that you want to configure a schema registry for, and choose **Edit**.
5. Under **Event poller configuration**, choose **Configure schema registry**. Your event source mapping must be in provisioned mode to see this option.
6. For **Schema registry URI**, enter the ARN of your AWS Glue schema registry, or the HTTPS URL of your Confluent Cloud schema registry or Self-Managed Confluent Schema Registry.
7. The following configuration steps tell Lambda how to access your schema registry. For more information, see [???](#).
 - For **Access configuration type**, choose the type of authentication Lambda uses to access your schema registry.
 - For **Access configuration URI**, enter the ARN of the Secrets Manager secret to authenticate with your schema registry, if applicable. Ensure that your function's [execution role](#) contains the correct permissions.
8. The **Encryption** field applies only if your schema registry is signed by a private Certificate Authority (CA) or a certificate authority (CA) that's not in the Lambda trust store.. If applicable, provide the secret key containing the private CA certificate used by your schema registry for TLS encryption.
9. For **Event record format**, choose how you want Lambda to deliver the records your function after schema validation. For more information, see [Payload format examples](#).

- If you choose **JSON**, Lambda delivers the attributes that you select in the Schema validation attribute below in standard JSON format. For the attributes that you don't select, Lambda delivers them as-is.
 - If you choose **SOURCE**, Lambda delivers the attributes that you select in the Schema validation attribute below in its original source format.
10. For **Schema validation attribute**, select the message attributes that you want Lambda to validate and deserialize using your schema registry. You must select at least one of either **KEY** or **VALUE**. If you chose JSON for event record format, Lambda also deserializes the selected message attributes before sending them to your function. For more information, see [Payload formats and deserialization behavior](#).
 11. Choose **Save**.

You can also use the Lambda API to create or update your event source mapping with a schema registry configuration. The following examples demonstrate how to configure an AWS Glue or Confluent schema registry using the AWS CLI, which corresponds to the [UpdateEventSourceMapping](#) and [CreateEventSourceMapping](#) API operations in the *AWS Lambda API Reference*:

Important

If you are updating any schema registry configuration field using the AWS CLI or the `update-event-source-mapping` API, you must update all the fields of schema registry configuration.

Create Event Source Mapping

```
aws lambda create-event-source-mapping \
  --function-name my-schema-validator-function \
  --event-source-arn arn:aws:kafka:us-east-1:123456789012:cluster/my-cluster/
a1b2c3d4-5678-90ab-cdef-11111EXAMPLE \
  --topics my-kafka-topic \
  --provisioned-poller-config MinimumPollers=1,MaximumPollers=1 \
  --amazon-managed-kafka-event-source-mapping '{
    "SchemaRegistryConfig" : {
      "SchemaRegistryURI": "https://abcd-ef123.us-west-2.aws.confluent.cloud",
      "AccessConfigs": [{
```

```

        "Type": "BASIC_AUTH",
        "URI": "arn:aws:secretsmanager:us-
east-1:123456789012:secret:secretName"
    }],
    "EventRecordFormat": "JSON",
    "SchemaValidationConfigs": [
        {
            "Attribute": "KEY"
        },
        {
            "Attribute": "VALUE"
        }
    ]
}
}'

```

Update AWS Glue Schema Registry

```

aws lambda update-event-source-mapping \
  --uuid a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 \
  --amazon-managed-kafka-event-source-mapping '{
    "SchemaRegistryConfig" : {
      "SchemaRegistryURI": "arn:aws:glue:us-east-1:123456789012:registry/
registryName",
      "EventRecordFormat": "JSON",
      "SchemaValidationConfigs": [
        {
          "Attribute": "KEY"
        },
        {
          "Attribute": "VALUE"
        }
      ]
    }
  }'

```

Update Confluent Schema Registry with Authentication

```

aws lambda update-event-source-mapping \
  --uuid a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 \
  --amazon-managed-kafka-event-source-mapping '{
    "SchemaRegistryConfig" : {
      "SchemaRegistryURI": "https://abcd-ef123.us-west-2.aws.confluent.cloud",
      "AccessConfigs": [{
        "Type": "BASIC_AUTH",

```

```

        "URI": "arn:aws:secretsmanager:us-
east-1:123456789012:secret:secretName"
    }],
    "EventRecordFormat": "JSON",
    "SchemaValidationConfigs": [
        {
            "Attribute": "KEY"
        },
        {
            "Attribute": "VALUE"
        }
    ]
}
}'

```

Update Confluent Schema Registry without Authentication

```

aws lambda update-event-source-mapping \
  --uuid a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 \
  --amazon-managed-kafka-event-source-mapping '{
    "SchemaRegistryConfig" : {
      "SchemaRegistryURI": "https://abcd-ef123.us-west-2.aws.confluent.cloud",
      "EventRecordFormat": "JSON",
      "SchemaValidationConfigs": [
        {
          "Attribute": "KEY"
        },
        {
          "Attribute": "VALUE"
        }
      ]
    }
  }'

```

Remove Schema Registry Configuration

To remove a schema registry configuration from your event source mapping, you can use the CLI command [UpdateEventSourceMapping](#) in the *AWS Lambda API Reference*.

```

aws lambda update-event-source-mapping \
  --uuid a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 \
  --amazon-managed-kafka-event-source-mapping '{
    "SchemaRegistryConfig" : {}
  }'

```

Filtering for Avro and Protobuf

When using Avro or Protobuf formats with a schema registry, you can apply event filtering to your Lambda function. The filter patterns are applied to the deserialized classic JSON representation of your data after schema validation. For example, with an Avro schema defining product details including price, you can filter messages based on the price value:

Note

When being deserialized, Avro is converted to standard JSON, which means it cannot be directly converted back to an Avro object. If you need to convert to an Avro object, use the **SOURCE** format instead.

For Protobuf deserialization, field names in the resulting JSON match those defined in your schema, rather than being converted to camel case as Protobuf typically does. Keep this in mind when creating filtering patterns.

```
aws lambda create-event-source-mapping \
  --function-name myAvroFunction \
  --topics myAvroTopic \
  --starting-position TRIM_HORIZON \
  --kafka-bootstrap-servers '["broker1:9092", "broker2:9092"]' \
  --schema-registry-config '{
    "SchemaRegistryURI": "arn:aws:glue:us-east-1:123456789012:registry/
myAvroRegistry",
    "EventRecordFormat": "JSON",
    "SchemaValidationConfigs": [
      {
        "Attribute": "VALUE"
      }
    ]
  }' \
  --filter-criteria '{
    "Filters": [
      {
        "Pattern": "{ \"value\" : { \"field_1\" : [\"value1\"], \"field_2\" :
[\"value2\"] } }"
      }
    ]
  }'
```

In this example, the filter pattern analyzes the `value` object, matching messages in `field_1` with `"value1"` and `field_2` with `"value2"`. The filter criteria are evaluated against the deserialized data, after Lambda converts the message from Avro format to JSON.

For more detailed information on event filtering, see [Lambda event filtering](#).

Payload formats and deserialization behavior

When using a schema registry, Lambda delivers the final payload to your function in a format similar to the [regular event payload](#), with some additional fields. The additional fields depend on the `SchemaValidationConfigs` parameter. For each attribute that you select for validation (key or value), Lambda adds corresponding schema metadata to the payload.

Note

You must update your [aws-lambda-java-events](#) to version 3.16.0 or above to use schema metadata fields.

For example, if you validate the `value` field, Lambda adds a field called `valueSchemaMetadata` to your payload. Similarly, for the `key` field, Lambda adds a field called `keySchemaMetadata`. This metadata contains information about the data format and the schema ID used for validation:

```
"valueSchemaMetadata": {  
  "dataFormat": "AVRO",  
  "schemaId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"  
}
```

The `EventRecordFormat` parameter can be set to either `JSON` or `SOURCE`, which determines how Lambda handles schema-validated data before delivering it to your function. Each option provides different processing capabilities:

- **JSON** - Lambda deserializes the validated attributes into standard JSON format, making the data ready for direct use in languages with native JSON support. This format is ideal when you don't need to preserve the original binary format or work with generated classes.
- **SOURCE** - Lambda preserves the original binary format of the data as a Base64-encoded string, allowing direct conversion to Avro or Protobuf objects. This format is essential when working with strongly-typed languages or when you need to maintain the full capabilities of Avro or Protobuf schemas.

Based on these format characteristics and language-specific considerations, we recommend the following formats:

Recommended formats based on programming language

Language	Avro	Protobuf	JSON
Java	SOURCE	SOURCE	SOURCE
Python	JSON	JSON	JSON
NodeJS	JSON	JSON	JSON
.NET	SOURCE	SOURCE	SOURCE
Others	JSON	JSON	JSON

The following sections describe these formats in detail and provide example payloads for each format.

JSON format

If you choose JSON as the `EventRecordFormat`, Lambda validates and deserializes the message attributes that you've selected in the `SchemaValidationConfigs` field (the key and/or value attributes). Lambda delivers these selected attributes as base64-encoded strings of their standard JSON representation in your function.

Note

When being deserialized, Avro is converted to standard JSON, which means it cannot be directly converted back to an Avro object. If you need to convert to an Avro object, use the `SOURCE` format instead.

For Protobuf deserialization, field names in the resulting JSON match those defined in your schema, rather than being converted to camel case as Protobuf typically does. Keep this in mind when creating filtering patterns.

The following shows an example payload, assuming you choose JSON as the `EventRecordFormat`, and both the key and value attributes as `SchemaValidationConfigs`:

```

{
  "eventSource": "aws:kafka",
  "eventSourceArn": "arn:aws:kafka:us-east-1:123456789012:cluster/vpc-2priv-2pub/
a1b2c3d4-5678-90ab-cdef-EXAMPLE11111-1",
  "bootstrapServers": "b-2.demo-cluster-1.a1bcde.c1.kafka.us-
east-1.amazonaws.com:9092,b-1.demo-cluster-1.a1bcde.c1.kafka.us-
east-1.amazonaws.com:9092",
  "records": {
    "mytopic-0": [
      {
        "topic": "mytopic",
        "partition": 0,
        "offset": 15,
        "timestamp": 1545084650987,
        "timestampType": "CREATE_TIME",
        "key": "abcDEFghiJKLmnoPQRstuVWXYZ1234==", //Base64 encoded string of JSON
        "keySchemaMetadata": {
          "dataFormat": "AVRO",
          "schemaId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
        },
        "value": "abcDEFghiJKLmnoPQRstuVWXYZ1234", //Base64 encoded string of JSON
        "valueSchemaMetadata": {
          "dataFormat": "AVRO",
          "schemaId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
        },
        "headers": [
          {
            "headerKey": [
              104,
              101,
              97,
              100,
              101,
              114,
              86,
              97,
              108,
              117,
              101
            ]
          }
        ]
      }
    ]
  }
}

```

```
    ]  
  }  
}
```

In this example:

- Both `key` and `value` are base64-encoded strings of their JSON representation after deserialization.
- Lambda includes schema metadata for both attributes in `keySchemaMetadata` and `valueSchemaMetadata`.
- Your function can decode the `key` and `value` strings to access the deserialized JSON data.

The JSON format is recommended for languages that aren't strongly typed, such as Python or Node.js. These languages have native support for converting JSON into objects.

Source format

If you choose `SOURCE` as the `EventRecordFormat`, Lambda still validates the record against the schema registry, but delivers the original binary data to your function without deserialization. This binary data is delivered as a Base64 encoded string of the original byte data, with producer-appended metadata removed. As a result, you can directly convert the raw binary data into Avro and Protobuf objects within your function code. We recommend using Powertools for AWS Lambda, which will deserialize the raw binary data and give you Avro and Protobuf objects directly.

For example, if you configure Lambda to validate both the `key` and `value` attributes but use the `SOURCE` format, your function receives a payload like this:

```
{  
  "eventSource": "aws:kafka",  
  "eventSourceArn": "arn:aws:kafka:us-east-1:123456789012:cluster/vpc-2priv-2pub/  
a1b2c3d4-5678-90ab-cdef-EXAMPLE11111-1",  
  "bootstrapServers": "b-2.demo-cluster-1.a1bcde.c1.kafka.us-  
east-1.amazonaws.com:9092,b-1.demo-cluster-1.a1bcde.c1.kafka.us-  
east-1.amazonaws.com:9092",  
  "records": {  
    "mytopic-0": [  
      {  
        "topic": "mytopic",  
        "partition": 0,  
        "offset": 15,  
        "key": "key",  
        "value": "value"  
      }  
    ]  
  }  
}
```

```

        "timestamp": 1545084650987,
        "timestampType": "CREATE_TIME",
        "key": "abcDEFghiJKLmnoPQRstuVWXyz1234==", // Base64 encoded string of
Original byte data, producer-appended metadata removed
        "keySchemaMetadata": {
            "dataFormat": "AVRO",
            "schemaId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
        },
        "value": "abcDEFghiJKLmnoPQRstuVWXyz1234==", // Base64 encoded string
of Original byte data, producer-appended metadata removed
        "valueSchemaMetadata": {
            "dataFormat": "AVRO",
            "schemaId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
        },
        "headers": [
            {
                "headerKey": [
                    104,
                    101,
                    97,
                    100,
                    101,
                    114,
                    86,
                    97,
                    108,
                    117,
                    101
                ]
            }
        ]
    }
}

```

In this example:

- Both key and value contain the original binary data as Base64 encoded strings.
- Your function needs to handle deserialization using the appropriate libraries.

Choosing `SOURCE` for `EventRecordFormat` is recommended if you're using Avro-generated or Protobuf-generated objects, especially with Java functions. This is because Java is strongly typed, and requires specific deserializers for Avro and Protobuf formats. In your function code, you can use your preferred Avro or Protobuf library to deserialize the data.

Working with deserialized data in Lambda functions

Powertools for AWS Lambda helps you deserialize Kafka records in your function code based on the format you use. This utility simplifies working with Kafka records by handling data conversion and providing ready-to-use objects.

To use Powertools for AWS Lambda in your function, you need to add Powertools for AWS Lambda either as a layer or include it as a dependency when building your Lambda function. For setup instructions and more information, see the Powertools for AWS Lambda documentation for your preferred language:

- [Powertools for AWS Lambda \(Java\)](#)
- [Powertools for AWS Lambda \(Python\)](#)
- [Powertools for AWS Lambda \(TypeScript\)](#)
- [Powertools for AWS Lambda \(.NET\)](#)

Note

When working with schema registry integration, you can choose `SOURCE` or `JSON` format. Each option supports different serialization formats as shown below:

Format	Supports
<code>SOURCE</code>	Avro and Protobuf (using Lambda Schema Registry integration)
<code>JSON</code>	JSON data

When using the `SOURCE` or `JSON` format, you can use Powertools for AWS to help deserialize the data in your function code. Here are examples of how to handle different data formats:

AVRO

Java example:

```
package org.demo.kafka;

import org.apache.kafka.clients.consumer.ConsumerRecord;
import org.apache.kafka.clients.consumer.ConsumerRecords;
import org.demo.kafka.avro.AvroProduct;
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;

import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;

import software.amazon.lambda.powertools.kafka.Deserialization;
import software.amazon.lambda.powertools.kafka.DeserializationType;
import software.amazon.lambda.powertools.logging.Logging;

public class AvroDeserializationFunction implements
    RequestHandler<ConsumerRecords<String, AvroProduct>, String> {

    private static final Logger LOGGER =
        LoggerFactory.getLogger(AvroDeserializationFunction.class);

    @Override
    @Logging
    @Deserialization(type = DeserializationType.KAFKA_AVRO)
    public String handleRequest(ConsumerRecords<String, AvroProduct> records,
        Context context) {
        for (ConsumerRecord<String, AvroProduct> consumerRecord : records) {
            LOGGER.info("ConsumerRecord: {}", consumerRecord);

            AvroProduct product = consumerRecord.value();
            LOGGER.info("AvroProduct: {}", product);

            String key = consumerRecord.key();
            LOGGER.info("Key: {}", key);
        }

        return "OK";
    }
}
```

```
}
```

Python example:

```
from aws_lambda_powertools.utilities.kafka_consumer.kafka_consumer import
    kafka_consumer
from aws_lambda_powertools.utilities.kafka_consumer.schema_config import
    SchemaConfig
from aws_lambda_powertools.utilities.kafka_consumer.consumer_records import
    ConsumerRecords

from aws_lambda_powertools.utilities.typing import LambdaContext
from aws_lambda_powertools import Logger

logger = Logger(service="kafkaConsumerPowertools")

value_schema_str = open("customer_profile.avsc", "r").read()

schema_config = SchemaConfig(
    value_schema_type="AVRO",
    value_schema=value_schema_str)

@kafka_consumer(schema_config=schema_config)
def lambda_handler(event: ConsumerRecords, context: LambdaContext):

    for record in event.records:
        value = record.value
        logger.info(f"Received value: {value}")
```

TypeScript example:

```
import { kafkaConsumer } from '@aws-lambda-powertools/kafka';

import type { ConsumerRecords } from '@aws-lambda-powertools/kafka/types';
import { Logger } from '@aws-lambda-powertools/logger';
import type { Context } from 'aws-lambda';

const logger = new Logger();

type Value = {
    id: number;
    name: string;
    price: number;
```

```
};

const schema = '{
  "type": "record",
  "name": "Product",
  "fields": [
    { "name": "id", "type": "int" },
    { "name": "name", "type": "string" },
    { "name": "price", "type": "double" }
  ]
}';

export const handler = kafkaConsumer<string, Value>(
  (event: ConsumerRecords<string, Value>, _context: Context) => {
    for (const record of event.records) {
      logger.info(Processing record with key: ${record.key});
      logger.info(Record value: ${JSON.stringify(record.value)});
      // You can add more processing logic here
    }
  },
  {
    value: {
      type: 'avro',
      schema: schema,
    },
  }
);
```

.NET example:

```
using Amazon.Lambda.Core;
using AWS.Lambda.Powertools.Kafka;
using AWS.Lambda.Powertools.Kafka.Avro;
using AWS.Lambda.Powertools.Logging;
using Com.Example;

// Assembly attribute to enable the Lambda function's Kafka event to be converted
// into a .NET class.
[assembly: LambdaSerializer(typeof(PowertoolsKafkaAvroSerializer))]

namespace ProtoBufClassLibrary;

public class Function
```

```

{
    public string FunctionHandler(ConsumerRecords<string, CustomerProfile> records,
    ILambdaContext context)
    {
        foreach (var record in records)
        {
            Logger.LogInformation("Processing messagem from topic: {topic}",
record.Topic);
            Logger.LogInformation("Partition: {partition}, Offset: {offset}",
record.Partition, record.Offset);
            Logger.LogInformation("Produced at: {timestamp}", record.Timestamp);

            foreach (var header in record.Headers.DecodedValues())
            {
                Logger.LogInformation($"{header.Key}: {header.Value}");
            }

            Logger.LogInformation("Processing order for: {fullName}",
record.Value.FullName);
        }

        return "Processed " + records.Count() + " records";
    }
}

```

PROTOBUF

Java example:

```

package org.demo.kafka;

import org.apache.kafka.clients.consumer.ConsumerRecord;
import org.apache.kafka.clients.consumer.ConsumerRecords;
import org.demo.kafka.protobuf.ProtobufProduct;
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;

import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;

import software.amazon.lambda.powertools.kafka.Deserialization;
import software.amazon.lambda.powertools.kafka.DeserializationType;
import software.amazon.lambda.powertools.logging.Logging;

```

```

public class ProtobufDeserializationFunction
    implements RequestHandler<ConsumerRecords<String, ProtobufProduct>, String>
{
    private static final Logger LOGGER =
        LoggerFactory.getLogger(ProtobufDeserializationFunction.class);

    @Override
    @Logging
    @Deserialization(type = DeserializationType.KAFKA_PROTOBUF)
    public String handleRequest(ConsumerRecords<String, ProtobufProduct> records,
        Context context) {
        for (ConsumerRecord<String, ProtobufProduct> consumerRecord : records) {
            LOGGER.info("ConsumerRecord: {}", consumerRecord);

            ProtobufProduct product = consumerRecord.value();
            LOGGER.info("ProtobufProduct: {}", product);

            String key = consumerRecord.key();
            LOGGER.info("Key: {}", key);
        }

        return "OK";
    }
}

```

Python example:

```

from aws_lambda_powertools.utilities.kafka_consumer.kafka_consumer import
    kafka_consumer

from aws_lambda_powertools.utilities.kafka_consumer.schema_config import
    SchemaConfig
from aws_lambda_powertools.utilities.kafka_consumer.consumer_records import
    ConsumerRecords

from aws_lambda_powertools.utilities.typing import LambdaContext
from aws_lambda_powertools import Logger

from user_pb2 import User # protobuf generated class

logger = Logger(service="kafkaConsumerPowertools")

```

```

schema_config = SchemaConfig(
    value_schema_type="PROTOBUF",
    value_schema=User)

@kafka_consumer(schema_config=schema_config)
def lambda_handler(event: ConsumerRecords, context: LambdaContext):

    for record in event.records:
        value = record.value
        logger.info(f"Received value: {value}")

```

TypeScript example:

```

import { kafkaConsumer } from '@aws-lambda-powertools/kafka';
import type { ConsumerRecords } from '@aws-lambda-powertools/kafka/types';
import { Logger } from '@aws-lambda-powertools/logger';
import type { Context } from 'aws-lambda';
import { Product } from './product.generated.js';

const logger = new Logger();

type Value = {
    id: number;
    name: string;
    price: number;
};

export const handler = kafkaConsumer<string, Value>(
    (event: ConsumerRecords<string, Value>, _context: Context) => {
        for (const record of event.records) {
            logger.info(Processing record with key: ${record.key});
            logger.info(Record value: ${JSON.stringify(record.value)});
        }
    },
    {
        value: {
            type: 'protobuf',
            schema: Product,
        },
    }
);

```

.NET example:

```
using Amazon.Lambda.Core;
using AWS.Lambda.Powertools.Kafka;
using AWS.Lambda.Powertools.Kafka.Protobuf;
using AWS.Lambda.Powertools.Logging;
using Com.Example;

// Assembly attribute to enable the Lambda function's Kafka event to be converted
// into a .NET class.
[assembly: LambdaSerializer(typeof(PowertoolsKafkaProtobufSerializer))]

namespace ProtoBufClassLibrary;

public class Function
{
    public string FunctionHandler(ConsumerRecords<string, CustomerProfile> records,
        ILambdaContext context)
    {
        foreach (var record in records)
        {
            Logger.LogInformation("Processing messagem from topic: {topic}",
                record.Topic);
            Logger.LogInformation("Partition: {partition}, Offset: {offset}",
                record.Partition, record.Offset);
            Logger.LogInformation("Produced at: {timestamp}", record.Timestamp);

            foreach (var header in record.Headers.DecodedValues())
            {
                Logger.LogInformation($"{header.Key}: {header.Value}");
            }

            Logger.LogInformation("Processing order for: {fullName}",
                record.Value.FullName);
        }

        return "Processed " + records.Count() + " records";
    }
}
```

JSON

Java example:

```

package org.demo.kafka;

import org.apache.kafka.clients.consumer.ConsumerRecord;
import org.apache.kafka.clients.consumer.ConsumerRecords;
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;

import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;

import software.amazon.lambda.powertools.kafka.Deserialization;
import software.amazon.lambda.powertools.kafka.DeserializationType;
import software.amazon.lambda.powertools.logging.Logging;

public class JsonDeserializationFunction implements
    RequestHandler<ConsumerRecords<String, Product>, String> {

    private static final Logger LOGGER =
        LoggerFactory.getLogger(JsonDeserializationFunction.class);

    @Override
    @Logging
    @Deserialization(type = DeserializationType.KAFKA_JSON)
    public String handleRequest(ConsumerRecords<String, Product> consumerRecords,
        Context context) {
        for (ConsumerRecord<String, Product> consumerRecord : consumerRecords) {
            LOGGER.info("ConsumerRecord: {}", consumerRecord);

            Product product = consumerRecord.value();
            LOGGER.info("Product: {}", product);

            String key = consumerRecord.key();
            LOGGER.info("Key: {}", key);
        }

        return "OK";
    }
}

```

Python example:

```

from aws_lambda_powertools.utilities.kafka_consumer.kafka_consumer import
    kafka_consumer

```

```

from aws_lambda_powertools.utilities.kafka_consumer.schema_config import
    SchemaConfig
from aws_lambda_powertools.utilities.kafka_consumer.consumer_records import
    ConsumerRecords

from aws_lambda_powertools.utilities.typing import LambdaContext
from aws_lambda_powertools import Logger

logger = Logger(service="kafkaConsumerPowertools")

schema_config = SchemaConfig(value_schema_type="JSON")

@kafka_consumer(schema_config=schema_config)
def lambda_handler(event: ConsumerRecords, context: LambdaContext):

    for record in event.records:
        value = record.value
        logger.info(f"Received value: {value}")

```

TypeScript example:

```

import { kafkaConsumer } from '@aws-lambda-powertools/kafka';
import type { ConsumerRecords } from '@aws-lambda-powertools/kafka/types';
import { Logger } from '@aws-lambda-powertools/logger';
import type { Context } from 'aws-lambda';

const logger = new Logger();

type Value = {
    id: number;
    name: string;
    price: number;
};

export const handler = kafkaConsumer<string, Value>(
    (event: ConsumerRecords<string, Value>, _context: Context) => {
        for (const record of event.records) {
            logger.info(Processing record with key: ${record.key});
            logger.info(Record value: ${JSON.stringify(record.value)});
            // You can add more processing logic here
        }
    },

```

```
{
    value: {
        type: 'json',
    },
}
);
```

.NET example:

```
using Amazon.Lambda.Core;
using AWS.Lambda.Powertools.Kafka;
using AWS.Lambda.Powertools.Kafka.Json;
using AWS.Lambda.Powertools.Logging;
using Com.Example;

// Assembly attribute to enable the Lambda function's Kafka event to be converted
// into a .NET class.
[assembly: LambdaSerializer(typeof(PowertoolsKafkaJsonSerializer))]

namespace JsonClassLibrary;

public class Function
{
    public string FunctionHandler(ConsumerRecords<string, CustomerProfile> records,
        ILambdaContext context)
    {
        foreach (var record in records)
        {
            Logger.LogInformation("Processing messagem from topic: {topic}",
                record.Topic);
            Logger.LogInformation("Partition: {partition}, Offset: {offset}",
                record.Partition, record.Offset);
            Logger.LogInformation("Produced at: {timestamp}", record.Timestamp);

            foreach (var header in record.Headers.DecodedValues())
            {
                Logger.LogInformation($"{header.Key}: {header.Value}");
            }

            Logger.LogInformation("Processing order for: {fullName}",
                record.Value.FullName);
        }
    }
}
```

```
        return "Processed " + records.Count() + " records";
    }
}
```

Authentication methods for your schema registry

To use a schema registry, Lambda needs to be able to securely access it. If you're working with an AWS Glue schema registry, Lambda relies on IAM authentication. This means that your function's [execution role](#) must have the following permissions to access the AWS Glue registry:

- [GetRegistry](#) in the *AWS Glue Web API Reference*
- [GetSchemaVersion](#) in the *AWS Glue Web API Reference*

Example of the required IAM policy:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:GetRegistry",
        "glue:GetSchemaVersion"
      ],
      "Resource": [
        "*"
      ]
    }
  ]
}
```

Note

For AWS Glue schema registries, if you provide `AccessConfigs` for a AWS Glue registry, Lambda will return a validation exception.

If you're working with a Confluent schema registry, you can choose one of three supported authentication methods for the `Type` parameter of your [KafkaSchemaRegistryAccessConfig](#) object:

- **BASIC_AUTH** — Lambda uses username and password or API Key and API Secret authentication to access your registry. If you choose this option, provide the Secrets Manager ARN containing your credentials in the `URI` field.
- **CLIENT_CERTIFICATE_TLS_AUTH** — Lambda uses mutual TLS authentication with client certificates. To use this option, Lambda needs access to both the certificate and the private key. Provide the Secrets Manager ARN containing these credentials in the `URI` field.
- **NO_AUTH** — The public CA certificate must be signed by a certificate authority (CA) that's in the Lambda trust store. For a private CA/self-signed certificate, you configure the server root CA certificate. To use this option, omit the `AccessConfigs` parameter.

Additionally, if Lambda needs access to a private CA certificate to verify your schema registry's TLS certificate, choose `SERVER_ROOT_CA_CERT` as the `Type` and provide the Secrets Manager ARN to the certificate in the `URI` field.

 **Note**

To configure the `SERVER_ROOT_CA_CERT` option in the console, provide the secret ARN containing the certificate in the **Encryption** field.

The authentication configuration for your schema registry is separate from any authentication you've configured for your Kafka cluster. You must configure both separately, even if they use similar authentication methods.

Error handling and troubleshooting for schema registry issues

When using a schema registry with your Amazon MSK event source, you may encounter various errors. This section provides guidance on common issues and how to resolve them.

Configuration errors

These errors occur when setting up your schema registry configuration.

Provisioned mode required

Error message: SchemaRegistryConfig is only available for Provisioned Mode. To configure Schema Registry, please enable Provisioned Mode by specifying MinimumPollers in ProvisionedPollerConfig.

Resolution: Enable provisioned mode for your event source mapping by configuring the MinimumPollers parameter in ProvisionedPollerConfig.

Invalid schema registry URL

Error message: Malformed SchemaRegistryURI provided. Please provide a valid URI or ARN. For example, `https://schema-registry.example.com:8081` or `arn:aws:glue:us-east-1:123456789012:registry/ExampleRegistry`.

Resolution: Provide a valid HTTPS URL for Confluent Schema Registry or a valid ARN for AWS Glue Schema Registry.

Invalid or missing event record format

Error message: EventRecordFormat is a required field for SchemaRegistryConfig. Please provide one of supported format types: SOURCE, JSON.

Resolution: Specify either SOURCE or JSON as the EventRecordFormat in your schema registry configuration.

Duplicate validation attributes

Error message: Duplicate KEY/VALUE Attribute in SchemaValidationConfigs. SchemaValidationConfigs must contain at most one KEY/VALUE Attribute.

Resolution: Remove duplicate KEY or VALUE attributes from your SchemaValidationConfigs. Each attribute type can only appear once.

Missing validation configuration

Error message: SchemaValidationConfigs is a required field for SchemaRegistryConfig.

Resolution: Add SchemaValidationConfigs to your configuration, specifying at least one validation attribute (KEY or VALUE).

Access and permission errors

These errors occur when Lambda cannot access the schema registry due to permission or authentication issues.

AWS Glue Schema Registry access denied

Error message: Cannot access Glue Schema with provided role. Please ensure the provided role can perform the `GetRegistry` and `GetSchemaVersion` Actions on your schema.

Resolution: Add the required permissions (`glue:GetRegistry` and `glue:GetSchemaVersion`) to your function's execution role.

Confluent Schema Registry access denied

Error message: Cannot access Confluent Schema with the provided access configuration.

Resolution: Verify that your authentication credentials (stored in Secrets Manager) are correct and have the necessary permissions to access the schema registry.

Cross-account AWS Glue Schema Registry

Error message: Cross-account Glue Schema Registry ARN not supported.

Resolution: Use a AWS Glue Schema Registry that's in the same AWS account as your Lambda function.

Cross-region AWS Glue Schema Registry

Error message: Cross-region Glue Schema Registry ARN not supported.

Resolution: Use a AWS Glue Schema Registry that's in the same region as your Lambda function.

Secret access issues

Error message: Lambda received `InvalidRequestException` from Secrets Manager.

Resolution: Verify that your function's execution role has permission to access the secret and that the secret is not encrypted with a default AWS KMS key if accessing from a different account.

Connection errors

These errors occur when Lambda cannot establish a connection to the schema registry.

VPC connectivity issues

Error message: Cannot connect to your Schema Registry. Your Kafka cluster's VPC must be able to connect to the schema registry. You can provide access by configuring AWS PrivateLink or a NAT Gateway or VPC Peering between Kafka Cluster VPC and the schema registry VPC.

Resolution: Configure your VPC networking to allow connections to the schema registry using AWS PrivateLink, a NAT Gateway, or VPC peering.

TLS handshake failure

Error message: Unable to establish TLS handshake with the schema registry. Please provide correct CA-certificate or client certificate using Secrets Manager to access your schema registry.

Resolution: Verify that your CA certificates and client certificates (for mTLS) are correct and properly configured in Secrets Manager.

Throttling

Error message: Receiving throttling errors when accessing the schema registry. Please increase API TPS limits for your schema registry.

Resolution: Increase the API rate limits for your schema registry or reduce the rate of requests from your application.

Self-managed schema registry errors

Error message: Lambda received an internal server an unexpected error from the provided self-managed schema registry.

Resolution: Check the health and configuration of your self-managed schema registry server.

Low latency processing for Kafka event sources

AWS Lambda natively supports low latency event processing for applications that require consistent end-to-end latencies of less than 100 milliseconds. This page provides configuration details and recommendations to enable low latency workflows.

Enable low latency processing

To enable low latency processing on a Kafka event source mapping, the following basic configuration is required:

- Enable provisioned mode. For more information, see [Provisioned mode](#).
- Set the event source mapping's `MaximumBatchingWindowInSeconds` parameter to 0. For more information, see [Batching behavior](#).

Fine-tuning your low latency Kafka ESM

Consider the following recommendations to optimize your Kafka event source mapping for low latency:

Provisioned mode configuration

In provisioned mode for Kafka event source mapping, Lambda allows you to fine-tune the throughput of your event source mapping by configuring a minimum and maximum number of resources called **event pollers**. An event poller (or a **poller**) represents a compute resource that underpins an event source mapping in the provisioned mode, and allocates up to 5 MB/s throughput. Each event poller supports up to 5 concurrent Lambda invocations.

To determine the optimal poller configuration for your application, consider your peak ingestion rate and processing requirements. Let's look at a simplified example:

With a batch size of 20 records and an average target function duration of 50ms, each poller can handle 2,000 records per second subject to 5 MB/s limit. This is calculated as: $(20 \text{ records} \times 1000\text{ms}/50\text{ms}) \times 5 \text{ concurrent Lambda invocations}$. Therefore, if your desired peak ingestion rate is 20,000 records per second, you would need at least 10 event pollers.

 **Note**

We recommend to provision additional event pollers as buffer to avoid consistently operating at maximum capacity.

Provisioned mode automatically scales your event pollers based on traffic patterns within configured minimum and maximum **event pollers** which can trigger rebalance, and therefore, introduce additional latency. You can disable auto-scaling by configuring same value for minimum and maximum **event poller**.

Additional considerations

Some of the additional considerations include:

- Cold starts from the invocation of your Lambda target function can potentially increase end-to-end latency. To reduce this risk, consider enabling [provisioned concurrency](#) or [SnapStart](#) on your event source mapping's target function. Additionally, optimize your function's memory allocation to ensure consistent and optimal executions.
- When `MaximumBatchingWindowInSeconds` is set to 0, Lambda will immediately process any available records without waiting to fill the complete batch size. For example, if your batch size is set to 1,000 records but only 100 records are available, Lambda will process those 100 records immediately rather than waiting for the full 1,000 records to accumulate.

 **Important**

The optimal configuration for low latency processing varies significantly based on your specific workload. We strongly recommend testing different configurations with your actual workload to determine the best settings for your use case.

Configuring error handling controls for Kafka event sources

You can configure how Lambda handles errors and retries for your Kafka event source mappings. These configurations help you control how Lambda processes failed records and manages retry behavior.

Available retry configurations

The following retry configurations are available for both Amazon MSK and self-managed Kafka event sources:

- **Maximum retry attempts** – The maximum number of times Lambda retries when your function returns an error. This doesn't count the initial invocation attempt. The default is -1 (infinite).
- **Maximum record age** – The maximum age of a record that Lambda sends to your function. The default is -1 (infinite).
- **Split batch on error** – When your function returns an error, split the batch into two smaller batches and retry each separately. This helps isolate problematic records.
- **Partial batch response** – Allow your function to return information about which records in a batch failed processing, so Lambda can retry only the failed records.

Configuring error handling controls (console)

You can configure retry behavior when creating or updating a Kafka event source mapping in the Lambda console.

To configure retry behavior for a Kafka event source (console)

1. Open the [Functions page](#) of the Lambda console.
2. Choose your function name.
3. Do one of the following:
 - To add a new Kafka trigger, under **Function overview**, choose **Add trigger**.
 - To modify an existing Kafka trigger, choose the trigger and then choose **Edit**.
4. Under **Event poller configuration**, select provisioned mode to configure error handling controls:
 - a. For **Retry attempts**, enter the maximum number of retry attempts (0-10000, or -1 for infinite).

- b. For **Maximum record age**, enter the maximum age in seconds (60-604800, or -1 for infinite).
 - c. To enable batch splitting when errors occur, select **Split batch on error**.
 - d. To enable partial batch response, select **ReportBatchItemFailures**.
5. Choose **Add** or **Save**.

Configuring retry behavior (AWS CLI)

Use the following AWS CLI commands to configure retry behavior for your Kafka event source mappings.

Creating an event source mapping with retry configurations

The following example creates a self-managed Kafka event source mapping with error handling controls:

```
aws lambda create-event-source-mapping \
  --function-name my-kafka-function \
  --topics my-kafka-topic \
  --source-access-configuration Type=SASL_SCRAM_512_AUTH,URI=arn:aws:secretsmanager:us-east-1:111122223333:secret:MyBrokerSecretName \
  --self-managed-event-source '{"Endpoints":{"KAFKA_BOOTSTRAP_SERVERS":["abc.xyz.com:9092"]}}' \
  --starting-position LATEST \
  --provisioned-poller-config MinimumPollers=1,MaximumPollers=1 \
  --maximum-retry-attempts 3 \
  --maximum-record-age-in-seconds 3600 \
  --bisect-batch-on-function-error \
  --function-response-types "ReportBatchItemFailures"
```

For Amazon MSK event sources:

```
aws lambda create-event-source-mapping \
  --event-source-arn arn:aws:kafka:us-east-1:111122223333:cluster/my-cluster/fc2f5bdf-fd1b-45ad-85dd-15b4a5a6247e-2 \
  --topics AWSMSKKafkaTopic \
  --starting-position LATEST \
  --function-name my-kafka-function \
  --source-access-configurations '[{"Type": "SASL_SCRAM_512_AUTH", "URI": "arn:aws:secretsmanager:us-east-1:111122223333:secret:my-secret"}]' \
```

```
--provisioned-poller-config MinimumPollers=1,MaximumPollers=1 \  
--maximum-retry-attempts 3 \  
--maximum-record-age-in-seconds 3600 \  
--bisect-batch-on-function-error \  
--function-response-types "ReportBatchItemFailures"
```

Updating retry configurations

Use the `update-event-source-mapping` command to modify retry configurations for an existing event source mapping:

```
aws lambda update-event-source-mapping \  
--uuid 12345678-1234-1234-1234-123456789012 \  
--maximum-retry-attempts 5 \  
--maximum-record-age-in-seconds 7200 \  
--bisect-batch-on-function-error \  
--function-response-types "ReportBatchItemFailures"
```

PartialBatchResponse

Partial batch response, also known as `ReportBatchItemFailures`, is a key feature for error handling in Lambda's integration with Kafka sources. Without this feature, when an error occurs in one of the items in a batch, it results in reprocessing all messages in that batch. With partial batch response enabled and implemented, the handler returns identifiers only for the failed messages, allowing Lambda to retry just those specific items. This provides greater control over how batches containing failed messages are processed.

To report batch errors, you will use this JSON schema:

```
{  
  "batchItemFailures": [  
    {  
      "itemIdentifier": {  
        "partition": "topic-partition_number",  
        "offset": 100  
      }  
    },  
    ...  
  ]  
}
```

⚠ Important

If you return an empty valid JSON or null, the event source mapping will consider a batch as successfully processed. Any invalid `topic-partition_number` or `offset` returned that was not present in the invoked event will be treated as failure and entire batch will be retried.

The following code examples show how to implement partial batch response for Lambda functions that receive events from Kafka sources. The function reports the batch item failures in the response, signaling to Lambda to retry those messages later.

Here is a Python Lambda handler implementation that shows this approach:

```
import base64
from typing import Any, Dict, List

def lambda_handler(event: Dict[str, Any], context: Any) -> Dict[str, List[Dict[str, Dict[str, Any]]]]:
    failures: List[Dict[str, Dict[str, Any]]] = []
    records_dict = event.get("records", {})

    for topic_partition, records_list in records_dict.items():
        for record in records_list:
            topic = record.get("topic")
            partition = record.get("partition")
            offset = record.get("offset")
            value_b64 = record.get("value")

            try:
                data = base64.b64decode(value_b64).decode("utf-8")
                process_message(data)
            except Exception as exc:
                print(f"Failed to process record topic={topic} partition={partition} offset={offset}: {exc}")
                item_identifier: Dict[str, Any] = {
                    "partition": f"{topic}-{partition}",
                    "offset": int(offset) if offset is not None else None,
                }
                failures.append({"itemIdentifier": item_identifier})

    return {"batchItemFailures": failures}
```

```
def process_message(data: str) -> None:
    # Your business logic for a single message
    pass
```

Here is a Node.js version:

```
const { Buffer } = require("buffer");

const handler = async (event) => {
    const failures = [];

    for (let topicPartition in event.records) {
        const records = event.records[topicPartition];

        for (const record of records) {
            const topic = record.topic;
            const partition = record.partition;
            const offset = record.offset;
            const valueBase64 = record.value;
            const data = Buffer.from(valueBase64, "base64").toString("utf8");

            try {
                await processMessage(data);
            } catch (error) {
                console.error("Failed to process record", { topic, partition, offset, error });
                const itemIdentifier = {
                    "partition": `${topic}-${partition}`,
                    offset: Number(offset),
                };
                failures.push({ itemIdentifier });
            }
        }
    }

    return { batchItemFailures: failures };
};

async function processMessage(payload) {
    // Your business logic for a single message
}

module.exports = { handler };
```

Capturing discarded batches for Amazon MSK and self-managed Apache Kafka event sources

To retain records of failed event source mapping invocations, add a destination to your function's event source mapping. Each record sent to the destination is a JSON document containing metadata about the failed invocation. For Amazon S3 destinations, Lambda also sends the entire invocation record along with the metadata. You can configure any Amazon SNS topic, Amazon SQS queue, Amazon S3 bucket, or Kafka as a destination.

With Amazon S3 destinations, you can use the [Amazon S3 Event Notifications](#) feature to receive notifications when objects are uploaded to your destination S3 bucket. You can also configure S3 Event Notifications to invoke another Lambda function to perform automated processing on failed batches.

Your execution role must have permissions for the destination:

- **For an SQS destination:** [sqs:SendMessage](#)
- **For an SNS destination:** [sns:Publish](#)
- **For an S3 destination:** [s3:PutObject](#) and [s3:ListBucket](#)
- **For a Kafka destination:** [kafka-cluster:WriteData](#)

You can configure a Kafka topic as an on-failure destination for your Kafka event source mappings. When Lambda can't process records after exhausting retry attempts or when records exceed the maximum age, Lambda sends the failed records to the specified Kafka topic for later processing. Refer to [the section called "Kafka on-failure destination"](#).

You must deploy a VPC endpoint for your on-failure destination service inside your Kafka cluster VPC.

Additionally, if you configured a KMS key on your destination, Lambda needs the following permissions depending on the destination type:

- If you've enabled encryption with your own KMS key for an S3 destination, [kms:GenerateDataKey](#) is required. If the KMS key and S3 bucket destination are in a different account from your Lambda function and execution role, configure the KMS key to trust the execution role to allow [kms:GenerateDataKey](#).
- If you've enabled encryption with your own KMS key for SQS destination, [kms:Decrypt](#) and [kms:GenerateDataKey](#) are required. If the KMS key and SQS queue destination are in a

different account from your Lambda function and execution role, configure the KMS key to trust the execution role to allow `kms:Decrypt`, `kms:GenerateDataKey`, [kms:DescribeKey](#), and [kms:ReEncrypt](#).

- If you've enabled encryption with your own KMS key for SNS destination, [kms:Decrypt](#) and [kms:GenerateDataKey](#) are required. If the KMS key and SNS topic destination are in a different account from your Lambda function and execution role, configure the KMS key to trust the execution role to allow `kms:Decrypt`, `kms:GenerateDataKey`, [kms:DescribeKey](#), and [kms:ReEncrypt](#).

Configuring on-failure destinations for a Kafka event source mapping

To configure an on-failure destination using the console, follow these steps:

1. Open the [Functions page](#) of the Lambda console.
2. Choose a function.
3. Under **Function overview**, choose **Add destination**.
4. For **Source**, choose **Event source mapping invocation**.
5. For **Event source mapping**, choose an event source that's configured for this function.
6. For **Condition**, select **On failure**. For event source mapping invocations, this is the only accepted condition.
7. For **Destination type**, choose the destination type that Lambda sends invocation records to.
8. For **Destination**, choose a resource.
9. Choose **Save**.

You can also configure an on-failure destination using the AWS CLI. For example, the following [create-event-source-mapping](#) command adds an event source mapping with an SQS on-failure destination to MyFunction:

```
aws lambda create-event-source-mapping \  
--function-name "MyFunction" \  
--event-source-arn arn:aws:kafka:us-east-1:123456789012:cluster/  
vpc-2priv-2pub/751d2973-a626-431c-9d4e-d7975eb44dd7-2 \  
--destination-config '{"OnFailure": {"Destination": "arn:aws:sqs:us-  
east-1:123456789012:dest-queue"}}'
```

The following [update-event-source-mapping](#) command adds an S3 on-failure destination to the event source associated with the input uuid:

```
aws lambda update-event-source-mapping \  
--uuid f89f8514-cdd9-4602-9e1f-01a5b77d449b \  
--destination-config '{"OnFailure": {"Destination": "arn:aws:s3:::dest-bucket"}}'
```

To remove a destination, supply an empty string as the argument to the `destination-config` parameter:

```
aws lambda update-event-source-mapping \  
--uuid f89f8514-cdd9-4602-9e1f-01a5b77d449b \  
--destination-config '{"OnFailure": {"Destination": ""}}'
```

Security best practices for Amazon S3 destinations

Deleting an S3 bucket that's configured as a destination without removing the destination from your function's configuration can create a security risk. If another user knows your destination bucket's name, they can recreate the bucket in their AWS account. Records of failed invocations will be sent to their bucket, potentially exposing data from your function.

Warning

To ensure that invocation records from your function can't be sent to an S3 bucket in another AWS account, add a condition to your function's execution role that limits `s3:PutObject` permissions to buckets in your account.

The following example shows an IAM policy that limits your function's `s3:PutObject` permissions to buckets in your account. This policy also gives Lambda the `s3:ListBucket` permission it needs to use an S3 bucket as a destination.

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Sid": "S3BucketResourceAccountWrite",  
      "Effect": "Allow",  
      "Action": [  

```

```
        "s3:PutObject",
        "s3:ListBucket"
    ],
    "Resource": [
        "arn:aws:s3:::*/*",
        "arn:aws:s3:::*"
    ],
    "Condition": {
        "StringEquals": {
            "s3:ResourceAccount": "111122223333"
        }
    }
}
]
```

To add a permissions policy to your function's execution role using the AWS Management Console or AWS CLI, refer to the instructions in the following procedures:

Console

To add a permissions policy to a function's execution role (console)

1. Open the [Functions page](#) of the Lambda console.
2. Select the Lambda function whose execution role you want to modify.
3. In the **Configuration** tab, select **Permissions**.
4. In the **Execution role** tab, select your function's **Role name** to open the role's IAM console page.
5. Add a permissions policy to the role by doing the following:
 - a. In the **Permissions policies** pane, choose **Add permissions** and select **Create inline policy**.
 - b. In **Policy editor**, select **JSON**.
 - c. Paste the policy you want to add into the editor (replacing the existing JSON), and then choose **Next**.
 - d. Under **Policy details**, enter a **Policy name**.
 - e. Choose **Create policy**.

AWS CLI

To add a permissions policy to a function's execution role (CLI)

1. Create a JSON policy document with the required permissions and save it in a local directory.
2. Use the IAM `put-role-policy` CLI command to add the permissions to your function's execution role. Run the following command from the directory you saved your JSON policy document in and replace the role name, policy name, and policy document with your own values.

```
aws iam put-role-policy \  
--role-name my_lambda_role \  
--policy-name LambdaS3DestinationPolicy \  
--policy-document file://my_policy.json
```

SNS and SQS example invocation record

The following example shows what Lambda sends to an SNS topic or SQS queue destination for a failed Kafka event source invocation. Each of the keys under `recordsInfo` contains both the Kafka topic and partition, separated by a hyphen. For example, for the key `"Topic-0"`, `Topic` is the Kafka topic, and `0` is the partition. For each topic and partition, you can use the offsets and timestamp data to find the original invocation records.

```
{  
  "requestContext": {  
    "requestId": "316aa6d0-8154-xmpl-9af7-85d5f4a6bc81",  
    "functionArn": "arn:aws:lambda:us-east-1:123456789012:function:myfunction",  
    "condition": "RetryAttemptsExhausted" | "MaximumPayloadSizeExceeded",  
    "approximateInvokeCount": 1  
  },  
  "responseContext": { // null if record is MaximumPayloadSizeExceeded  
    "statusCode": 200,  
    "executedVersion": "$LATEST",  
    "functionError": "Unhandled"  
  },  
  "version": "1.0",  
  "timestamp": "2019-11-14T00:38:06.021Z",  
  "KafkaBatchInfo": {  
    "batchSize": 500,  

```

```

    "eventSourceArn": "arn:aws:kafka:us-east-1:123456789012:cluster/
vpc-2priv-2pub/751d2973-a626-431c-9d4e-d7975eb44dd7-2",
    "bootstrapServers": "...",
    "payloadSize": 2039086, // In bytes
    "recordsInfo": {
        "Topic-0": {
            "firstRecordOffset":
"49601189658422359378836298521827638475320189012309704722",
            "lastRecordOffset":
"49601189658422359378836298522902373528957594348623495186",
            "firstRecordTimestamp": "2019-11-14T00:38:04.835Z",
            "lastRecordTimestamp": "2019-11-14T00:38:05.580Z",
        },
        "Topic-1": {
            "firstRecordOffset":
"49601189658422359378836298521827638475320189012309704722",
            "lastRecordOffset":
"49601189658422359378836298522902373528957594348623495186",
            "firstRecordTimestamp": "2019-11-14T00:38:04.835Z",
            "lastRecordTimestamp": "2019-11-14T00:38:05.580Z",
        }
    }
}

```

S3 destination example invocation record

For S3 destinations, Lambda sends the entire invocation record along with the metadata to the destination. The following example shows that Lambda sends to an S3 bucket destination for a failed Kafka event source invocation. In addition to all of the fields from the previous example for SQS and SNS destinations, the `payload` field contains the original invocation record as an escaped JSON string.

```

{
    "requestContext": {
        "requestId": "316aa6d0-8154-xmpl-9af7-85d5f4a6bc81",
        "functionArn": "arn:aws:lambda:us-east-1:123456789012:function:myfunction",
        "condition": "RetryAttemptsExhausted" | "MaximumPayloadSizeExceeded",
        "approximateInvokeCount": 1
    },
    "responseContext": { // null if record is MaximumPayloadSizeExceeded
        "statusCode": 200,
        "executedVersion": "$LATEST",

```

```

    "functionError": "Unhandled"
  },
  "version": "1.0",
  "timestamp": "2019-11-14T00:38:06.021Z",
  "KafkaBatchInfo": {
    "batchSize": 500,
    "eventSourceArn": "arn:aws:kafka:us-east-1:123456789012:cluster/
vpc-2priv-2pub/751d2973-a626-431c-9d4e-d7975eb44dd7-2",
    "bootstrapServers": "...",
    "payloadSize": 2039086, // In bytes
    "recordsInfo": {
      "Topic-0": {
        "firstRecordOffset":
"49601189658422359378836298521827638475320189012309704722",
        "lastRecordOffset":
"49601189658422359378836298522902373528957594348623495186",
        "firstRecordTimestamp": "2019-11-14T00:38:04.835Z",
        "lastRecordTimestamp": "2019-11-14T00:38:05.580Z",
      },
      "Topic-1": {
        "firstRecordOffset":
"49601189658422359378836298521827638475320189012309704722",
        "lastRecordOffset":

        "firstRecordTimestamp": "2019-11-14T00:38:04.835Z",
        "lastRecordTimestamp": "2019-11-14T00:38:05.580Z",
      }
    }
  },
  "payload": "<Whole Event>" // Only available in S3
}

```

Tip

We recommend enabling S3 versioning on your destination bucket.

Using a Kafka topic as an on-failure destination

You can configure a Kafka topic as an on-failure destination for your Kafka event source mappings. When Lambda can't process records after exhausting retry attempts or when records exceed the maximum age, Lambda sends the failed records to the specified Kafka topic for later processing.

How a Kafka on-failure destination works

When you configure a Kafka topic as an on-failure destination, Lambda acts as a Kafka producer and writes failed records to the destination topic. This creates a dead letter topic (DLT) pattern within your Kafka infrastructure.

- **Same cluster requirement** – The destination topic must exist in the same Kafka cluster as your source topics.
- **Actual record content** – Kafka destinations receive the actual failed records along with failure metadata.
- **Recursion prevention** – Lambda prevents infinite loops by blocking configurations where the source and destination topics are the same.

Configuring a Kafka on-failure destination

You can configure a Kafka topic as an on-failure destination when creating or updating a Kafka event source mapping.

Configuring a Kafka destination (console)

To configure a Kafka topic as an on-failure destination (console)

1. Open the [Functions page](#) of the Lambda console.
2. Choose your function name.
3. Do one of the following:
 - To add a new Kafka trigger, under **Function overview**, choose **Add trigger**.
 - To modify an existing Kafka trigger, choose the trigger and then choose **Edit**.
4. Under **Additional settings**, for **On-failure destination**, choose **Kafka topic**.
5. For **Topic name**, enter the name of the Kafka topic where you want to send failed records.
6. Choose **Add** or **Save**.

Configuring a Kafka destination (AWS CLI)

Use the `kafka://` prefix to specify a Kafka topic as an on-failure destination.

Creating an event source mapping with Kafka destination

The following example creates a Amazon MSK event source mapping with a Kafka topic as the on-failure destination:

```
aws lambda create-event-source-mapping \  
  --function-name my-kafka-function \  
  --topics AWSKafkaTopic \  
  --event-source-arn arn:aws:kafka:us-east-1:123456789012:cluster/my-cluster/abc123 \  
  --starting-position LATEST \  
  --provisioned-poller-config MinimumPollers=1,MaximumPollers=3 \  
  --destination-config '{"OnFailure":{"Destination":"kafka://failed-records-topic"}}'
```

For self-managed Kafka, use the same syntax:

```
aws lambda create-event-source-mapping \  
  --function-name my-kafka-function \  
  --topics AWSKafkaTopic \  
  --self-managed-event-source '{"Endpoints":{"KAFKA_BOOTSTRAP_SERVERS":  
["abc.xyz.com:9092"]}}' \  
  --starting-position LATEST \  
  --provisioned-poller-config MinimumPollers=1,MaximumPollers=3 \  
  --destination-config '{"OnFailure":{"Destination":"kafka://failed-records-topic"}}'
```

Updating a Kafka destination

Use the `update-event-source-mapping` command to add or modify a Kafka destination:

```
aws lambda update-event-source-mapping \  
  --uuid 12345678-1234-1234-1234-123456789012 \  
  --destination-config '{"OnFailure":{"Destination":"kafka://failed-records-topic"}}'
```

Record format for a Kafka destination

When Lambda sends failed records to a Kafka topic, each message contains both metadata about the failure and the actual record content.

Failure metadata

The metadata includes information about why the record failed and details about the original batch:

```
{
  "requestContext": {
    "requestId": "e4b46cbf-b738-xmpl-8880-a18cdf61200e",
    "functionArn": "arn:aws:lambda:us-east-1:123456789012:function:my-function:
$LATEST",
    "condition": "RetriesExhausted",
    "approximateInvokeCount": 3
  },
  "responseContext": {
    "statusCode": 200,
    "executedVersion": "$LATEST",
    "functionError": "Unhandled"
  },
  "version": "1.0",
  "timestamp": "2019-11-14T18:16:05.568Z",
  "KafkaBatchInfo": {
    "batchSize": 1,
    "eventSourceArn": "arn:aws:kafka:us-east-1:123456789012:cluster/my-cluster/abc123",
    "bootstrapServers": "b-1.mycluster.abc123.kafka.us-east-1.amazonaws.com:9098",
    "payloadSize": 1162,
    "recordInfo": {
      "offset": "49601189658422359378836298521827638475320189012309704722",
      "timestamp": "2019-11-14T18:16:04.835Z"
    }
  },
  "payload": {
    "bootstrapServers": "b-1.mycluster.abc123.kafka.us-east-1.amazonaws.com:9098",
    "eventSource": "aws:kafka",
    "eventSourceArn": "arn:aws:kafka:us-east-1:123456789012:cluster/my-cluster/abc123",
    "records": {
      "my-topic-0": [
        {
          "headers": [],
          "key": "dGVzdC1rZXk=",
          "offset": 100,
          "partition": 0,
          "timestamp": 1749116692330,
          "timestampType": "CREATE_TIME",
          "topic": "my-topic",
```

```

        "value": "dGVzdC12YWx1ZQ=="
      }
    ]
  }
}

```

Partition key behavior

Lambda uses the same partition key from the original record when producing to the destination topic. If the original record had no key, Lambda uses Kafka's default round-robin partitioning across all available partitions in the destination topic.

Requirements and limitations

- **Provisioned mode required** – A Kafka on-failure destination is only available for event source mappings with provisioned mode enabled.
- **Same cluster only** – The destination topic must exist in the same Kafka cluster as your source topics.
- **Topic permissions** – Your event source mapping must have write permissions to the destination topic. Example:

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ClusterPermissions",
      "Effect": "Allow",
      "Action": [
        "kafka-cluster:Connect",
        "kafka-cluster:DescribeCluster",
        "kafka-cluster:DescribeTopic",
        "kafka-cluster:WriteData",
        "kafka-cluster:ReadData"
      ],
      "Resource": [
        "arn:aws:kafka:*:*:cluster/*"
      ]
    },
    {
      "Sid": "TopicPermissions",

```

```

        "Effect": "Allow",
        "Action": [
            "kafka-cluster:DescribeTopic",
            "kafka-cluster:WriteData",
            "kafka-cluster:ReadData"
        ],
        "Resource": [
            "arn:aws:kafka:*:*:topic/*/*"
        ]
    },
    {
        "Effect": "Allow",
        "Action": [
            "kafka:DescribeCluster",
            "kafka:GetBootstrapBrokers",
            "kafka:Produce"
        ],
        "Resource": "arn:aws:kafka:*:*:cluster/*"
    },
    {
        "Effect": "Allow",
        "Action": [
            "ec2:CreateNetworkInterface",
            "ec2:DescribeNetworkInterfaces",
            "ec2>DeleteNetworkInterface",
            "ec2:DescribeSubnets",
            "ec2:DescribeSecurityGroups"
        ],
        "Resource": "*"
    }
]
}

```

- **No recursion** – The destination topic name cannot be the same as any of your source topic names.

Kafka event source mapping logging

You can configure the system-level logging for your Kafka event source mappings to enable and filter the system logs that Lambda event pollers send to CloudWatch.

This feature is only available for Kafka event source mappings, and with [Provisioned mode](#).

For event source mapping with logging config, you can also check the system logs from pre-built log queries in the **Monitor** tab from the page Console **Lambda > Additional resources > event source mappings** now.

How the logging works

When you set the logging config with log level in your event source mapping, the Lambda event poller sends out corresponding logs (event source mapping system logs).

The event source mapping reuses the same [log destination](#) with your Lambda function. Make sure the execution role of your Lambda function has the necessary logging permissions.

The event source mapping will have its own log stream, with date and event source mapping UUID as the log stream name, like `2020/01/01/12345678-1234-1234-1234-12345678901`.

For event source mapping system logs, you can choose between the following log levels.

Log level	Usage
DEBUG (most detail)	Detailed information for event source processing progress
INFO	Messages about the normal operation of your event source mapping
WARN (least detail)	Messages about potential warns and errors that may lead to unexpected behavior

When you select a log level, Lambda event poller sends logs at that level and lower. For example, if you set the event source mapping system log level to INFO, event poller doesn't send log outputs at the DEBUG level.

Configuring logging

You can set the logging configure when creating or updating a Kafka event source mapping.

Configuring logging (console)

To configure the logging (console)

1. Open the [Functions page](#) of the Lambda console.
2. Choose your function name.
3. Do one of the following:
 - To add a new Kafka trigger, under **Function overview**, choose **Add trigger**.
 - To modify an existing Kafka trigger, choose the trigger and then choose **Edit**.
4. Under **Event poller configuration**, for **Provisioned mode**, enable the **Configure** checkbox. And the **Log level** setting would show up.
5. Click **Log level** dropdown list and select a level for the event source mapping.
6. Choose **Add** or **Save** at the bottom to create or update the event source mapping.

Configuring logging (AWS CLI)

Creating an event source mapping with logging

The following example creates a Amazon MSK event source mapping with logging config:

```
aws lambda create-event-source-mapping \  
  --function-name my-kafka-function \  
  --topics AWSKafkaTopic \  
  --event-source-arn arn:aws:kafka:us-east-1:123456789012:cluster/my-cluster/abc123 \  
  --starting-position LATEST \  
  --provisioned-poller-config MinimumPollers=1,MaximumPollers=3 \  
  --logging-config '{"SystemLogLevel":"DEBUG"}'
```

For self-managed Kafka, use the same syntax:

```
aws lambda create-event-source-mapping \  
  --function-name my-kafka-function \  
  --topics AWSKafkaTopic \  
  --self-managed-event-source '{"Endpoints":{"KAFKA_BOOTSTRAP_SERVERS":  
["abc.xyz.com:9092"]}}' \  
  --logging-config '{"SystemLogLevel":"DEBUG"}'
```

```
--starting-position LATEST \  
--provisioned-poller-config MinimumPollers=1,MaximumPollers=3 \  
--logging-config '{"SystemLogLevel":"DEBUG"}'
```

Updating logging config

Use the `update-event-source-mapping` command to add or modify logging config:

```
aws lambda update-event-source-mapping \  
--uuid 12345678-1234-1234-1234-123456789012 \  
--logging-config '{"SystemLogLevel":"WARN"}'
```

Record format for a Kafka event source mapping system log

When Lambda event poller sends the log, each log entry contains general event source mapping metadata and also event specific content.

WARN log record

WARN record contains errors or warnings from the event poller, and it's emitted when the event happened. For example:

```
{  
  "eventType": "ESM_PROCESSING_EVENT",  
  "timestamp": 1546347650000,  
  "resourceArn": "arn:aws:lambda:us-east-1:123456789012:event-source-mapping:12345678-1234-1234-1234-123456789012",  
  "eventSourceArn": "arn:aws:kafka:us-east-1:123456789012:cluster/tests-cluster/87654321-4321-4321-4321-876543221-s1",  
  "eventProcessorId": "12345678-1234-1234-1234-123456789012/0",  
  "logLevel": "WARN",  
  "error": {  
    "errorMessage": "Timeout expired while fetching topic metadata",  
    "errorCode": "org.apache.kafka.common.errors.TimeoutException"  
  }  
}
```

INFO log record

INFO record contains Kafka consumer client configurations in each event poller, and it's emitted on the event of a consumer being built or changed. For example:

```
{
  "eventType": "POLLER_STATUS_EVENT",
  "timestamp": 1546347660000,
  "resourceArn": "arn:aws:lambda:us-east-1:123456789012:event-source-
mapping:12345678-1234-1234-1234-123456789012",
  "eventSourceArn": "arn:aws:kafka:us-east-1:123456789012:cluster/tests-
cluster/87654321-4321-4321-4321-876543221-s1",
  "eventProcessorId": "12345678-1234-1234-1234-123456789012/0",
  "logLevel": "INFO",
  "kafkaEventSourceConnection": {
    "brokerEndpoints": "boot-abcd1234.c2.kafka-serverless.us-
east-1.amazonaws.com:9098",
    "consumerId": "12345678-1234-1234-1234-123456789012-0",
    "topics": [
      "test"
    ],
    "consumerGroupId": "12345678-1234-1234-1234-123456789012",
    "securityProtocol": "SASL_SSL",
    "saslMechanism": "AWS_MSK_IAM",
    "totalPartitionCount": 2,
    "assignedPartitionCount": 2,
    "partitionsAssignmentGeneration": 5,
    "assignedPartitions": [
      "test-0",
      "test-1"
    ],
    "networkConfig": {
      "ipAddresses": [
        "10.100.141.1"
      ],
      "subnetCidrBlock": "10.100.128.0/20",
      "securityGroups": [
        "sg-abcdefabcdefabcdef"
      ]
    }
  }
}
```

DEBUG log record

DEBUG log contains the Kafka offsets related info in event source mapping processing, and the offset info is emitted per minute. For example:

```
{
  "eventType": "KAFKA_STATUS_EVENT",
  "timestamp": 1546347670000,
  "resourceArn": "arn:aws:lambda:us-east-1:123456789012:event-source-
mapping:12345678-1234-1234-1234-123456789012",
  "eventSourceArn": "arn:aws:kafka:us-east-1:123456789012:cluster/tests-
cluster/87654321-4321-4321-4321-876543221-s1",
  "eventProcessorId": "12345678-1234-1234-1234-123456789012/0",
  "logLevel": "DEBUG",
  "kafkaPartitionOffsets": {
    "partition": "test-1",
    "endOffset": 5004,
    "consumedOffset": 5003,
    "processedOffset": 5003,
    "committedOffset": 5004
  }
}
```

Troubleshooting Kafka event source mapping errors

The following topics provide troubleshooting advice for errors and issues that you might encounter when using Amazon MSK or self-managed Apache Kafka with Lambda.

For more help with troubleshooting, visit the [AWS Knowledge Center](#).

Authentication and authorization errors

If any of the permissions required to consume data from the Kafka cluster are missing, Lambda displays one of the following error messages in the event source mapping under **LastProcessingResult**.

Error messages

- [Cluster failed to authorize Lambda](#)
- [SASL authentication failed](#)
- [Server failed to authenticate Lambda](#)
- [Lambda failed to authenticate server](#)
- [Provided certificate or private key is invalid](#)

Cluster failed to authorize Lambda

For SASL/SCRAM or mTLS, this error indicates that the provided user doesn't have all of the following required Kafka access control list (ACL) permissions:

- DescribeConfigs Cluster
- Describe Group
- Read Group
- Describe Topic
- Read Topic

When you create Kafka ACLs with the required `kafka-cluster` permissions, specify the topic and group as resources. The topic name must match the topic in the event source mapping. The group name must match the event source mapping's UUID.

After you add the required permissions to the execution role, it might take several minutes for the changes to take effect.

The following is an example ESM system-level log after enabling [Logging Config](#) for this issue:

```
{
  "eventType": "ESM_PROCESSING_EVENT",
  "timestamp": 1734567890123,
  "resourceArn": "arn:aws:lambda:us-east-1:123456789012:event-source-
mapping:a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
  "eventSourceArn": "arn:aws:kafka:us-east-1:123456789012:cluster/my-kafka-
cluster/12345678-abcd-1234-efgh-EXAMPLE11111-1",
  "eventProcessorId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111/0",
  "logLevel": "WARN",
  "error": {
    "errorMessage": "Not authorized to access topics: [my-topic]",
    "errorCode": "org.apache.kafka.common.errors.TopicAuthorizationException"
  }
}
```

SASL authentication failed

For SASL/SCRAM or SASL/PLAIN, this error indicates that the provided sign-in credentials aren't valid.

For IAM access control, the execution role is missing the `kafka-cluster:Connect` permission for the cluster. Add this permission to the role and specify the cluster's Amazon Resource Name (ARN) as a resource.

You might see this error occurring intermittently. The cluster rejects connections after the number of TCP connections exceeds the service quota. Lambda backs off and retries until a connection is successful. After Lambda connects to the cluster and polls for records, the last processing result changes to OK.

The following is an example ESM system-level log after enabling [Logging Config](#) for this issue when using IAM authentication:

```
{
  "eventType": "ESM_PROCESSING_EVENT",
  "timestamp": 1734567890456,
  "resourceArn": "arn:aws:lambda:us-east-1:123456789012:event-source-
mapping:a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
  "eventSourceArn": "arn:aws:kafka:us-east-1:123456789012:cluster/my-kafka-
cluster/12345678-abcd-1234-efgh-EXAMPLE22222-1",
  "eventProcessorId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222/0",
}
```

```
"logLevel": "WARN",
"error": {
  "errorMessage": "[a1b2c3d4-5678-90ab-cdef-EXAMPLE22222]: Access denied",
  "errorCode": "org.apache.kafka.common.errors.SaslAuthenticationException"
}
```

Server failed to authenticate Lambda

This error indicates that the Kafka broker failed to authenticate Lambda. This can occur for any of the following reasons:

- You didn't provide a client certificate for mTLS authentication.
- You provided a client certificate, but the Kafka brokers aren't configured to use mTLS authentication.
- A client certificate isn't trusted by the Kafka brokers.

Lambda failed to authenticate server

This error indicates that Lambda failed to authenticate the Kafka broker. This can occur for any of the following reasons:

- For self-managed Apache Kafka: The Kafka brokers use self-signed certificates or a private CA, but didn't provide the server root CA certificate.
- For self-managed Apache Kafka: The server root CA certificate doesn't match the root CA that signed the broker's certificate.
- Hostname validation failed because the broker's certificate doesn't contain the broker's DNS name or IP address as a subject alternative name.

Provided certificate or private key is invalid

This error indicates that the Kafka consumer couldn't use the provided certificate or private key. Make sure that the certificate and key use PEM format, and that the private key encryption uses a PBES1 algorithm.

The following is an example ESM system-level log after enabling [Logging Config](#) for this issue:

```
{
```

```

    "eventType": "ESM_PROCESSING_EVENT",
    "timestamp": 1734567891234,
    "resourceArn": "arn:aws:lambda:us-east-1:123456789012:event-source-
mapping:a1b2c3d4-5678-90ab-cdef-EXAMPLE44444",
    "eventSourceArn": "arn:aws:kafka:us-east-1:123456789012:cluster/my-kafka-
cluster/12345678-abcd-1234-efgh-EXAMPLE44444-1",
    "eventProcessorId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE44444/0",
    "logLevel": "WARN",
    "error": {
      "errorMessage": "Invalid PEM keystore configs",
      "errorCode": "org.apache.kafka.common.errors.InvalidConfigurationException"
    }
  }
}

```

Network and connectivity errors

Network configuration issues can prevent Lambda from connecting to your Kafka cluster. The following topics describe common network-related errors.

Error messages

- [Connection timeout due to security group configuration](#)
- [Kafka broker endpoints cannot be resolved](#)

Connection timeout due to security group configuration

If the security group associated with your Kafka cluster doesn't allow inbound traffic from itself, Lambda can't connect to the cluster. Make sure that the security group's inbound rules allow traffic from the security group itself on the Kafka broker ports.

The following is an example ESM system-level log after enabling [Logging Config](#) for this issue:

```

{
  "eventType": "ESM_PROCESSING_EVENT",
  "timestamp": 1734567892345,
  "resourceArn": "arn:aws:lambda:us-east-1:123456789012:event-source-
mapping:a1b2c3d4-5678-90ab-cdef-EXAMPLE55555",
  "eventSourceArn": "arn:aws:kafka:us-east-1:123456789012:cluster/my-kafka-
cluster/12345678-abcd-1234-efgh-EXAMPLE55555-1",
  "eventProcessorId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE55555/0",
  "logLevel": "WARN",
  "error": {

```

```

    "errorMessage": "Timeout expired while fetching topic metadata",
    "errorCode": "org.apache.kafka.common.errors.TimeoutException"
  }
}

```

You can also check the Kafka consumer INFO log to verify the connection and network configuration. The `brokerEndpoints` field shows the Kafka broker addresses, `securityProtocol` and `saslMechanism` (if applicable) show the authentication method, and the `networkConfig` field shows the IP addresses, subnet CIDR block, and security groups used by the event source mapping. Verify that the security groups listed allow the required inbound traffic:

```

{
  "eventType": "POLLER_STATUS_EVENT",
  "timestamp": 1734567892456,
  "resourceArn": "arn:aws:lambda:us-east-1:123456789012:event-source-
mapping:a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
  "eventSourceArn": "arn:aws:kafka:us-east-1:123456789012:cluster/my-kafka-cluster/
a1b2c3d4-5678-90ab-cdef-11111EXAMPLE-1",
  "eventProcessorId": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE/0",
  "logLevel": "INFO",
  "kafkaEventSourceConnection": {
    "brokerEndpoints": "boot-abcd1234.c2.kafka-serverless.us-
east-1.amazonaws.com:9098",
    "consumerId": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE-0",
    "topics": [
      "my-topic"
    ],
    "consumerGroupId": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",

Kafka broker endpoints cannot be resolved

This error indicates that the Kafka cluster doesn't exist or has been deleted. Verify that the cluster specified in the event source mapping exists and is in an active state.

The following is an example ESM system-level log after enabling [Logging Config](#) for this issue:

```

{
  "eventType": "ESM_PROCESSING_EVENT",
  "timestamp": 1734567893456,
  "resourceArn": "arn:aws:lambda:us-east-1:123456789012:event-source-
mapping:a1b2c3d4-5678-90ab-cdef-EXAMPLE66666",
  "eventSourceArn": "arn:aws:kafka:us-east-1:123456789012:cluster/my-kafka-
cluster/12345678-abcd-1234-efgh-EXAMPLE66666-1",
  "eventProcessorId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE66666/0",
  "logLevel": "WARN",
  "error": {
    "errorMessage": "No resolvable bootstrap urls given in bootstrap.servers",
    "errorCode": "org.apache.kafka.common.config.ConfigException"
  }
}

```

Event source mapping errors

When you add your Apache Kafka cluster as an [event source](#) for your Lambda function, if your function encounters an error, your Kafka consumer stops processing records. Consumers of a topic partition are those that subscribe to, read, and process your records. Your other Kafka consumers can continue processing records, provided they don't encounter the same error.

To determine the cause of a stopped consumer, check the `StateTransitionReason` field in the response of `EventSourceMapping`. The following list describes the event source errors that you can receive:

ESM_CONFIG_NOT_VALID

The event source mapping configuration isn't valid.

EVENT_SOURCE_AUTHN_ERROR

Lambda couldn't authenticate the event source.

EVENT_SOURCE_AUTHZ_ERROR

Lambda doesn't have the required permissions to access the event source.

FUNCTION_CONFIG_NOT_VALID

The function configuration isn't valid.

 **Note**

If your Lambda event records exceed the allowed size limit of 6 MB, they can go unprocessed.

Invoking a Lambda function using an Amazon API Gateway endpoint

You can create a web API with an HTTP endpoint for your Lambda function by using Amazon API Gateway. API Gateway provides tools for creating and documenting web APIs that route HTTP requests to Lambda functions. You can secure access to your API with authentication and authorization controls. Your APIs can serve traffic over the internet or can be accessible only within your VPC.

Tip

Lambda offers two ways to invoke your function through an HTTP endpoint: API Gateway and Lambda function URLs. If you're not sure which is the best method for your use case, see [the section called "API Gateway vs function URLs"](#).

Resources in your API define one or more methods, such as GET or POST. Methods have an integration that routes requests to a Lambda function or another integration type. You can define each resource and method individually, or use special resource and method types to match all requests that fit a pattern. A [proxy resource](#) catches all paths beneath a resource. The ANY method catches all HTTP methods.

Sections

- [Choosing an API type](#)
- [Adding an endpoint to your Lambda function](#)
- [Proxy integration](#)
- [Event format](#)
- [Response format](#)
- [Permissions](#)
- [Sample application](#)
- [The event handler from Powertools for AWS Lambda](#)
- [Tutorial: Using Lambda with API Gateway](#)
- [Handling Lambda errors with an API Gateway API](#)
- [Select a method to invoke your Lambda function using an HTTP request](#)

Choosing an API type

API Gateway supports three types of APIs that invoke Lambda functions:

- [HTTP API](#): A lightweight, low-latency RESTful API.
- [REST API](#): A customizable, feature-rich RESTful API.
- [WebSocket API](#): A web API that maintains persistent connections with clients for full-duplex communication.

HTTP APIs and REST APIs are both RESTful APIs that process HTTP requests and return responses. HTTP APIs are newer and are built with the API Gateway version 2 API. The following features are new for HTTP APIs:

HTTP API features

- **Automatic deployments** – When you modify routes or integrations, changes deploy automatically to stages that have automatic deployment enabled.
- **Default stage** – You can create a default stage (`$default`) to serve requests at the root path of your API's URL. For named stages, you must include the stage name at the beginning of the path.
- **CORS configuration** – You can configure your API to add CORS headers to outgoing responses, instead of adding them manually in your function code.

REST APIs are the classic RESTful APIs that API Gateway has supported since launch. REST APIs currently have more customization, integration, and management features.

REST API features

- **Integration types** – REST APIs support custom Lambda integrations. With a custom integration, you can send just the body of the request to the function, or apply a transform template to the request body before sending it to the function.
- **Access control** – REST APIs support more options for authentication and authorization.
- **Monitoring and tracing** – REST APIs support AWS X-Ray tracing and additional logging options.

For a detailed comparison, see [Choose between HTTP APIs and REST APIs](#) in the *API Gateway Developer Guide*.

WebSocket APIs also use the API Gateway version 2 API and support a similar feature set. Use a WebSocket API for applications that benefit from a persistent connection between the client and API. WebSocket APIs provide full-duplex communication, which means that both the client and the API can send messages continuously without waiting for a response.

HTTP APIs support a simplified event format (version 2.0). For an example of an event from an HTTP API, see [Create AWS Lambda proxy integrations for HTTP APIs in API Gateway](#).

For more information, see [Create AWS Lambda proxy integrations for HTTP APIs in API Gateway](#).

Adding an endpoint to your Lambda function

To add a public endpoint to your Lambda function

1. Open the [Functions page](#) of the Lambda console.
2. Choose a function.
3. Under **Function overview**, choose **Add trigger**.
4. Select **API Gateway**.
5. Choose **Create an API** or **Use an existing API**.
 - a. **New API:** For **API type**, choose **HTTP API**. For more information, see [Choosing an API type](#).
 - b. **Existing API:** Select the API from the dropdown list or enter the API ID (for example, r3pmxmplak).
6. For **Security**, choose **Open**.
7. Choose **Add**.

Proxy integration

API Gateway APIs are comprised of stages, resources, methods, and integrations. The stage and resource determine the path of the endpoint:

API path format

- /prod/ – The prod stage and root resource.
- /prod/user – The prod stage and user resource.

- `/dev/{proxy+}` – Any route in the dev stage.
- `/` – (HTTP APIs) The default stage and root resource.

A Lambda integration maps a path and HTTP method combination to a Lambda function. You can configure API Gateway to pass the body of the HTTP request as-is (custom integration), or to encapsulate the request body in a document that includes all of the request information including headers, resource, path, and method.

For more information, see [Lambda proxy integrations in API Gateway](#).

Event format

Amazon API Gateway invokes your function [synchronously](#) with an event that contains a JSON representation of the HTTP request. For a custom integration, the event is the body of the request. For a proxy integration, the event has a defined structure. For an example of a proxy event from an API Gateway REST API, see [Input format of a Lambda function for proxy integration](#) in the *API Gateway Developer Guide*.

Response format

API Gateway waits for a response from your function and relays the result to the caller. For a custom integration, you define an integration response and a method response to convert the output from the function to an HTTP response. For a proxy integration, the function must respond with a representation of the response in a specific format.

The following example shows a response object from a Node.js function. The response object represents a successful HTTP response that contains a JSON document.

Example `index.mjs` – Proxy integration response object (Node.js)

```
var response = {
  "statusCode": 200,
  "headers": {
    "Content-Type": "application/json"
  },
  "isBase64Encoded": false,
  "multiValueHeaders": {
    "X-Custom-Header": ["My value", "My other value"],
  },
}
```

```
"body": "{\n  \"TotalCodeSize\": 104330022,\n  \"FunctionCount\": 26\n}"
```

The Lambda runtime serializes the response object into JSON and sends it to the API. The API parses the response and uses it to create an HTTP response, which it then sends to the client that made the original request.

Example HTTP response

```
< HTTP/1.1 200 OK
< Content-Type: application/json
< Content-Length: 55
< Connection: keep-alive
< x-amzn-RequestId: 32998fea-xmpl-4268-8c72-16138d629356
< X-Custom-Header: My value
< X-Custom-Header: My other value
< X-Amzn-Trace-Id: Root=1-5e6aa925-ccecxmplbae116148e52f036
<
{
  "TotalCodeSize": 104330022,
  "FunctionCount": 26
}
```

Permissions

Amazon API Gateway gets permission to invoke your function from the function's [resource-based policy](#). You can grant invoke permission to an entire API, or grant limited access to a stage, resource, or method.

When you add an API to your function by using the Lambda console, using the API Gateway console, or in an AWS SAM template, the function's resource-based policy is updated automatically. The following is an example function policy.

Example function policy

JSON

```
{
  "Version": "2012-10-17",
  "Id": "default",
```

```

"Statement": [
  {
    "Sid": "nodejs-apig-functiongetEndpointPermissionProd-BWDBXMPLXE2F",
    "Effect": "Allow",
    "Principal": {
      "Service": "apigateway.amazonaws.com"
    },
    "Action": "lambda:InvokeFunction",
    "Resource": "arn:aws:lambda:us-east-2:111122223333:function:nodejs-apig-
function-1G3MXMPLXVXYI",
    "Condition": {
      "StringEquals": {
        "aws:SourceAccount": "111122223333"
      },
      "ArnLike": {
        "aws:SourceArn": "arn:aws:execute-api:us-
east-2:111122223333:ktvxxmpls1/*/GET/"
      }
    }
  }
]
}

```

You can manage function policy permissions manually with the following API operations:

- [AddPermission](#)
- [RemovePermission](#)
- [GetPolicy](#)

To grant invocation permission to an existing API, use the `add-permission` command. Example:

```

aws lambda add-permission \
  --function-name my-function \
  --statement-id apigateway-get --action lambda:InvokeFunction \
  --principal apigateway.amazonaws.com \
  --source-arn "arn:aws:execute-api:us-east-2:123456789012:mnh1xmpli7/default/GET/"

```

You should see the following output:

```
{
```

```
"Statement": "{\n  \"Sid\": \"apigateway-test-2\",\n  \"Effect\": \"Allow\",\n  \"Principal\": {\n    \"Service\": \"apigateway.amazonaws.com\"\n  },\n  \"Action\": \"lambda:InvokeFunction\",\n  \"Resource\": \"arn:aws:lambda:us-east-2:123456789012:function:my-function\",\n  \"Condition\": {\n    \"ArnLike\": {\n      \"AWS:SourceArn\": \"arn:aws:execute-api:us-east-2:123456789012:mnh1xmpli7/default/GET\"\n    }\n  }\n}
```

Note

If your function and API are in different AWS Regions, the Region identifier in the source ARN must match the Region of the function, not the Region of the API. When API Gateway invokes a function, it uses a resource ARN that is based on the ARN of the API, but modified to match the function's Region.

The source ARN in this example grants permission to an integration on the GET method of the root resource in the default stage of an API, with ID `mnh1xmpli7`. You can use an asterisk in the source ARN to grant permissions to multiple stages, methods, or resources.

Resource patterns

- `mnh1xmpli7/*/GET/*` – GET method on all resources in all stages.
- `mnh1xmpli7/prod/ANY/user` – ANY method on the `user` resource in the `prod` stage.
- `mnh1xmpli7/*/*/*` – Any method on all resources in all stages.

For details on viewing the policy and removing statements, see [Viewing resource-based IAM policies in Lambda](#).

Sample application

The [API Gateway with Node.js](#) sample app includes a function with an AWS SAM template that creates a REST API that has AWS X-Ray tracing enabled. It also includes scripts for deploying, invoking the function, testing the API, and cleanup.

The event handler from Powertools for AWS Lambda

The event handler from the Powertools for AWS Lambda toolkit provides routing, middleware, CORS configuration, OpenAPI spec generation, request validation, error handling, and other useful

features when writing Lambda functions invoked by an API Gateway endpoint (HTTP or REST). The event handler utility is available for Python and TypeScript/JavaScript. For more information, see [Event Handler REST API](#) in the *Powertools for AWS Lambda (Python) documentation* and [Event Handler REST API](#) in the *Powertools for AWS Lambda (TypeScript) documentation*.

Python

```
from aws_lambda_powertools import Logger
from aws_lambda_powertools.event_handler import APIGatewayRestResolver
from aws_lambda_powertools.logging import correlation_paths
from aws_lambda_powertools.utilities.typing.lambda_context import LambdaContext

app = APIGatewayRestResolver()
logger = Logger()

@app.get("/healthz")
def ping():
    return {"message": "health status ok"}

@logger.inject_lambda_context(correlation_id_path=correlation_paths.API_GATEWAY_REST)
def lambda_handler(event: dict, context: LambdaContext) -> dict:
    return app.resolve(event, context)
```

Typescript

```
import { Router } from '@aws-lambda-powertools/event-handler/experimental-rest';
import { Logger } from '@aws-lambda-powertools/logger';
import {
    correlationPaths,
    search,
} from '@aws-lambda-powertools/logger/correlationId';
import type { Context } from 'aws-lambda/handler';

const logger = new Logger({
    correlationIdSearchFn: search,
});

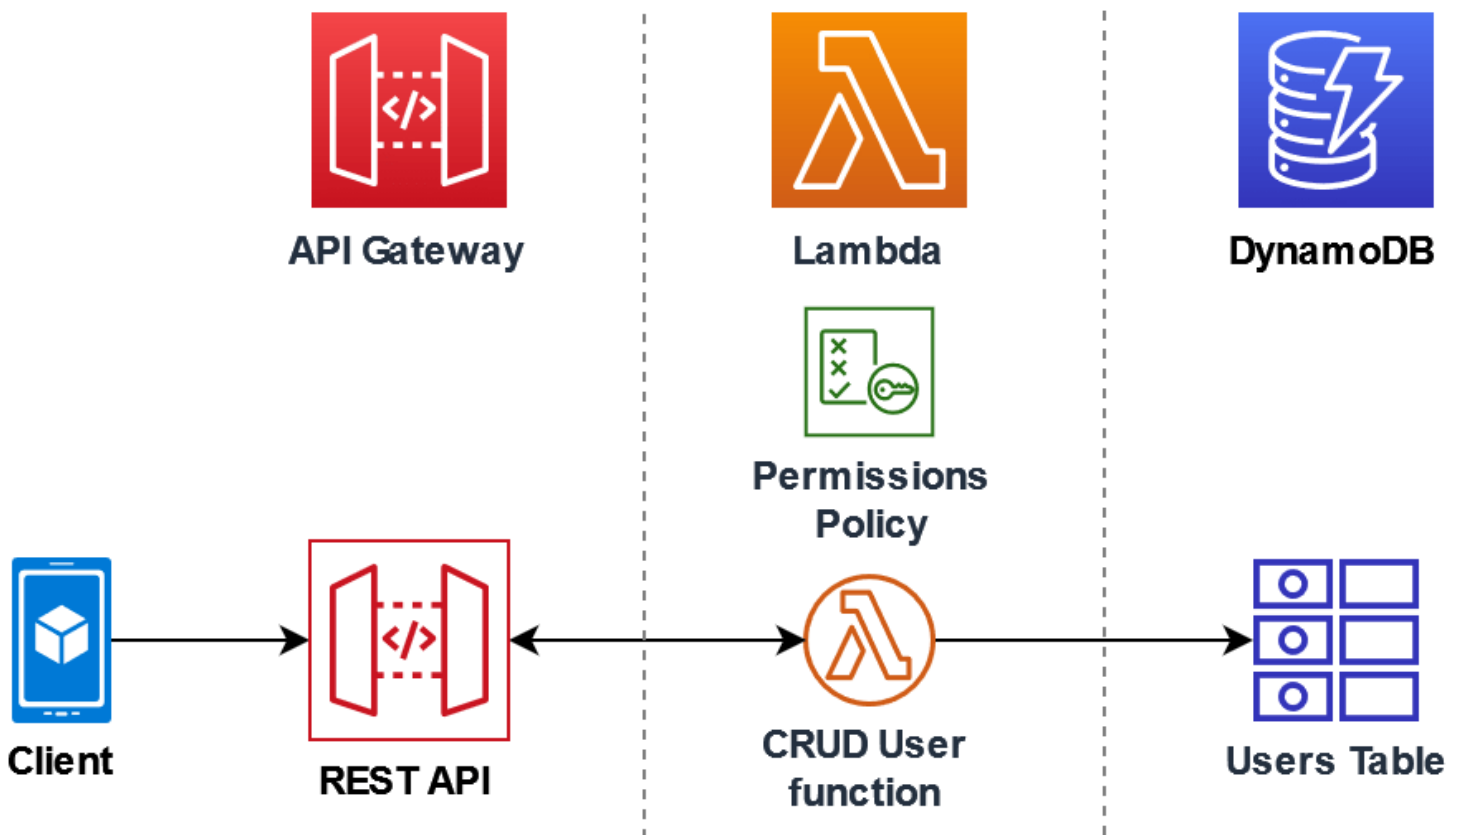

const app = new Router({ logger });

app.get("/healthz", async () => {
    return { message: "health status ok" };
});
```

```
export const handler = async (event: unknown, context: Context) => {  
  // You can continue using other utilities just as before  
  logger.addContext(context);  
  logger.setCorrelationId(event, correlationPaths.API_GATEWAY_REST);  
  return app.resolve(event, context);  
};
```

Tutorial: Using Lambda with API Gateway

In this tutorial, you create a REST API through which you invoke a Lambda function using an HTTP request. Your Lambda function will perform create, read, update, and delete (CRUD) operations on a DynamoDB table. This function is provided here for demonstration, but you will learn to configure an API Gateway REST API that can invoke any Lambda function.

Using API Gateway provides users with a secure HTTP endpoint to invoke your Lambda function and can help manage large volumes of calls to your function by throttling traffic and automatically validating and authorizing API calls. API Gateway also provides flexible security controls using AWS Identity and Access Management (IAM) and Amazon Cognito. This is useful for use cases where advance authorization is required for calls to your application.

Tip

Lambda offers two ways to invoke your function through an HTTP endpoint: API Gateway and Lambda function URLs. If you're not sure which is the best method for your use case, see [the section called "API Gateway vs function URLs"](#).

To complete this tutorial, you will go through the following stages:

1. Create and configure a Lambda function in Python or Node.js to perform operations on a DynamoDB table.
2. Create a REST API in API Gateway to connect to your Lambda function.
3. Create a DynamoDB table and test it with your Lambda function in the console.
4. Deploy your API and test the full setup using curl in a terminal.

By completing these stages, you will learn how to use API Gateway to create an HTTP endpoint that can securely invoke a Lambda function at any scale. You will also learn how to deploy your API, and how to test it in the console and by sending an HTTP request using a terminal.

Create a permissions policy

Before you can create an [execution role](#) for your Lambda function, you first need to create a permissions policy to give your function permission to access the required AWS resources. For this tutorial, the policy allows Lambda to perform CRUD operations on a DynamoDB table and write to Amazon CloudWatch Logs.

To create the policy

1. Open the [Policies page](#) of the IAM console.
2. Choose **Create Policy**.
3. Choose the **JSON** tab, and then paste the following custom policy into the JSON editor.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
```

```
{
  "Sid": "Stmt1428341300017",
  "Action": [
    "dynamodb:DeleteItem",
    "dynamodb:GetItem",
    "dynamodb:PutItem",
    "dynamodb:Query",
    "dynamodb:Scan",
    "dynamodb:UpdateItem"
  ],
  "Effect": "Allow",
  "Resource": "*"
},
{
  "Sid": "",
  "Resource": "*",
  "Action": [
    "logs:CreateLogGroup",
    "logs:CreateLogStream",
    "logs:PutLogEvents"
  ],
  "Effect": "Allow"
}
]
```

4. Choose **Next: Tags**.
5. Choose **Next: Review**.
6. Under **Review policy**, for the policy **Name**, enter **lambda-apigateway-policy**.
7. Choose **Create policy**.

Create an execution role

An [execution role](#) is an AWS Identity and Access Management (IAM) role that grants a Lambda function permission to access AWS services and resources. To enable your function to perform operations on a DynamoDB table, you attach the permissions policy you created in the previous step.

To create an execution role and attach your custom permissions policy

1. Open the [Roles page](#) of the IAM console.

2. Choose **Create role**.
3. For the type of trusted entity, choose **AWS service**, then for the use case, choose **Lambda**.
4. Choose **Next**.
5. In the policy search box, enter **lambda-apigateway-policy**.
6. In the search results, select the policy that you created (lambda-apigateway-policy), and then choose **Next**.
7. Under **Role details**, for the **Role name**, enter **lambda-apigateway-role**, then choose **Create role**.

Create the Lambda function

1. Open the [Functions page](#) of the Lambda console and choose **Create Function**.
2. Choose **Author from scratch**.
3. For **Function name**, enter LambdaFunctionOverHttps.
4. For **Runtime**, choose the latest Node.js or Python runtime.
5. Under **Permissions**, expand **Change default execution role**.
6. Choose **Use an existing role**, and then select the **lambda-apigateway-role** role that you created earlier.
7. Choose **Create function**.
8. In the **Code source** pane, replace the default code with the following Node.js or Python code.

Node.js

The region setting must match the AWS Region where you deploy the function and [create the DynamoDB table](#).

Example index.mjs

```
import { DynamoDBDocumentClient, PutCommand, GetCommand,
        UpdateCommand, DeleteCommand } from "@aws-sdk/lib-dynamodb";
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";

const ddbClient = new DynamoDBClient({ region: "us-east-2" });
const ddbDocClient = DynamoDBDocumentClient.from(ddbClient);

// Define the name of the DDB table to perform the CRUD operations on
```

```
const tablename = "lambda-apigateway";

/**
 * Provide an event that contains the following keys:
 *
 * - operation: one of 'create,' 'read,' 'update,' 'delete,' or 'echo'
 * - payload: a JSON object containing the parameters for the table item
 *   to perform the operation on
 */
export const handler = async (event, context) => {

    const operation = event.operation;

    if (operation == 'echo'){
        return(event.payload);
    }

    else {
        event.payload.TableName = tablename;
        let response;

        switch (operation) {
            case 'create':
                response = await ddbDocClient.send(new
PutCommand(event.payload));
                break;
            case 'read':
                response = await ddbDocClient.send(new
GetCommand(event.payload));
                break;
            case 'update':
                response = ddbDocClient.send(new UpdateCommand(event.payload));
                break;
            case 'delete':
                response = ddbDocClient.send(new DeleteCommand(event.payload));
                break;
            default:
                response = 'Unknown operation: ${operation}';
        }
        console.log(response);
        return response;
    }
};
```

Python

Example lambda_function.py

```
import boto3

# Define the DynamoDB table that Lambda will connect to
table_name = "lambda-apigateway"

# Create the DynamoDB resource
dynamo = boto3.resource('dynamodb').Table(table_name)

# Define some functions to perform the CRUD operations
def create(payload):
    return dynamo.put_item(Item=payload['Item'])

def read(payload):
    return dynamo.get_item(Key=payload['Key'])

def update(payload):
    return dynamo.update_item(**{k: payload[k] for k in ['Key',
'UpdateExpression',
'ExpressionAttributeNames', 'ExpressionAttributeValues'] if k in payload})

def delete(payload):
    return dynamo.delete_item(Key=payload['Key'])

def echo(payload):
    return payload

operations = {
    'create': create,
    'read': read,
    'update': update,
    'delete': delete,
    'echo': echo,
}

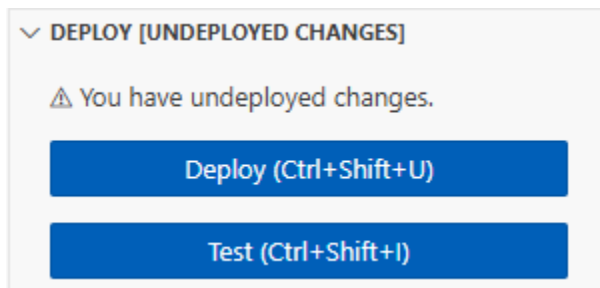

def lambda_handler(event, context):
    '''Provide an event that contains the following keys:
    - operation: one of the operations in the operations dict below
    - payload: a JSON object containing parameters to pass to the
    operation being performed'''
```

```
'''  
  
operation = event['operation']  
payload = event['payload']  
  
if operation in operations:  
    return operations[operation](payload)  
  
else:  
    raise ValueError(f'Unrecognized operation "{operation}"')
```

Note

In this example, the name of the DynamoDB table is defined as a variable in your function code. In a real application, best practice is to pass this parameter as an environment variable and to avoid hardcoding the table name. For more information see [Using AWS Lambda environment variables](#).

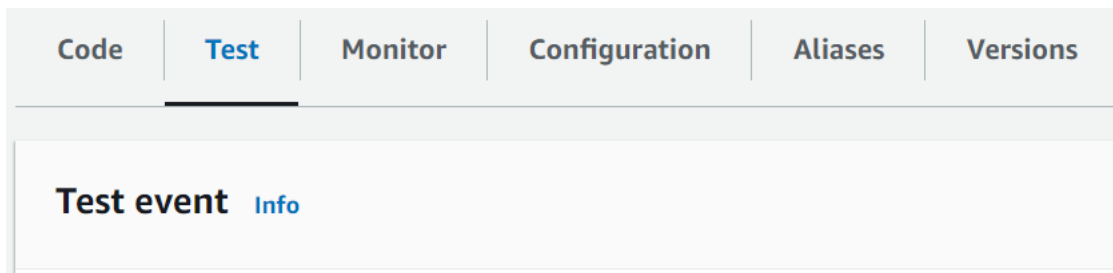

9. In the **DEPLOY** section, choose **Deploy** to update your function's code:

Test the function

Before integrating your function with API Gateway, confirm that you have deployed the function successfully. Use the Lambda console to send a test event to your function.

1. On the Lambda console page for your function, choose the **Test** tab.

2. Scroll down to the **Event JSON** section and replace the default event with the following. This event matches the structure expected by the Lambda function.

```
{
  "operation": "echo",
  "payload": {
    "somekey1": "somevalue1",
    "somekey2": "somevalue2"
  }
}
```

3. Choose **Test**.
4. Under **Executing function: succeeded**, expand **Details**. You should see the following response:

```
{
  "somekey1": "somevalue1",
  "somekey2": "somevalue2"
}
```

Create a REST API using API Gateway

In this step, you create the API Gateway REST API you will use to invoke your Lambda function.

To create the API

1. Open the [API Gateway console](#).
2. Choose **Create API**.
3. In the **REST API** box, choose **Build**.
4. Under **API details**, leave **New API** selected, and for **API Name**, enter **DynamoDBOperations**.
5. Choose **Create API**.

Create a resource on your REST API

To add an HTTP method to your API, you first need to create a resource for that method to operate on. Here you create the resource to manage your DynamoDB table.

To create the resource

1. In the [API Gateway console](#), on the **Resources** page for your API, choose **Create resource**.
2. In **Resource details**, for **Resource name** enter **DynamoDBManager**.
3. Choose **Create Resource**.

Create an HTTP POST method

In this step, you create a method (POST) for your DynamoDBManager resource. You link this POST method to your Lambda function so that when the method receives an HTTP request, API Gateway invokes your Lambda function.

Note

For the purpose of this tutorial, one HTTP method (POST) is used to invoke a single Lambda function which carries out all of the operations on your DynamoDB table. In a real application, best practice is to use a different Lambda function and HTTP method for each operation. For more information, see [The Lambda monolith](#) in Serverless Land.

To create the POST method

1. On the **Resources** page for your API, ensure that the `/DynamoDBManager` resource is highlighted. Then, in the **Methods** pane, choose **Create method**.
2. For **Method type**, choose **POST**.
3. For **Integration type**, leave **Lambda function** selected.
4. For **Lambda function**, choose the Amazon Resource Name (ARN) for your function (`LambdaFunctionOverHttps`).
5. Choose **Create method**.

Create a DynamoDB table

Create an empty DynamoDB table that your Lambda function will perform CRUD operations on.

To create the DynamoDB table

1. Open the [Tables page](#) of the DynamoDB console.
2. Choose **Create table**.
3. Under **Table details**, do the following:
 1. For **Table name**, enter **lambda-apigateway**.
 2. For **Partition key**, enter **id**, and keep the data type set as **String**.
4. Under **Table settings**, keep the **Default settings**.
5. Choose **Create table**.

Test the integration of API Gateway, Lambda, and DynamoDB

You're now ready to test the integration of your API Gateway API method with your Lambda function and your DynamoDB table. Using the API Gateway console, you send requests directly to your POST method using the console's test function. In this step, you first use a create operation to add a new item to your DynamoDB table, then you use an update operation to modify the item.

Test 1: To create a new item in your DynamoDB table

1. In the [API Gateway console](#), choose your API (DynamoDBOperations).
2. Choose the **POST** method under the `DynamoDBManager` resource.
3. Choose the **Test** tab. You might need to choose the right arrow button to show the tab.
4. Under **Test method**, leave **Query strings** and **Headers** empty. For **Request body**, paste the following JSON:

```
{
  "operation": "create",
  "payload": {
    "Item": {
      "id": "1234ABCD",
      "number": 5
    }
  }
}
```

```
}

```

5. Choose **Test**.

The results that are displayed when the test completes should show status 200. This status code indicates that the create operation was successful.

To confirm, check that your DynamoDB table now contains the new item.

6. Open the [Tables page](#) of the DynamoDB console and choose the `lambda-apigateway` table.
7. Chose **Explore table items**. In the **Items returned** pane, you should see one item with the **id** 1234ABCD and the **number** 5. Example:

Items returned (1)

<input type="checkbox"/>	id (String)	<input type="checkbox"/>	number
<input type="checkbox"/>	1234ABCD		5

Test 2: To update the item in your DynamoDB table

1. In the [API Gateway console](#), return to your POST method's **Test** tab.
2. Under **Test method**, leave **Query strings** and **Headers** empty. For **Request body**, paste the following JSON:

```
{
  "operation": "update",
  "payload": {
    "Key": {
      "id": "1234ABCD"
    },
    "UpdateExpression": "SET #num = :newNum",
    "ExpressionAttributeNames": {
      "#num": "number"
    },
    "ExpressionAttributeValues": {
      ":newNum": 10
    }
  }
}
```

```
}
```

3. Choose **Test**.

The results which are displayed when the test completes should show status 200. This status code indicates that the update operation was successful.

To confirm, check that the item in your DynamoDB table has been modified.

4. Open the [Tables page](#) of the DynamoDB console and choose the `lambda-apigateway` table.
5. Chose **Explore table items**. In the **Items returned** pane, you should see one item with the **id** 1234ABCD and the **number** 10.

Items returned (1)

<input type="checkbox"/>	<code>id (String)</code>	<input type="checkbox"/>	<code>number</code>
<input type="checkbox"/>	1234ABCD		10

Deploy the API

For a client to call the API, you must create a deployment and an associated stage. A stage represents a snapshot of your API including its methods and integrations.

To deploy the API

1. Open the **APIs** page of the [API Gateway console](#) and choose the `DynamoDBOperations` API.
2. On the **Resources** page for your API choose **Deploy API**.
3. For **Stage**, choose ***New stage***, then for **Stage name**, enter **test**.
4. Choose **Deploy**.
5. In the **Stage details** pane, copy the **Invoke URL**. You will use this in the next step to invoke your function using an HTTP request.

Use curl to invoke your function using HTTP requests

You can now invoke your Lambda function by issuing an HTTP request to your API. In this step, you will create a new item in your DynamoDB table and then perform read, update, and delete operations on that item.

To create an item in your DynamoDB table using curl

1. Open a terminal or command prompt on your local machine and run the following `curl` command using the invoke URL you copied in the previous step. This command uses the following options:
 - `-H`: Adds a custom header to the request. Here, it specifies the content type as JSON.
 - `-d`: Sends data in the request body. This option uses an HTTP POST method by default.

Linux/macOS

```
curl https://l8togsqxd8.execute-api.us-east-2.amazonaws.com/test/DynamoDBManager \
-H "Content-Type: application/json" \
-d '{"operation": "create", "payload": {"Item": {"id": "5678EFGH", "number": 15}}}'
```

PowerShell

```
curl.exe 'https://l8togsqxd8.execute-api.us-east-2.amazonaws.com/test/DynamoDBManager' -H 'Content-Type: application/json' -d '{"operation": "create", "payload": {"Item": {"id": "5678EFGH", "number": 15}}}'
```

If the operation was successful, you should see a response returned with an HTTP status code of 200.

2. You can also use the DynamoDB console to verify that the new item is in your table by doing the following:
 1. Open the [Tables page](#) of the DynamoDB console and choose the `lambda-apigateway` table.
 2. Choose **Explore table items**. In the **Items returned** pane, you should see an item with the `id` `5678EFGH` and the `number` `15`.

To read the item in your DynamoDB table using curl

- In your terminal or command prompt, run the following `curl` command to read the value of the item you just created. Use your own invoke URL.

Linux/macOS

```
curl https://l8togsqxd8.execute-api.us-east-2.amazonaws.com/test/DynamoDBManager \
-H "Content-Type: application/json" \
-d '{"operation": "read", "payload": {"Key": {"id": "5678EFGH"}}}'
```

PowerShell

```
curl.exe 'https://l8togsqxd8.execute-api.us-east-2.amazonaws.com/test/DynamoDBManager' -H 'Content-Type: application/json' -d '{"operation": "read", "payload": {"Key": {"id": "5678EFGH"}}}'
```

You should see output like one of the following depending on whether you chose the Node.js or Python function code:

Node.js

```
{"$metadata":  
{"statusCode":200,"requestId":"7BP3G5Q0C001E50FBQI9NS099JVV4KQNS05AEMVJF66Q9ASUAAJG",  
"attempts":1,"totalRetryDelay":0},"Item":{"id":"5678EFGH","number":15}}
```

Python

```
{"Item":{"id":"5678EFGH","number":15},"ResponseMetadata":  
{"RequestId":"QNDJICE52E86B82VETR6RKBE5BVV4KQNS05AEMVJF66Q9ASUAAJG",  
"HTTPStatusCode":200,"HTTPHeaders":{"server":"Server","date":"Wed, 31 Jul 2024  
00:37:01 GMT","content-type":"application/x-amz-json-1.0",  
"content-length":"52","connection":"keep-alive","x-amzn-  
requestid":"QNDJICE52E86B82VETR6RKBE5BVV4KQNS05AEMVJF66Q9ASUAAJG","x-amz-  
crc32":"2589610852"},  
"RetryAttempts":0}}
```

To update the item in your DynamoDB table using curl

1. In your terminal or command prompt, run the following `curl` command to update the item you just created by changing the number value. Use your own invoke URL.

Linux/macOS

```
curl https://l8togsqxd8.execute-api.us-east-2.amazonaws.com/test/DynamoDBManager \
-H "Content-Type: application/json" \
-d '{"operation": "update", "payload": {"Key": {"id": "5678EFGH"},
  "UpdateExpression": "SET #num = :new_value", "ExpressionAttributeNames":
  {"#num": "number"}, "ExpressionAttributeValues": {":new_value": 42}}}'
```

PowerShell

```
curl.exe 'https://l8togsqxd8.execute-api.us-east-2.amazonaws.com/test/
DynamoDBManager' -H 'Content-Type: application/json' -d '{"operation\":
 \"update\", \"payload\": {\"Key\": {\"id\": \"5678EFGH\"}, \"UpdateExpression
 \": \"SET #num = :new_value\", \"ExpressionAttributeNames\": {\"#num\": \"number
 \"}, \"ExpressionAttributeValues\": {\":new_value\": 42}}}'
```

2. To confirm that the value of number for the item has been updated, run another read command:

Linux/macOS

```
curl https://l8togsqxd8.execute-api.us-east-2.amazonaws.com/test/DynamoDBManager \
-H "Content-Type: application/json" \
-d '{"operation": "read", "payload": {"Key": {"id": "5678EFGH"}}}'
```

PowerShell

```
curl.exe 'https://l8togsqxd8.execute-api.us-east-2.amazonaws.com/test/
DynamoDBManager' -H 'Content-Type: application/json' -d '{"operation\": \"read
\", \"payload\": {\"Key\": {\"id\": \"5678EFGH\"}}}'
```

To delete the item in your DynamoDB table using curl

1. In your terminal or command prompt, run the following `curl` command to delete the item you just created. Use your own invoke URL.

Linux/macOS

```
curl https://l8togsqxd8.execute-api.us-east-2.amazonaws.com/test/DynamoDBManager \
-H "Content-Type: application/json" \
-d '{"operation": "delete", "payload": {"Key": {"id": "5678EFGH"}}}'
```

PowerShell

```
curl.exe 'https://l8togsqxd8.execute-api.us-east-2.amazonaws.com/test/DynamoDBManager' -H 'Content-Type: application/json' -d '{"operation": "delete", "payload": {"Key": {"id": "5678EFGH"}}}'
```

2. Confirm that the delete operation was successful. In the **Items returned** pane of the DynamoDB console **Explore items** page, verify that the item with **id** 5678EFGH is no longer in the table.

Clean up your resources (optional)

You can now delete the resources that you created for this tutorial, unless you want to retain them. By deleting AWS resources that you're no longer using, you prevent unnecessary charges to your AWS account.

To delete the Lambda function

1. Open the [Functions page](#) of the Lambda console.
2. Select the function that you created.
3. Choose **Actions, Delete**.
4. Type **confirm** in the text input field and choose **Delete**.

To delete the execution role

1. Open the [Roles page](#) of the IAM console.

2. Select the execution role that you created.
3. Choose **Delete**.
4. Enter the name of the role in the text input field and choose **Delete**.

To delete the API

1. Open the [APIs page](#) of the API Gateway console.
2. Select the API you created.
3. Choose **Actions, Delete**.
4. Choose **Delete**.

To delete the DynamoDB table

1. Open the [Tables page](#) of the DynamoDB console.
2. Select the table you created.
3. Choose **Delete**.
4. Enter **delete** in the text box.
5. Choose **Delete table**.

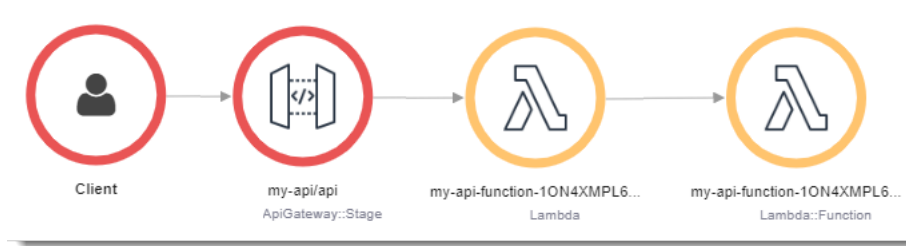

Handling Lambda errors with an API Gateway API

API Gateway treats all invocation and function errors as internal errors. If the Lambda API rejects the invocation request, API Gateway returns a 500 error code. If the function runs but returns an error, or returns a response in the wrong format, API Gateway returns a 502. In both cases, the body of the response from API Gateway is `{"message": "Internal server error"}`.

Note

API Gateway does not retry any Lambda invocations. If Lambda returns an error, API Gateway returns an error response to the client.

The following example shows an X-Ray trace map for a request that resulted in a function error and a 502 from API Gateway. The client receives the generic error message.

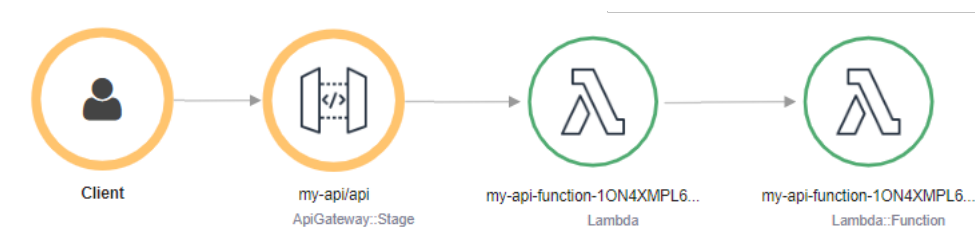

To customize the error response, you must catch errors in your code and format a response in the required format.

Example [index.mjs](#) – Error formatting

```

var formatError = function(error){
  var response = {
    "statusCode": error.statusCode,
    "headers": {
      "Content-Type": "text/plain",
      "x-amzn-ErrorType": error.code
    },
    "isBase64Encoded": false,
    "body": error.code + ": " + error.message
  }
  return response
}
  
```

API Gateway converts this response into an HTTP error with a custom status code and body. In the trace map, the function node is green because it handled the error.

Select a method to invoke your Lambda function using an HTTP request

Many common use cases for Lambda involve invoking your function using an HTTP request. For example, you might want a web application to invoke your function through a browser request.

Lambda functions can also be used to create full REST APIs, handle user interactions from mobile apps, process data from external services via HTTP calls, or create custom webhooks.

The following sections explain what your choices are for invoking Lambda through HTTP and provide information to help you make the right decision for your particular use case.

What are your choices when selecting an HTTP invoke method?

Lambda offers two main methods to invoke a function using an HTTP request - [function URLs](#) and [API Gateway](#). The key differences between these two options are as follows:

- **Lambda function URLs** provide a simple, direct HTTP endpoint for a Lambda function. They are optimized for simplicity and cost-effectiveness and provide the fastest path to expose a Lambda function via HTTP.
- **API Gateway** is a more advanced service for building fully-featured APIs. API Gateway is optimized for building and managing productions APIs at scale and provides comprehensive tools for security, monitoring, and traffic management.

Recommendations if you already know your requirements

If you're already clear on your requirements, here are our basic recommendations:

We recommend [function URLs](#) for simple applications or prototyping where you only need basic authentication methods and request/response handling and where you want to keep costs and complexity to a minimum.

[API Gateway](#) is a better choice for production applications at scale or for cases where you need more advanced features like [OpenAPI Description](#) support, a choice of authentication options, custom domain names, or rich request/response handling including throttling, caching, and request/response transformation.

What to consider when selecting a method to invoke your Lambda function

When selecting between function URLs and API Gateway, you need to consider the following factors:

- Your authentication needs, such as whether you require OAuth or Amazon Cognito to authenticate users
- Your scaling requirements and the complexity of the API you want to implement

- Whether you need advanced features such as request validation and request/response formatting
- Your monitoring requirements
- Your cost goals

By understanding these factors, you can select the option that best balances your security, complexity, and cost requirements.

The following information summarizes the main differences between the two options.

Authentication

- **Function URLs** provide basic authentication options through AWS Identity and Access Management (IAM). You can configure your endpoints to be either public (no authentication) or to require IAM authentication. With IAM authentication, you can use standard AWS credentials or IAM roles to control access. While straightforward to set up, this approach provides limited options compared with other authentication methods.
- **API Gateway** provides access to a more comprehensive range of authentication options. As well as IAM authentication, you can use [Lambda authorizers](#) (custom authentication logic), [Amazon Cognito](#) user pools, and OAuth2.0 flows. This flexibility allows you to implement complex authentication schemes, including third-party authentication providers, token-based authentication, and multi-factor authentication.

Request/response handling

- **Function URLs** provide basic HTTP request and response handling. They support standard HTTP methods and include built-in cross-origin resource sharing (CORS) support. While they can handle JSON payloads and query parameters naturally, they don't offer request transformation or validation capabilities. Response handling is similarly straightforward – the client receives the response from your Lambda function exactly as Lambda returns it.
- **API Gateway** provides sophisticated request and response handling capabilities. You can define request validators, transform requests and responses using mapping templates, set up request/response headers, and implement response caching. API Gateway also supports binary payloads and custom domain names and can modify responses before they reach the client. You can set up models for request/response validation and transformation using JSON Schema.

Scaling

- **Function URLs** scale directly with your Lambda function's concurrency limits and handle traffic spikes by scaling your function up to its maximum configured concurrency limit. Once that limit is reached, Lambda responds to additional requests with HTTP 429 responses. There's no built-in queuing mechanism, so handling scaling is entirely dependent on your Lambda function's configuration. By default, Lambda functions have a limit of 1,000 concurrent executions per AWS Region.
- **API Gateway** provides additional scaling capabilities on top of Lambda's own scaling. It includes built-in request queuing and throttling controls, allowing you to manage traffic spikes more gracefully. API Gateway can handle up to 10,000 requests per second per region by default, with a burst capacity of 5,000 requests per second. It also provides tools to throttle requests at different levels (API, stage, or method) to protect your backend.

Monitoring

- **Function URLs** offer basic monitoring through Amazon CloudWatch metrics, including request count, latency, and error rates. You get access to standard Lambda metrics and logs, which show the raw requests coming into your function. While this provides essential operational visibility, the metrics are focused mainly on function execution.
- **API Gateway** provides comprehensive monitoring capabilities including detailed metrics, logging, and tracing options. You can monitor API calls, latency, error rates, and cache hit/miss rates through CloudWatch. API Gateway also integrates with AWS X-Ray for distributed tracing and provides customizable logging formats.

Cost

- **Function URLs** follow the standard Lambda pricing model – you only pay for function invocations and compute time. There are no additional charges for the URL endpoint itself. This makes it a cost-effective choice for simple APIs or low-traffic applications if you don't need the additional features of API Gateway.
- **API Gateway** offers a [free tier](#) that includes one million API calls received for REST APIs and one million API calls received for HTTP APIs. After this, API Gateway charges for API calls, data transfer, and caching (if enabled). Refer to the API Gateway [pricing page](#) to understand the costs for your own use case.

Other features

- **Function URLs** are designed for simplicity and direct Lambda integration. They support both HTTP and HTTPS endpoints, offer built-in CORS support, and provide dual-stack (IPv4 and IPv6) endpoints. While they lack advanced features, they excel in scenarios where you need a quick, straightforward way to expose Lambda functions via HTTP.
- **API Gateway** includes numerous additional features such as API versioning, stage management, API keys for usage plans, API documentation through Swagger/OpenAPI, WebSocket APIs, private APIs within a VPC, and WAF integration for additional security. It also supports canary deployments, mock integrations for testing, and integration with other AWS services beyond Lambda.

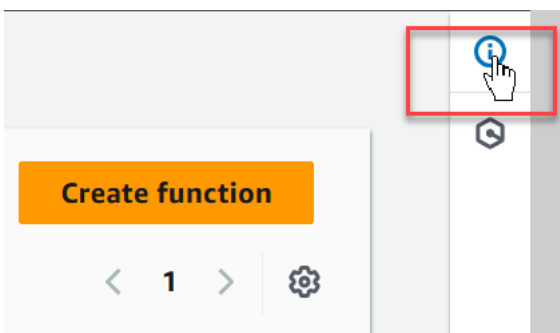

Select a method to invoke your Lambda function

Now that you've read about the criteria for selecting between Lambda function URLs and API Gateway and the key differences between them, you can select the option that best meets your needs and use the following resources to help you get started using it.

Function URLs

Get started with function URLs with the following resources

- Follow the tutorial [Creating a Lambda function with a function URL](#)
- Learn more about function URLs in the [the section called "Function URLs"](#) chapter of this guide
- Try the in-console guided tutorial **Create a simple web app** by doing the following:
 1. Open the [functions page](#) of the Lambda console.
 2. Open the help panel by choosing the icon in the top right corner of the screen.

3. Select **Tutorials**.
4. In **Create a simple web app**, choose **Start tutorial**.

API Gateway

Get started with Lambda and API Gateway with the following resources

- Follow the tutorial [Using Lambda with API Gateway](#) to create a REST API integrated with a backend Lambda function.
- Learn more about the different kinds of API offered by API Gateway in the following sections of the *Amazon API Gateway Developer Guide*:
 - [API Gateway REST APIs](#)
 - [API Gateway HTTP APIs](#)
 - [API Gateway WebSocket APIs](#)
- Try one or more of the examples in the [Tutorials and workshops](#) section of the *Amazon API Gateway Developer Guide*.

Using AWS Lambda with AWS Infrastructure Composer

AWS Infrastructure Composer is a visual builder for designing modern applications on AWS. You design your application architecture by dragging, grouping, and connecting AWS services in a visual canvas. Infrastructure Composer creates infrastructure as code (IaC) templates from your design that you can deploy using [AWS SAM](#) or [CloudFormation](#).

Exporting a Lambda function to Infrastructure Composer

You can get started using Infrastructure Composer by creating a new project based on the configuration of an existing Lambda function using the Lambda console. To export your function's configuration and code to Infrastructure Composer to create a new project, do the following:

1. Open the [Functions page](#) of the Lambda console.
2. Select the function you want to use as a basis for your Infrastructure Composer project.
3. In the **Function overview** pane, choose **Export to Infrastructure Composer**.

To export your function's configuration and code to Infrastructure Composer, Lambda creates an Amazon S3 bucket in your account to temporarily store this data.

4. In the dialog box, choose **Confirm and create project** to accept the default name for this bucket and export your function's configuration and code to Infrastructure Composer.
5. (Optional) To choose another name for the Amazon S3 bucket that Lambda creates, enter a new name and choose **Confirm and create project**. Amazon S3 bucket names must be globally unique and follow the [bucket naming rules](#).
6. To save your project and function files in Infrastructure Composer, activate [local sync mode](#).

Note

If you've used the **Export to Application Composer** feature before and created an Amazon S3 bucket using the default name, Lambda can re-use this bucket if it still exists. Accept the default bucket name in the dialog box to re-use the existing bucket.

Amazon S3 transfer bucket configuration

The Amazon S3 bucket that Lambda creates to transfer your function's configuration automatically encrypts objects using the AES 256 encryption standard. Lambda also configures the bucket to use the [bucket owner condition](#) to ensure that only your AWS account is able to add objects to the bucket.

Lambda configures the bucket to automatically delete objects 10 days after they are uploaded. However, Lambda doesn't automatically delete the bucket itself. To delete the bucket from your AWS account, follow the instructions in [Deleting a bucket](#). The default bucket name uses the prefix `lambdasam`, a 10-digit alphanumeric string, and the AWS Region you created your function in:

```
lambdasam-06f22da95b-us-east-1
```

To avoid additional charges being added to your AWS account, we recommend that you delete the Amazon S3 bucket as soon as you have finished exporting your function to Infrastructure Composer.

Standard [Amazon S3 pricing](#) applies.

Required permissions

To use the Lambda integration with Infrastructure Composer feature, you need certain permissions to download an AWS SAM template and to write your function's configuration to Amazon S3.

To download an AWS SAM template, you must have permission to use the following API actions:

- [GetPolicy](#)
- [iam:GetPolicyVersion](#)
- [iam:GetRole](#)
- [iam:GetRolePolicy](#)
- [iam:ListAttachedRolePolicies](#)
- [iam:ListRolePolicies](#)
- [iam:ListRoles](#)

You can grant permission to use all of these actions by adding the [AWSLambda_ReadOnlyAccess](#) AWS managed policy to your IAM user role.

For Lambda to write your function's configuration to Amazon S3, you must have permission to use the following API actions:

- [S3:PutObject](#)
- [S3:CreateBucket](#)
- [S3:PutBucketEncryption](#)
- [S3:PutBucketLifecycleConfiguration](#)

If you are unable to export your function's configuration to Infrastructure Composer, check that your account has the required permissions for these operations. If you have the required permissions, but still cannot export your function's configuration, check for any [resource-based policies](#) that might limit access to Amazon S3.

Other resources

For a more detailed tutorial on how to design a serverless application in Infrastructure Composer based on an existing Lambda function, see [the section called “Infrastructure as code \(IaC\)”](#).

To use Infrastructure Composer and AWS SAM to design and deploy a complete serverless application using Lambda, you can also follow the [AWS Infrastructure Composer tutorial](#) in the [AWS Serverless Patterns Workshop](#).

Using AWS Lambda with CloudFormation

In an AWS CloudFormation template, you can specify a Lambda function as the target of a custom resource. Use custom resources to process parameters, retrieve configuration values, or call other AWS services during stack lifecycle events.

The following example invokes a function that's defined elsewhere in the template.

Example – Custom resource definition

```
Resources:
  primerinvoke:
    Type: AWS::CloudFormation::CustomResource
    Version: "1.0"
    Properties:
      ServiceToken: !GetAtt primer.Arn
      FunctionName: !Ref randomerror
```

The service token is the Amazon Resource Name (ARN) of the function that CloudFormation invokes when you create, update, or delete the stack. You can also include additional properties like `FunctionName`, which CloudFormation passes to your function as is.

CloudFormation invokes your Lambda function [asynchronously](#) with an event that includes a callback URL.

Example – CloudFormation message event

```
{
  "RequestType": "Create",
  "ServiceToken": "arn:aws:lambda:us-east-1:123456789012:function:lambda-error-processor-primer-14R0R2T3JKU66",
  "ResponseURL": "https://cloudformation-custom-resource-response-useast1.s3-us-east-1.amazonaws.com/arn%3Aaws%3Acloudformation%3Aus-east-1%3A123456789012%3Astack/lambda-error-processor/1134083a-2608-1e91-9897-022501a2c456%7Cprimerinvoke%7C5d478078-13e9-baf0-464a-7ef285ecc786?AWSAccessKeyId=AKIAIOSFODNN7EXAMPLE&Expires=1555451971&Signature=28UijZePE5I4dvukKQqM%2F9Rf1o4%3D",
  "StackId": "arn:aws:cloudformation:us-east-1:123456789012:stack/lambda-error-processor/1134083a-2608-1e91-9897-022501a2c456",
  "RequestId": "5d478078-13e9-baf0-464a-7ef285ecc786",
  "LogicalResourceId": "primerinvoke",
  "ResourceType": "AWS::CloudFormation::CustomResource",
```

```

    "ResourceProperties": {
      "ServiceToken": "arn:aws:lambda:us-east-1:123456789012:function:lambda-error-processor-primer-14R0R2T3JKU66",
      "FunctionName": "lambda-error-processor-randomerror-ZWUC391MQAJK"
    }
  }
}

```

The function is responsible for returning a response to the callback URL that indicates success or failure. For the full response syntax, see [Custom resource response objects](#).

Example – CloudFormation custom resource response

```

{
  "Status": "SUCCESS",
  "PhysicalResourceId": "2019/04/18/[$LATEST]b3d1bfc65f19ec610654e4d9b9de47a0",
  "StackId": "arn:aws:cloudformation:us-east-1:123456789012:stack/lambda-error-processor/1134083a-2608-1e91-9897-022501a2c456",
  "RequestId": "5d478078-13e9-baf0-464a-7ef285ecc786",
  "LogicalResourceId": "primerinvoke"
}

```

CloudFormation provides a library called `cfn-response` that handles sending the response. If you define your function within a template, you can require the library by name. CloudFormation then adds the library to the deployment package that it creates for the function.

If your function that a Custom Resource uses has an [Elastic Network Interface](#) attached to it, add the following resources to the VPC policy where **region** is the Region the function is in without the dashes. For example, `us-east-1` is `useast1`. This will allow the Custom Resource to respond to the callback URL that sends a signal back to the CloudFormation stack.

```

arn:aws:s3:::cloudformation-custom-resource-response-region",
"arn:aws:s3:::cloudformation-custom-resource-response-region/*",

```

The following example function invokes a second function. If the call succeeds, the function sends a success response to CloudFormation, and the stack update continues. The template uses the [AWS::Serverless::Function](#) resource type provided by AWS Serverless Application Model.

Example – Custom resource function

```

Transform: 'AWS::Serverless-2016-10-31'

```

Resources:

primer:

Type: [AWS::Serverless::Function](#)

Properties:

Handler: index.handler

Runtime: nodejs16.x

InlineCode: |

`var aws = require('aws-sdk');``var response = require('cfn-response');``exports.handler = function(event, context) {` `// For Delete requests, immediately send a SUCCESS response.` `if (event.RequestType == "Delete") {` `response.send(event, context, "SUCCESS");` `return;` `}` `var responseStatus = "FAILED";` `var responseData = {};` `var functionName = event.ResourceProperties.FunctionName` `var lambda = new aws.Lambda();` `lambda.invoke({ FunctionName: functionName }, function(err, invokeResult) {` `if (err) {` `responseData = {Error: "Invoke call failed"};` `console.log(responseData.Error + ":\n", err);` `}` `else responseStatus = "SUCCESS";` `response.send(event, context, responseStatus, responseData);` `});``};`

Description: Invoke a function to create a log stream.

MemorySize: 128

Timeout: 8

Role: !GetAtt role.Arn

Tracing: Active

If the function that the custom resource invokes isn't defined in a template, you can get the source code for `cfn-response` from [cfn-response module](#) in the AWS CloudFormation User Guide.

For more information about custom resources, see [Custom resources](#) in the *AWS CloudFormation User Guide*.

Process Amazon DocumentDB events with Lambda

You can use a Lambda function to process events in an [Amazon DocumentDB \(with MongoDB compatibility\) change stream](#) by configuring an Amazon DocumentDB cluster as an event source. Then, you can automate event-driven workloads by invoking your Lambda function each time that data changes with your Amazon DocumentDB cluster.

Note

Lambda supports version 4.0 and 5.0 of Amazon DocumentDB only. Lambda doesn't support version 3.6.

Also, for event source mappings, Lambda supports instance-based clusters and regional clusters only. Lambda doesn't support [elastic clusters](#) or [global clusters](#). This limitation doesn't apply when using Lambda as a client to connect to Amazon DocumentDB. Lambda can connect to all cluster types to perform CRUD operations.

Lambda processes events from Amazon DocumentDB change streams sequentially in the order in which they arrive. Because of this, your function can handle only one concurrent invocation from Amazon DocumentDB at a time. To monitor your function, you can track its [concurrency metrics](#).

Warning

Lambda event source mappings process each event at least once, and duplicate processing of records can occur. To avoid potential issues related to duplicate events, we strongly recommend that you make your function code idempotent. To learn more, see [How do I make my Lambda function idempotent](#) in the AWS Knowledge Center.

Example Amazon DocumentDB event

```
{
  "eventSourceArn": "arn:aws:rds:us-east-1:123456789012:cluster:canaryclusterb2a659a2-qo5tcmqkc103",
  "events": [
    {
      "event": {
        "_id": {
          "_data": "0163eeb6e7000000090100000009000041e1"
        },
        "clusterTime": {
          "$timestamp": {
            "t": 1676588775,
            "i": 9
          }
        },
        "documentKey": {
          "_id": {
            "$oid": "63eeb6e7d418cd98afb1c1d7"
          }
        },
        "fullDocument": {
          "_id": {
            "$oid": "63eeb6e7d418cd98afb1c1d7"
          },
          "anyField": "sampleValue"
        },
        "ns": {
          "db": "test_database",
          "coll": "test_collection"
        },
        "operationType": "insert"
      }
    }
  ],
  "eventSource": "aws:docdb"
}
```

For more information about the events in this example and their shapes, see [Change Events](#) on the MongoDB Documentation website.

Prerequisites and permissions

Before you can use Amazon DocumentDB as an event source for your Lambda function, note the following prerequisites. You must:

- **Have an existing Amazon DocumentDB cluster in the same AWS account and AWS Region as your function.** If you don't have an existing cluster, you can create one by following the steps in [Get Started with Amazon DocumentDB](#) in the *Amazon DocumentDB Developer Guide*. Alternatively, the first set of steps in [Tutorial: Using AWS Lambda with Amazon DocumentDB Streams](#) guide you through creating an Amazon DocumentDB cluster with all the necessary prerequisites.
- **Allow Lambda to access the Amazon Virtual Private Cloud (Amazon VPC) resources associated with your Amazon DocumentDB cluster.** For more information, see [Configure network security](#).
- **Enable TLS on your Amazon DocumentDB cluster.** This is the default setting. If you disable TLS, then Lambda cannot communicate with your cluster.
- **Activate change streams on your Amazon DocumentDB cluster.** For more information, see [Using Change Streams with Amazon DocumentDB](#) in the *Amazon DocumentDB Developer Guide*.
- **Provide Lambda with credentials to access your Amazon DocumentDB cluster.** When setting up the event source, provide the [AWS Secrets Manager](#) key that contains the authentication details (username and password) required to access your cluster. To provide this key during setup, do either of the following:
 - If you're using the Lambda console for setup, then provide the key in the **Secrets manager key** field.
 - If you're using the AWS Command Line Interface (AWS CLI) for setup, then provide this key in the `source-access-configurations` option. You can include this option with either the [create-event-source-mapping](#) command or the [update-event-source-mapping](#) command. For example:

```
aws lambda create-event-source-mapping \  
    ...  
    --source-access-configurations  
    '[{"Type":"BASIC_AUTH","URI":"arn:aws:secretsmanager:us-  
west-2:123456789012:secret:DocDBSecret-AbC4E6"}]' \  
    ...
```

- **Grant Lambda permissions to manage resources related to your Amazon DocumentDB stream.** Manually add the following permissions to your function's [execution role](#):
 - [rds:DescribeDBClusters](#)
 - [rds:DescribeDBClusterParameters](#)
 - [rds:DescribeDBSubnetGroups](#)
 - [ec2:CreateNetworkInterface](#)
 - [ec2:DescribeNetworkInterfaces](#)
 - [ec2:DescribeVpcs](#)
 - [ec2>DeleteNetworkInterface](#)
 - [ec2:DescribeSubnets](#)
 - [ec2:DescribeSecurityGroups](#)
 - [kms:Decrypt](#)
 - [secretsmanager:GetSecretValue](#)
- **Keep the size of Amazon DocumentDB change stream events that you send to Lambda under 6 MB.** Lambda supports payload sizes of up to 6 MB. If your change stream tries to send Lambda an event larger than 6 MB, then Lambda drops the message and emits the `OversizedRecordCount` metric. Lambda emits all metrics on a best-effort basis.

Note

While Lambda functions typically have a maximum timeout limit of 15 minutes, event source mappings for Amazon MSK, self-managed Apache Kafka, Amazon DocumentDB, and Amazon MQ for ActiveMQ and RabbitMQ only support functions with maximum timeout limits of 14 minutes. This constraint ensures that the event source mapping can properly handle function errors and retries.

Configure network security

To give Lambda full access to Amazon DocumentDB through your event source mapping, either your cluster must use a public endpoint (public IP address), or you must provide access to the Amazon VPC you created the cluster in.

When you use Amazon DocumentDB with Lambda, create [AWS PrivateLink VPC endpoints](#) that provide your function access to the resources in your Amazon VPC.

 **Note**

AWS PrivateLink VPC endpoints are required for functions with event source mappings that use the default (on-demand) mode for event pollers. If your event source mapping uses [provisioned mode](#), you don't need to configure AWS PrivateLink VPC endpoints.

Create an endpoint to provide access to the following resources:

- Lambda — Create an endpoint for the Lambda service principal.
- AWS STS — Create an endpoint for the AWS STS in order for a service principal to assume a role on your behalf.
- Secrets Manager — If your cluster uses Secrets Manager to store credentials, create an endpoint for Secrets Manager.

Alternatively, configure a NAT gateway on each public subnet in the Amazon VPC. For more information, see [the section called “Internet access for VPC functions”](#).

When you create an event source mapping for Amazon DocumentDB, Lambda checks whether Elastic Network Interfaces (ENIs) are already present for the subnets and security groups configured for your Amazon VPC. If Lambda finds existing ENIs, it attempts to re-use them. Otherwise, Lambda creates new ENIs to connect to the event source and invoke your function.

 **Note**

Lambda functions always run inside VPCs owned by the Lambda service. Your function's VPC configuration does not affect the event source mapping. Only the networking configuration of the event source's determines how Lambda connects to your event source.

Configure the security groups for the Amazon VPC containing your cluster. By default, Amazon DocumentDB uses the following ports: 27017.

- Inbound rules – Allow all traffic on the default broker port for the security group associated with your event source. Alternatively, you can use a self-referencing security group rule to allow access from instances within the same security group.
- Outbound rules – Allow all traffic on port 443 for external destinations if your function needs to communicate with AWS services. Alternatively, you can also use a self-referencing security group rule to limit access to the broker if you don't need to communicate with other AWS services.
- Amazon VPC endpoint inbound rules — If you are using an Amazon VPC endpoint, the security group associated with your Amazon VPC endpoint must allow inbound traffic on port 443 from the cluster security group.

If your cluster uses authentication, you can also restrict the endpoint policy for the Secrets Manager endpoint. To call the Secrets Manager API, Lambda uses your function role, not the Lambda service principal.

Example VPC endpoint policy — Secrets Manager endpoint

```
{
  "Statement": [
    {
      "Action": "secretsmanager:GetSecretValue",
      "Effect": "Allow",
      "Principal": {
        "AWS": [
          "arn:aws::iam::123456789012:role/my-role"
        ]
      },
      "Resource": "arn:aws::secretsmanager:us-west-2:123456789012:secret:my-secret"
    }
  ]
}
```

When you use Amazon VPC endpoints, AWS routes your API calls to invoke your function using the endpoint's Elastic Network Interface (ENI). The Lambda service principal needs to call `lambda:InvokeFunction` on any roles and functions that use those ENIs.

By default, Amazon VPC endpoints have open IAM policies that allow broad access to resources. Best practice is to restrict these policies to perform the needed actions using that endpoint. To ensure that your event source mapping is able to invoke your Lambda function, the VPC

endpoint policy must allow the Lambda service principal to call `sts:AssumeRole` and `lambda:InvokeFunction`. Restricting your VPC endpoint policies to allow only API calls originating within your organization prevents the event source mapping from functioning properly, so `"Resource": "*"` is required in these policies.

The following example VPC endpoint policies show how to grant the required access to the Lambda service principal for the AWS STS and Lambda endpoints.

Example VPC Endpoint policy — AWS STS endpoint

```
{
  "Statement": [
    {
      "Action": "sts:AssumeRole",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "lambda.amazonaws.com"
        ]
      },
      "Resource": "*"
    }
  ]
}
```

Example VPC Endpoint policy — Lambda endpoint

```
{
  "Statement": [
    {
      "Action": "lambda:InvokeFunction",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "lambda.amazonaws.com"
        ]
      },
      "Resource": "*"
    }
  ]
}
```

Creating an Amazon DocumentDB event source mapping (console)

For a Lambda function to read from an Amazon DocumentDB cluster's change stream, create an [event source mapping](#). This section describes how to do this from the Lambda console. For AWS SDK and AWS CLI instructions, see [the section called "Creating an Amazon DocumentDB event source mapping \(SDK or CLI\)"](#).

To create an Amazon DocumentDB event source mapping (console)

1. Open the [Functions page](#) of the Lambda console.
2. Choose the name of a function.
3. Under **Function overview**, choose **Add trigger**.
4. Under **Trigger configuration**, in the dropdown list, choose **DocumentDB**.
5. Configure the required options, and then choose **Add**.

Lambda supports the following options for Amazon DocumentDB event sources:

- **DocumentDB cluster** – Select an Amazon DocumentDB cluster.
- **Activate trigger** – Choose whether you want to activate the trigger immediately. If you select this check box, then your function immediately starts receiving traffic from the specified Amazon DocumentDB change stream upon creation of the event source mapping. We recommend that you clear the check box to create the event source mapping in a deactivated state for testing. After creation, you can activate the event source mapping at any time.
- **Database name** – Enter the name of a database within the cluster to consume.
- (Optional) **Collection name** – Enter the name of a collection within the database to consume. If you don't specify a collection, then Lambda listens to all events from each collection in the database.
- **Batch size** – Set the maximum number of messages to retrieve in a single batch, up to 10,000. The default batch size is 100.
- **Starting position** – Choose the position in the stream to start reading records from.
 - **Latest** – Process only new records that are added to the stream. Your function starts processing records only after Lambda finishes creating your event source. This means that some records may be dropped until your event source is created successfully.
 - **Trim horizon** – Process all records in the stream. Lambda uses the log retention duration of your cluster to determine where to start reading events from. Specifically, Lambda starts

reading from `current_time - log_retention_duration`. Your change stream must already be active before this timestamp for Lambda to read all events properly.

- **At timestamp** – Process records starting from a specific time. Your change stream must already be active before the specified timestamp for Lambda to read all events properly.
- **Authentication** – Choose the authentication method for accessing the brokers in your cluster.
 - **BASIC_AUTH** – With basic authentication, you must provide the Secrets Manager key that contains the credentials to access your cluster.
- **Secrets Manager key** – Choose the Secrets Manager key that contains the authentication details (username and password) required to access your Amazon DocumentDB cluster.
- (Optional) **Batch window** – Set the maximum amount of time in seconds to gather records before invoking your function, up to 300.
- (Optional) **Full document configuration** – For document update operations, choose what you want to send to the stream. The default value is `Default`, which means that for each change stream event, Amazon DocumentDB sends only a delta describing the changes made. For more information about this field, see [FullDocument](#) in the MongoDB Javadoc API documentation.
 - **Default** – Lambda sends only a partial document describing the changes made.
 - **UpdateLookup** – Lambda sends a delta describing the changes, along with a copy of the entire document.

Creating an Amazon DocumentDB event source mapping (SDK or CLI)

To create or manage an Amazon DocumentDB event source mapping with an [AWS SDK](#), you can use the following API operations:

- [CreateEventSourceMapping](#)
- [ListEventSourceMappings](#)
- [GetEventSourceMapping](#)
- [UpdateEventSourceMapping](#)
- [DeleteEventSourceMapping](#)

To create the event source mapping with the AWS CLI, use the [create-event-source-mapping](#) command. The following example uses this command to map a function named `my-function` to an Amazon DocumentDB change stream. The event source is specified by an Amazon Resource Name (ARN), with a batch size of 500, starting from the timestamp in Unix time. The command

also specifies the Secrets Manager key that Lambda uses to connect to Amazon DocumentDB. Additionally, it includes `document-db-event-source-config` parameters that specify the database and the collection to read from.

```
aws lambda create-event-source-mapping --function-name my-function \
    --event-source-arn arn:aws:rds:us-west-2:123456789012:cluster:privatecluster7de2-
    epzcyvu4pjoy
    --batch-size 500 \
    --starting-position AT_TIMESTAMP \
    --starting-position-timestamp 1541139109 \
    --source-access-configurations
    '["Type":"BASIC_AUTH","URI":"arn:aws:secretsmanager:us-
    east-1:123456789012:secret:DocDBSecret-BATjxi"]]' \
    --document-db-event-source-config '{"DatabaseName":"test_database",
    "CollectionName": "test_collection"}' \
```

You should see output that looks like this:

```
{
  "UUID": "2b733gdc-8ac3-cdf5-af3a-1827b3b11284",
  "BatchSize": 500,
  "DocumentDBEventSourceConfig": {
    "CollectionName": "test_collection",
    "DatabaseName": "test_database",
    "FullDocument": "Default"
  },
  "MaximumBatchingWindowInSeconds": 0,
  "EventSourceArn": "arn:aws:rds:us-west-2:123456789012:cluster:privatecluster7de2-
  epzcyvu4pjoy",
  "FunctionArn": "arn:aws:lambda:us-west-2:123456789012:function:my-function",
  "LastModified": 1541348195.412,
  "LastProcessingResult": "No records processed",
  "State": "Creating",
  "StateTransitionReason": "User action"
}
```

After creation, you can use the [update-event-source-mapping](#) command to update the settings for your Amazon DocumentDB event source. The following example updates the batch size to 1,000 and the batch window to 10 seconds. For this command, you need the UUID of your event source mapping, which you can retrieve using the `list-event-source-mapping` command or the Lambda console.

```
aws lambda update-event-source-mapping --function-name my-function \  
--uuid f89f8514-cdd9-4602-9e1f-01a5b77d449b \  
--batch-size 1000 \  
--batch-window 10
```

You should see this output that looks like this:

```
{  
  "UUID": "2b733gdc-8ac3-cdf5-af3a-1827b3b11284",  
  "BatchSize": 500,  
  "DocumentDBEventSourceConfig": {  
    "CollectionName": "test_collection",  
    "DatabaseName": "test_database",  
    "FullDocument": "Default"  
  },  
  "MaximumBatchingWindowInSeconds": 0,  
  "EventSourceArn": "arn:aws:rds:us-west-2:123456789012:cluster:privatecluster7de2-  
epzcyvu4pjoy",  
  "FunctionArn": "arn:aws:lambda:us-west-2:123456789012:function:my-function",  
  "LastModified": 1541359182.919,  
  "LastProcessingResult": "OK",  
  "State": "Updating",  
  "StateTransitionReason": "User action"  
}
```

Lambda updates settings asynchronously, so you may not see these changes in the output until the process completes. To view the current settings of your event source mapping, use the [get-event-source-mapping](#) command.

```
aws lambda get-event-source-mapping --uuid f89f8514-cdd9-4602-9e1f-01a5b77d449b
```

You should see this output that looks like this:

```
{  
  "UUID": "2b733gdc-8ac3-cdf5-af3a-1827b3b11284",  
  "DocumentDBEventSourceConfig": {  
    "CollectionName": "test_collection",  
    "DatabaseName": "test_database",  
    "FullDocument": "Default"  
  },  
  "BatchSize": 1000,
```

```
{
  "MaximumBatchingWindowInSeconds": 10,
  "EventSourceArn": "arn:aws:rds:us-west-2:123456789012:cluster:privatecluster7de2-epzcyvu4pjoy",
  "FunctionArn": "arn:aws:lambda:us-west-2:123456789012:function:my-function",
  "LastModified": 1541359182.919,
  "LastProcessingResult": "OK",
  "State": "Enabled",
  "StateTransitionReason": "User action"
}
```

To delete your Amazon DocumentDB event source mapping, use the [delete-event-source-mapping](#) command.

```
aws lambda delete-event-source-mapping \
  --uuid 2b733gdc-8ac3-cdf5-af3a-1827b3b11284
```

Polling and stream starting positions

Be aware that stream polling during event source mapping creation and updates is eventually consistent.

- During event source mapping creation, it may take several minutes to start polling events from the stream.
- During event source mapping updates, it may take several minutes to stop and restart polling events from the stream.

This behavior means that if you specify LATEST as the starting position for the stream, the event source mapping could miss events during creation or updates. To ensure that no events are missed, specify the stream starting position as TRIM_HORIZON or AT_TIMESTAMP.

Monitoring your Amazon DocumentDB event source

To help you monitor your Amazon DocumentDB event source, Lambda emits the `IteratorAge` metric when your function finishes processing a batch of records. *Iterator age* is the difference between the timestamp of the most recent event and the current timestamp. Essentially, the `IteratorAge` metric indicates how old the last processed record in the batch is. If your function is currently processing new events, then you can use the iterator age to estimate the latency between when a record is added and when your function processes it. An increasing trend in `IteratorAge`

can indicate issues with your function. For more information, see [Using CloudWatch metrics with Lambda](#).

Amazon DocumentDB change streams aren't optimized to handle large time gaps between events. If your Amazon DocumentDB event source doesn't receive any events for an extended period of time, Lambda may disable the event source mapping. The length of this time period can vary from a few weeks to a few months depending on cluster size and other workloads.

Lambda supports payloads of up to 6 MB. However, Amazon DocumentDB change stream events can be up to 16 MB in size. If your change stream tries to send Lambda a change stream event larger than 6 MB, then Lambda drops the message and emits the `OversizedRecordCount` metric. Lambda emits all metrics on a best-effort basis.

Tutorial: Using AWS Lambda with Amazon DocumentDB Streams

In this tutorial, you create a basic Lambda function that consumes events from an Amazon DocumentDB (with MongoDB compatibility) change stream. To complete this tutorial, you will go through the following stages:

- Set up your Amazon DocumentDB cluster, connect to it, and activate change streams on it.
- Create your Lambda function, and configure your Amazon DocumentDB cluster as an event source for your function.
- Test the setup by inserting items into your Amazon DocumentDB database.

Create the Amazon DocumentDB cluster

1. Open the [Amazon DocumentDB console](#). Under **Clusters**, choose **Create**.
2. Create a cluster with the following configuration:
 - For **Cluster type**, choose **Instance-based cluster**. This is the default option.
 - Under **Cluster configuration**, make sure that **Engine version** 5.0.0 is selected. This is the default option.
 - Under **Instance configuration**:
 - For **DB instance class**, select **Memory optimized classes**. This is the default option.
 - For **Number of regular replica instances**, choose 1.
 - For **Instance class**, use the default selection.

- Under **Authentication**, enter a username for the primary user, and then choose **Self managed**. Enter a password, then confirm it.
 - Keep all other default settings.
3. Choose **Create cluster**.

Create the secret in Secrets Manager

While Amazon DocumentDB is creating your cluster, create an AWS Secrets Manager secret to store your database credentials. You'll provide this secret when you create the Lambda event source mapping in a later step.

To create the secret in Secrets Manager

1. Open the [Secrets Manager](#) console and choose **Store a new secret**.
2. For **Choose secret type**, choose the following options:
 - Under **Basic details**:
 - **Secret type**: Credentials for your Amazon DocumentDB database
 - Under **Credentials**, enter the same username and password that you used to create your Amazon DocumentDB cluster.
 - **Database**: Choose your Amazon DocumentDB cluster.
 - Choose **Next**.
3. For **Configure secret**, choose the following options:
 - **Secret name**: DocumentDBSecret
 - Choose **Next**.
4. Choose **Next**.
5. Choose **Store**.
6. Refresh the console to verify that you successfully stored the DocumentDBSecret secret.

Note the **Secret ARN**. You'll need it in a later step.

Connect to the cluster

Connect to your Amazon DocumentDB cluster using AWS CloudShell

1. On the Amazon DocumentDB management console, under **Clusters**, locate the cluster you created. Choose your cluster by clicking the check box next to it.
2. Choose **Connect to cluster**. The CloudShell **Run command** screen appears.
3. In the **New environment name** field, enter a unique name, such as "test" and choose **Create and run**.
4. When prompted, enter your password. When the prompt becomes `rs0 [direct: primary] <env-name>>`, you are successfully connected to your Amazon DocumentDB cluster.

Activate change streams

For this tutorial, you'll track changes to the `products` collection of the `docdbdemo` database in your Amazon DocumentDB cluster. You do this by activating [change streams](#).

To create a new database within your cluster

1. Run the following command to create a new database called `docdbdemo`:

```
use docdbdemo
```

2. In the terminal window, use the following command to insert a record into `docdbdemo`:

```
db.products.insertOne({"hello":"world"})
```

You should see an output like this:

```
{
  acknowledged: true,
  insertedId: ObjectId('67f85066ca526410fd531d59')
}
```

3. Next, activate change streams on the `products` collection of the `docdbdemo` database using the following command:

```
db.adminCommand({modifyChangeStreams: 1,
  database: "docdbdemo",
```

```
collection: "products",  
enable: true});
```

You should see output that looks like this:

```
{ "ok" : 1, "operationTime" : Timestamp(1680126165, 1) }
```

Create interface VPC endpoints

Next, create [interface VPC endpoints](#) to ensure that Lambda and Secrets Manager (used later to store our cluster access credentials) can connect to your default VPC.

To create interface VPC endpoints

1. Open the [VPC console](#). In the left menu, under **Virtual private cloud**, choose **Endpoints**.
2. Choose **Create endpoint**. Create an endpoint with the following configuration:
 - For **Name tag**, enter `lambda-default-vpc`.
 - For **Service category**, choose AWS services.
 - For **Services**, enter `lambda` in the search box. Choose the service with format `com.amazonaws.<region>.lambda`.
 - For **VPC**, choose the VPC that your Amazon DocumentDB cluster is in. This is typically the [default VPC](#).
 - For **Subnets**, check the boxes next to each availability zone. Choose the correct subnet ID for each availability zone.
 - For **IP address type**, select IPv4.
 - For **Security groups**, choose the security group that your Amazon DocumentDB cluster uses. This is typically the default security group.
 - Keep all other default settings.
 - Choose **Create endpoint**.
3. Again, choose **Create endpoint**. Create an endpoint with the following configuration:
 - For **Name tag**, enter `secretsmanager-default-vpc`.
 - For **Service category**, choose AWS services.

- For **Services**, enter `secretsmanager` in the search box. Choose the service with format `com.amazonaws.<region>.secretsmanager`.
- For **VPC**, choose the VPC that your Amazon DocumentDB cluster is in. This is typically the [default VPC](#).
- For **Subnets**, check the boxes next to each availability zone. Choose the correct subnet ID for each availability zone.
- For **IP address type**, select IPv4.
- For **Security groups**, choose the security group that your Amazon DocumentDB cluster uses. This is typically the default security group.
- Keep all other default settings.
- Choose **Create endpoint**.

This completes the cluster setup portion of this tutorial.

Create the execution role

In the next set of steps, you'll create your Lambda function. First, you need to create the execution role that gives your function permission to access your cluster. You do this by creating an IAM policy first, then attaching this policy to an IAM role.

To create IAM policy

1. Open the [Policies page](#) in the IAM console and choose **Create policy**.
2. Choose the **JSON** tab. In the following policy, replace the Secrets Manager resource ARN in the final line of the statement with your secret ARN from earlier, and copy the policy into the editor.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "LambdaESMNetworkingAccess",
      "Effect": "Allow",
      "Action": [
        "ec2:CreateNetworkInterface",
```

```

        "ec2:DescribeNetworkInterfaces",
        "ec2:DescribeVpcs",
        "ec2:DeleteNetworkInterface",
        "ec2:DescribeSubnets",
        "ec2:DescribeSecurityGroups",
        "kms:Decrypt"
    ],
    "Resource": "*"
},
{
    "Sid": "LambdaDocDBESMAccess",
    "Effect": "Allow",
    "Action": [
        "rds:DescribeDBClusters",
        "rds:DescribeDBClusterParameters",
        "rds:DescribeDBSubnetGroups"
    ],
    "Resource": "*"
},
{
    "Sid": "LambdaDocDBESMGetSecretValueAccess",
    "Effect": "Allow",
    "Action": [
        "secretsmanager:GetSecretValue"
    ],
    "Resource": "arn:aws:secretsmanager:us-east-1:123456789012:secret:DocumentDBSecret"
}
]
}

```

3. Choose **Next: Tags**, then choose **Next: Review**.
4. For **Name**, enter `AWSDocumentDBLambdaPolicy`.
5. Choose **Create policy**.

To create the IAM role

1. Open the [Roles page](#) in the IAM console and choose **Create role**.
2. For **Select trusted entity**, choose the following options:
 - **Trusted entity type**: AWS service

- **Service or use case:** Lambda
 - Choose **Next**.
3. For **Add permissions**, choose the `AWSDocumentDBLambdaPolicy` policy you just created, as well as the `AWSLambdaBasicExecutionRole` to give your function permissions to write to Amazon CloudWatch Logs.
 4. Choose **Next**.
 5. For **Role name**, enter `AWSDocumentDBLambdaExecutionRole`.
 6. Choose **Create role**.

Create the Lambda function

This tutorial uses the Python 3.14 runtime, but we've also provided example code files for other runtimes. You can select the tab in the following box to see the code for the runtime you're interested in.

The code receives an Amazon DocumentDB event input and processes the message that it contains.

To create the Lambda function

1. Open the [Functions page](#) of the Lambda console.
2. Choose **Create function**.
3. Choose **Author from scratch**
4. Under **Basic information**, do the following:
 - a. For **Function name**, enter `ProcessDocumentDBRecords`
 - b. For **Runtime**, choose **Python 3.14**.
 - c. For **Architecture**, choose **x86_64**.
5. In the **Change default execution role** tab, do the following:
 - a. Expand the tab, then choose **Use an existing role**.
 - b. Select the `AWSDocumentDBLambdaExecutionRole` you created earlier.
6. Choose **Create function**.

To deploy the function code

1. Choose the **Python** tab in the following box and copy the code.

Rust

SDK for Rust

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Serverless examples](#) repository.

Consuming a Amazon DocumentDB event with Lambda using Rust.

```
use lambda_runtime::{service_fn, tracing, Error, LambdaEvent};
use aws_lambda_events::{
    event::documentdb::{DocumentDbEvent, DocumentDbInnerEvent},
};

// Built with the following dependencies:
//lambda_runtime = "0.11.1"
//serde_json = "1.0"
//tokio = { version = "1", features = ["macros"] }
//tracing = { version = "0.1", features = ["log"] }
//tracing-subscriber = { version = "0.3", default-features = false, features
    = ["fmt"] }
//aws_lambda_events = "0.15.0"

async fn function_handler(event: LambdaEvent<DocumentDbEvent>) -> Result<(),
    Error> {

    tracing::info!("Event Source ARN: {:?}", event.payload.event_source_arn);
    tracing::info!("Event Source: {:?}", event.payload.event_source);

    let records = &event.payload.events;

    if records.is_empty() {
        tracing::info!("No records found. Exiting.");
        return Ok(());
    }
}
```

```
        for record in records{
            log_document_db_event(record);
        }

        tracing::info!("Document db records processed");

        // Prepare the response
        Ok(())
    }

    fn log_document_db_event(record: &DocumentDbInnerEvent)-> Result<(), Error>{
        tracing::info!("Change Event: {:?}", record.event);

        Ok(())
    }

    #[tokio::main]
    async fn main() -> Result<(), Error> {
        tracing_subscriber::fmt()
            .with_max_level(tracing::Level::INFO)
            .with_target(false)
            .without_time()
            .init();

        let func = service_fn(function_handler);
        lambda_runtime::run(func).await?;
        Ok(())
    }
}
```

2. In the **Code source** pane on the Lambda console, paste the code into the code editor, replacing the code that Lambda created.
3. In the **DEPLOY** section, choose **Deploy** to update your function's code:

Create the Lambda event source mapping

Create the event source mapping that associates your Amazon DocumentDB change stream with your Lambda function. After you create this event source mapping, AWS Lambda immediately starts polling the stream.

To create the event source mapping

1. Open the [Functions page](#) in the Lambda console.
2. Choose the `ProcessDocumentDBRecords` function you created earlier.
3. Choose the **Configuration** tab, then choose **Triggers** in the left menu.
4. Choose **Add trigger**.
5. Under **Trigger configuration**, for the source, select **Amazon DocumentDB**.
6. Create the event source mapping with the following configuration:
 - **Amazon DocumentDB cluster:** Choose the cluster you created earlier.
 - **Database name:** docdbdemo
 - **Collection name:** products
 - **Batch size:** 1
 - **Starting position:** Latest
 - **Authentication:** BASIC_AUTH
 - **Secrets Manager key:** Choose the secret for your Amazon DocumentDB cluster. It will be called something like `rds!cluster-12345678-a6f0-52c0-b290-db4aga89274f`.
 - **Batch window:** 1
 - **Full document configuration:** UpdateLookup
7. Choose **Add**. Creating your event source mapping can take a few minutes.

Test your function

Wait for the event source mapping to reach the **Enabled** state. This can take several minutes. Then, test the end-to-end setup by inserting, updating, and deleting database records. Before you begin:

1. [Reconnect to your Amazon DocumentDB cluster](#) in your CloudShell environment.
2. Run the following command to ensure that you’re using the docdbdemo database:

```
use docdbdemo
```

Insert a record

Insert a record into the products collection of the docdbdemo database:

```
db.products.insertOne({"name":"Pencil", "price": 1.00})
```

Verify that your function successfully processed this event by [checking CloudWatch Logs](#). You should see a log entry like this:

▶	Timestamp	Message
▶	2025-05-05T23:55:23.474Z	Operation type: insert
▶	2025-05-05T23:55:23.474Z	db: docdbdemo
▶	2025-05-05T23:55:23.474Z	collection: products
▶	2025-05-05T23:55:23.474Z	Full document: {
▶	2025-05-05T23:55:23.474Z	"_id": {
▶	2025-05-05T23:55:23.474Z	"\$oid": "68194fea08d12462ea531d58"
▶	2025-05-05T23:55:23.474Z	},
▶	2025-05-05T23:55:23.474Z	"name": "Pencil",
▶	2025-05-05T23:55:23.474Z	"price": 1
▶	2025-05-05T23:55:23.474Z	}

Update a record

Update the record you just inserted with the following command:

```
db.products.updateOne(  
  { "name": "Pencil" },  
  { $set: { "price": 0.50 } }  
)
```

Verify that your function successfully processed this event by [checking CloudWatch Logs](#). You should see a log entry like this:

▶	Timestamp	Message
▶	2025-05-05T23:55:27.918Z	Operation type: update
▶	2025-05-05T23:55:27.918Z	db: docdbdemo
▶	2025-05-05T23:55:27.918Z	collection: products
▶	2025-05-05T23:55:27.918Z	Full document: {
▶	2025-05-05T23:55:27.918Z	"_id": {
▶	2025-05-05T23:55:27.918Z	"\$oid": "68194fea08d12462ea531d58"
▶	2025-05-05T23:55:27.918Z	},
▶	2025-05-05T23:55:27.918Z	"name": "Pencil",
▶	2025-05-05T23:55:27.918Z	"price": 0.5
▶	2025-05-05T23:55:27.918Z	}

Delete a record

Delete the record that you just updated with the following command:

```
db.products.deleteOne( { "name": "Pencil" } )
```

Verify that your function successfully processed this event by [checking CloudWatch Logs](#). You should see a log entry like this:

▶	Timestamp	Message
▶	2025-05-05T23:55:32.362Z	Operation type: delete
▶	2025-05-05T23:55:32.362Z	db: docdbdemo
▶	2025-05-05T23:55:32.362Z	collection: products
▶	2025-05-05T23:55:32.362Z	Full document: {}

Troubleshooting

If you don't see any database events in your function's CloudWatch logs, check the following:

- Make sure that the Lambda event source mapping (also known as a trigger) is in the **Enabled** state. Event source mappings can take several minutes to create.
- If the event source mapping is **Enabled** but you still don't see database events in CloudWatch:
 - Make sure that the **Database name** in the event source mapping is set to docdbdemo.

☐ Trigger

Amazon DocumentDB: [arn:aws:rds:us-east-2:██████████:cluster:docdb-2025-██████████](#)

arn:aws:rds:us-east-2:██████████:cluster:docdb-2025-██████████

state: **Enabled**

▼ Details

Activate trigger: **Yes**

Authentication: **BASIC_AUTH**

Batch size: **1**

Batch window: **1**

Collection name: **products**

Database name: **docdbdemo**

- Check the event source mapping **Last processing result** field for the following message
 "PROBLEM: Connection error. Your VPC must be able to connect to Lambda and STS, as well as Secrets Manager if authentication is required." If you see this error, make sure that you [created the Lambda and Secrets Manager VPC interface endpoints](#), and that the endpoints use the same VPC and subnets that your Amazon DocumentDB cluster uses.

Trigger

Amazon DocumentDB: [arn:aws:rds:us-west-2:\[redacted\]:cluster:docdb-2025-\[redacted\]](#)

arn:aws:rds:us-west-2:[redacted]:cluster:docdb-2025-[redacted]

Last processing result: **PROBLEM: Connection error. Your VPC must be able to connect to Lambda and STS, as well as Secrets Manager if authentication is required. You can provide access by configuring PrivateLink or a NAT Gateway.**

On-failure destination: **None**

Clean up your resources

You can now delete the resources that you created for this tutorial, unless you want to retain them. By deleting AWS resources that you're no longer using, you prevent unnecessary charges to your AWS account.

To delete the Lambda function

1. Open the [Functions page](#) of the Lambda console.
2. Select the function that you created.
3. Choose **Actions, Delete**.
4. Type **confirm** in the text input field and choose **Delete**.

To delete the execution role

1. Open the [Roles page](#) of the IAM console.
2. Select the execution role that you created.
3. Choose **Delete**.
4. Enter the name of the role in the text input field and choose **Delete**.

To delete the VPC endpoints

1. Open the [VPC console](#). In the left menu, under **Virtual private cloud**, choose **Endpoints**.
2. Select the endpoints you created.
3. Choose **Actions, Delete VPC endpoints**.
4. Enter **delete** in the text input field.
5. Choose **Delete**.

To delete the Amazon DocumentDB cluster

1. Open the [Amazon DocumentDB console](#).
2. Choose the Amazon DocumentDB cluster you created for this tutorial, and disable deletion protection.
3. In the main **Clusters** page, choose your Amazon DocumentDB cluster again.
4. Choose **Actions, Delete**.
5. For **Create final cluster snapshot**, select **No**.
6. Enter **delete** in the text input field.
7. Choose **Delete**.

To delete the secret in Secrets Manager

1. Open the [Secrets Manager](#) console.
2. Choose the secret you created for this tutorial.
3. Choose **Actions, Delete secret**.
4. Choose **Schedule deletion**.

Using AWS Lambda with Amazon DynamoDB

Note

If you want to send data to a target other than a Lambda function or enrich the data before sending it, see [Amazon EventBridge Pipes](#).

You can use an AWS Lambda function to process records in an [Amazon DynamoDB stream](#). With DynamoDB Streams, you can trigger a Lambda function to perform additional work each time a DynamoDB table is updated.

When processing DynamoDB streams, you need to implement partial batch response logic to prevent successfully processed records from being retried when some records in a batch fail. The [Batch Processor utility](#) from Powertools for AWS Lambda is available in Python, TypeScript, .NET, and Java and simplifies this implementation by automatically handling partial batch response logic, reducing development time and improving reliability.

Topics

- [Polling and batching streams](#)
- [Polling and stream starting positions](#)
- [Simultaneous readers of a shard in DynamoDB Streams](#)
- [Example event](#)
- [Process DynamoDB records with Lambda](#)
- [Configuring partial batch response with DynamoDB and Lambda](#)
- [Retain discarded records for a DynamoDB event source in Lambda](#)
- [Implementing stateful DynamoDB stream processing in Lambda](#)
- [Lambda parameters for Amazon DynamoDB event source mappings](#)
- [Using event filtering with a DynamoDB event source](#)
- [Tutorial: Using AWS Lambda with Amazon DynamoDB streams](#)

Polling and batching streams

Lambda polls shards in your DynamoDB stream for records at a base rate of 4 times per second. When records are available, Lambda invokes your function and waits for the result. If processing succeeds, Lambda resumes polling until it receives more records.

By default, Lambda invokes your function as soon as records are available. If the batch that Lambda reads from the event source has only one record in it, Lambda sends only one record to the function. To avoid invoking the function with a small number of records, you can tell the event source to buffer records for up to 5 minutes by configuring a *batching window*. Before invoking the function, Lambda continues to read records from the event source until it has gathered a full batch, the batching window expires, or the batch reaches the payload limit of 6 MB. For more information, see [Batching behavior](#).

Warning

Lambda event source mappings process each event at least once, and duplicate processing of records can occur. To avoid potential issues related to duplicate events, we strongly recommend that you make your function code idempotent. To learn more, see [How do I make my Lambda function idempotent](#) in the AWS Knowledge Center.

Lambda doesn't wait for any configured [extensions](#) to complete before sending the next batch for processing. In other words, your extensions may continue to run as Lambda processes the next batch of records. This can cause throttling issues if you breach any of your account's [concurrency](#) settings or limits. To detect whether this is a potential issue, monitor your functions and check whether you're seeing higher [concurrency metrics](#) than expected for your event source mapping. Due to short times in between invokes, Lambda may briefly report higher concurrency usage than the number of shards. This can be true even for Lambda functions without extensions.

Configure the [ParallelizationFactor](#) setting to process one shard of a DynamoDB stream with more than one Lambda invocation simultaneously. You can specify the number of concurrent batches that Lambda polls from a shard via a parallelization factor from 1 (default) to 10. For example, when you set `ParallelizationFactor` to 2, you can have 200 concurrent Lambda invocations at maximum to process 100 DynamoDB stream shards (though in practice, you may see different values for the `ConcurrentExecutions` metric). This helps scale up the processing throughput when the data volume is volatile and the [IteratorAge](#) is high. When you increase the number of

concurrent batches per shard, Lambda still ensures in-order processing at the item (partition and sort key) level.

Polling and stream starting positions

Be aware that stream polling during event source mapping creation and updates is eventually consistent.

- During event source mapping creation, it may take several minutes to start polling events from the stream.
- During event source mapping updates, it may take several minutes to stop and restart polling events from the stream.

This behavior means that if you specify LATEST as the starting position for the stream, the event source mapping could miss events during creation or updates. To ensure that no events are missed, specify the stream starting position as TRIM_HORIZON.

Simultaneous readers of a shard in DynamoDB Streams

For single-Region tables that are not global tables, you can design for up to two Lambda functions to read from the same DynamoDB Streams shard at the same time. Exceeding this limit can result in request throttling. For global tables, we recommend you limit the number of simultaneous functions to one to avoid request throttling.

Example event

Example

```
{
  "Records": [
    {
      "eventID": "1",
      "eventVersion": "1.0",

}
```

Process DynamoDB records with Lambda

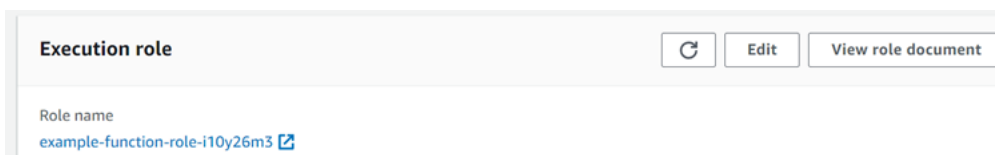

Create an event source mapping to tell Lambda to send records from your stream to a Lambda function. You can create multiple event source mappings to process the same data with multiple Lambda functions, or to process items from multiple streams with a single function.

You can configure event source mappings to process records from a stream in a different AWS account. To learn more, see [the section called “Cross-account mappings”](#).

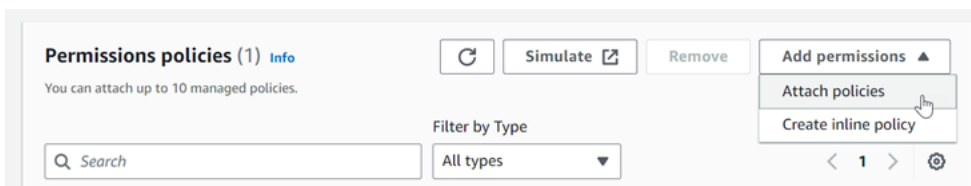

To configure your function to read from DynamoDB Streams, attach the [AWSLambdaDynamoDBExecutionRole](#) AWS managed policy to your execution role and then create a **DynamoDB** trigger.

To add permissions and create a trigger

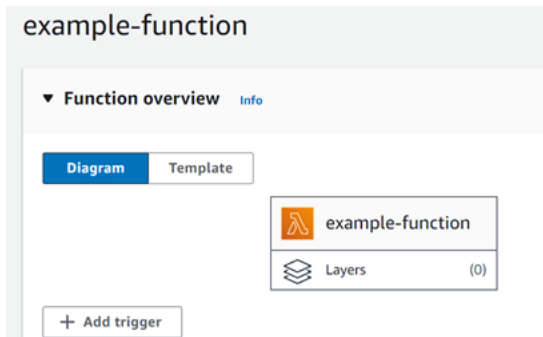

1. Open the [Functions page](#) of the Lambda console.
2. Choose the name of a function.
3. Choose the **Configuration** tab, and then choose **Permissions**.
4. Under **Role name**, choose the link to your execution role. This link opens the role in the IAM console.

5. Choose **Add permissions**, and then choose **Attach policies**.

6. In the search field, enter `AWSLambdaDynamoDBExecutionRole`. Add this policy to your execution role. This is an AWS managed policy that contains the permissions your function needs to read from the DynamoDB stream. For more information about this policy, see [AWSLambdaDynamoDBExecutionRole](#) in the *AWS Managed Policy Reference*.
7. Go back to your function in the Lambda console. Under **Function overview**, choose **Add trigger**.

8. Choose a trigger type.
9. Configure the required options, and then choose **Add**.

Lambda supports the following options for DynamoDB event sources:

Event source options

- **DynamoDB table** – The DynamoDB table to read records from.
- **Batch size** – The number of records to send to the function in each batch, up to 10,000. Lambda passes all of the records in the batch to the function in a single call, as long as the total size of the events doesn't exceed the [payload limit](#) for synchronous invocation (6 MB).
- **Batch window** – Specify the maximum amount of time to gather records before invoking the function, in seconds.
- **Starting position** – Process only new records, or all existing records.
 - **Latest** – Process new records that are added to the stream.
 - **Trim horizon** – Process all records in the stream.

After processing any existing records, the function is caught up and continues to process new records.

- **On-failure destination** – A standard SQS queue or standard SNS topic for records that can't be processed. When Lambda discards a batch of records that's too old or has exhausted all retries, Lambda sends details about the batch to the queue or topic.

- **Retry attempts** – The maximum number of times that Lambda retries when the function returns an error. This doesn't apply to service errors or throttles where the batch didn't reach the function.
- **Maximum age of record** – The maximum age of a record that Lambda sends to your function.
- **Split batch on error** – When the function returns an error, split the batch into two before retrying. Your original batch size setting remains unchanged.
- **Concurrent batches per shard** – Concurrently process multiple batches from the same shard.
- **Enabled** – Set to true to enable the event source mapping. Set to false to stop processing records. Lambda keeps track of the last record processed and resumes processing from that point when the mapping is reenabled.

Note

You are not charged for GetRecords API calls invoked by Lambda as part of DynamoDB triggers.

To manage the event source configuration later, choose the trigger in the designer.

Creating a cross-account event source mapping

Amazon DynamoDB now supports [resource-based policies](#). With this capability, you can process data from a DynamoDB stream in one AWS account with a Lambda function in another account.

To create an event source mapping for your Lambda function using a DynamoDB stream in a different AWS account, you must configure the stream using a resource-based policy to give your Lambda function permission to read records. To learn how to configure your stream for cross-account access, see [Share access with cross-account Lambda functions](#) in the *Amazon DynamoDB Developer Guide*.

Once you have configured your stream with a resource-based policy that gives your Lambda function the required permissions, create the event source mapping with your cross-account stream ARN. You can find the stream ARN under the table's **Exports and streams** tab in the cross-account DynamoDB console.

When using the Lambda console, paste the stream ARN directly into the DynamoDB table input field in the event source mapping creation page.

Note: Cross-region triggers are not supported.

Configuring partial batch response with DynamoDB and Lambda

When consuming and processing streaming data from an event source, by default Lambda checkpoints to the highest sequence number of a batch only when the batch is a complete success. Lambda treats all other results as a complete failure and retries processing the batch up to the retry limit. To allow for partial successes while processing batches from a stream, turn on `ReportBatchItemFailures`. Allowing partial successes can help to reduce the number of retries on a record, though it doesn't entirely prevent the possibility of retries in a successful record.

To turn on `ReportBatchItemFailures`, include the enum value **`ReportBatchItemFailures`** in the [FunctionResponseTypes](#) list. This list indicates which response types are enabled for your function. You can configure this list when you [create](#) or [update](#) an event source mapping.

Note

Even when your function code returns partial batch failure responses, these responses will not be processed by Lambda unless the `ReportBatchItemFailures` feature is explicitly turned on for your event source mapping.

Report syntax

When configuring reporting on batch item failures, the `StreamsEventResponse` class is returned with a list of batch item failures. You can use a `StreamsEventResponse` object to return the sequence number of the first failed record in the batch. You can also create your own custom class using the correct response syntax. The following JSON structure shows the required response syntax:

```
{
  "batchItemFailures": [
    {
      "itemIdentifier": "<SequenceNumber>"
    }
  ]
}
```

Note

If the `batchItemFailures` array contains multiple items, Lambda uses the record with the lowest sequence number as the checkpoint. Lambda then retries all records starting from that checkpoint.

Success and failure conditions

Lambda treats a batch as a complete success if you return any of the following:

- An empty `batchItemFailure` list
- A null `batchItemFailure` list
- An empty `EventResponse`
- A null `EventResponse`

Lambda treats a batch as a complete failure if you return any of the following:

- An empty string `itemIdentifier`
- A null `itemIdentifier`
- An `itemIdentifier` with a bad key name

Lambda retries failures based on your retry strategy.

Bisecting a batch

If your invocation fails and `BisectBatchOnFunctionError` is turned on, the batch is bisected regardless of your `ReportBatchItemFailures` setting.

When a partial batch success response is received and both `BisectBatchOnFunctionError` and `ReportBatchItemFailures` are turned on, the batch is bisected at the returned sequence number and Lambda retries only the remaining records.

To simplify the implementation of partial batch response logic, consider using the [Batch Processor utility](#) from Powertools for AWS Lambda, which automatically handles these complexities for you.

Here are some examples of function code that return the list of failed message IDs in the batch:

        time.
        .without_time()
        .init();

    run(service_fn(function_handler)).await
}

```

Using Powertools for AWS Lambda batch processor

The batch processor utility from Powertools for AWS Lambda automatically handles partial batch response logic, reducing the complexity of implementing batch failure reporting. Here are examples using the batch processor:

Python

Note

For complete examples and setup instructions, see the [batch processor documentation](#).

Processing DynamoDB stream records with AWS Lambda batch processor.

```
import json
from aws_lambda_powertools import Logger
from aws_lambda_powertools.utilities.batch import BatchProcessor, EventType,
    process_partial_response
from aws_lambda_powertools.utilities.data_classes import DynamoDBStreamEvent
from aws_lambda_powertools.utilities.typing import LambdaContext

processor = BatchProcessor(event_type=EventType.DynamoDBStreams)
logger = Logger()

def record_handler(record):
    logger.info(record)
    # Your business logic here
    # Raise an exception to mark this record as failed

def lambda_handler(event, context: LambdaContext):
    return process_partial_response(
        event=event,
        record_handler=record_handler,
        processor=processor,
        context=context
    )
```

TypeScript

Note

For complete examples and setup instructions, see the [batch processor documentation](#).

Processing DynamoDB stream records with AWS Lambda batch processor.

```
import { BatchProcessor, EventType, processPartialResponse } from '@aws-lambda-powertools/batch';
import { Logger } from '@aws-lambda-powertools/logger';
import type { DynamoDBStreamEvent, Context } from 'aws-lambda';

const processor = new BatchProcessor(EventType.DynamoDBStreams);
const logger = new Logger();

const recordHandler = async (record: any): Promise<void> => {
  logger.info('Processing record', { record });
  // Your business logic here
  // Throw an error to mark this record as failed
};

export const handler = async (event: DynamoDBStreamEvent, context: Context) => {
  return processPartialResponse(event, recordHandler, processor, {
    context,
  });
};
```

    private void processMessage(DynamodbEvent.DynamodbStreamRecord
dynamodbStreamRecord, Context context) {
        // Process the change record
    }
}

```

.NET

Note

For complete examples and setup instructions, see the [batch processor documentation](#).

Processing DynamoDB stream records with AWS Lambda batch processor.

```

using System;
using System.Threading;
using System.Threading.Tasks;
using Amazon.Lambda.Core;
using Amazon.Lambda.DynamoDBEvents;
using Amazon.Lambda.Serialization.SystemTextJson;
using AWS.Lambda.Powertools.BatchProcessing;

```

```
[assembly: LambdaSerializer(typeof(DefaultLambdaJsonSerializer))]

namespace HelloWorld;

public class Customer
{
    public string? CustomerId { get; set; }
    public string? Name { get; set; }
    public string? Email { get; set; }
    public DateTime CreatedAt { get; set; }
}

internal class TypedDynamoDbRecordHandler : ITypedRecordHandler<Customer>
{
    public async Task<RecordHandlerResult> HandleAsync(Customer customer,
        CancellationToken cancellationToken)
    {
        if (string.IsNullOrEmpty(customer.Email))
        {
            throw new ArgumentException("Customer email is required");
        }

        return await Task.FromResult(RecordHandlerResult.None);
    }
}

public class Function
{
    [BatchProcessor(TypedRecordHandler = typeof(TypedDynamoDbRecordHandler))]
    public BatchItemFailuresResponse HandlerUsingTypedAttribute(DynamoDBEvent _)
    {
        return TypedDynamoDbStreamBatchProcessor.Result.BatchItemFailuresResponse;
    }
}
```

Retain discarded records for a DynamoDB event source in Lambda

Error handling for DynamoDB event source mappings depends on whether the error occurs before the function is invoked or during function invocation:

- **Before invocation:** If a Lambda event source mapping is unable to invoke the function due to throttling or other issues, it retries until the records expire or exceed the maximum age configured on the event source mapping ([MaximumRecordAgeInSeconds](#)).
- **During invocation:** If the function is invoked but returns an error, Lambda retries until the records expire, exceed the maximum age ([MaximumRecordAgeInSeconds](#)), or reach the configured retry quota ([MaximumRetryAttempts](#)). For function errors, you can also configure [BisectBatchOnFunctionError](#), which splits a failed batch into two smaller batches, isolating bad records and avoiding timeouts. Splitting batches doesn't consume the retry quota.

If the error handling measures fail, Lambda discards the records and continues processing batches from the stream. With the default settings, this means that a bad record can block processing on the affected shard for up to one day. To avoid this, configure your function's event source mapping with a reasonable number of retries and a maximum record age that fits your use case.

Configuring destinations for failed invocations

To retain records of failed event source mapping invocations, add a destination to your function's event source mapping. Each record sent to the destination is a JSON document containing metadata about the failed invocation. For Amazon S3 destinations, Lambda also sends the entire invocation record along with the metadata. You can configure any Amazon SNS topic, Amazon SQS queue, Amazon S3 bucket, or Kafka as a destination.

With Amazon S3 destinations, you can use the [Amazon S3 Event Notifications](#) feature to receive notifications when objects are uploaded to your destination S3 bucket. You can also configure S3 Event Notifications to invoke another Lambda function to perform automated processing on failed batches.

Your execution role must have permissions for the destination:

- **For an SQS destination:** [sqs:SendMessage](#)
- **For an SNS destination:** [sns:Publish](#)
- **For an S3 destination:** [s3:PutObject](#) and [s3:ListBucket](#)
- **For a Kafka destination:** [kafka-cluster:WriteData](#)

You can configure a Kafka topic as an on-failure destination for your Kafka event source mappings. When Lambda can't process records after exhausting retry attempts or when records exceed the

maximum age, Lambda sends the failed records to the specified Kafka topic for later processing. Refer to [the section called “Kafka on-failure destination”](#).

If you've enabled encryption with your own KMS key for an S3 destination, your function's execution role must also have permission to call [kms:GenerateDataKey](#). If the KMS key and S3 bucket destination are in a different account from your Lambda function and execution role, configure the KMS key to trust the execution role to allow `kms:GenerateDataKey`.

To configure an on-failure destination using the console, follow these steps:

1. Open the [Functions page](#) of the Lambda console.
2. Choose a function.
3. Under **Function overview**, choose **Add destination**.
4. For **Source**, choose **Event source mapping invocation**.
5. For **Event source mapping**, choose an event source that's configured for this function.
6. For **Condition**, select **On failure**. For event source mapping invocations, this is the only accepted condition.
7. For **Destination type**, choose the destination type that Lambda sends invocation records to.
8. For **Destination**, choose a resource.
9. Choose **Save**.

You can also configure an on-failure destination using the AWS Command Line Interface (AWS CLI). For example, the following [create-event-source-mapping](#) command adds an event source mapping with an SQS on-failure destination to MyFunction:

```
aws lambda create-event-source-mapping \  
--function-name "MyFunction" \  
--event-source-arn arn:aws:dynamodb:us-east-2:123456789012:table/my-table/  
stream/2024-06-10T19:26:16.525 \  
--destination-config '{"OnFailure": {"Destination": "arn:aws:sqs:us-  
east-1:123456789012:dest-queue"}}'
```

The following [update-event-source-mapping](#) command updates an event source mapping to send failed invocation records to an SNS destination after two retry attempts, or if the records are more than an hour old.

```
aws lambda update-event-source-mapping \  

```

```
--uuid f89f8514-cdd9-4602-9e1f-01a5b77d449b \  
--maximum-retry-attempts 2 \  
--maximum-record-age-in-seconds 3600 \  
--destination-config '{"OnFailure": {"Destination": "arn:aws:sns:us-  
east-1:123456789012:dest-topic"}}'
```

Updated settings are applied asynchronously and aren't reflected in the output until the process completes. Use the [get-event-source-mapping](#) command to view the current status.

To remove a destination, supply an empty string as the argument to the `destination-config` parameter:

```
aws lambda update-event-source-mapping \  
--uuid f89f8514-cdd9-4602-9e1f-01a5b77d449b \  
--destination-config '{"OnFailure": {"Destination": ""}}'
```

Security best practices for Amazon S3 destinations

Deleting an S3 bucket that's configured as a destination without removing the destination from your function's configuration can create a security risk. If another user knows your destination bucket's name, they can recreate the bucket in their AWS account. Records of failed invocations will be sent to their bucket, potentially exposing data from your function.

Warning

To ensure that invocation records from your function can't be sent to an S3 bucket in another AWS account, add a condition to your function's execution role that limits `s3:PutObject` permissions to buckets in your account.

The following example shows an IAM policy that limits your function's `s3:PutObject` permissions to buckets in your account. This policy also gives Lambda the `s3:ListBucket` permission it needs to use an S3 bucket as a destination.

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Sid": "S3BucketResourceAccountWrite",
```

```

    "Effect": "Allow",
    "Action": [
        "s3:PutObject",
        "s3:ListBucket"
    ],
    "Resource": [
        "arn:aws:s3:::*/*",
        "arn:aws:s3:::*"
    ],
    "Condition": {
        "StringEquals": {
            "s3:ResourceAccount": "111122223333"
        }
    }
}
]
}

```

To add a permissions policy to your function's execution role using the AWS Management Console or AWS CLI, refer to the instructions in the following procedures:

Console

To add a permissions policy to a function's execution role (console)

1. Open the [Functions page](#) of the Lambda console.
2. Select the Lambda function whose execution role you want to modify.
3. In the **Configuration** tab, select **Permissions**.
4. In the **Execution role** tab, select your function's **Role name** to open the role's IAM console page.
5. Add a permissions policy to the role by doing the following:
 - a. In the **Permissions policies** pane, choose **Add permissions** and select **Create inline policy**.
 - b. In **Policy editor**, select **JSON**.
 - c. Paste the policy you want to add into the editor (replacing the existing JSON), and then choose **Next**.
 - d. Under **Policy details**, enter a **Policy name**.
 - e. Choose **Create policy**.

AWS CLI

To add a permissions policy to a function's execution role (CLI)

1. Create a JSON policy document with the required permissions and save it in a local directory.
2. Use the IAM `put-role-policy` CLI command to add the permissions to your function's execution role. Run the following command from the directory you saved your JSON policy document in and replace the role name, policy name, and policy document with your own values.

```
aws iam put-role-policy \  
--role-name my_lambda_role \  
--policy-name LambdaS3DestinationPolicy \  
--policy-document file://my_policy.json
```

Example Amazon SNS and Amazon SQS invocation record

The following example shows an invocation record Lambda sends to an SQS or SNS destination for a DynamoDB stream.

```
{  
  "requestContext": {  
    "requestId": "316aa6d0-8154-xmpl-9af7-85d5f4a6bc81",  
    "functionArn": "arn:aws:lambda:us-east-2:123456789012:function:myfunction",  
    "condition": "RetryAttemptsExhausted",  
    "approximateInvokeCount": 1  
  },  
  "responseContext": {  
    "statusCode": 200,  
    "executedVersion": "$LATEST",  
    "functionError": "Unhandled"  
  },  
  "version": "1.0",  
  "timestamp": "2019-11-14T00:13:49.717Z",  
  "DDBStreamBatchInfo": {  
    "shardId": "shardId-000000001573689847184-864758bb",  
    "startSequenceNumber": "800000000003126276362",  
    "endSequenceNumber": "800000000003126276362",  
    "approximateArrivalOfFirstRecord": "2019-11-14T00:13:19Z",  
    "approximateArrivalOfLastRecord": "2019-11-14T00:13:19Z",  
  }  
}
```

```

        "batchSize": 1,
        "streamArn": "arn:aws:dynamodb:us-east-2:123456789012:table/mytable/
stream/2019-11-14T00:04:06.388"
    }
}

```

You can use this information to retrieve the affected records from the stream for troubleshooting. The actual records aren't included, so you must process this record and retrieve them from the stream before they expire and are lost.

Example Amazon S3 invocation record

The following example shows an invocation record Lambda sends to an S3 bucket for a DynamoDB stream. In addition to all of the fields from the previous example for SQS and SNS destinations, the `payload` field contains the original invocation record as an escaped JSON string.

```

{
  "requestContext": {
    "requestId": "316aa6d0-8154-xmpl-9af7-85d5f4a6bc81",
    "functionArn": "arn:aws:lambda:us-east-2:123456789012:function:myfunction",
    "condition": "RetryAttemptsExhausted",
    "approximateInvokeCount": 1
  },
  "responseContext": {
    "statusCode": 200,
    "executedVersion": "$LATEST",
    "functionError": "Unhandled"
  },
  "version": "1.0",
  "timestamp": "2019-11-14T00:13:49.717Z",
  "DDBStreamBatchInfo": {
    "shardId": "shardId-00000001573689847184-864758bb",
    "startSequenceNumber": "800000000003126276362",
    "endSequenceNumber": "800000000003126276362",
    "approximateArrivalOfFirstRecord": "2019-11-14T00:13:19Z",
    "approximateArrivalOfLastRecord": "2019-11-14T00:13:19Z",
    "batchSize": 1,
    "streamArn": "arn:aws:dynamodb:us-east-2:123456789012:table/mytable/
stream/2019-11-14T00:04:06.388"
  },
  "payload": "<Whole Event>" // Only available in S3
}

```

The S3 object containing the invocation record uses the following naming convention:

```
aws/lambda/<ESM-UUID>/<shardID>/YYYY/MM/DD/YYYY-MM-DDTHH.MM.SS-<Random UUID>
```

Implementing stateful DynamoDB stream processing in Lambda

Lambda functions can run continuous stream processing applications. A stream represents unbounded data that flows continuously through your application. To analyze information from this continuously updating input, you can bound the included records using a window defined in terms of time.

Tumbling windows are distinct time windows that open and close at regular intervals. By default, Lambda invocations are stateless—you cannot use them for processing data across multiple continuous invocations without an external database. However, with tumbling windows, you can maintain your state across invocations. This state contains the aggregate result of the messages previously processed for the current window. Your state can be a maximum of 1 MB per shard. If it exceeds that size, Lambda terminates the window early.

Each record in a stream belongs to a specific window. Lambda will process each record at least once, but doesn't guarantee that each record will be processed only once. In rare cases, such as error handling, some records might be processed more than once. Records are always processed in order the first time. If records are processed more than once, they might be processed out of order.

Aggregation and processing

Your user managed function is invoked both for aggregation and for processing the final results of that aggregation. Lambda aggregates all records received in the window. You can receive these records in multiple batches, each as a separate invocation. Each invocation receives a state. Thus, when using tumbling windows, your Lambda function response must contain a state property. If the response does not contain a state property, Lambda considers this a failed invocation. To satisfy this condition, your function can return a `TimeWindowEventResponse` object, which has the following JSON shape:

Example `TimeWindowEventResponse` values

```
{
  "state": {
    "1": 282,
    "2": 715
  },

```

```
"batchItemFailures": []  
}
```

Note

For Java functions, we recommend using a `Map<String, String>` to represent the state.

At the end of the window, the flag `isFinalInvokeForWindow` is set to `true` to indicate that this is the final state and that it's ready for processing. After processing, the window completes and your final invocation completes, and then the state is dropped.

At the end of your window, Lambda uses final processing for actions on the aggregation results. Your final processing is synchronously invoked. After successful invocation, your function checkpoints the sequence number and stream processing continues. If invocation is unsuccessful, your Lambda function suspends further processing until a successful invocation.

Example `DynamodbTimeWindowEvent`

```
{  
  "Records": [  
    {  
      "eventID": "1",  
      "eventName": "INSERT",  
      "eventVersion": "1.0",  
      "eventSource": "aws:dynamodb",  
      "awsRegion": "us-east-1",  
      "dynamodb": {  
        "Keys": {  
          "Id": {  
            "N": "101"  
          }  
        },  
        "NewImage": {  
          "Message": {  
            "S": "New item!"  
          },  
          "Id": {  
            "N": "101"  
          }  
        }  
      },  
    ],  
  ],  
}
```

```

        "SequenceNumber": "111",
        "SizeBytes": 26,
        "StreamViewType": "NEW_AND_OLD_IMAGES"
    },
    "eventSourceARN": "stream-ARN"
},
{
    "eventID": "2",
    "eventName": "MODIFY",
    "eventVersion": "1.0",
    "eventSource": "aws:dynamodb",
    "awsRegion": "us-east-1",
    "dynamodb": {
        "Keys": {
            "Id": {
                "N": "101"
            }
        },
        "NewImage": {
            "Message": {
                "S": "This item has changed"
            },
            "Id": {
                "N": "101"
            }
        },
        "OldImage": {
            "Message": {
                "S": "New item!"
            },
            "Id": {
                "N": "101"
            }
        },
        "SequenceNumber": "222",
        "SizeBytes": 59,
        "StreamViewType": "NEW_AND_OLD_IMAGES"
    },
    "eventSourceARN": "stream-ARN"
},
{
    "eventID": "3",
    "eventName": "REMOVE",
    "eventVersion": "1.0",

```

```

    "eventSource": "aws:dynamodb",
    "awsRegion": "us-east-1",
    "dynamodb": {
        "Keys": {
            "Id": {
                "N": "101"
            }
        },
        "OldImage": {
            "Message": {
                "S": "This item has changed"
            },
            "Id": {
                "N": "101"
            }
        },
        "SequenceNumber": "333",
        "SizeBytes": 38,
        "StreamViewType": "NEW_AND_OLD_IMAGES"
    },
    "eventSourceARN": "stream-ARN"
}
],
"window": {
    "start": "2020-07-30T17:00:00Z",
    "end": "2020-07-30T17:05:00Z"
},
"state": {
    "1": "state1"
},
"shardId": "shard123456789",
"eventSourceARN": "stream-ARN",
"isFinalInvokeForWindow": false,
"isWindowTerminatedEarly": false
}

```

Configuration

You can configure tumbling windows when you create or update an event source mapping. To configure a tumbling window, specify the window in seconds ([TumblingWindowInSeconds](#)). The following example AWS Command Line Interface (AWS CLI) command creates a streaming event source mapping that has a tumbling window of 120 seconds. The Lambda function defined for aggregation and processing is named `tumbling-window-example-function`.

```
aws lambda create-event-source-mapping \  
--event-source-arn arn:aws:dynamodb:us-east-2:123456789012:table/my-table/  
stream/2024-06-10T19:26:16.525 \  
--function-name tumbling-window-example-function \  
--starting-position TRIM_HORIZON \  
--tumbling-window-in-seconds 120
```

Lambda determines tumbling window boundaries based on the time when records were inserted into the stream. All records have an approximate timestamp available that Lambda uses in boundary determinations.

Tumbling window aggregations do not support resharding. When the shard ends, Lambda considers the window closed, and the child shards start their own window in a fresh state.

Tumbling windows fully support the existing retry policies `maxRetryAttempts` and `maxRecordAge`.

Example Handler.py – Aggregation and processing

The following Python function demonstrates how to aggregate and then process your final state:

```
def lambda_handler(event, context):  
    print('Incoming event: ', event)  
    print('Incoming state: ', event['state'])  
  
    #Check if this is the end of the window to either aggregate or process.  
    if event['isFinalInvokeForWindow']:  
        # logic to handle final state of the window  
        print('Destination invoke')  
    else:  
        print('Aggregate invoke')  
  
    #Check for early terminations  
    if event['isWindowTerminatedEarly']:  
        print('Window terminated early')  
  
    #Aggregation logic  
    state = event['state']  
    for record in event['Records']:  
        state[record['dynamodb']['NewImage']['Id']] = state.get(record['dynamodb']  
        ['NewImage']['Id'], 0) + 1  
  
    print('Returning state: ', state)
```

```
return {'state': state}
```

Lambda parameters for Amazon DynamoDB event source mappings

All Lambda event source types share the same [CreateEventSourceMapping](#) and [UpdateEventSourceMapping](#) API operations. However, only some of the parameters apply to DynamoDB Streams.

Parameter	Required	Default	Notes
BatchSize	N	100	Maximum: 10,000
BisectBatchOnFunctionError	N	false	none
DestinationConfig	N	N/A	Standard Amazon SQS queue or standard Amazon SNS topic destination for discarded records
Enabled	N	true	none
EventSourceArn	Y	N/A	ARN of the data stream or a stream consumer
FilterCriteria	N	N/A	Control which events Lambda sends to your function
FunctionName	Y	N/A	none
FunctionResponseType	N	N/A	To let your function report specific failures in a batch, include the value <code>ReportBatchItemFailures</code>

Parameter	Required	Default	Notes
			in FunctionResponseTypes . For more information, see Configuring partial batch response with DynamoDB and Lambda .
MaximumBatchingWindowInSeconds	N	0	none
MaximumRecordAgeInSeconds	N	-1	-1 means infinite: failed records are retried until the record expires. The data retention limit for DynamoDB Streams is 24 hours. Minimum: -1 Maximum: 604,800
MaximumRetryAttempts	N	-1	-1 means infinite: failed records are retried until the record expires Minimum: 0 Maximum: 10,000
ParallelizationFactor	N	1	Maximum: 10

Parameter	Required	Default	Notes
StartingPosition	Y	N/A	TRIM_HORIZON or LATEST
TumblingWindowInSeconds	N	N/A	Minimum: 0 Maximum: 900

Using event filtering with a DynamoDB event source

You can use event filtering to control which records from a stream or queue Lambda sends to your function. For general information about how event filtering works, see [the section called “Event filtering”](#).

This section focuses on event filtering for DynamoDB event sources.

Note

DynamoDB event source mappings only support filtering on the dynamodb key.

Topics

- [DynamoDB event](#)
- [Filtering with table attributes](#)
- [Filtering with Boolean expressions](#)
- [Using the Exists operator](#)
- [JSON format for DynamoDB filtering](#)

DynamoDB event

Suppose you have a DynamoDB table with the primary key `CustomerName` and attributes `AccountManager` and `PaymentTerms`. The following shows an example record from your DynamoDB table's stream.

```
{  
    "eventID": "1",
```

```

    "eventVersion": "1.0",
    "dynamodb": {
      "ApproximateCreationDateTime": "1678831218.0",
      "Keys": {
        "CustomerName": {
          "S": "AnyCompany Industries"
        }
      },
      "NewImage": {
        "AccountManager": {
          "S": "Pat Candella"
        },
        "PaymentTerms": {
          "S": "60 days"
        },
        "CustomerName": {
          "S": "AnyCompany Industries"
        }
      },
      "SequenceNumber": "111",
      "SizeBytes": 26,
      "StreamViewType": "NEW_IMAGE"
    }
  }
}

```

To filter based on the key and attribute values in your DynamoDB table, use the `dynamodb` key in the record. The following sections provide examples for different filter types.

Filtering with table keys

Suppose you want your function to process only those records where the primary key `CustomerName` is "AnyCompany Industries." The `FilterCriteria` object would be as follows.

```

{
  "Filters": [
    {
      "Pattern": "{ \"dynamodb\" : { \"Keys\" : { \"CustomerName\" : { \"S\" : [ \"AnyCompany Industries\" ] } } } }"
    }
  ]
}

```

For added clarity, here is the value of the filter's `Pattern` expanded in plain JSON.

```
{
  "dynamodb": {
    "Keys": {
      "CustomerName": {
        "S": [ "AnyCompany Industries" ]
      }
    }
  }
}
```

You can add your filter using the console, AWS CLI or an AWS SAM template.

Console

To add this filter using the console, follow the instructions in [Attaching filter criteria to an event source mapping \(console\)](#) and enter the following string for the **Filter criteria**.

```
{ "dynamodb" : { "Keys" : { "CustomerName" : { "S" : [ "AnyCompany Industries" ] } } } }
```

AWS CLI

To create a new event source mapping with these filter criteria using the AWS Command Line Interface (AWS CLI), run the following command.

```
aws lambda create-event-source-mapping \
  --function-name my-function \
  --event-source-arn arn:aws:dynamodb:us-east-2:123456789012:table/my-table \
  --filter-criteria '{"Filters": [{"Pattern": "{ \"dynamodb\" : { \"Keys\" : { \"CustomerName\" : { \"S\" : [ \"AnyCompany Industries\" ] } } } }"]}]'
```

To add these filter criteria to an existing event source mapping, run the following command.

```
aws lambda update-event-source-mapping \
  --uuid "a1b2c3d4-5678-90ab-cdef-1111EXAMPLE" \
  --filter-criteria '{"Filters": [{"Pattern": "{ \"dynamodb\" : { \"Keys\" : { \"CustomerName\" : { \"S\" : [ \"AnyCompany Industries\" ] } } } }"]}]'
```

AWS SAM

To add this filter using AWS SAM, add the following snippet to the YAML template for your event source.

```
FilterCriteria:
  Filters:
    - Pattern: '{ "dynamodb" : { "Keys" : { "CustomerName" : { "S" : [ "AnyCompany Industries" ] } } } }'
```

Filtering with table attributes

With DynamoDB, you can also use the `NewImage` and `OldImage` keys to filter for attribute values. Suppose you want to filter records where the `AccountManager` attribute in the latest table image is "Pat Candella" or "Shirley Rodriguez." The `FilterCriteria` object would be as follows.

```
{
  "Filters": [
    {
      "Pattern": "{ \"dynamodb\" : { \"NewImage\" : { \"AccountManager\" : { \"S\" : [ \"Pat Candella\", \"Shirley Rodriguez\" ] } } } }"    }
  ]
}
```

For added clarity, here is the value of the filter's `Pattern` expanded in plain JSON.

```
{
  "dynamodb": {
    "NewImage": {
      "AccountManager": {
        "S": [ "Pat Candella", "Shirley Rodriguez" ]
      }
    }
  }
}
```

You can add your filter using the console, AWS CLI or an AWS SAM template.

Console

To add this filter using the console, follow the instructions in [Attaching filter criteria to an event source mapping \(console\)](#) and enter the following string for the **Filter criteria**.

```
{ "dynamodb" : { "NewImage" : { "AccountManager" : { "S" : [ "Pat Candella",
"Shirley Rodriguez" ] } } } }
```

AWS CLI

To create a new event source mapping with these filter criteria using the AWS Command Line Interface (AWS CLI), run the following command.

```
aws lambda create-event-source-mapping \
  --function-name my-function \
  --event-source-arn arn:aws:dynamodb:us-east-2:123456789012:table/my-table \
  --filter-criteria '{"Filters": [{"Pattern": "{ \"dynamodb\" : { \"NewImage\" : { \"AccountManager\" : { \"S\" : [ \"Pat Candella\", \"Shirley Rodriguez\" ] } } } }"}]}'
```

To add these filter criteria to an existing event source mapping, run the following command.

```
aws lambda update-event-source-mapping \
  --uuid "a1b2c3d4-5678-90ab-cdef-1111EXAMPLE" \
  --filter-criteria '{"Filters": [{"Pattern": "{ \"dynamodb\" : { \"NewImage\" : { \"AccountManager\" : { \"S\" : [ \"Pat Candella\", \"Shirley Rodriguez\" ] } } } }"}]}'
```

AWS SAM

To add this filter using AWS SAM, add the following snippet to the YAML template for your event source.

```
FilterCriteria:
  Filters:
    - Pattern: '{ "dynamodb" : { "NewImage" : { "AccountManager" : { "S" : [ "Pat Candella", "Shirley Rodriguez" ] } } } }'
```

Filtering with Boolean expressions

You can also create filters using Boolean AND expressions. These expressions can include both your table's key and attribute parameters. Suppose you want to filter records where the `NewImage` value of `AccountManager` is "Pat Candella" and the `OldImage` value is "Terry Whitlock". The `FilterCriteria` object would be as follows.

```
{
  "Filters": [
    {
      "Pattern": "{ \"dynamodb\" : { \"NewImage\" : { \"AccountManager\" : { \"S\" : [ \"Pat Candella\" ] } } } , \"dynamodb\" : { \"OldImage\" : { \"AccountManager\" : { \"S\" : [ \"Terry Whitlock\" ] } } } }"
    }
  ]
}
```

For added clarity, here is the value of the filter's Pattern expanded in plain JSON.

```
{
  "dynamodb" : {
    "NewImage" : {
      "AccountManager" : {
        "S" : [
          "Pat Candella"
        ]
      }
    }
  },
  "dynamodb": {
    "OldImage": {
      "AccountManager": {
        "S": [
          "Terry Whitlock"
        ]
      }
    }
  }
}
```

You can add your filter using the console, AWS CLI or an AWS SAM template.

Console

To add this filter using the console, follow the instructions in [Attaching filter criteria to an event source mapping \(console\)](#) and enter the following string for the **Filter criteria**.

```
{ "dynamodb" : { "NewImage" : { "AccountManager" : { "S" : [ "Pat
Candella" ] } } } , "dynamodb" : { "OldImage" : { "AccountManager" : { "S" :
[ "Terry Whitlock" ] } } } }
```

AWS CLI

To create a new event source mapping with these filter criteria using the AWS Command Line Interface (AWS CLI), run the following command.

```
aws lambda create-event-source-mapping \
  --function-name my-function \
  --event-source-arn arn:aws:dynamodb:us-east-2:123456789012:table/my-table \
  --filter-criteria '{"Filters": [{"Pattern": "{ \"dynamodb\" : { \"NewImage\" : { \"AccountManager\" : { \"S\" : [ \"Pat Candella\" ] } } } , \"dynamodb\" : { \"OldImage\" : { \"AccountManager\" : { \"S\" : [ \"Terry Whitlock\" ] } } } } }']}'
```

To add these filter criteria to an existing event source mapping, run the following command.

```
aws lambda update-event-source-mapping \
  --uuid "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE" \
  --filter-criteria '{"Filters": [{"Pattern": "{ \"dynamodb\" : { \"NewImage\" : { \"AccountManager\" : { \"S\" : [ \"Pat Candella\" ] } } } , \"dynamodb\" : { \"OldImage\" : { \"AccountManager\" : { \"S\" : [ \"Terry Whitlock\" ] } } } } }']}'
```

AWS SAM

To add this filter using AWS SAM, add the following snippet to the YAML template for your event source.

```
FilterCriteria:
  Filters:
    - Pattern: '{ "dynamodb" : { "NewImage" : { "AccountManager" : { "S" : [ "Pat Candella" ] } } } , "dynamodb" : { "OldImage" : { "AccountManager" : { "S" : [ "Terry Whitlock" ] } } } }'
```

Note

DynamoDB event filtering doesn't support the use of numeric operators (numeric equals and numeric range). Even if items in your table are stored as numbers, these parameters are converted to strings in the JSON record object.

Using the Exists operator

Because of the way that JSON event objects from DynamoDB are structured, using the Exists operator requires special care. The Exists operator only works on leaf nodes in the event JSON, so if your filter pattern uses Exists to test for an intermediate node, it won't work. Consider the following DynamoDB table item:

```
{
  "UserID": {"S": "12345"},
  "Name": {"S": "John Doe"},
  "Organizations": {"L": [
    {"S": "Sales"},
    {"S": "Marketing"},
    {"S": "Support"}
  ]}
}
```

You might want to create a filter pattern like the following that would test for events containing "Organizations":

```
{ "dynamodb" : { "NewImage" : { "Organizations" : [ { "exists": true } ] } } }
```

However, this filter pattern would never return a match because "Organizations" is not a leaf node. The following example shows how to properly use the Exists operator to construct the desired filter pattern:

```
{ "dynamodb" : { "NewImage" : {"Organizations": {"L": {"S": [ {"exists":
true } ] } } } }
```

JSON format for DynamoDB filtering

To properly filter events from DynamoDB sources, both the data field and your filter criteria for the data field (dynamodb) must be in valid JSON format. If either field isn't in a valid JSON format, Lambda drops the message or throws an exception. The following table summarizes the specific behavior:

Incoming data format	Filter pattern format for data properties	Resulting action
Valid JSON	Valid JSON	Lambda filters based on your filter criteria.
Valid JSON	No filter pattern for data properties	Lambda filters (on the other metadata properties only) based on your filter criteria.
Valid JSON	Non-JSON	Lambda throws an exception at the time of the event source mapping creation or update. The filter pattern for data properties must be in a valid JSON format.
Non-JSON	Valid JSON	Lambda drops the record.
Non-JSON	No filter pattern for data properties	Lambda filters (on the other metadata properties only) based on your filter criteria.
Non-JSON	Non-JSON	Lambda throws an exception at the time of the event source mapping creation or update. The filter pattern for data properties must be in a valid JSON format.

Tutorial: Using AWS Lambda with Amazon DynamoDB streams

In this tutorial, you create a Lambda function to consume events from an Amazon DynamoDB stream.

Prerequisites

Install the AWS Command Line Interface

If you have not yet installed the AWS Command Line Interface, follow the steps at [Installing or updating the latest version of the AWS CLI](#) to install it.

The tutorial requires a command line terminal or shell to run commands. In Linux and macOS, use your preferred shell and package manager.

Note

In Windows, some Bash CLI commands that you commonly use with Lambda (such as `zip`) are not supported by the operating system's built-in terminals. To get a Windows-integrated version of Ubuntu and Bash, [install the Windows Subsystem for Linux](#).

Create the execution role

Create the [execution role](#) that gives your function permission to access AWS resources.

To create an execution role

1. Open the [roles page](#) in the IAM console.
2. Choose **Create role**.
3. Create a role with the following properties.
 - **Trusted entity** – Lambda.
 - **Permissions** – `AWSLambdaDynamoDBExecutionRole`.
 - **Role name** – `lambda-dynamodb-role`.

The `AWSLambdaDynamoDBExecutionRole` has the permissions that the function needs to read items from DynamoDB and write logs to CloudWatch Logs.

Create the function

Create a Lambda function that processes your DynamoDB events. The function code writes some of the incoming event data to CloudWatch Logs.

Consuming a DynamoDB event with Lambda using Python.

```
import json

def lambda_handler(event, context):
    print(json.dumps(event, indent=2))

    for record in event['Records']:
        log_dynamodb_record(record)

def log_dynamodb_record(record):
    print(record['eventID'])
    print(record['eventName'])
    print(f"DynamoDB Record: {json.dumps(record['dynamodb'])}")
```

Ruby

SDK for Ruby

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Serverless examples](#) repository.

Consuming a DynamoDB event with Lambda using Ruby.

```
def lambda_handler(event:, context:):
    return 'received empty event' if event['Records'].empty?

    event['Records'].each do |record|
        log_dynamodb_record(record)
    end

    "Records processed: #{event['Records'].length}"
end

def log_dynamodb_record(record)
    puts record['eventID']
    puts record['eventName']
    puts "DynamoDB Record: #{JSON.generate(record['dynamodb'])}"
end
```

Rust

SDK for Rust

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Serverless examples](#) repository.

Consuming a DynamoDB event with Lambda using Rust.

```
use lambda_runtime::{service_fn, tracing, Error, LambdaEvent};
use aws_lambda_events::{
    event::dynamodb::{Event, EventRecord},
};

// Built with the following dependencies:
//lambda_runtime = "0.11.1"
//serde_json = "1.0"
//tokio = { version = "1", features = ["macros"] }
//tracing = { version = "0.1", features = ["log"] }
```

```

//tracing-subscriber = { version = "0.3", default-features = false, features =
  ["fmt"] }
//aws_lambda_events = "0.15.0"

async fn function_handler(event: LambdaEvent<Event>) -> Result<(), Error> {

    let records = &event.payload.records;
    tracing::info!("event payload: {:?}", records);
    if records.is_empty() {
        tracing::info!("No records found. Exiting.");
        return Ok(());
    }

    for record in records{
        log_dynamo_dbrecord(record);
    }

    tracing::info!("Dynamo db records processed");

    // Prepare the response
    Ok(())
}

fn log_dynamo_dbrecord(record: &EventRecord)-> Result<(), Error>{
    tracing::info!("EventId: {}", record.event_id);
    tracing::info!("EventName: {}", record.event_name);
    tracing::info!("DynamoDB Record: {:?}", record.change );
    Ok(())
}

#[tokio::main]
async fn main() -> Result<(), Error> {
    tracing_subscriber::fmt()
        .with_max_level(tracing::Level::INFO)
        .with_target(false)
        .without_time()
        .init();

    let func = service_fn(function_handler);
    lambda_runtime::run(func).await?;
    Ok(())
}

```

```
}
```

To create the function

1. Copy the sample code into a file named `example.js`.
2. Create a deployment package.

```
zip function.zip example.js
```

3. Create a Lambda function with the `create-function` command.

```
aws lambda create-function --function-name ProcessDynamoDBRecords \  
    --zip-file fileb://function.zip --handler example.handler --runtime nodejs24.x \  
    \  
    --role arn:aws:iam::111122223333:role/lambda-dynamodb-role
```

Test the Lambda function

In this step, you invoke your Lambda function manually using the `invoke` AWS Lambda CLI command and the following sample DynamoDB event. Copy the following into a file named `input.txt`.

Example `input.txt`

```
{  
  "Records": [  
    {  
      "eventID": "1",  
      "eventName": "INSERT",  
      "eventVersion": "1.0",  
      "eventSource": "aws:dynamodb",  
      "awsRegion": "us-east-1",  
      "dynamodb": {  
        "Keys": {  
          "Id": {  
            "N": "101"  
          }  
        },  
        "NewImage": {
```

```
        "Message":{
            "S":"New item!"
        },
        "Id":{
            "N":"101"
        }
    },
    "SequenceNumber":"111",
    "SizeBytes":26,
    "StreamViewType":"NEW_AND_OLD_IMAGES"
},
"eventSourceARN":"stream-ARN"
},
{
    "eventID":"2",
    "eventName":"MODIFY",
    "eventVersion":"1.0",
    "eventSource":"aws:dynamodb",
    "awsRegion":"us-east-1",
    "dynamodb":{
        "Keys":{
            "Id":{
                "N":"101"
            }
        },
        "NewImage":{
            "Message":{
                "S":"This item has changed"
            },
            "Id":{
                "N":"101"
            }
        },
        "OldImage":{
            "Message":{
                "S":"New item!"
            },
            "Id":{
                "N":"101"
            }
        },
        "SequenceNumber":"222",
        "SizeBytes":59,
        "StreamViewType":"NEW_AND_OLD_IMAGES"
    }
}
```

```

    },
    "eventSourceARN":"stream-ARN"
  },
  {
    "eventID":"3",
    "eventName":"REMOVE",
    "eventVersion":"1.0",
    "eventSource":"aws:dynamodb",
    "awsRegion":"us-east-1",
    "dynamodb":{
      "Keys":{
        "Id":{
          "N":"101"
        }
      },
      "OldImage":{
        "Message":{
          "S":"This item has changed"
        },
        "Id":{
          "N":"101"
        }
      },
      "SequenceNumber":"333",
      "SizeBytes":38,
      "StreamViewType":"NEW_AND_OLD_IMAGES"
    },
    "eventSourceARN":"stream-ARN"
  }
]
}

```

Run the following `invoke` command.

```

aws lambda invoke --function-name ProcessDynamoDBRecords \
  --cli-binary-format raw-in-base64-out \
  --payload file://input.txt outputfile.txt

```

The **cli-binary-format** option is required if you're using AWS CLI version 2. To make this the default setting, run `aws configure set cli-binary-format raw-in-base64-out`. For more information, see [AWS CLI supported global command line options](#) in the *AWS Command Line Interface User Guide for Version 2*.

The function returns the string message in the response body.

Verify the output in the `outputfile.txt` file.

Create a DynamoDB table with a stream enabled

Create an Amazon DynamoDB table with a stream enabled.

To create a DynamoDB table

1. Open the [DynamoDB console](#).
2. Choose **Create table**.
3. Create a table with the following settings.
 - **Table name** – `lambda-dynamodb-stream`
 - **Primary key** – `id` (string)
4. Choose **Create**.

To enable streams

1. Open the [DynamoDB console](#).
2. Choose **Tables**.
3. Choose the `lambda-dynamodb-stream` table.
4. Under **Exports and streams**, choose **DynamoDB stream details**.
5. Choose **Turn on**.
6. For **View type**, choose **Key attributes only**.
7. Choose **Turn on stream**.

Write down the stream ARN. You need this in the next step when you associate the stream with your Lambda function. For more information on enabling streams, see [Capturing table activity with DynamoDB Streams](#).

Add an event source in AWS Lambda

Create an event source mapping in AWS Lambda. This event source mapping associates the DynamoDB stream with your Lambda function. After you create this event source mapping, AWS Lambda starts polling the stream.

Run the following AWS CLI `create-event-source-mapping` command. After the command runs, note down the UUID. You'll need this UUID to refer to the event source mapping in any commands, for example, when deleting the event source mapping.

```
aws lambda create-event-source-mapping --function-name ProcessDynamoDBRecords \  
--batch-size 100 --starting-position LATEST --event-source DynamoDB-stream-arn
```

This creates a mapping between the specified DynamoDB stream and the Lambda function. You can associate a DynamoDB stream with multiple Lambda functions, and associate the same Lambda function with multiple streams. However, the Lambda functions will share the read throughput for the stream they share.

You can get the list of event source mappings by running the following command.

```
aws lambda list-event-source-mappings
```

The list returns all of the event source mappings you created, and for each mapping it shows the `LastProcessingResult`, among other things. This field is used to provide an informative message if there are any problems. Values such as `No records processed` (indicates that AWS Lambda has not started polling or that there are no records in the stream) and `OK` (indicates AWS Lambda successfully read records from the stream and invoked your Lambda function) indicate that there are no issues. If there are issues, you receive an error message.

If you have a lot of event source mappings, use the function name parameter to narrow down the results.

```
aws lambda list-event-source-mappings --function-name ProcessDynamoDBRecords
```

Test the setup

Test the end-to-end experience. As you perform table updates, DynamoDB writes event records to the stream. As AWS Lambda polls the stream, it detects new records in the stream and invokes your Lambda function on your behalf by passing events to the function.

1. In the DynamoDB console, add, update, and delete items to the table. DynamoDB writes records of these actions to the stream.
2. AWS Lambda polls the stream and when it detects updates to the stream, it invokes your Lambda function by passing in the event data it finds in the stream.

3. Your function runs and creates logs in Amazon CloudWatch. You can verify the logs reported in the Amazon CloudWatch console.

Next steps

This tutorial showed you the basics of processing DynamoDB stream events with Lambda. For production workloads, consider implementing partial batch response logic to handle individual record failures more efficiently. The [batch processor utility](#) from Powertools for AWS Lambda is available in Python, TypeScript, .NET, and Java and provides a robust solution for this, automatically handling the complexity of partial batch responses and reducing the number of retries for successfully processed records.

Clean up your resources

You can now delete the resources that you created for this tutorial, unless you want to retain them. By deleting AWS resources that you're no longer using, you prevent unnecessary charges to your AWS account.

To delete the Lambda function

1. Open the [Functions page](#) of the Lambda console.
2. Select the function that you created.
3. Choose **Actions, Delete**.
4. Type **confirm** in the text input field and choose **Delete**.

To delete the execution role

1. Open the [Roles page](#) of the IAM console.
2. Select the execution role that you created.
3. Choose **Delete**.
4. Enter the name of the role in the text input field and choose **Delete**.

To delete the DynamoDB table

1. Open the [Tables page](#) of the DynamoDB console.
2. Select the table you created.

3. Choose **Delete**.
4. Enter **delete** in the text box.
5. Choose **Delete table**.

Process Amazon EC2 lifecycle events with a Lambda function

You can use AWS Lambda to process lifecycle events from Amazon Elastic Compute Cloud and manage Amazon EC2 resources. Amazon EC2 sends events to [Amazon EventBridge \(CloudWatch Events\)](#) for [lifecycle events](#) such as when an instance changes state, when an Amazon Elastic Block Store volume snapshot completes, or when a spot instance is scheduled to be terminated. You configure EventBridge (CloudWatch Events) to forward those events to a Lambda function for processing.

EventBridge (CloudWatch Events) invokes your Lambda function asynchronously with the event document from Amazon EC2.

Example instance lifecycle event

```
{
  "version": "0",
  "id": "b6ba298a-7732-2226-xmpl-976312c1a050",
  "detail-type": "EC2 Instance State-change Notification",
  "source": "aws.ec2",
  "account": "111122223333",
  "time": "2019-10-02T17:59:30Z",
  "region": "us-east-1",
  "resources": [
    "arn:aws:ec2:us-east-1:111122223333:instance/i-0c314xmplcd5b8173"
  ],
  "detail": {
    "instance-id": "i-0c314xmplcd5b8173",
    "state": "running"
  }
}
```

For details on configuring events, see [Invoke a Lambda function on a schedule](#). For an example function that processes Amazon EBS snapshot notifications, see [EventBridge Scheduler for Amazon EBS](#).

You can also use the AWS SDK to manage instances and other resources with the Amazon EC2 API.

Granting permissions to EventBridge (CloudWatch Events)

To process lifecycle events from Amazon EC2, EventBridge (CloudWatch Events) needs permission to invoke your function. This permission comes from the function's [resource-based policy](#). If

you use the EventBridge (CloudWatch Events) console to configure an event trigger, the console updates the resource-based policy on your behalf. Otherwise, add a statement like the following:

Example resource-based policy statement for Amazon EC2 lifecycle notifications

```
{
  "Sid": "ec2-events",
  "Effect": "Allow",
  "Principal": {
    "Service": "events.amazonaws.com"
  },
  "Action": "lambda:InvokeFunction",
  "Resource": "arn:aws:lambda:us-east-1:12456789012:function:my-function",
  "Condition": {
    "ArnLike": {
      "AWS:SourceArn": "arn:aws:events:us-east-1:12456789012:rule/*"
    }
  }
}
```

To add a statement, use the add-permission AWS CLI command.

```
aws lambda add-permission --action lambda:InvokeFunction --statement-id ec2-events \
--principal events.amazonaws.com --function-name my-function --source-arn
'arn:aws:events:us-east-1:12456789012:rule/*'
```

If your function uses the AWS SDK to manage Amazon EC2 resources, add Amazon EC2 permissions to the function's [execution role](#).

Process Application Load Balancer requests with Lambda

You can use a Lambda function to process requests from an Application Load Balancer. Elastic Load Balancing supports Lambda functions as a target for an Application Load Balancer. Use load balancer rules to route HTTP requests to a function, based on path or header values. Process the request and return an HTTP response from your Lambda function.

Elastic Load Balancing invokes your Lambda function synchronously with an event that contains the request body and metadata.

Example Application Load Balancer request event

```
{
  "requestContext": {
    "elb": {
      "targetGroupArn": "arn:aws:elasticloadbalancing:us-
east-1:123456789012:targetgroup/lambda-279XGJDqGZ5rsrHC2Fjr/49e9d65c45c6791a"
    }
  },
  "httpMethod": "GET",
  "path": "/lambda",
  "queryStringParameters": {
    "query": "1234ABCD"
  },
  "headers": {
    "accept": "text/html,application/xhtml+xml,application/xml;q=0.9,image/
webp,image/apng,*/*;q=0.8",
    "accept-encoding": "gzip",
    "accept-language": "en-US,en;q=0.9",
    "connection": "keep-alive",
    "host": "lambda-alb-123578498.us-east-1.elb.amazonaws.com",
    "upgrade-insecure-requests": "1",
    "user-agent": "Mozilla/5.0 (Windows NT 10.0; Win64; x64) AppleWebKit/537.36
(KHTML, like Gecko) Chrome/71.0.3578.98 Safari/537.36",
    "x-amzn-trace-id": "Root=1-5c536348-3d683b8b04734faae651f476",
    "x-forwarded-for": "72.12.164.125",
    "x-forwarded-port": "80",
    "x-forwarded-proto": "http",
    "x-imforwards": "20"
  },
  "body": "",
  "isBase64Encoded": False
}
```

```
}
```

Your function processes the event and returns a response document to the load balancer in JSON. Elastic Load Balancing converts the document to an HTTP success or error response and returns it to the user.

Example response document format

```
{
  "statusCode": 200,
  "statusDescription": "200 OK",
  "isBase64Encoded": False,
  "headers": {
    "Content-Type": "text/html"
  },
  "body": "<h1>Hello from Lambda!</h1>"
}
```

To configure an Application Load Balancer as a function trigger, grant Elastic Load Balancing permission to run the function, create a target group that routes requests to the function, and add a rule to the load balancer that sends requests to the target group.

Use the `add-permission` command to add a permission statement to your function's resource-based policy.

```
aws lambda add-permission --function-name alb-function \
--statement-id load-balancer --action "lambda:InvokeFunction" \
--principal elasticloadbalancing.amazonaws.com
```

You should see the following output:

```
{
  "Statement": "{ \"Sid\": \"load-balancer\", \"Effect\": \"Allow\", \"Principal\": { \"Service\": \"elasticloadbalancing.amazonaws.com\" }, \"Action\": \"lambda:InvokeFunction\", \"Resource\": \"arn:aws:lambda:us-west-2:123456789012:function:alb-function\" }"
}
```

For instructions on configuring the Application Load Balancer listener and target group, see [Lambda functions as a target](#) in the *User Guide for Application Load Balancers*.

Event Handler from Powertools for AWS Lambda

The event handler from the Powertools for AWS Lambda toolkit provides routing, middleware, CORS configuration, OpenAPI spec generation, request validation, error handling, and other useful features when writing Lambda functions invoked by an Application Load Balancer. The Event Handler utility is available for Python. For more information, see [Event Handler REST API](#) in the *Powertools for AWS Lambda (Python) documentation*.

Python

```
import requests
from requests import Response

from aws_lambda_powertools import Logger, Tracer
from aws_lambda_powertools.event_handler import ALBResolver
from aws_lambda_powertools.logging import correlation_paths
from aws_lambda_powertools.utilities.typing import LambdaContext

tracer = Tracer()
logger = Logger()
app = ALBResolver()

@app.get("/todos")
@tracer.capture_method
def get_todos():
    todos: Response = requests.get("https://jsonplaceholder.typicode.com/todos")
    todos.raise_for_status()

    # for brevity, we'll limit to the first 10 only
    return {"todos": todos.json()[:10]}

# You can continue to use other utilities just as before
@logger.inject_lambda_context(correlation_id_path=correlation_paths.APPLICATION_LOAD_BALANCER)
@tracer.capture_lambda_handler
def lambda_handler(event: dict, context: LambdaContext) -> dict:
    return app.resolve(event, context)
```

Invoke a Lambda function on a schedule

[Amazon EventBridge Scheduler](#) is a serverless scheduler that allows you to create, run, and manage tasks from one central, managed service. With EventBridge Scheduler, you can create schedules using cron and rate expressions for recurring patterns, or configure one-time invocations. You can set up flexible time windows for delivery, define retry limits, and set the maximum retention time for unprocessed events.

When you set up EventBridge Scheduler with Lambda, EventBridge Scheduler invokes your Lambda function asynchronously. This page explains how to use EventBridge Scheduler to invoke a Lambda function on a schedule.

Set up the execution role

When you create a new schedule, EventBridge Scheduler must have permission to invoke its target API operation on your behalf. You grant these permissions to EventBridge Scheduler using an *execution role*. The permission policy you attach to your schedule's execution role defines the required permissions. These permissions depend on the target API you want EventBridge Scheduler to invoke.

When you use the EventBridge Scheduler console to create a schedule, as in the following procedure, EventBridge Scheduler automatically sets up an execution role based on your selected target. If you want to create a schedule using one of the EventBridge Scheduler SDKs, the AWS CLI, or CloudFormation, you must have an existing execution role that grants the permissions EventBridge Scheduler requires to invoke a target. For more information about manually setting up an execution role for your schedule, see [Setting up an execution role](#) in the *EventBridge Scheduler User Guide*.

Create a schedule

To create a schedule by using the console

1. Open the Amazon EventBridge Scheduler console at <https://console.aws.amazon.com/scheduler/home>.
2. On the **Schedules** page, choose **Create schedule**.
3. On the **Specify schedule detail** page, in the **Schedule name and description** section, do the following:

- a. For **Schedule name**, enter a name for your schedule. For example, **MyTestSchedule**.
- b. (Optional) For **Description**, enter a description for your schedule. For example, **My first schedule**.
- c. For **Schedule group**, choose a schedule group from the dropdown list. If you don't have a group, choose **default**. To create a schedule group, choose **create your own schedule**.

You use schedule groups to add tags to groups of schedules.

4. • Choose your schedule options.

Occurrence	Do this...
<p>One-time schedule</p> <p>A one-time schedule invokes a target only once at the date and time that you specify.</p>	<p>For Date and time, do the following:</p> <ul style="list-style-type: none"> • Enter a valid date in YYYY/MM/DD format. • Enter a timestamp in 24-hour hh:mm format. • For Timezone, choose the timezone.
<p>Recurring schedule</p> <p>A recurring schedule invokes a target at a rate that you specify using a cron expression or rate expression.</p>	<p>a. For Schedule type, do one of the following:</p> <ul style="list-style-type: none"> • To use a cron expression to define the schedule, choose Cron-based schedule and enter the cron expression. • To use a rate expression to define the schedule, choose Rate-based schedule and enter the rate expression.

Occurrence	Do this...	
	<p>For more information about cron and rate expressions, see Schedule types on EventBridge Scheduler in the <i>Amazon EventBridge Scheduler User Guide</i>.</p> <p>b. For Flexible time window, choose Off to turn off the option, or choose one of the pre-defined time windows. For example, if you choose 15 minutes and you set a recurring schedule to invoke its target once every hour, the schedule runs within 15 minutes after the start of every hour.</p>	

5. (Optional) If you chose **Recurring schedule** in the previous step, in the **Timeframe** section, do the following:
 - a. For **Timezone**, choose a timezone.
 - b. For **Start date and time**, enter a valid date in YYYY/MM/DD format, and then specify a timestamp in 24-hour hh:mm format.
 - c. For **End date and time**, enter a valid date in YYYY/MM/DD format, and then specify a timestamp in 24-hour hh:mm format.
6. Choose **Next**.
7. On the **Select target** page, choose the AWS API operation that EventBridge Scheduler invokes:
 - a. Choose **AWS Lambda Invoke**.

- b.

In the **Invoke** section, select a function or choose **Create new Lambda function**.
- c.

(Optional) Enter a JSON payload. If you don't enter a payload, EventBridge Scheduler uses an empty event to invoke the function.
8.

Choose **Next**.
9.

On the **Settings** page, do the following:

a.

To turn on the schedule, under **Schedule state**, toggle **Enable schedule**.

b.

To configure a retry policy for your schedule, under **Retry policy and dead-letter queue (DLQ)**, do the following:

•

Toggle **Retry**.

•

For **Maximum age of event**, enter the maximum **hour(s)** and **min(s)** that EventBridge Scheduler must keep an unprocessed event.

•

The maximum time is 24 hours.

•

For **Maximum retries**, enter the maximum number of times EventBridge Scheduler retries the schedule if the target returns an error.

The maximum value is 185 retries.

With retry policies, if a schedule fails to invoke its target, EventBridge Scheduler re-runs the schedule. If configured, you must set the maximum retention time and retries for the schedule.

- c.

Choose where EventBridge Scheduler stores undelivered events.

Dead-letter queue (DLQ) option	Do this...	
Don't store	Choose None .	
Store the event in the same AWS account where you're creating the schedule	a. Choose Select an Amazon SQS queue in my AWS account as a DLQ .	

Dead-letter queue (DLQ) option	Do this...	
	b. Choose the Amazon Resource Name (ARN) of the Amazon SQS queue.	
Store the event in a different AWS account from where you're creating the schedule	a. Choose Specify an Amazon SQS queue in other AWS accounts as a DLQ . b. Enter the Amazon Resource Name (ARN) of the Amazon SQS queue.	

- d. To use a customer managed key to encrypt your target input, under **Encryption**, choose **Customize encryption settings (advanced)**.

If you choose this option, enter an existing KMS key ARN or choose **Create an AWS KMS key** to navigate to the AWS KMS console. For more information about how EventBridge Scheduler encrypts your data at rest, see [Encryption at rest](#) in the *Amazon EventBridge Scheduler User Guide*.

- e. To have EventBridge Scheduler create a new execution role for you, choose **Create new role for this schedule**. Then, enter a name for **Role name**. If you choose this option, EventBridge Scheduler attaches the required permissions necessary for your templated target to the role.

10. Choose **Next**.

11. In the **Review and create schedule** page, review the details of your schedule. In each section, choose **Edit** to go back to that step and edit its details.

12. Choose **Create schedule**.

You can view a list of your new and existing schedules on the **Schedules** page. Under the **Status** column, verify that your new schedule is **Enabled**.

To confirm that EventBridge Scheduler invoked the function, [check the function's Amazon CloudWatch logs](#).

For more information about EventBridge Scheduler, see the following:

- [EventBridge Scheduler User Guide](#)
- [EventBridge Scheduler API Reference](#)
- [EventBridge Scheduler Pricing](#)

Using AWS Lambda with AWS IoT

AWS IoT provides secure communication between internet-connected devices (such as sensors) and the AWS Cloud. This makes it possible for you to collect, store, and analyze telemetry data from multiple devices.

You can create AWS IoT rules for your devices to interact with AWS services. The AWS IoT [Rules Engine](#) provides a SQL-based language to select data from message payloads and send the data to other services, such as Amazon S3, Amazon DynamoDB, and AWS Lambda. You define a rule to invoke a Lambda function when you want to invoke another AWS service or a third-party service.

When an incoming IoT message triggers the rule, AWS IoT invokes your Lambda function [asynchronously](#) and passes data from the IoT message to the function.

The following example shows a moisture reading from a greenhouse sensor. The **row** and **pos** values identify the location of the sensor. This example event is based on the greenhouse type in the [AWS IoT Rules tutorials](#).

Example AWS IoT message event

```
{
  "row" : "10",
  "pos" : "23",
  "moisture" : "75"
}
```

For asynchronous invocation, Lambda queues the message and [retries](#) if your function returns an error. Configure your function with a [destination](#) to retain events that your function could not process.

You need to grant permission for the AWS IoT service to invoke your Lambda function. Use the `add-permission` command to add a permission statement to your function's resource-based policy.

```
aws lambda add-permission --function-name my-function \
--statement-id iot-events --action "lambda:InvokeFunction" --principal
iot.amazonaws.com
```

You should see the following output:

```
{
  "Statement": "{\\"Sid\\":\\"iot-events\\",\\"Effect\\":\\"Allow\\",\\"Principal\\":
  {\\"Service\\":\\"iot.amazonaws.com\\"},\\"Action\\":\\"lambda:InvokeFunction\\",\\"Resource\\":
  \\"arn:aws:lambda:us-east-1:123456789012:function:my-function\\"}"
}
```

For more information about how to use Lambda with AWS IoT, see [Creating an AWS Lambda rule](#).

Using Lambda to process records from Amazon Kinesis Data Streams

You can use a Lambda function to process records in an [Amazon Kinesis data stream](#). You can map a Lambda function to a Kinesis Data Streams shared-throughput consumer (standard iterator), or to a dedicated-throughput consumer with [enhanced fan-out](#). For standard iterators, Lambda polls each shard in your Kinesis stream for records using HTTP protocol. The event source mapping shares read throughput with other consumers of the shard.

For details about Kinesis data streams, see [Reading Data from Amazon Kinesis Data Streams](#).

Note

Kinesis charges for each shard and, for enhanced fan-out, data read from the stream. For pricing details, see [Amazon Kinesis pricing](#).

Polling and batching streams

Lambda reads records from the data stream and invokes your function [synchronously](#) with an event that contains stream records. Lambda reads records in batches and invokes your function to process records from the batch. Each batch contains records from a single shard/data stream.

Your Lambda function is a consumer application for your data stream. It processes one batch of records at a time from each shard. You can map a Lambda function to a shared-throughput consumer (standard iterator), or to a dedicated-throughput consumer with enhanced fan-out.

- **Standard iterator:** Lambda polls each shard in your Kinesis stream for records at a base rate of once per second. When more records are available, Lambda keeps processing batches until the function catches up with the stream. The event source mapping shares read throughput with other consumers of the shard.
- **Enhanced fan-out:** To minimize latency and maximize read throughput, create a data stream consumer with [enhanced fan-out](#). Enhanced fan-out consumers get a dedicated connection to each shard that doesn't impact other applications reading from the stream. Stream consumers use HTTP/2 to reduce latency by pushing records to Lambda over a long-lived connection and by compressing request headers. You can create a stream consumer with the Kinesis [RegisterStreamConsumer](#) API.

```
aws kinesis register-stream-consumer \  
--consumer-name con1 \  
--stream-arn arn:aws:kinesis:us-east-2:123456789012:stream/lambda-stream
```

You should see the following output:

```
{  
  "Consumer": {  
    "ConsumerName": "con1",  
    "ConsumerARN": "arn:aws:kinesis:us-east-2:123456789012:stream/lambda-stream/  
consumer/con1:1540591608",  
    "ConsumerStatus": "CREATING",  
    "ConsumerCreationTimestamp": 1540591608.0  
  }  
}
```

To increase the speed at which your function processes records, [add shards to your data stream](#). Lambda processes records in each shard in order. It stops processing additional records in a shard if your function returns an error. With more shards, there are more batches being processed at once, which lowers the impact of errors on concurrency.

If your function can't scale up to handle the total number of concurrent batches, [request a quota increase](#) or [reserve concurrency](#) for your function.

By default, Lambda invokes your function as soon as records are available. If the batch that Lambda reads from the event source has only one record in it, Lambda sends only one record to the function. To avoid invoking the function with a small number of records, you can tell the event source to buffer records for up to 5 minutes by configuring a *batching window*. Before invoking the function, Lambda continues to read records from the event source until it has gathered a full batch, the batching window expires, or the batch reaches the payload limit of 6 MB. For more information, see [Batching behavior](#).

Warning

Lambda event source mappings process each event at least once, and duplicate processing of records can occur. To avoid potential issues related to duplicate events, we strongly recommend that you make your function code idempotent. To learn more, see [How do I make my Lambda function idempotent](#) in the AWS Knowledge Center.

Lambda doesn't wait for any configured [extensions](#) to complete before sending the next batch for processing. In other words, your extensions may continue to run as Lambda processes the next batch of records. This can cause throttling issues if you breach any of your account's [concurrency](#) settings or limits. To detect whether this is a potential issue, monitor your functions and check whether you're seeing higher [concurrency metrics](#) than expected for your event source mapping. Due to short times in between invokes, Lambda may briefly report higher concurrency usage than the number of shards. This can be true even for Lambda functions without extensions.

Configure the [ParallelizationFactor](#) setting to process one shard of a Kinesis data stream with more than one Lambda invocation simultaneously. You can specify the number of concurrent batches that Lambda polls from a shard via a parallelization factor from 1 (default) to 10. For example, when you set `ParallelizationFactor` to 2, you can have 200 concurrent Lambda invocations at maximum to process 100 Kinesis data shards (though in practice, you may see different values for the `ConcurrentExecutions` metric). This helps scale up the processing throughput when the data volume is volatile and the `IteratorAge` is high. When you increase the number of concurrent batches per shard, Lambda still ensures in-order processing at the partition-key level.

You can also use `ParallelizationFactor` with Kinesis aggregation. The behavior of the event source mapping depends on whether you're using [enhanced fan-out](#):

- **Without enhanced fan-out:** All of the events inside an aggregated event must have the same partition key. The partition key must also match that of the aggregated event. If the events inside the aggregated event have different partition keys, Lambda cannot guarantee in-order processing of the events by partition key.
- **With enhanced fan-out:** First, Lambda decodes the aggregated event into its individual events. The aggregated event can have a different partition key than events it contains. However, events that don't correspond to the partition key are [dropped and lost](#). Lambda doesn't process these events, and doesn't send them to a configured failure destination.

Example event

Example

```
{
  "Records": [
    {
      "kinesis": {
        "kinesisSchemaVersion": "1.0",
```

```

        "partitionKey": "1",
        "sequenceNumber":
"49590338271490256608559692538361571095921575989136588898",

```

Process Amazon Kinesis Data Streams records with Lambda

To process Amazon Kinesis Data Streams records with Lambda, create a Lambda event source mapping. You can map a Lambda function to a standard iterator or enhanced fan-out consumer. For more information, see [Polling and batching streams](#).

Create an Kinesis event source mapping

To invoke your Lambda function with records from your data stream, create an [event source mapping](#). You can create multiple event source mappings to process the same data with multiple Lambda functions, or to process items from multiple data streams with a single function. When processing items from multiple streams, each batch contains records from only a single shard or stream.

You can configure event source mappings to process records from a stream in a different AWS account. To learn more, see [the section called “Cross-account mappings”](#).

Before you create an event source mapping, you need to give your Lambda function permission to read from a Kinesis data stream. Lambda needs the following permissions to manage resources related to your Kinesis data stream:

- [kinesis:DescribeStream](#)
- [kinesis:DescribeStreamSummary](#)
- [kinesis:GetRecords](#)
- [kinesis:GetShardIterator](#)
- [kinesis:ListShards](#)
- [kinesis:SubscribeToShard](#)

The AWS managed policy [AWSLambdaKinesisExecutionRole](#) includes these permissions. Add this managed policy to your function as described in the following procedure.

Note

- You don't need the `kinesis:ListStreams` permission to create and manage event source mappings for Kinesis. However, if you create an event source mapping in the console and you don't have this permission, you won't be able to select a Kinesis stream from a dropdown list and the console will display an error. To create the event source mapping, you'll need to manually enter the Amazon Resource Name (ARN) of your stream.
- Lambda makes `kinesis:GetRecords` and `kinesis:GetShardIterator` API calls when retrying failed invocations.

AWS Management Console

To add Kinesis permissions to your function

1. Open the [Functions page](#) of the Lambda console and select your function.
2. In the **Configuration** tab, select **Permissions**.
3. In the **Execution role** pane, under **Role name**, choose the link to your function's execution role. This link opens the page for that role in the IAM console.
4. In the **Permissions policies** pane, choose **Add permissions**, then select **Attach policies**.
5. In the search field, enter **AWSLambdaKinesisExecutionRole**.
6. Select the checkbox next to the policy and choose **Add permission**.

AWS CLI

To add Kinesis permissions to your function

- Run the following CLI command to add the AWSLambdaKinesisExecutionRole policy to your function's execution role:

```
aws iam attach-role-policy \
--role-name MyFunctionRole \
--policy-arn arn:aws:iam::aws:policy/service-role/AWSLambdaKinesisExecutionRole
```

AWS SAM

To add Kinesis permissions to your function

- In your function's definition, add the Policies property as shown in the following example:

```
Resources:
  MyFunction:
    Type: AWS::Serverless::Function
    Properties:
      CodeUri: ./my-function/
      Handler: index.handler
      Runtime: nodejs24.x
      Policies:
```

- AWSLambdaKinesisExecutionRole

After configuring the required permissions, create the event source mapping.

AWS Management Console

To create the Kinesis event source mapping

1. Open the [Functions page](#) of the Lambda console and select your function.
2. In the **Function overview** pane, choose **Add trigger**.
3. Under **Trigger configuration**, for the source, select **Kinesis**.
4. Select the Kinesis stream you want to create the event source mapping for and, optionally, a consumer of your stream.
5. (Optional) edit the **Batch size**, **Starting position**, and **Batch window** for your event source mapping.
6. Choose **Add**.

When creating your event source mapping from the console, your IAM role must have the [kinesis:ListStreams](#) and [kinesis:ListStreamConsumers](#) permissions.

AWS CLI

To create the Kinesis event source mapping

- Run the following CLI command to create a Kinesis event source mapping. Choose your own batch size and starting position according to your use case.

```
aws lambda create-event-source-mapping \  
--function-name MyFunction \  
--event-source-arn arn:aws:kinesis:us-east-2:123456789012:stream/lambda-stream \  
--starting-position LATEST \  
--batch-size 100
```

To specify a batching window, add the `--maximum-batching-window-in-seconds` option. For more information about using this and other parameters, see [create-event-source-mapping](#) in the *AWS CLI Command Reference*.

AWS SAM

To create the Kinesis event source mapping

- In your function's definition, add the `KinesisEvent` property as shown in the following example:

```
Resources:
  MyFunction:
    Type: AWS::Serverless::Function
    Properties:
      CodeUri: ./my-function/
      Handler: index.handler
      Runtime: nodejs24.x
      Policies:
        - AWSLambdaKinesisExecutionRole
      Events:
        KinesisEvent:
          Type: Kinesis
          Properties:
            Stream: !GetAtt MyKinesisStream.Arn
            StartingPosition: LATEST
            BatchSize: 100

  MyKinesisStream:
    Type: AWS::Kinesis::Stream
    Properties:
      ShardCount: 1
```

To learn more about creating an event source mapping for Kinesis Data Streams in AWS SAM, see [Kinesis](#) in the *AWS Serverless Application Model Developer Guide*.

Polling and stream starting position

Be aware that stream polling during event source mapping creation and updates is eventually consistent.

- During event source mapping creation, it may take several minutes to start polling events from the stream.

- During event source mapping updates, it may take several minutes to stop and restart polling events from the stream.

This behavior means that if you specify LATEST as the starting position for the stream, the event source mapping could miss events during creation or updates. To ensure that no events are missed, specify the stream starting position as TRIM_HORIZON or AT_TIMESTAMP.

Creating a cross-account event source mapping

Amazon Kinesis Data Streams supports [resource-based policies](#). Because of this, you can process data ingested into a stream in one AWS account with a Lambda function in another account.

To create an event source mapping for your Lambda function using a Kinesis stream in a different AWS account, you must configure the stream using a resource-based policy to give your Lambda function permission to read items. To learn how to configure your stream to allow cross-account access, see [Sharing access with cross-account AWS Lambda functions](#) in the *Amazon Kinesis Streams Developer guide*.

Once you've configured your stream with a resource-based policy that gives your Lambda function the required permissions, create the event source mapping using any of the methods described in the previous section.

If you choose to create your event source mapping using the Lambda console, paste the ARN of your stream directly into the input field. If you want to specify a consumer for your stream, pasting the ARN of the consumer automatically populates the stream field.

Configuring partial batch response with Kinesis Data Streams and Lambda

When consuming and processing streaming data from an event source, by default Lambda checkpoints to the highest sequence number of a batch only when the batch is a complete success. Lambda treats all other results as a complete failure and retries processing the batch up to the retry limit. To allow for partial successes while processing batches from a stream, turn on `ReportBatchItemFailures`. Allowing partial successes can help to reduce the number of retries on a record, though it doesn't entirely prevent the possibility of retries in a successful record.

To turn on `ReportBatchItemFailures`, include the enum value **ReportBatchItemFailures** in the [FunctionResponseTypes](#) list. This list indicates which response types are enabled for your function. You can configure this list when you [create](#) or [update](#) an event source mapping.

Note

Even when your function code returns partial batch failure responses, these responses will not be processed by Lambda unless the `ReportBatchItemFailures` feature is explicitly turned on for your event source mapping.

Report syntax

When configuring reporting on batch item failures, the `StreamsEventResponse` class is returned with a list of batch item failures. You can use a `StreamsEventResponse` object to return the sequence number of the first failed record in the batch. You can also create your own custom class using the correct response syntax. The following JSON structure shows the required response syntax:

```
{
  "batchItemFailures": [
    {
      "itemIdentifier": "<SequenceNumber>"
    }
  ]
}
```

Note

If the `batchItemFailures` array contains multiple items, Lambda uses the record with the lowest sequence number as the checkpoint. Lambda then retries all records starting from that checkpoint.

Success and failure conditions

Lambda treats a batch as a complete success if you return any of the following:

- An empty `batchItemFailure` list
- A null `batchItemFailure` list
- An empty `EventResponse`
- A null `EventResponse`

Lambda treats a batch as a complete failure if you return any of the following:

- An empty string `itemIdentifier`
- A null `itemIdentifier`
- An `itemIdentifier` with a bad key name

Lambda retries failures based on your retry strategy.

Bisecting a batch

If your invocation fails and `BisectBatchOnFunctionError` is turned on, the batch is bisected regardless of your `ReportBatchItemFailures` setting.

When a partial batch success response is received and both `BisectBatchOnFunctionError` and `ReportBatchItemFailures` are turned on, the batch is bisected at the returned sequence number and Lambda retries only the remaining records.

To simplify the implementation of partial batch response logic, consider using the [Batch Processor utility](#) from Powertools for AWS Lambda, which automatically handles these complexities for you.

Here are some examples of function code that return the list of failed message IDs in the batch:

    tracing::info!("Data: {}", record_data);

    Ok(())
}

#[tokio::main]
async fn main() -> Result<(), Error> {
    tracing_subscriber::fmt()

```

```
        .with_max_level(tracing::Level::INFO)
        // disable printing the name of the module in every log line.
        .with_target(false)
        // disabling time is handy because CloudWatch will add the ingestion
time.
        .without_time()
        .init();

    run(service_fn(function_handler)).await
}
```

Using Powertools for AWS Lambda batch processor

The batch processor utility from Powertools for AWS Lambda automatically handles partial batch response logic, reducing the complexity of implementing batch failure reporting. Here are examples using the batch processor:

Python

Note

For complete examples and setup instructions, see the [batch processor documentation](#).

Processing Kinesis Data Streams stream records with AWS Lambda batch processor.

```
import json
from aws_lambda_powertools import Logger
from aws_lambda_powertools.utilities.batch import BatchProcessor, EventType,
    process_partial_response
from aws_lambda_powertools.utilities.data_classes import KinesisEvent
from aws_lambda_powertools.utilities.typing import LambdaContext

processor = BatchProcessor(event_type=EventType.KinesisDataStreams)
logger = Logger()

def record_handler(record):
    logger.info(record)
    # Your business logic here
    # Raise an exception to mark this record as failed
```

```
def lambda_handler(event, context: LambdaContext):
    return process_partial_response(
        event=event,
        record_handler=record_handler,
        processor=processor,
        context=context
    )
```

TypeScript

Note

For complete examples and setup instructions, see the [batch processor documentation](#).

Processing Kinesis Data Streams stream records with AWS Lambda batch processor.

```
import { BatchProcessor, EventType, processPartialResponse } from '@aws-lambda-
powertools/batch';
import { Logger } from '@aws-lambda-powertools/logger';
import type { KinesisEvent, Context } from 'aws-lambda';

const processor = new BatchProcessor(EventType.KinesisDataStreams);
const logger = new Logger();

const recordHandler = async (record: any): Promise<void> => {
    logger.info('Processing record', { record });
    // Your business logic here
    // Throw an error to mark this record as failed
};

export const handler = async (event: KinesisEvent, context: Context) => {
    return processPartialResponse(event, recordHandler, processor, {
        context,
    });
};
```

Java

Note

For complete examples and setup instructions, see the [batch processor documentation](#).

Processing Kinesis Data Streams stream records with AWS Lambda batch processor.

```
import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;
import com.amazonaws.services.lambda.runtime.events.KinesisEvent;
import com.amazonaws.services.lambda.runtime.events.StreamsEventResponse;
import software.amazon.lambda.powertools.batch.BatchMessageHandlerBuilder;
import software.amazon.lambda.powertools.batch.handler.BatchMessageHandler;

public class KinesisStreamBatchHandler implements RequestHandler<KinesisEvent,
StreamsEventResponse> {

    private final BatchMessageHandler<KinesisEvent, StreamsEventResponse> handler;

    public KinesisStreamBatchHandler() {
        handler = new BatchMessageHandlerBuilder()
            .withKinesisBatchHandler()
            .buildWithRawMessageHandler(this::processMessage);
    }

    @Override
    public StreamsEventResponse handleRequest(KinesisEvent kinesisEvent, Context
context) {
        return handler.processBatch(kinesisEvent, context);
    }

    private void processMessage(KinesisEvent.KinesisEventRecord kinesisEventRecord,
Context context) {
        // Process the stream record
    }
}
```

.NET

Note

For complete examples and setup instructions, see the [batch processor documentation](#).

Processing Kinesis Data Streams stream records with AWS Lambda batch processor.

```
using System;
using System.Threading;
using System.Threading.Tasks;
using Amazon.Lambda.Core;
using Amazon.Lambda.KinesisEvents;
using Amazon.Lambda.Serialization.SystemTextJson;
using AWS.Lambda.Powertools.BatchProcessing;

[assembly: LambdaSerializer(typeof(DefaultLambdaJsonSerializer))]

namespace HelloWorld;

public class OrderEvent
{
    public string? OrderId { get; set; }
    public string? CustomerId { get; set; }
    public decimal Amount { get; set; }
    public DateTime OrderDate { get; set; }
}

internal class TypedKinesisRecordHandler : ITypedRecordHandler<OrderEvent>
{
    public async Task<RecordHandlerResult> HandleAsync(OrderEvent orderEvent,
        CancellationToken cancellation_token)
    {
        if (string.IsNullOrEmpty(orderEvent.OrderId))
        {
            throw new ArgumentException("Order ID is required");
        }

        return await Task.FromResult(RecordHandlerResult.None);
    }
}
```

```
public class Function
{
    [BatchProcessor(TypedRecordHandler = typeof(TypedKinesisRecordHandler))]
    public BatchItemFailuresResponse HandlerUsingTypedAttribute(KinesisEvent _)
    {
        return TypedKinesisStreamBatchProcessor.Result.BatchItemFailuresResponse;
    }
}
```

Retain discarded batch records for a Kinesis Data Streams event source in Lambda

Error handling for Kinesis event source mappings depends on whether the error occurs before the function is invoked or during function invocation:

- **Before invocation:** If a Lambda event source mapping is unable to invoke the function due to throttling or other issues, it retries until the records expire or exceed the maximum age configured on the event source mapping ([MaximumRecordAgeInSeconds](#)).
- **During invocation:** If the function is invoked but returns an error, Lambda retries until the records expire, exceed the maximum age ([MaximumRecordAgeInSeconds](#)), or reach the configured retry quota ([MaximumRetryAttempts](#)). For function errors, you can also configure [BisectBatchOnFunctionError](#), which splits a failed batch into two smaller batches, isolating bad records and avoiding timeouts. Splitting batches doesn't consume the retry quota.

If the error handling measures fail, Lambda discards the records and continues processing batches from the stream. With the default settings, this means that a bad record can block processing on the affected shard for up to one week. To avoid this, configure your function's event source mapping with a reasonable number of retries and a maximum record age that fits your use case.

Configuring destinations for failed invocations

To retain records of failed event source mapping invocations, add a destination to your function's event source mapping. Each record sent to the destination is a JSON document containing metadata about the failed invocation. For Amazon S3 destinations, Lambda also sends the entire invocation record along with the metadata. You can configure any Amazon SNS topic, Amazon SQS queue, Amazon S3 bucket, or Kafka as a destination.

With Amazon S3 destinations, you can use the [Amazon S3 Event Notifications](#) feature to receive notifications when objects are uploaded to your destination S3 bucket. You can also configure S3 Event Notifications to invoke another Lambda function to perform automated processing on failed batches.

Your execution role must have permissions for the destination:

- **For an SQS destination:** [sqs:SendMessage](#)
- **For an SNS destination:** [sns:Publish](#)
- **For an S3 destination:** [s3:PutObject](#) and [s3:ListBucket](#)
- **For a Kafka destination:** [kafka-cluster:WriteData](#)

You can configure a Kafka topic as an on-failure destination for your Kafka event source mappings. When Lambda can't process records after exhausting retry attempts or when records exceed the maximum age, Lambda sends the failed records to the specified Kafka topic for later processing. Refer to [the section called "Kafka on-failure destination"](#).

If you've enabled encryption with your own KMS key for an S3 destination, your function's execution role must also have permission to call [kms:GenerateDataKey](#). If the KMS key and S3 bucket destination are in a different account from your Lambda function and execution role, configure the KMS key to trust the execution role to allow `kms:GenerateDataKey`.

To configure an on-failure destination using the console, follow these steps:

1. Open the [Functions page](#) of the Lambda console.
2. Choose a function.
3. Under **Function overview**, choose **Add destination**.
4. For **Source**, choose **Event source mapping invocation**.
5. For **Event source mapping**, choose an event source that's configured for this function.
6. For **Condition**, select **On failure**. For event source mapping invocations, this is the only accepted condition.
7. For **Destination type**, choose the destination type that Lambda sends invocation records to.
8. For **Destination**, choose a resource.
9. Choose **Save**.

You can also configure an on-failure destination using the AWS Command Line Interface (AWS CLI). For example, the following [create-event-source-mapping](#) command adds an event source mapping with an SQS on-failure destination to MyFunction:

```
aws lambda create-event-source-mapping \  
--function-name "MyFunction" \  
--event-source-arn arn:aws:kinesis:us-east-2:123456789012:stream/lambda-stream \  
--destination-config '{"OnFailure": {"Destination": "arn:aws:sqs:us-  
east-1:123456789012:dest-queue"}}'
```

The following [update-event-source-mapping](#) command updates an event source mapping to send failed invocation records to an SNS destination after two retry attempts, or if the records are more than an hour old.

```
aws lambda update-event-source-mapping \  
--uuid f89f8514-cdd9-4602-9e1f-01a5b77d449b \  
--maximum-retry-attempts 2 \  
--maximum-record-age-in-seconds 3600 \  
--destination-config '{"OnFailure": {"Destination": "arn:aws:sns:us-  
east-1:123456789012:dest-topic"}}'
```

Updated settings are applied asynchronously and aren't reflected in the output until the process completes. Use the [get-event-source-mapping](#) command to view the current status.

To remove a destination, supply an empty string as the argument to the `destination-config` parameter:

```
aws lambda update-event-source-mapping \  
--uuid f89f8514-cdd9-4602-9e1f-01a5b77d449b \  
--destination-config '{"OnFailure": {"Destination": ""}}'
```

Security best practices for Amazon S3 destinations

Deleting an S3 bucket that's configured as a destination without removing the destination from your function's configuration can create a security risk. If another user knows your destination bucket's name, they can recreate the bucket in their AWS account. Records of failed invocations will be sent to their bucket, potentially exposing data from your function.

⚠ Warning

To ensure that invocation records from your function can't be sent to an S3 bucket in another AWS account, add a condition to your function's execution role that limits `s3:PutObject` permissions to buckets in your account.

The following example shows an IAM policy that limits your function's `s3:PutObject` permissions to buckets in your account. This policy also gives Lambda the `s3:ListBucket` permission it needs to use an S3 bucket as a destination.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "S3BucketResourceAccountWrite",
      "Effect": "Allow",
      "Action": [
        "s3:PutObject",
        "s3:ListBucket"
      ],
      "Resource": [
        "arn:aws:s3:::*/*",
        "arn:aws:s3:::*"
      ],
      "Condition": {
        "StringEquals": {
          "s3:ResourceAccount": "111122223333"
        }
      }
    }
  ]
}
```

To add a permissions policy to your function's execution role using the AWS Management Console or AWS CLI, refer to the instructions in the following procedures:

Console

To add a permissions policy to a function's execution role (console)

1. Open the [Functions page](#) of the Lambda console.
2. Select the Lambda function whose execution role you want to modify.
3. In the **Configuration** tab, select **Permissions**.
4. In the **Execution role** tab, select your function's **Role name** to open the role's IAM console page.
5. Add a permissions policy to the role by doing the following:
 - a. In the **Permissions policies** pane, choose **Add permissions** and select **Create inline policy**.
 - b. In **Policy editor**, select **JSON**.
 - c. Paste the policy you want to add into the editor (replacing the existing JSON), and then choose **Next**.
 - d. Under **Policy details**, enter a **Policy name**.
 - e. Choose **Create policy**.

AWS CLI

To add a permissions policy to a function's execution role (CLI)

1. Create a JSON policy document with the required permissions and save it in a local directory.
2. Use the IAM `put-role-policy` CLI command to add the permissions to your function's execution role. Run the following command from the directory you saved your JSON policy document in and replace the role name, policy name, and policy document with your own values.

```
aws iam put-role-policy \
--role-name my_lambda_role \
--policy-name LambdaS3DestinationPolicy \
--policy-document file://my_policy.json
```

Example Amazon SNS and Amazon SQS invocation record

The following example shows what Lambda sends to an SQS queue or SNS topic for a failed Kinesis event source invocation. Because Lambda sends only the metadata for these destination types, use the `streamArn`, `shardId`, `startSequenceNumber`, and `endSequenceNumber` fields to obtain the full original record. All of the fields shown in the `KinesisBatchInfo` property will always be present.

```
{
  "requestContext": {
    "requestId": "c9b8fa9f-5a7f-xmpl-af9c-0c604cde93a5",
    "functionArn": "arn:aws:lambda:us-east-2:123456789012:function:myfunction",
    "condition": "RetryAttemptsExhausted",
    "approximateInvokeCount": 1
  },
  "responseContext": {
    "statusCode": 200,
    "executedVersion": "$LATEST",
    "functionError": "Unhandled"
  },
  "version": "1.0",
  "timestamp": "2019-11-14T00:38:06.021Z",
  "KinesisBatchInfo": {
    "shardId": "shardId-000000000001",
    "startSequenceNumber":
"49601189658422359378836298521827638475320189012309704722",
    "endSequenceNumber":
"49601189658422359378836298522902373528957594348623495186",
    "approximateArrivalOfFirstRecord": "2019-11-14T00:38:04.835Z",
    "approximateArrivalOfLastRecord": "2019-11-14T00:38:05.580Z",
    "batchSize": 500,
    "streamArn": "arn:aws:kinesis:us-east-2:123456789012:stream/mystream"
  }
}
```

You can use this information to retrieve the affected records from the stream for troubleshooting. The actual records aren't included, so you must process this record and retrieve them from the stream before they expire and are lost.

Example Amazon S3 invocation record

The following example shows what Lambda sends to an Amazon S3 bucket for a failed Kinesis event source invocation. In addition to all of the fields from the previous example for SQS and SNS destinations, the payload field contains the original invocation record as an escaped JSON string.

```
{
  "requestContext": {
    "requestId": "c9b8fa9f-5a7f-xmpl-af9c-0c604cde93a5",
    "functionArn": "arn:aws:lambda:us-east-2:123456789012:function:myfunction",
    "condition": "RetryAttemptsExhausted",
    "approximateInvokeCount": 1
  },
  "responseContext": {
    "statusCode": 200,
    "executedVersion": "$LATEST",
    "functionError": "Unhandled"
  },
  "version": "1.0",
  "timestamp": "2019-11-14T00:38:06.021Z",
  "KinesisBatchInfo": {
    "shardId": "shardId-000000000001",
    "startSequenceNumber":
"49601189658422359378836298521827638475320189012309704722",
    "endSequenceNumber":
"49601189658422359378836298522902373528957594348623495186",
    "approximateArrivalOfFirstRecord": "2019-11-14T00:38:04.835Z",
    "approximateArrivalOfLastRecord": "2019-11-14T00:38:05.580Z",
    "batchSize": 500,
    "streamArn": "arn:aws:kinesis:us-east-2:123456789012:stream/mystream"
  },
  "payload": "<Whole Event>" // Only available in S3
}
```

The S3 object containing the invocation record uses the following naming convention:

```
aws/lambda/<ESM-UUID>/<shardID>/YYYY/MM/DD/YYYY-MM-DDTHH.MM.SS-<Random UUID>
```

Implementing stateful Kinesis Data Streams processing in Lambda

Lambda functions can run continuous stream processing applications. A stream represents unbounded data that flows continuously through your application. To analyze information from

this continuously updating input, you can bound the included records using a window defined in terms of time.

Tumbling windows are distinct time windows that open and close at regular intervals. By default, Lambda invocations are stateless—you cannot use them for processing data across multiple continuous invocations without an external database. However, with tumbling windows, you can maintain your state across invocations. This state contains the aggregate result of the messages previously processed for the current window. Your state can be a maximum of 1 MB per shard. If it exceeds that size, Lambda terminates the window early.

Each record in a stream belongs to a specific window. Lambda will process each record at least once, but doesn't guarantee that each record will be processed only once. In rare cases, such as error handling, some records might be processed more than once. Records are always processed in order the first time. If records are processed more than once, they might be processed out of order.

Aggregation and processing

Your user managed function is invoked both for aggregation and for processing the final results of that aggregation. Lambda aggregates all records received in the window. You can receive these records in multiple batches, each as a separate invocation. Each invocation receives a state. Thus, when using tumbling windows, your Lambda function response must contain a state property. If the response does not contain a state property, Lambda considers this a failed invocation. To satisfy this condition, your function can return a `TimeWindowEventResponse` object, which has the following JSON shape:

Example `TimeWindowEventResponse` values

```
{
  "state": {
    "1": 282,
    "2": 715
  },
  "batchItemFailures": []
}
```

Note

For Java functions, we recommend using a `Map<String, String>` to represent the state.

At the end of the window, the flag `isFinalInvokeForWindow` is set to `true` to indicate that this is the final state and that it's ready for processing. After processing, the window completes and your final invocation completes, and then the state is dropped.

At the end of your window, Lambda uses final processing for actions on the aggregation results. Your final processing is synchronously invoked. After successful invocation, your function checkpoints the sequence number and stream processing continues. If invocation is unsuccessful, your Lambda function suspends further processing until a successful invocation.

Example KinesisTimeWindowEvent

```
{
  "Records": [
    {
      "kinesis": {
        "kinesisSchemaVersion": "1.0",
        "partitionKey": "1",
        "sequenceNumber":
"49590338271490256608559692538361571095921575989136588898",
        "data": "SGVsbG8sIHRoaXMgaXMgYSB0ZXN0Lg==",
        "approximateArrivalTimestamp": 1607497475.000
      },
      "eventSource": "aws:kinesis",
      "eventVersion": "1.0",
      "eventID":
"shardId-0000000000006:49590338271490256608559692538361571095921575989136588898",
      "eventName": "aws:kinesis:record",
      "invokeIdentityArn": "arn:aws:iam::123456789012:role/lambda-kinesis-role",
      "awsRegion": "us-east-1",
      "eventSourceARN": "arn:aws:kinesis:us-east-1:123456789012:stream/lambda-
stream"
    }
  ],
  "window": {
    "start": "2020-12-09T07:04:00Z",
    "end": "2020-12-09T07:06:00Z"
  },
  "state": {
    "1": 282,
    "2": 715
  },
  "shardId": "shardId-0000000000006",
}
```

```
"eventSourceARN": "arn:aws:kinesis:us-east-1:123456789012:stream/lambda-stream",
"isFinalInvokeForWindow": false,
"isWindowTerminatedEarly": false
}
```

Configuration

You can configure tumbling windows when you create or update an event source mapping. To configure a tumbling window, specify the window in seconds ([TumblingWindowInSeconds](#)). The following example AWS Command Line Interface (AWS CLI) command creates a streaming event source mapping that has a tumbling window of 120 seconds. The Lambda function defined for aggregation and processing is named `tumbling-window-example-function`.

```
aws lambda create-event-source-mapping \
--event-source-arn arn:aws:kinesis:us-east-1:123456789012:stream/lambda-stream \
--function-name tumbling-window-example-function \
--starting-position TRIM_HORIZON \
--tumbling-window-in-seconds 120
```

Lambda determines tumbling window boundaries based on the time when records were inserted into the stream. All records have an approximate timestamp available that Lambda uses in boundary determinations.

Tumbling window aggregations do not support resharding. When a shard ends, Lambda considers the current window to be closed, and any child shards will start their own window in a fresh state. When no new records are being added to the current window, Lambda waits for up to 2 minutes before assuming that the window is over. This helps ensure that the function reads all records in the current window, even if the records are added intermittently.

Tumbling windows fully support the existing retry policies `maxRetryAttempts` and `maxRecordAge`.

Example Handler.py – Aggregation and processing

The following Python function demonstrates how to aggregate and then process your final state:

```
def lambda_handler(event, context):
    print('Incoming event: ', event)
    print('Incoming state: ', event['state'])
```

```
#Check if this is the end of the window to either aggregate or process.
    if event['isFinalInvokeForWindow']:
        # logic to handle final state of the window
        print('Destination invoke')
    else:
        print('Aggregate invoke')

#Check for early terminations
    if event['isWindowTerminatedEarly']:
        print('Window terminated early')

    #Aggregation logic
    state = event['state']
    for record in event['Records']:
        state[record['kinesis']['partitionKey']] = state.get(record['kinesis']
['partitionKey'], 0) + 1

    print('Returning state: ', state)
    return {'state': state}
```

Lambda parameters for Amazon Kinesis Data Streams event source mappings

All Lambda event source mappings share the same [CreateEventSourceMapping](#) and [UpdateEventSourceMapping](#) API operations. However, only some of the parameters apply to Kinesis.

Parameter	Required	Default	Notes
BatchSize	N	100	Maximum: 10,000
BisectBatchOnFunctionError	N	false	none
DestinationConfig	N	N/A	Amazon SQS queue or Amazon SNS topic destination for discarded records. For more information, see Configuring

Parameter	Required	Default	Notes
			destinations for failed invocations.
Enabled	N	true	none
EventSourceArn	Y	N/A	ARN of the data stream or a stream consumer
FunctionName	Y	N/A	none
FunctionResponseTypes	N	N/A	To let your function report specific failures in a batch, include the value <code>ReportBatchItemFailures</code> in <code>FunctionResponseTypes</code> . For more information, see Configuring partial batch response with Kinesis Data Streams and Lambda.
MaximumBatchingWindowInSeconds	N	0	none

Parameter	Required	Default	Notes
MaximumRecordAgeInSeconds	N	-1	-1 means infinite: Lambda doesn't discard records (Kinesis Data Streams data retention settings still apply) Minimum: -1 Maximum: 604,800
MaximumRetryAttempts	N	-1	-1 means infinite: failed records are retried until the record expires Minimum: -1 Maximum: 10,000
ParallelizationFactor	N	1	Maximum: 10
StartingPosition	Y	N/A	AT_TIMESTAMP, TRIM_HORIZON, or LATEST
StartingPositionTimestamp	N	N/A	Only valid if StartingPosition is set to AT_TIMESTAMP. The time from which to start reading, in Unix time seconds
TumblingWindowInSeconds	N	N/A	Minimum: 0 Maximum: 900

```
"eventSourceARN": "arn:aws:kinesis:us-east-2:123456789012:stream/lambda-stream"
}
```

As long as the data the producer puts into the stream is valid JSON, you can use event filtering to filter records using the data key. Suppose a producer is putting records into your Kinesis stream in the following JSON format.

```
{
  "record": 12345,
  "order": {
    "type": "buy",
    "stock": "ANYCO",
    "quantity": 1000
  }
}
```

To filter only those records where the order type is “buy,” the `FilterCriteria` object would be as follows.

```
{
  "Filters": [
    {
      "Pattern": "{ \"data\" : { \"order\" : { \"type\" : [ \"buy\" ] } } }"
    }
  ]
}
```

For added clarity, here is the value of the filter's `Pattern` expanded in plain JSON.

```
{
  "data": {
    "order": {
      "type": [ "buy" ]
    }
  }
}
```

You can add your filter using the console, AWS CLI or an AWS SAM template.

Console

To add this filter using the console, follow the instructions in [Attaching filter criteria to an event source mapping \(console\)](#) and enter the following string for the **Filter criteria**.

```
{ "data" : { "order" : { "type" : [ "buy" ] } } }
```

AWS CLI

To create a new event source mapping with these filter criteria using the AWS Command Line Interface (AWS CLI), run the following command.

```
aws lambda create-event-source-mapping \
  --function-name my-function \
  --event-source-arn arn:aws:kinesis:us-east-2:123456789012:stream/my-stream \
  --filter-criteria '{"Filters": [{"Pattern": "{ \"data\" : { \"order\" : { \"type
\" : [ \"buy\" ] } } }"]}]'
```

To add these filter criteria to an existing event source mapping, run the following command.

```
aws lambda update-event-source-mapping \
  --uuid "a1b2c3d4-5678-90ab-cdef-1111EXAMPLE" \
  --filter-criteria '{"Filters": [{"Pattern": "{ \"data\" : { \"order\" : { \"type
\" : [ \"buy\" ] } } }"]}]'
```

AWS SAM

To add this filter using AWS SAM, add the following snippet to the YAML template for your event source.

```
FilterCriteria:
  Filters:
    - Pattern: '{ "data" : { "order" : { "type" : [ "buy" ] } } }'
```

To properly filter events from Kinesis sources, both the data field and your filter criteria for the data field must be in valid JSON format. If either field isn't in a valid JSON format, Lambda drops the message or throws an exception. The following table summarizes the specific behavior:

Incoming data format	Filter pattern format for data properties	Resulting action
Valid JSON	Valid JSON	Lambda filters based on your filter criteria.
Valid JSON	No filter pattern for data properties	Lambda filters (on the other metadata properties only) based on your filter criteria.
Valid JSON	Non-JSON	Lambda throws an exception at the time of the event source mapping creation or update. The filter pattern for data properties must be in a valid JSON format.
Non-JSON	Valid JSON	Lambda drops the record.
Non-JSON	No filter pattern for data properties	Lambda filters (on the other metadata properties only) based on your filter criteria.
Non-JSON	Non-JSON	Lambda throws an exception at the time of the event source mapping creation or update. The filter pattern for data properties must be in a valid JSON format.

Filtering Kinesis aggregated records

With Kinesis, you can aggregate multiple records into a single Kinesis Data Streams record to increase your data throughput. Lambda can only apply filter criteria to aggregated records when you use Kinesis [enhanced fan-out](#). Filtering aggregated records with standard Kinesis isn't supported. When using enhanced fan-out, you configure a Kinesis dedicated-throughput consumer

to act as the trigger for your Lambda function. Lambda then filters the aggregated records and passes only those records that meet your filter criteria.

To learn more about Kinesis record aggregation, refer to the [Aggregation](#) section on the Kinesis Producer Library (KPL) Key Concepts page. To learn more about using Lambda with Kinesis enhanced fan-out, see [Increasing real-time stream processing performance with Amazon Kinesis Data Streams enhanced fan-out and AWS Lambda](#) on the AWS compute blog.

Tutorial: Using Lambda with Kinesis Data Streams

In this tutorial, you create a Lambda function to consume events from an Amazon Kinesis data stream.

1. Custom app writes records to the stream.
2. AWS Lambda polls the stream and, when it detects new records in the stream, invokes your Lambda function.
3. AWS Lambda runs the Lambda function by assuming the execution role you specified at the time you created the Lambda function.

Prerequisites

Install the AWS Command Line Interface

If you have not yet installed the AWS Command Line Interface, follow the steps at [Installing or updating the latest version of the AWS CLI](#) to install it.

The tutorial requires a command line terminal or shell to run commands. In Linux and macOS, use your preferred shell and package manager.

Note

In Windows, some Bash CLI commands that you commonly use with Lambda (such as `zip`) are not supported by the operating system's built-in terminals. To get a Windows-integrated version of Ubuntu and Bash, [install the Windows Subsystem for Linux](#).

Create the execution role

Create the [execution role](#) that gives your function permission to access AWS resources.

To create an execution role

1. Open the [roles page](#) in the IAM console.
2. Choose **Create role**.
3. Create a role with the following properties.
 - **Trusted entity** – **AWS Lambda**.
 - **Permissions** – **AWSLambdaKinesisExecutionRole**.
 - **Role name** – **lambda-kinesis-role**.

The **AWSLambdaKinesisExecutionRole** policy has the permissions that the function needs to read items from Kinesis and write logs to CloudWatch Logs.

Create the function

Create a Lambda function that processes your Kinesis messages. The function code logs the event ID and event data of the Kinesis record to CloudWatch Logs.

This tutorial uses the Node.js 24 runtime, but we've also provided example code in other runtime languages. You can select the tab in the following box to see code for the runtime you're interested in. The JavaScript code you'll use in this step is in the first example shown in the **JavaScript** tab.

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Serverless examples](#) repository.

Consuming an Kinesis event with Lambda using Rust.

```

// Copyright Amazon.com, Inc. or its affiliates. All Rights Reserved.
// SPDX-License-Identifier: Apache-2.0
use aws_lambda_events::event::kinesis::KinesisEvent;
use lambda_runtime::{run, service_fn, Error, LambdaEvent};

async fn function_handler(event: LambdaEvent<KinesisEvent>) -> Result<(), Error>
{
    if event.payload.records.is_empty() {
        tracing::info!("No records found. Exiting.");
        return Ok(());
    }

    event.payload.records.iter().for_each(|record| {

```

```

        tracing::info!("EventId:
        {}", record.event_id.as_deref().unwrap_or_default());

        let record_data = std::str::from_utf8(&record.kinesis.data);

        match record_data {
            Ok(data) => {
                // log the record data
                tracing::info!("Data: {}", data);
            }
            Err(e) => {
                tracing::error!("Error: {}", e);
            }
        }
    });

    tracing::info!(
        "Successfully processed {} records",
        event.payload.records.len()
    );

    Ok(())
}

#[tokio::main]
async fn main() -> Result<(), Error> {
    tracing_subscriber::fmt()
        .with_max_level(tracing::Level::INFO)
        // disable printing the name of the module in every log line.
        .with_target(false)
        // disabling time is handy because CloudWatch will add the ingestion
        time.
        .without_time()
        .init();

    run(service_fn(function_handler)).await
}

```

To create the function

1. Create a directory for the project, and then switch to that directory.

```
mkdir kinesis-tutorial
cd kinesis-tutorial
```

2. Copy the sample JavaScript code into a new file named `index.js`.
3. Create a deployment package.

```
zip function.zip index.js
```

4. Create a Lambda function with the `create-function` command.

```
aws lambda create-function --function-name ProcessKinesisRecords \
--zip-file fileb://function.zip --handler index.handler --runtime nodejs24.x \
--role arn:aws:iam::111122223333:role/lambda-kinesis-role
```

Test the Lambda function

Invoke your Lambda function manually using the `invoke` AWS Lambda CLI command and a sample Kinesis event.

To test the Lambda function

1. Copy the following JSON into a file and save it as `input.txt`.

```
{
  "Records": [
    {
      "kinesis": {
        "kinesisSchemaVersion": "1.0",
        "partitionKey": "1",
        "sequenceNumber":
"49590338271490256608559692538361571095921575989136588898",
        "data": "SGVsbG8sIHRoaXMgaXMgYSB0ZXN0Lg==",
        "approximateArrivalTimestamp": 1545084650.987
      },
      "eventSource": "aws:kinesis",
      "eventVersion": "1.0",
      "eventID":
"shardId-000000000006:49590338271490256608559692538361571095921575989136588898",
      "eventName": "aws:kinesis:record",
    }
  ]
}
```

```
        "invokeIdentityArn": "arn:aws:iam::111122223333:role/lambda-kinesis-
role",
        "awsRegion": "us-east-2",
        "eventSourceARN": "arn:aws:kinesis:us-east-2:111122223333:stream/
lambda-stream"
    }
  ]
}
```

2. Use the `invoke` command to send the event to the function.

```
aws lambda invoke --function-name ProcessKinesisRecords \
--cli-binary-format raw-in-base64-out \
--payload file://input.txt outputfile.txt
```

The **cli-binary-format** option is required if you're using AWS CLI version 2. To make this the default setting, run `aws configure set cli-binary-format raw-in-base64-out`. For more information, see [AWS CLI supported global command line options](#) in the *AWS Command Line Interface User Guide for Version 2*.

The response is saved to `out.txt`.

Create a Kinesis stream

Use the `create-stream` command to create a stream.

```
aws kinesis create-stream --stream-name lambda-stream --shard-count 1
```

Run the following `describe-stream` command to get the stream ARN.

```
aws kinesis describe-stream --stream-name lambda-stream
```

You should see the following output:

```
{
  "StreamDescription": {
    "Shards": [
      {
        "ShardId": "shardId-000000000000",
        "HashKeyRange": {
```

```

        "StartingHashKey": "0",
        "EndingHashKey": "340282366920746074317682119384634633455"
    },
    "SequenceNumberRange": {
        "StartingSequenceNumber":
"49591073947768692513481539594623130411957558361251844610"
    }
},
"StreamARN": "arn:aws:kinesis:us-east-1:111122223333:stream/lambda-stream",
"StreamName": "lambda-stream",
"StreamStatus": "ACTIVE",
"RetentionPeriodHours": 24,
"EnhancedMonitoring": [
    {
        "ShardLevelMetrics": []
    }
],
"EncryptionType": "NONE",
"KeyId": null,
"StreamCreationTimestamp": 1544828156.0
}
}

```

You use the stream ARN in the next step to associate the stream with your Lambda function.

Add an event source in AWS Lambda

Run the following AWS CLI `add-event-source` command.

```

aws lambda create-event-source-mapping --function-name ProcessKinesisRecords \
--event-source arn:aws:kinesis:us-east-1:111122223333:stream/lambda-stream \
--batch-size 100 --starting-position LATEST

```

Note the mapping ID for later use. You can get a list of event source mappings by running the `list-event-source-mappings` command.

```

aws lambda list-event-source-mappings --function-name ProcessKinesisRecords \
--event-source arn:aws:kinesis:us-east-1:111122223333:stream/lambda-stream

```

In the response, you can verify the status value is enabled. Event source mappings can be disabled to pause polling temporarily without losing any records.

Test the setup

To test the event source mapping, add event records to your Kinesis stream. The `--data` value is a string that the CLI encodes to base64 prior to sending it to Kinesis. You can run the same command more than once to add multiple records to the stream.

```
aws kinesis put-record --stream-name lambda-stream --partition-key 1 \  
--data "Hello, this is a test."
```

Lambda uses the execution role to read records from the stream. Then it invokes your Lambda function, passing in batches of records. The function decodes data from each record and logs it, sending the output to CloudWatch Logs. View the logs in the [CloudWatch console](#).

Clean up your resources

You can now delete the resources that you created for this tutorial, unless you want to retain them. By deleting AWS resources that you're no longer using, you prevent unnecessary charges to your AWS account.

To delete the execution role

1. Open the [Roles page](#) of the IAM console.
2. Select the execution role that you created.
3. Choose **Delete**.
4. Enter the name of the role in the text input field and choose **Delete**.

To delete the Lambda function

1. Open the [Functions page](#) of the Lambda console.
2. Select the function that you created.
3. Choose **Actions, Delete**.
4. Type **confirm** in the text input field and choose **Delete**.

To delete the Kinesis stream

1. Sign in to the AWS Management Console and open the Kinesis console at <https://console.aws.amazon.com/kinesis>.

2. Select the stream you created.
3. Choose **Actions, Delete**.
4. Enter **delete** in the text input field.
5. Choose **Delete**.

Using Lambda with Kubernetes

You can deploy and manage Lambda functions with the Kubernetes API using [AWS Controllers for Kubernetes \(ACK\)](#) or [Crossplane](#).

AWS Controllers for Kubernetes (ACK)

You can use ACK to deploy and manage AWS resources from the Kubernetes API. Through ACK, AWS provides open-source custom controllers for AWS services such as Lambda, Amazon Elastic Container Registry (Amazon ECR), Amazon Simple Storage Service (Amazon S3), and Amazon SageMaker AI. Each supported AWS service has its own custom controller. In your Kubernetes cluster, install a controller for each AWS service that you want to use. Then, create a [Custom Resource Definition \(CRD\)](#) to define the AWS resources.

We recommend that you use [Helm 3.8 or later](#) to install ACK controllers. Every ACK controller comes with its own Helm chart, which installs the controller, CRDs, and Kubernetes RBAC rules. For more information, see [Install an ACK Controller](#) in the ACK documentation.

After you create the ACK custom resource, you can use it like any other built-in Kubernetes object. For example, you can deploy and manage Lambda functions with your preferred Kubernetes toolchains, including [kubectrl](#).

Here are some example use cases for provisioning Lambda functions through ACK:

- Your organization uses [role-based access control \(RBAC\)](#) and [IAM roles for service accounts](#) to create permissions boundaries. With ACK, you can reuse this security model for Lambda without having to create new users and policies.
- Your organization has a DevOps process to deploy resources into an Amazon Elastic Kubernetes Service (Amazon EKS) cluster using Kubernetes manifests. With ACK, you can use a manifest to provision Lambda functions without creating separate infrastructure as code templates.

For more information about using ACK, see the [Lambda tutorial in the ACK documentation](#).

Crossplane

[Crossplane](#) is an open-source Cloud Native Computing Foundation (CNCF) project that uses Kubernetes to manage cloud infrastructure resources. With Crossplane, developers can request infrastructure without needing to understand its complexities. Platform teams retain control over how the infrastructure is provisioned and managed.

Using Crossplane, you can deploy and manage Lambda functions with your preferred Kubernetes toolchains such as [kubectrl](#), and any CI/CD pipeline that can deploy manifests to Kubernetes. Here are some example use cases for provisioning Lambda functions through Crossplane:

- Your organization wants to enforce compliance by ensuring that Lambda functions have the correct [tags](#). Platform teams can use [Crossplane Compositions](#) to define this policy through API abstractions. Developers can then use these abstractions to deploy Lambda functions with tags.
- Your project uses GitOps with Kubernetes. In this model, Kubernetes continuously reconciles the git repository (desired state) with the resources running inside the cluster (current state). If there are differences, the GitOps process automatically makes changes to the cluster. You can use GitOps with Kubernetes for deploying and managing Lambda functions through Crossplane, using familiar Kubernetes tools and concepts such as [CRDs](#) and [Controllers](#).

To learn more about using Crossplane with Lambda, see the following:

- [AWS Blueprints for Crossplane](#): This repository includes examples of how to use Crossplane to deploy AWS resources, including Lambda functions.

 **Note**

AWS Blueprints for Crossplane are under active development and should not be used in production.

- [Deploying Lambda with Amazon EKS and Crossplane](#): This video demonstrates an advanced example of deploying an AWS serverless architecture with Crossplane, exploring the design from both the developer and platform perspectives.

Using Lambda with Amazon MQ

Note

If you want to send data to a target other than a Lambda function or enrich the data before sending it, see [Amazon EventBridge Pipes](#).

Amazon MQ is a managed message broker service for [Apache ActiveMQ](#) and [RabbitMQ](#). A *message broker* enables software applications and components to communicate using various programming languages, operating systems, and formal messaging protocols through either topic or queue event destinations.

Amazon MQ can also manage Amazon Elastic Compute Cloud (Amazon EC2) instances on your behalf by installing ActiveMQ or RabbitMQ brokers and by providing different network topologies and other infrastructure needs.

You can use a Lambda function to process records from your Amazon MQ message broker. Lambda invokes your function through an [event source mapping](#), a Lambda resource that reads messages from your broker and invokes the function [synchronously](#).

Warning

Lambda event source mappings process each event at least once, and duplicate processing of records can occur. To avoid potential issues related to duplicate events, we strongly recommend that you make your function code idempotent. To learn more, see [How do I make my Lambda function idempotent](#) in the AWS Knowledge Center.

The Amazon MQ event source mapping has the following configuration restrictions:

- **Concurrency** – Lambda functions that use an Amazon MQ event source mapping have a default maximum [concurrency](#) setting. For ActiveMQ, the Lambda service limits the number of concurrent execution environments to five per Amazon MQ event source mapping. For RabbitMQ, the number of concurrent execution environments is limited to 1 per Amazon MQ event source mapping. Even if you change your function's reserved or provisioned concurrency settings, the Lambda service won't make more execution environments available. To request an increase in the default maximum concurrency for a single Amazon MQ event source mapping,

contact Support with the event source mapping UUID, as well as the region. Because increases are applied at the specific event source mapping level, not the account or region level, you need to manually request a scaling increase for each event source mapping.

- Cross account – Lambda does not support cross-account processing. You cannot use Lambda to process records from an Amazon MQ message broker that is in a different AWS account.
- Authentication – For ActiveMQ, only the ActiveMQ [SimpleAuthenticationPlugin](#) is supported. For RabbitMQ, only the [PLAIN](#) authentication mechanism is supported. Users must use AWS Secrets Manager to manage their credentials. For more information about ActiveMQ authentication, see [Integrating ActiveMQ brokers with LDAP](#) in the *Amazon MQ Developer Guide*.
- Connection quota – Brokers have a maximum number of allowed connections per wire-level protocol. This quota is based on the broker instance type. For more information, see the [Brokers](#) section of **Quotas in Amazon MQ** in the *Amazon MQ Developer Guide*.
- Connectivity – You can create brokers in a public or private virtual private cloud (VPC). For private VPCs, your Lambda function needs access to the VPC to receive messages. For more information, see [the section called “Configure network security”](#) later in this section.
- Event destinations – Only queue destinations are supported. However, you can use a virtual topic, which behaves as a topic internally while interacting with Lambda as a queue. For more information, see [Virtual Destinations](#) on the Apache ActiveMQ website, and [Virtual Hosts](#) on the RabbitMQ website.
- Network topology – For ActiveMQ, only one single-instance or standby broker is supported per event source mapping. For RabbitMQ, only one single-instance broker or cluster deployment is supported per event source mapping. Single-instance brokers require a failover endpoint. For more information about these broker deployment modes, see [Active MQ Broker Architecture](#) and [Rabbit MQ Broker Architecture](#) in the *Amazon MQ Developer Guide*.
- Protocols – Supported protocols depend on the type of Amazon MQ integration.
 - For ActiveMQ integrations, Lambda consumes messages using the OpenWire/Java Message Service (JMS) protocol. No other protocols are supported for consuming messages. Within the JMS protocol, only [TextMessage](#) and [BytesMessage](#) are supported. Lambda also supports JMS custom properties. For more information about the OpenWire protocol, see [OpenWire](#) on the Apache ActiveMQ website.
 - For RabbitMQ integrations, Lambda consumes messages using the AMQP 0-9-1 protocol. No other protocols are supported for consuming messages. For more information about RabbitMQ's implementation of the AMQP 0-9-1 protocol, see [AMQP 0-9-1 Complete Reference Guide](#) on the RabbitMQ website.

Lambda automatically supports the latest versions of ActiveMQ and RabbitMQ that Amazon MQ supports. For the latest supported versions, see [Amazon MQ release notes](#) in the *Amazon MQ Developer Guide*.

 **Note**

By default, Amazon MQ has a weekly maintenance window for brokers. During that window of time, brokers are unavailable. For brokers without standby, Lambda cannot process any messages during that window.

Topics

- [Understanding the Lambda consumer group for Amazon MQ](#)
- [Configuring Amazon MQ event source for Lambda](#)

- [Troubleshoot Amazon MQ event source mapping errors](#)

Understanding the Lambda consumer group for Amazon MQ

To interact with Amazon MQ, Lambda creates a consumer group which can read from your Amazon MQ brokers. The consumer group is created with the same ID as the event source mapping UUID.

For Amazon MQ event sources, Lambda batches records together and sends them to your function in a single payload. To control behavior, you can configure the batching window and batch size. Lambda pulls messages until it processes the payload size maximum of 6 MB, the batching window expires, or the number of records reaches the full batch size. For more information, see [Batching behavior](#).

The consumer group retrieves the messages as a BLOB of bytes, base64-encodes them into a single JSON payload, and then invokes your function. If your function returns an error for any of the messages in a batch, Lambda retries the whole batch of messages until processing succeeds or the messages expire.

Note

While Lambda functions typically have a maximum timeout limit of 15 minutes, event source mappings for Amazon MSK, self-managed Apache Kafka, Amazon DocumentDB, and Amazon MQ for ActiveMQ and RabbitMQ only support functions with maximum timeout limits of 14 minutes. This constraint ensures that the event source mapping can properly handle function errors and retries.

You can monitor a given function's concurrency usage using the `ConcurrentExecutions` metric in Amazon CloudWatch. For more information about concurrency, see [the section called "Configuring reserved concurrency"](#).

Example Amazon MQ record events**ActiveMQ**

```
{

                    108,
                    117,
                    101,
                    49
                ]
            },
            "header2": {
                "bytes": [
                    118,
                    97,
                    108,
                    117,
                    101,
                    50
                ]
            },
            "numberInHeader": 10
        },
        "deliveryMode": 1,
        "priority": 34,
        "correlationId": null,
        "replyTo": null,
        "expiration": "60000",
        "messageId": null,
        "timestamp": "Jan 1, 1970, 12:33:41 AM",
        "type": null,
        "userId": "AIDACKCEVSQ6C2EXAMPLE",
        "appId": null,
        "clusterId": null,
        "bodySize": 80
    },
    "redelivered": false,
    "data": "eyJ0aW1lb3V0IjowLCJkYXRhIjoiQ1pybWYwR3c4T3Y0YnFMUXhENEUifQ=="
}
]
}
}

```

Note

In the RabbitMQ example, `pizzaQueue` is the name of the RabbitMQ queue, and `/` is the name of the virtual host. When receiving messages, the event source lists messages under `pizzaQueue:./`.

Configuring Amazon MQ event source for Lambda

Topics

- [Configure network security](#)
- [Create the event source mapping](#)

Configure network security

To give Lambda full access to Amazon MQ through your event source mapping, either your broker must use a public endpoint (public IP address), or you must provide access to the Amazon VPC you created the broker in.

When you use Amazon MQ with Lambda, create [AWS PrivateLink VPC endpoints](#) that provide your function access to the resources in your Amazon VPC.

Note

AWS PrivateLink VPC endpoints are required for functions with event source mappings that use the default (on-demand) mode for event pollers. If your event source mapping uses [provisioned mode](#), you don't need to configure AWS PrivateLink VPC endpoints.

Create an endpoint to provide access to the following resources:

- Lambda — Create an endpoint for the Lambda service principal.
- AWS STS — Create an endpoint for the AWS STS in order for a service principal to assume a role on your behalf.
- Secrets Manager — If your broker uses Secrets Manager to store credentials, create an endpoint for Secrets Manager.

Alternatively, configure a NAT gateway on each public subnet in the Amazon VPC. For more information, see [the section called “Internet access for VPC functions”](#).

When you create an event source mapping for Amazon MQ, Lambda checks whether Elastic Network Interfaces (ENIs) are already present for the subnets and security groups configured for your Amazon VPC. If Lambda finds existing ENIs, it attempts to re-use them. Otherwise, Lambda creates new ENIs to connect to the event source and invoke your function.

Note

Lambda functions always run inside VPCs owned by the Lambda service. Your function's VPC configuration does not affect the event source mapping. Only the networking configuration of the event source's determines how Lambda connects to your event source.

Configure the security groups for the Amazon VPC containing your broker. By default, Amazon MQ uses the following ports: 61617 (Amazon MQ for ActiveMQ), and 5671 (Amazon MQ for RabbitMQ).

- Inbound rules – Allow all traffic on the default broker port for the security group associated with your event source. Alternatively, you can use a self-referencing security group rule to allow access from instances within the same security group.
- Outbound rules – Allow all traffic on port 443 for external destinations if your function needs to communicate with AWS services. Alternatively, you can also use a self-referencing security group rule to limit access to the broker if you don't need to communicate with other AWS services.
- Amazon VPC endpoint inbound rules — If you are using an Amazon VPC endpoint, the security group associated with your Amazon VPC endpoint must allow inbound traffic on port 443 from the broker security group.

If your broker uses authentication, you can also restrict the endpoint policy for the Secrets Manager endpoint. To call the Secrets Manager API, Lambda uses your function role, not the Lambda service principal.

Example VPC endpoint policy — Secrets Manager endpoint

```
{  
    "Statement": [  
        {
```

```

        "Action": "secretsmanager:GetSecretValue",
        "Effect": "Allow",
        "Principal": {
            "AWS": [
                "arn:aws::iam::123456789012:role/my-role"
            ]
        },
        "Resource": "arn:aws::secretsmanager:us-west-2:123456789012:secret:my-secret"
    }
]
}

```

When you use Amazon VPC endpoints, AWS routes your API calls to invoke your function using the endpoint's Elastic Network Interface (ENI). The Lambda service principal needs to call `lambda:InvokeFunction` on any roles and functions that use those ENIs.

By default, Amazon VPC endpoints have open IAM policies that allow broad access to resources. Best practice is to restrict these policies to perform the needed actions using that endpoint. To ensure that your event source mapping is able to invoke your Lambda function, the VPC endpoint policy must allow the Lambda service principal to call `sts:AssumeRole` and `lambda:InvokeFunction`. Restricting your VPC endpoint policies to allow only API calls originating within your organization prevents the event source mapping from functioning properly, so `"Resource": "*" is required in these policies.`

The following example VPC endpoint policies show how to grant the required access to the Lambda service principal for the AWS STS and Lambda endpoints.

Example VPC Endpoint policy — AWS STS endpoint

```

{
    "Statement": [
        {
            "Action": "sts:AssumeRole",
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "lambda.amazonaws.com"
                ]
            },
            "Resource": "*"
        }
    ]
}

```

```
]
}
```

Example VPC Endpoint policy — Lambda endpoint

```
{
  "Statement": [
    {
      "Action": "lambda:InvokeFunction",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "lambda.amazonaws.com"
        ]
      },
      "Resource": "*"
    }
  ]
}
```

Create the event source mapping

Create an [event source mapping](#) to tell Lambda to send records from an Amazon MQ broker to a Lambda function. You can create multiple event source mappings to process the same data with multiple functions, or to process items from multiple sources with a single function.

To configure your function to read from Amazon MQ, add the required permissions and create an **MQ** trigger in the Lambda console.

To read records from an Amazon MQ broker, your Lambda function needs the following permissions. You grant Lambda permission to interact with your Amazon MQ broker and its underlying resources by adding permission statements to your function [execution role](#):

- [mq:DescribeBroker](#)
- [secretsmanager:GetSecretValue](#)
- [ec2:CreateNetworkInterface](#)
- [ec2:DeleteNetworkInterface](#)
- [ec2:DescribeNetworkInterfaces](#)
- [ec2:DescribeSecurityGroups](#)
- [ec2:DescribeSubnets](#)

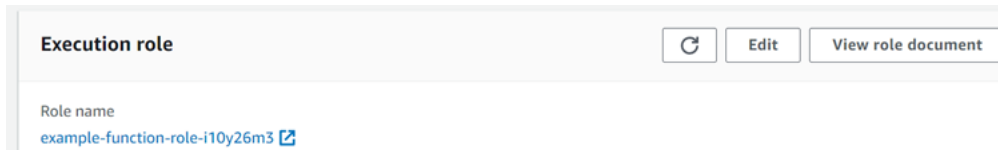

- [ec2:DescribeVpcs](#)
- [logs:CreateLogGroup](#)
- [logs:CreateLogStream](#)
- [logs:PutLogEvents](#)

Note

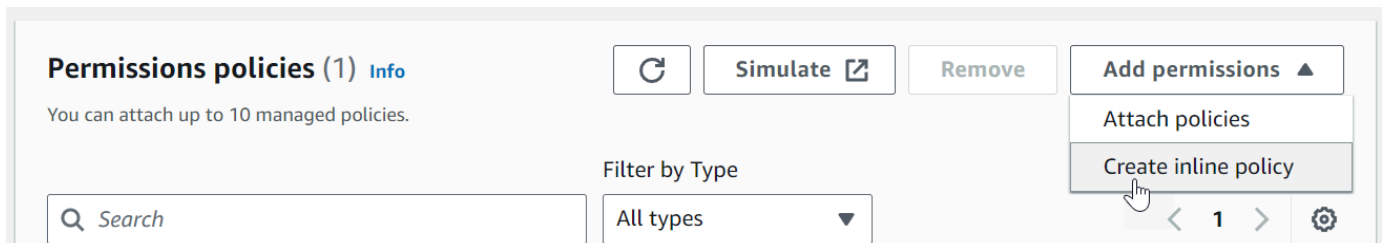

When using an encrypted customer managed key, add the [kms:Decrypt](#) permission as well.

To add permissions and create a trigger

1. Open the [Functions page](#) of the Lambda console.
2. Choose the name of a function.
3. Choose the **Configuration** tab, and then choose **Permissions**.
4. Under **Role name**, choose the link to your execution role. This link opens the role in the IAM console.

5. Choose **Add permissions**, and then choose **Create inline policy**.

6. In the **Policy editor**, choose **JSON**. Enter the following policy. Your function needs these permissions to read from an Amazon MQ broker.

JSON

```
{  
  "Version": "2012-10-17",
```

```

    "Statement": [
      {
        "Effect": "Allow",
        "Action": [
          "mq:DescribeBroker",
          "secretsmanager:GetSecretValue",
          "ec2:CreateNetworkInterface",
          "ec2:DeleteNetworkInterface",
          "ec2:DescribeNetworkInterfaces",
          "ec2:DescribeSecurityGroups",
          "ec2:DescribeSubnets",
          "ec2:DescribeVpcs",
          "logs:CreateLogGroup",
          "logs:CreateLogStream",
          "logs:PutLogEvents"
        ],
        "Resource": "*"
      }
    ]
  }
}

```

Note

When using an encrypted customer managed key, you must also add the `kms:Decrypt` permission.

7. Choose **Next**. Enter a policy name and then choose **Create policy**.
8. Go back to your function in the Lambda console. Under **Function overview**, choose **Add trigger**.

9. Choose the **MQ** trigger type.
10. Configure the required options, and then choose **Add**.

Lambda supports the following options for Amazon MQ event sources:

- **MQ broker** – Select an Amazon MQ broker.
- **Batch size** – Set the maximum number of messages to retrieve in a single batch.
- **Queue name** – Enter the Amazon MQ queue to consume.
- **Source access configuration** – Enter virtual host information and the Secrets Manager secret that stores your broker credentials.
- **Enable trigger** – Disable the trigger to stop processing records.

To enable or disable the trigger (or delete it), choose the **MQ** trigger in the designer. To reconfigure the trigger, use the event source mapping API operations.

Event source mapping parameters

All Lambda event source types share the same [CreateEventSourceMapping](#) and [UpdateEventSourceMapping](#) API operations. However, only some of the parameters apply to Amazon MQ and RabbitMQ.

Parameter	Required	Default	Notes
BatchSize	N	100	Maximum: 10,000
Enabled	N	true	none
FunctionName	Y	N/A	none
FilterCriteria	N	N/A	Control which events Lambda sends to your function
MaximumBatchingWindowInSeconds	N	500 ms	Batching behavior
Queues	N	N/A	The name of the Amazon MQ broker destination queue to consume.

Parameter	Required	Default	Notes
SourceAccessConfigurations	N	N/A	For ActiveMQ, BASIC_AUTH credentials. For RabbitMQ, can contain both BASIC_AUTH credentials and VIRTUAL_HOST information.

Filter events from an Amazon MQ event source

You can use event filtering to control which records from a stream or queue Lambda sends to your function. For general information about how event filtering works, see [the section called “Event filtering”](#).

This section focuses on event filtering for Amazon MQ event sources.

Note

Amazon MQ event source mappings only support filtering on the data key.

Topics

- [Amazon MQ event filtering basics](#)

Amazon MQ event filtering basics

Suppose your Amazon MQ message queue contains messages either in valid JSON format or as plain strings. An example record would look like the following, with the data converted to a Base64 encoded string in the data field.

ActiveMQ

```
{
```

```

    "messageID": "ID:b-9bcfa592-423a-4942-879d-eb284b418fc8-1.mq.us-east-2.amazonaws.com-37557-1234520418293-4:1:1:1:1",
    "messageType": "jms/text-message",
    "deliveryMode": 1,
    "replyTo": null,
    "type": null,
    "expiration": "60000",
    "priority": 1,
    "correlationId": "myJMScoID",
    "redelivered": false,
    "destination": {
      "physicalName": "testQueue"
    },
    "data": "QUJD0kFBQUE=",
    "timestamp": 1598827811958,
    "brokerInTime": 1598827811958,
    "brokerOutTime": 1598827811959,
    "properties": {
      "index": "1",
      "doAlarm": "false",
      "myCustomProperty": "value"
    }
  }
}

```

RabbitMQ

```

{
  "basicProperties": {
    "contentType": "text/plain",
    "contentEncoding": null,
    "headers": {
      "header1": {
        "bytes": [
          118,
          97,
          108,
          105,
          110,
          49
        ]
      },
      "header2": {
        "bytes": [

```

```

        118,
        97,
        108,
        117,
        101,
        50
    ]
},
"numberInHeader": 10
},
"deliveryMode": 1,
"priority": 34,
"correlationId": null,
"replyTo": null,
"expiration": "60000",
"messageId": null,
"timestamp": "Jan 1, 1970, 12:33:41 AM",
"type": null,
"userId": "AIDACKCEVSQ6C2EXAMPLE",
"appId": null,
"clusterId": null,
"bodySize": 80
},
"redelivered": false,
"data": "eyJ0aW1lb3V0IjowLCJkYXRhIjoiQ1pybWYwR3c4T3Y0YnFMUXhENEUifQ=="
}

```

For both Active MQ and Rabbit MQ brokers, you can use event filtering to filter records using the data key. Suppose your Amazon MQ queue contains messages in the following JSON format.

```

{
  "timeout": 0,
  "IPAddress": "203.0.113.254"
}

```

To filter only those records where the timeout field is greater than 0, the `FilterCriteria` object would be as follows.

```

{
  "Filters": [
    {

```

```

    "Pattern": "{ \"data\" : { \"timeout\" : [ { \"numeric\": [ \">\",
0] } } ] } }"
    }
  ]
}

```

For added clarity, here is the value of the filter's Pattern expanded in plain JSON.

```

{
  "data": {
    "timeout": [ { "numeric": [ ">", 0 ] } ]
  }
}

```

You can add your filter using the console, AWS CLI or an AWS SAM template.

Console

to add this filter using the console, follow the instructions in [Attaching filter criteria to an event source mapping \(console\)](#) and enter the following string for the **Filter criteria**.

```
{ "data" : { "timeout" : [ { "numeric": [ ">", 0 ] } ] } }
```

AWS CLI

To create a new event source mapping with these filter criteria using the AWS Command Line Interface (AWS CLI), run the following command.

```

aws lambda create-event-source-mapping \
  --function-name my-function \
  --event-source-arn arn:aws:mq:us-east-2:123456789012:broker:my-  
broker:b-8ac7cc01-5898-482d-be2f-a6b596050ea8 \
  --filter-criteria '{"Filters": [{"Pattern": "{ \"data\" : { \"timeout\" :  
[ { \"numeric\": [ \">\", 0 ] } ] } }"]}]}'

```

To add these filter criteria to an existing event source mapping, run the following command.

```

aws lambda update-event-source-mapping \
  --uuid "a1b2c3d4-5678-90ab-cdef-1111EXAMPLE" \
  --filter-criteria '{"Filters": [{"Pattern": "{ \"data\" : { \"timeout\" :  
[ { \"numeric\": [ \">\", 0 ] } ] } }"]}]}'

```

To add these filter criteria to an existing event source mapping, run the following command.

```
aws lambda update-event-source-mapping \
  --uuid "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE" \
  --filter-criteria '{"Filters": [{"Pattern": "{ \"data\" : { \"timeout\" : [ { \"numeric\" : [ \">\", 0 ] } ] } }"]}]'
```

AWS SAM

To add this filter using AWS SAM, add the following snippet to the YAML template for your event source.

```
FilterCriteria:
  Filters:
    - Pattern: '{ "data" : { "timeout" : [ { "numeric": [ ">", 0 ] } ] } }'
```

With Amazon MQ, you can also filter records where the message is a plain string. Suppose you want to process only records where the message begins with "Result: ". The `FilterCriteria` object would look as follows.

```
{
  "Filters": [
    {
      "Pattern": "{ \"data\" : [ { \"prefix\": \"Result: \" } ] }"
    }
  ]
}
```

For added clarity, here is the value of the filter's `Pattern` expanded in plain JSON.

```
{
  "data": [
    {
      "prefix": "Result: "
    }
  ]
}
```

You can add your filter using the console, AWS CLI or an AWS SAM template.

Console

To add this filter using the console, follow the instructions in [Attaching filter criteria to an event source mapping \(console\)](#) and enter the following string for the **Filter criteria**.

```
{ "data" : [ { "prefix": "Result: " } ] }
```

AWS CLI

To create a new event source mapping with these filter criteria using the AWS Command Line Interface (AWS CLI), run the following command.

```
aws lambda create-event-source-mapping \
  --function-name my-function \
  --event-source-arn arn:aws:mq:us-east-2:123456789012:broker:my-  
broker:b-8ac7cc01-5898-482d-be2f-a6b596050ea8 \
  --filter-criteria '{"Filters": [{"Pattern": "{ \"data\" : [ { \"prefix\":  
\"Result: \" } ] }"]}]'
```

To add these filter criteria to an existing event source mapping, run the following command.

```
aws lambda update-event-source-mapping \
  --uuid "a1b2c3d4-5678-90ab-cdef-1111EXAMPLE" \
  --filter-criteria '{"Filters": [{"Pattern": "{ \"data\" : [ { \"prefix\":  
\"Result: \" } ] }"]}]'
```

AWS SAM

To add this filter using AWS SAM, add the following snippet to the YAML template for your event source.

```
FilterCriteria:
  Filters:
    - Pattern: '{ "data" : [ { "prefix": "Result " } ] }'
```

Amazon MQ messages must be UTF-8 encoded strings, either plain strings or in JSON format. That's because Lambda decodes Amazon MQ byte arrays into UTF-8 before applying filter criteria. If your messages use another encoding, such as UTF-16 or ASCII, or if the message format doesn't match the `FilterCriteria` format, Lambda processes metadata filters only. The following table summarizes the specific behavior:

Incoming message format	Filter pattern format for message properties	Resulting action
Plain string	Plain string	Lambda filters based on your filter criteria.
Plain string	No filter pattern for data properties	Lambda filters (on the other metadata properties only) based on your filter criteria.
Plain string	Valid JSON	Lambda filters (on the other metadata properties only) based on your filter criteria.
Valid JSON	Plain string	Lambda filters (on the other metadata properties only) based on your filter criteria.
Valid JSON	No filter pattern for data properties	Lambda filters (on the other metadata properties only) based on your filter criteria.
Valid JSON	Valid JSON	Lambda filters based on your filter criteria.
Non-UTF-8 encoded string	JSON, plain string, or no pattern	Lambda filters (on the other metadata properties only) based on your filter criteria.

Troubleshoot Amazon MQ event source mapping errors

When a Lambda function encounters an unrecoverable error, your Amazon MQ consumer stops processing records. Any other consumers can continue processing, provided that they do not encounter the same error. To determine the potential cause of a stopped consumer, check the `StateTransitionReason` field in the return details of your `EventSourceMapping` for one of the following codes:

ESM_CONFIG_NOT_VALID

The event source mapping configuration is not valid.

EVENT_SOURCE_AUTHN_ERROR

Lambda failed to authenticate the event source.

EVENT_SOURCE_AUTHZ_ERROR

Lambda does not have the required permissions to access the event source.

FUNCTION_CONFIG_NOT_VALID

The function's configuration is not valid.

Records also go unprocessed if Lambda drops them due to their size. The size limit for Lambda records is 6 MB. To redeliver messages upon function error, you can use a dead-letter queue (DLQ). For more information, see [Message Redelivery and DLQ Handling](#) on the Apache ActiveMQ website and [Reliability Guide](#) on the RabbitMQ website.

 **Note**

Lambda does not support custom redelivery policies. Instead, Lambda uses a policy with the default values from the [Redelivery Policy](#) page on the Apache ActiveMQ website, with `maximumRedeliveries` set to 6.

Using AWS Lambda with Amazon RDS

You can connect a Lambda function to an Amazon Relational Database Service (Amazon RDS) database directly and through an Amazon RDS Proxy. Direct connections are useful in simple scenarios, and proxies are recommended for production. A database proxy manages a pool of shared database connections which enables your function to reach high concurrency levels without exhausting database connections.

We recommend using Amazon RDS Proxy for Lambda functions that make frequent short database connections, or open and close large numbers of database connections. For more information, see [Automatically connecting a Lambda function and a DB instance](#) in the Amazon Relational Database Service Developer Guide.

Tip

To quickly connect a Lambda function to an Amazon RDS database, you can use the in-console guided wizard. To open the wizard, do the following:

1. Open the [Functions page](#) of the Lambda console.
2. Select the function you want to connect a database to.
3. On the **Configuration** tab, select **RDS databases**.
4. Choose **Connect to RDS database**.

After you've connected your function to a database, you can create a proxy by choosing **Add proxy**.

Configuring your function to work with RDS resources

In the Lambda console, you can provision, and configure, Amazon RDS database instances and proxy resources. You can do this by navigating to **RDS databases** under the **Configuration** tab. Alternatively, you can also create and configure connections to Lambda functions in the Amazon RDS console. When configuring an RDS database instance to use with Lambda, note the following criteria:

- To connect to a database, your function must be in the same Amazon VPC where your database runs.

- You can use Amazon RDS databases with MySQL, MariaDB, PostgreSQL, or Microsoft SQL Server engines.
- You can also use Aurora DB clusters with MySQL or PostgreSQL engines.
- You need to provide a Secrets Manager secret for database authentication.
- An IAM role must provide permission to use the secret, and a trust policy must allow Amazon RDS to assume the role.
- The IAM principal that uses the console to configure the Amazon RDS resource, and connect it to your function must have the following permissions:

Example permissions policy

Note

You need the Amazon RDS Proxy permissions only if you configure an Amazon RDS Proxy to manage a pool of your database connections.

Amazon RDS charges an hourly rate for proxies based on the database instance size, see [RDS Proxy pricing](#) for details. For more information on proxy connections in general, see [Using Amazon RDS Proxy](#) in the Amazon RDS User Guide.

SSL/TLS requirements for Amazon RDS connections

To make secure SSL/TLS connections to an Amazon RDS database instance, your Lambda function must verify the database server's identity using a trusted certificate. Lambda handles these certificates differently depending on your deployment package type:

- [.zip file archives](#): Certificate handling varies by runtime:
 - **Node.js 18 and earlier**: Lambda automatically includes CA certificates and RDS certificates.
 - **Node.js 20 and later**: Lambda no longer loads additional CA certificates by default. Set the `NODE_EXTRA_CA_CERTS` environment variable to `/var/runtime/ca-cert.pem`.

It might take up to 4 weeks for Amazon RDS certificates for new AWS Regions to be added to the Lambda managed runtimes.

- [Container images](#): AWS base images include only CA certificates. If your function connects to an Amazon RDS database instance, you must include the appropriate certificates in your container image. In your Dockerfile, download the [certificate bundle that corresponds with the AWS Region where you host your database](#). Example:

```
RUN curl https://truststore.pki.rds.amazonaws.com/us-east-1/us-east-1-bundle.pem -o /  
us-east-1-bundle.pem
```

This command downloads the Amazon RDS certificate bundle and saves it at the absolute path `/us-east-1-bundle.pem` in your container's root directory. When configuring the database connection in your function code, you must reference this exact path. Example:

Node.js

The `readFileSync` function is required because Node.js database clients need the actual certificate content in memory, not just the path to the certificate file. Without `readFileSync`, the client interprets the path string as certificate content, resulting in a "self-signed certificate in certificate chain" error.

Example Node.js connection config for OCI function

```
import { readFileSync } from 'fs';

// ...

let connectionConfig = {
  host: process.env.ProxyHostName,
  user: process.env.DBUserName,
  password: token,
  database: process.env.DBName,
  ssl: {
    ca: readFileSync('/us-east-1-bundle.pem') // Load RDS certificate content
    from file into memory
  }
};
```

Python

Example Python connection config for OCI function

```
connection = pymysql.connect(
    host=proxy_host_name,
    user=db_username,
    password=token,
    db=db_name,
    port=port,
    ssl={'ca': '/us-east-1-bundle.pem'} #Path to the certificate in container
)
```

Java

For Java functions using JDBC connections, the connection string must include:

- `useSSL=true`

- `requireSSL=true`
- An `sslCA` parameter that points to the location of the Amazon RDS certificate in the container image

Example Java connection string for OCI function

```
// Define connection string
String connectionString = String.format("jdbc:mysql://%s:%s/%s?
useSSL=true&requireSSL=true&sslCA=/us-east-1-bundle.pem", // Path to the certificate
in container
    System.getenv("ProxyHostName"),
    System.getenv("Port"),
    System.getenv("DBName"));
```

.NET

Example .NET connection string for MySQL connection in OCI function

```
/// Build the Connection String with the Token
string connectionString =
    $"Server={Environment.GetEnvironmentVariable("RDS_ENDPOINT")};" +
        $"Port={Environment.GetEnvironmentVariable("RDS_PORT")};" +

    $"Uid={Environment.GetEnvironmentVariable("RDS_USERNAME")};" +
        $"Pwd={authToken};" +
        "SslMode=Required;" +
        "SslCa=/us-east-1-bundle.pem"; // Path to the certificate
in container
```

Go

For Go functions using MySQL connections, load the Amazon RDS certificate into a certificate pool and register it with the MySQL driver. The connection string must then reference this configuration using the `tls` parameter.

Example Go code for MySQL connection in OCI function

```
import (
    "crypto/tls"
    "crypto/x509"
    "os"
```

```

    "github.com/go-sql-driver/mysql"
)

...

// Create certificate pool and register TLS config
rootCertPool := x509.NewCertPool()
pem, err := os.ReadFile("/us-east-1-bundle.pem") // Path to the certificate in
container
if err != nil {
    panic("failed to read certificate file: " + err.Error())
}
if ok := rootCertPool.AppendCertsFromPEM(pem); !ok {
    panic("failed to append PEM")
}

mysql.RegisterTLSConfig("custom", &tls.Config{
    RootCAs: rootCertPool,
})

dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?allowCleartextPasswords=true&tls=custom",
    dbUser, authenticationToken, dbEndpoint, dbName,
)

```

Ruby

Example Ruby connection config for OCI function

```

conn = Mysql2::Client.new(
  host: endpoint,
  username: user,
  password: token,
  port: port,
  database: db_name,
  sslca: '/us-east-1-bundle.pem', # Path to the certificate in container
  sslverify: true
)

```

Connecting to an Amazon RDS database in a Lambda function

The following code examples shows how to implement a Lambda function that connects to an Amazon RDS database. The function makes a simple database request and returns the result.

Note

These code examples are valid for [.zip deployment packages](#) only. If you're deploying your function using a [container image](#), you must specify the Amazon RDS certificate file in your function code, as explained in the [preceding section](#).

.NET**SDK for .NET****Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [Serverless examples](#) repository.

Connecting to an Amazon RDS database in a Lambda function using .NET.

```
using System.Data;
using System.Text.Json;
using Amazon.Lambda.APIGatewayEvents;
using Amazon.Lambda.Core;
using MySql.Data.MySqlClient;

// Assembly attribute to enable the Lambda function's JSON input to be converted
// into a .NET class.
[assembly:
    LambdaSerializer(typeof(Amazon.Lambda.Serialization.SystemTextJson.DefaultLambdaJsonSerializer))]

namespace aws_rds;

public class InputModel
{
    public string key1 { get; set; }
    public string key2 { get; set; }
}

public class Function
{
    /// <summary>
```

```

    // Handles the Lambda function execution for connecting to RDS using IAM
    authentication.
    /// </summary>
    /// <param name="input">The input event data passed to the Lambda function</
param>
    /// <param name="context">The Lambda execution context that provides runtime
information</param>
    /// <returns>A response object containing the execution result</returns>

    public async Task<APIGatewayProxyResponse>
    FunctionHandler(APIGatewayProxyRequest request, ILambdaContext context)
    {
        // Sample Input: {"body": "{\"key1\":\"20\", \"key2\":\"25\"}"}
        var input = JsonSerializer.Deserialize<InputModel>(request.Body);

        /// Obtain authentication token
        var authToken = RDSAuthTokenGenerator.GenerateAuthToken(
            Environment.GetEnvironmentVariable("RDS_ENDPOINT"),
            Convert.ToInt32(Environment.GetEnvironmentVariable("RDS_PORT")),
            Environment.GetEnvironmentVariable("RDS_USERNAME")
        );

        /// Build the Connection String with the Token
        string connectionString =
        $"Server={Environment.GetEnvironmentVariable("RDS_ENDPOINT"));";

        $"Port={Environment.GetEnvironmentVariable("RDS_PORT"));";

        $"Uid={Environment.GetEnvironmentVariable("RDS_USERNAME"));";
        $"Pwd={authToken});";

        try
        {
            await using var connection = new MySqlConnection(connectionString);
            await connection.OpenAsync();

            const string sql = "SELECT @param1 + @param2 AS Sum";

            await using var command = new MySqlCommand(sql, connection);
            command.Parameters.AddWithValue("@param1", int.Parse(input.key1 ??
"0"));
            command.Parameters.AddWithValue("@param2", int.Parse(input.key2 ??
"0"));

```

```

        await using var reader = await command.ExecuteReaderAsync();
        if (await reader.ReadAsync())
        {
            int result = reader.GetInt32("Sum");

            //Sample Response: {"statusCode":200,"body":{"\"message\": \"The
sum is: 45\\\""},"isBase64Encoded":false}
            return new APIGatewayProxyResponse
            {
                StatusCode = 200,
                Body = JsonSerializer.Serialize(new { message = $"The sum is:
{result}" })
            };
        }

        catch (Exception ex)
        {
            Console.WriteLine($"Error: {ex.Message}");
        }

        return new APIGatewayProxyResponse
        {
            StatusCode = 500,
            Body = JsonSerializer.Serialize(new { error = "Internal server
error" })
        };
    }
}

```

  const token = await signer.getAuthToken();
  return token;
}

async function dbOps() {

  // Obtain auth token
  const token = await createAuthToken();
  // Define connection configuration
  let connectionConfig = {
    host: process.env.ProxyHostName,
    user: process.env.DBUserName,
    password: token,
    database: process.env.DBName,
    ssl: 'Amazon RDS'
  }
  // Create the connection to the DB
  const conn = await mysql.createConnection(connectionConfig);
  // Obtain the result of the query
  const [res,] = await conn.execute('select ?+? as sum', [3, 2]);
  return res;
}

export const handler = async (event) => {
  // Execute database flow
  const result = await dbOps();
  // Return result
  return {
    statusCode: 200,
    body: JSON.stringify("The selected sum is: " + result[0].sum)
  }
};
```

Connecting to an Amazon RDS database in a Lambda function using TypeScript.

```
import { Signer } from "@aws-sdk/rds-signer";
import mysql from 'mysql2/promise';

// RDS settings
// Using '!' (non-null assertion operator) to tell the TypeScript compiler that
// the DB settings are not null or undefined,
const proxy_host_name = process.env.PROXY_HOST_NAME!
const port = parseInt(process.env.PORT!)
const db_name = process.env.DB_NAME!
const db_user_name = process.env.DB_USER_NAME!
const aws_region = process.env.AWS_REGION!

async function createAuthToken(): Promise<string> {

    // Create RDS Signer object
    const signer = new Signer({
        hostname: proxy_host_name,
        port: port,
        region: aws_region,
        username: db_user_name
    });

    // Request authorization token from RDS, specifying the username
    const token = await signer.getAuthToken();
    return token;
}

async function dbOps(): Promise<mysql.QueryResult | undefined> {
    try {
        // Obtain auth token
        const token = await createAuthToken();
        const conn = await mysql.createConnection({
            host: proxy_host_name,
            user: db_user_name,
            password: token,
            database: db_name,
            ssl: 'Amazon RDS' // Ensure you have the CA bundle for SSL connection
        });
        const [rows, fields] = await conn.execute('SELECT ? + ? AS sum', [3, 2]);
        console.log('result:', rows);
    }
}
```

```
        return rows;
    }
    catch (err) {
        console.log(err);
    }
}

export const lambdaHandler = async (event: any): Promise<{ statusCode: number;
body: string }> => {
    // Execute database flow
    const result = await dbOps();

    // Return error if result is undefined
    if (result == undefined)
        return {
            statusCode: 500,
            body: JSON.stringify(`Error with connection to DB host`)
        }

    // Return result
    return {
        statusCode: 200,
        body: JSON.stringify(`The selected sum is: ${result[0].sum}`)
    };
};
```

    })))
}

```

Processing event notifications from Amazon RDS

You can use Lambda to process event notifications from an Amazon RDS database. Amazon RDS sends notifications to an Amazon Simple Notification Service (Amazon SNS) topic, which you can configure to invoke a Lambda function. Amazon SNS wraps the message from Amazon RDS in its own event document and sends it to your function.

For more information about configuring an Amazon RDS database to send notifications, see [Using Amazon RDS event notifications](#).

Example Amazon RDS message in an Amazon SNS event

```
{
  "Records": [
    {
      "EventVersion": "1.0",
      "EventSubscriptionArn": "arn:aws:sns:us-east-2:123456789012:rds-

Complete Lambda and Amazon RDS tutorial

- [Using a Lambda function to access an Amazon RDS database](#) – From the Amazon RDS User Guide, learn how to use a Lambda function to write data to an Amazon RDS database through an Amazon RDS Proxy. Your Lambda function will read records from an Amazon SQS queue and write new items to a table in your database whenever a message is added.

Select a database service for your Lambda-based applications

Many serverless applications need to store and retrieve data. AWS offers multiple database options that work with Lambda functions. Two of the most popular choices are Amazon DynamoDB, a NoSQL database service, and Amazon RDS, a traditional relational database solution. The following sections explain the key differences between these services when using them with Lambda and help you select the right database service for your serverless application.

To learn more about the other database services offered by AWS, and to understand their use cases and tradeoffs more generally, see [Choosing an AWS database service](#). All of the AWS database services are compatible with Lambda, but not all of them may be suited to your particular use case.

What are your choices when selecting a database service with Lambda?

AWS offers multiple database services. For serverless applications, two of the most popular choices are DynamoDB and Amazon RDS.

- **DynamoDB** is a fully managed NoSQL database service optimized for serverless applications. It provides seamless scaling and consistent single-digit millisecond performance at any scale.
- **Amazon RDS** is a managed relational database service that supports multiple database engines including MySQL and PostgreSQL. It provides familiar SQL capabilities with managed infrastructure.

Recommendations if you already know your requirements

If you're already clear on your requirements, here are our basic recommendations:

We recommend [DynamoDB](#) for serverless applications that need consistent low-latency performance, automatic scaling, and don't require complex joins or transactions. It's particularly well-suited for Lambda-based applications due to its serverless nature.

[Amazon RDS](#) is a better choice when you need complex SQL queries, joins, or have existing applications using relational databases. However, be aware that connecting Lambda functions to Amazon RDS requires additional configuration and can impact cold start times.

What to consider when selecting a database service

When selecting between DynamoDB and Amazon RDS for your Lambda applications, consider these factors:

- Connection management and cold starts
- Data access patterns
- Query complexity
- Data consistency requirements
- Scaling characteristics
- Cost model

By understanding these factors, you can select the option that best meets the needs of your particular use case.

Connection management and cold starts

- DynamoDB uses an HTTP API for all operations. Lambda functions can make immediate requests without maintaining connections, resulting in better cold start performance. Each request is authenticated using AWS credentials without connection overhead.
- Amazon RDS requires managing connection pools since it uses traditional database connections. This can impact cold starts as new Lambda instances need to establish connections. You'll need to implement connection pooling strategies and potentially use [Amazon RDS Proxy](#) to manage connections effectively. Note that using Amazon RDS Proxy incurs additional costs.

Data access patterns

- DynamoDB works best with known access patterns and single-table designs. It's ideal for Lambda applications that need consistent low-latency access to data based on primary keys or secondary indexes.
- Amazon RDS provides flexibility for complex queries and changing access patterns. It's better suited when your Lambda functions need to perform unique, tailored queries or complex joins across multiple tables.

Query complexity

- DynamoDB excels at simple, key-based operations and predefined access patterns. Complex queries must be designed around index structures, and joins must be handled in application code.
- Amazon RDS supports complex SQL queries with joins, subqueries, and aggregations. This can simplify your Lambda function code when complex data operations are needed.

Data consistency requirements

- DynamoDB offers both eventual and strong consistency options, with strong consistency available for single-item reads. Transactions are supported but with some limitations.
- Amazon RDS provides full atomicity, consistency, isolation, and durability (ACID) compliance and complex transaction support. If your Lambda functions require complex transactions or strong consistency across multiple records, Amazon RDS might be more suitable.

Scaling characteristics

- DynamoDB scales automatically with your workload. It can handle sudden spikes in traffic from Lambda functions without pre-provisioning. You can use on-demand capacity mode to pay only for what you use, perfectly matching Lambda's scaling model.
- Amazon RDS has fixed capacity based on the instance size you choose. If multiple Lambda functions try to connect simultaneously, you may exceed your connection quota. You need to carefully manage connection pools and potentially implement retry logic.

Cost model

- DynamoDB's pricing aligns well with serverless applications. With on-demand capacity, you pay only for the actual reads and writes performed by your Lambda functions. There are no charges for idle time.
- Amazon RDS charges for the running instance regardless of usage. This can be less cost-effective for sporadic workloads that can be typical in serverless applications. However, it might be more economical for high-throughput workloads with consistent usage.

Getting started with your chosen database service

Now that you've read about the criteria for selecting between DynamoDB and Amazon RDS and the key differences between them, you can select the option that best matches your needs and use the following resources to get started using it.

DynamoDB

Get started with DynamoDB with the following resources

- For an introduction to the DynamoDB service, read [What is DynamoDB?](#) in the *Amazon DynamoDB Developer Guide*.
- Follow the tutorial [Using Lambda with API Gateway](#) to see an example of using a Lambda function to perform CRUD operations on a DynamoDB table in response to an API request.
- Read [Programming with DynamoDB and the AWS SDKs](#) in the *Amazon DynamoDB Developer Guide* to learn more about how to access DynamoDB from within your Lambda function by using one of the AWS SDKs.

Amazon RDS

Get started with Amazon RDS with the following resources

- For an introduction to the Amazon RDS service, read [What is Amazon Relational Database Service \(Amazon RDS\)?](#) in the *Amazon Relational Database Service User Guide*.
- Follow the tutorial [Using a Lambda function to access an Amazon RDS database](#) in the *Amazon Relational Database Service User Guide*.
- Learn more about using Lambda with Amazon RDS by reading [the section called "RDS"](#).

Process Amazon S3 event notifications with Lambda

You can use Lambda to process [event notifications](#) from Amazon Simple Storage Service. Amazon S3 can send an event to a Lambda function when an object is created or deleted. You configure notification settings on a bucket, and grant Amazon S3 permission to invoke a function on the function's resource-based permissions policy.

Warning

If your Lambda function uses the same bucket that triggers it, it could cause the function to run in a loop. For example, if the bucket triggers a function each time an object is uploaded, and the function uploads an object to the bucket, then the function indirectly triggers itself. To avoid this, use two buckets, or configure the trigger to only apply to a prefix used for incoming objects.

Amazon S3 invokes your function [asynchronously](#) with an event that contains details about the object. The following example shows an event that Amazon S3 sent when a deployment package was uploaded to Amazon S3.

Example Amazon S3 notification event

```
{
  "Records": [
    {
      "eventVersion": "2.1",
      "eventSource": "aws:s3",
      "awsRegion": "us-east-2",
      "eventTime": "2019-09-03T19:37:27.192Z",
      "eventName": "ObjectCreated:Put",
      "userIdentity": {
        "principalId": "AWS:AIDAINPONIXQXHT3IKHL2"
      },
      "requestParameters": {
        "sourceIPAddress": "205.255.255.255"
      },
      "responseElements": {
        "x-amz-request-id": "D82B88E5F771F645",
        "x-amz-id-2": "v1R7PnpV2Ce81l0PRw6jlUpck7Jo5ZsQjryTjK1c5aLWGVHPZLj5NeC6qMa0emYBDX0o6QBU0Wo="
      }
    }
  ]
}
```

```

"s3": {
  "s3SchemaVersion": "1.0",
  "configurationId": "828aa6fc-f7b5-4305-8584-487c791949c1",
  "bucket": {
    "name": "amzn-s3-demo-bucket",
    "ownerIdentity": {
      "principalId": "A3I5XTEXAMAI3E"
    },
    "arn": "arn:aws:s3:::lambda-artifacts-deafc19498e3f2df"
  },
  "object": {
    "key": "b21b84d653bb07b05b1e6b33684dc11b",
    "size": 1305107,
    "eTag": "b21b84d653bb07b05b1e6b33684dc11b",
    "sequencer": "0C0F6F405D6ED209E1"
  }
}
}
]
}

```

To invoke your function, Amazon S3 needs permission from the function's [resource-based policy](#). When you configure an Amazon S3 trigger in the Lambda console, the console modifies the resource-based policy to allow Amazon S3 to invoke the function if the bucket name and account ID match. If you configure the notification in Amazon S3, you use the Lambda API to update the policy. You can also use the Lambda API to grant permission to another account, or restrict permission to a designated alias.

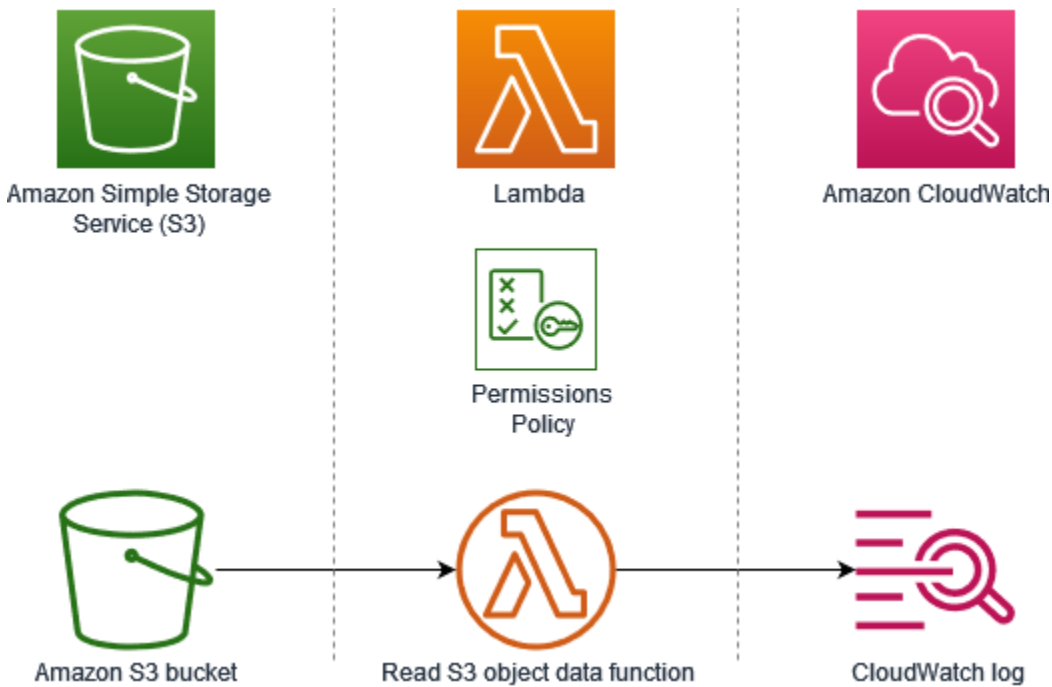

If your function uses the AWS SDK to manage Amazon S3 resources, it also needs Amazon S3 permissions in its [execution role](#).

- [Tutorial: Using an Amazon S3 trigger to create thumbnail images](#)

Tutorial: Using an Amazon S3 trigger to invoke a Lambda function

In this tutorial, you use the console to create a Lambda function and configure a trigger for an Amazon Simple Storage Service (Amazon S3) bucket. Every time that you add an object to your Amazon S3 bucket, your function runs and outputs the object type to Amazon CloudWatch Logs.

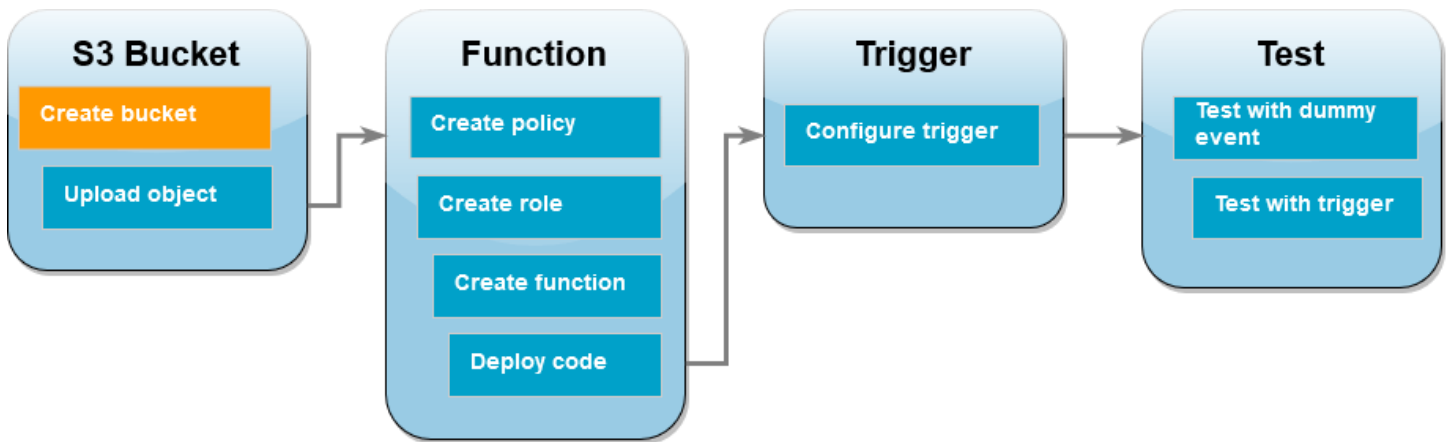

This tutorial demonstrates how to:

1. Create an Amazon S3 bucket.
2. Create a Lambda function that returns the object type of objects in an Amazon S3 bucket.
3. Configure a Lambda trigger that invokes your function when objects are uploaded to your bucket.
4. Test your function, first with a dummy event, and then using the trigger.

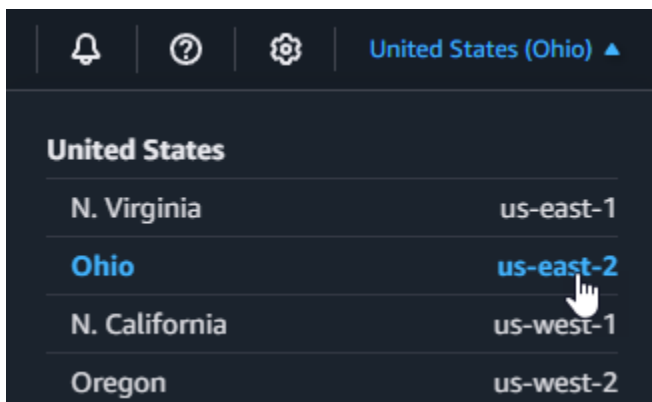

By completing these steps, you'll learn how to configure a Lambda function to run whenever objects are added to or deleted from an Amazon S3 bucket. You can complete this tutorial using only the AWS Management Console.

Create an Amazon S3 bucket

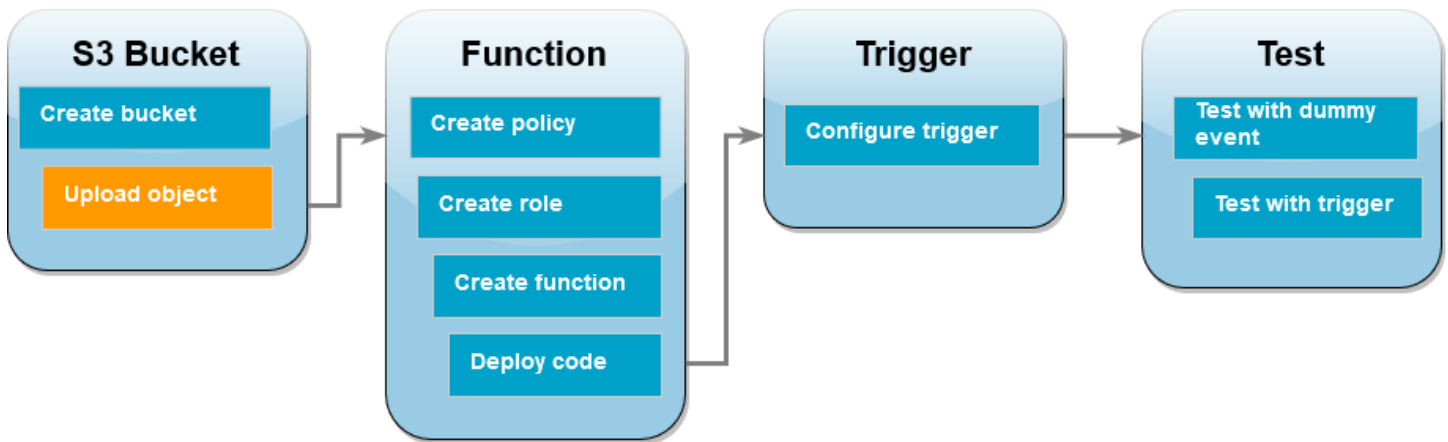

To create an Amazon S3 bucket

1. Open the [Amazon S3 console](#) and select the **General purpose buckets** page.
2. Select the AWS Region closest to your geographical location. You can change your region using the drop-down list at the top of the screen. Later in the tutorial, you must create your Lambda function in the same Region.

3. Choose **Create bucket**.
4. Under **General configuration**, do the following:
 - a. For **Bucket type**, ensure **General purpose** is selected.
 - b. For **Bucket name**, enter a globally unique name that meets the Amazon S3 [Bucket naming rules](#). Bucket names can contain only lower case letters, numbers, dots (.), and hyphens (-).
5. Leave all other options set to their default values and choose **Create bucket**.

Upload a test object to your bucket

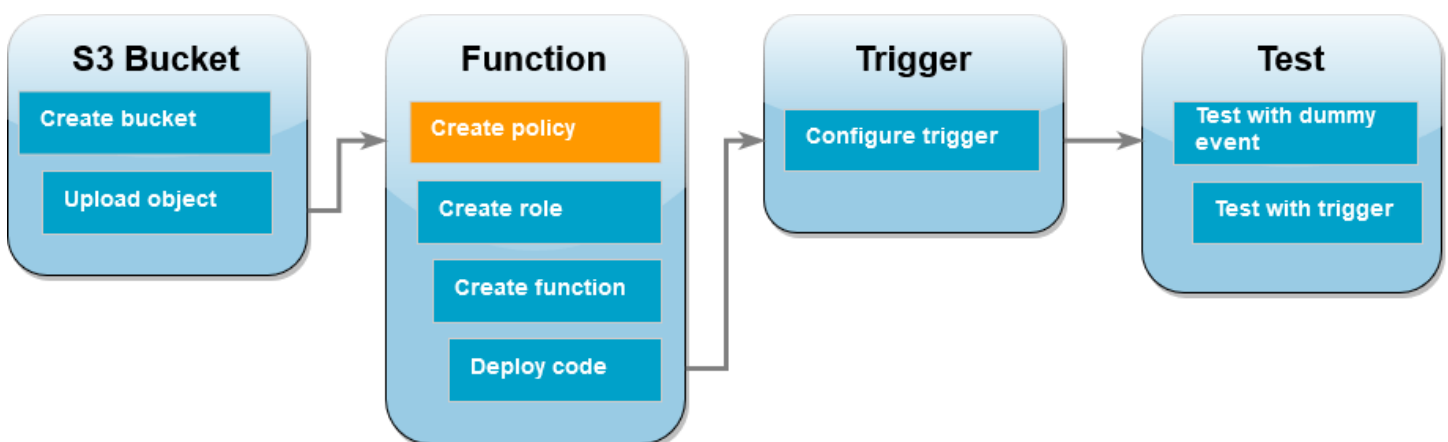

To upload a test object

1. Open the [Buckets](#) page of the Amazon S3 console and choose the bucket you created during the previous step.
2. Choose **Upload**.
3. Choose **Add files** and select the object that you want to upload. You can select any file (for example, `HappyFace.jpg`).
4. Choose **Open**, then choose **Upload**.

Later in the tutorial, you'll test your Lambda function using this object.

Create a permissions policy

Create a permissions policy that allows Lambda to get objects from an Amazon S3 bucket and to write to Amazon CloudWatch Logs.

To create the policy

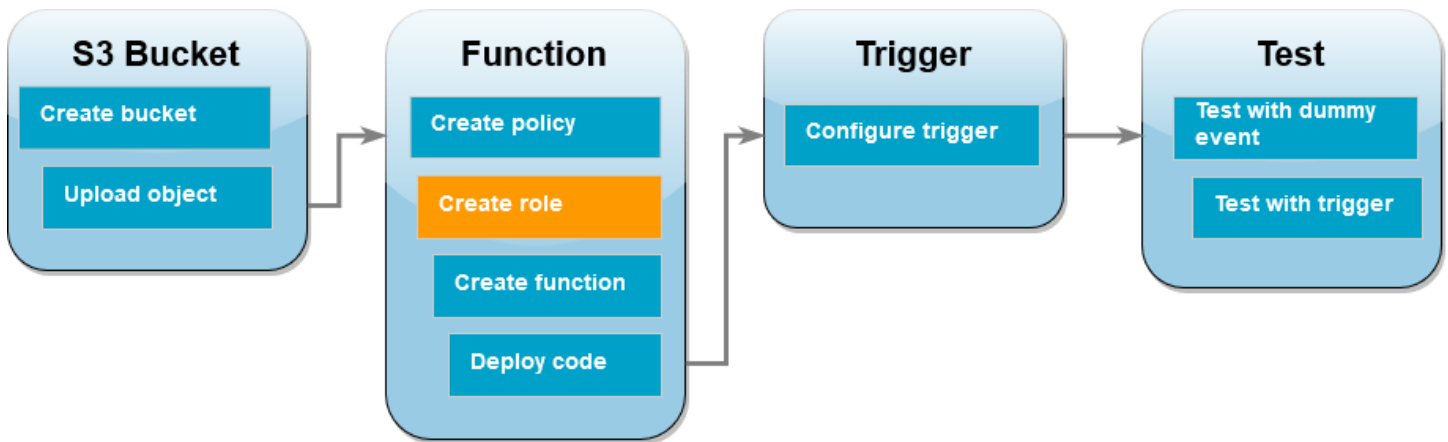

1. Open the [Policies page](#) of the IAM console.
2. Choose **Create Policy**.
3. Choose the **JSON** tab, and then paste the following custom policy into the JSON editor.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "logs:PutLogEvents",
        "logs:CreateLogGroup",
        "logs:CreateLogStream"
      ],
      "Resource": "arn:aws:logs:*:*:*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject"
      ],
      "Resource": "arn:aws:s3:::*/*"
    }
  ]
}
```

4. Choose **Next: Tags**.
5. Choose **Next: Review**.
6. Under **Review policy**, for the policy **Name**, enter **s3-trigger-tutorial**.
7. Choose **Create policy**.

Create an execution role

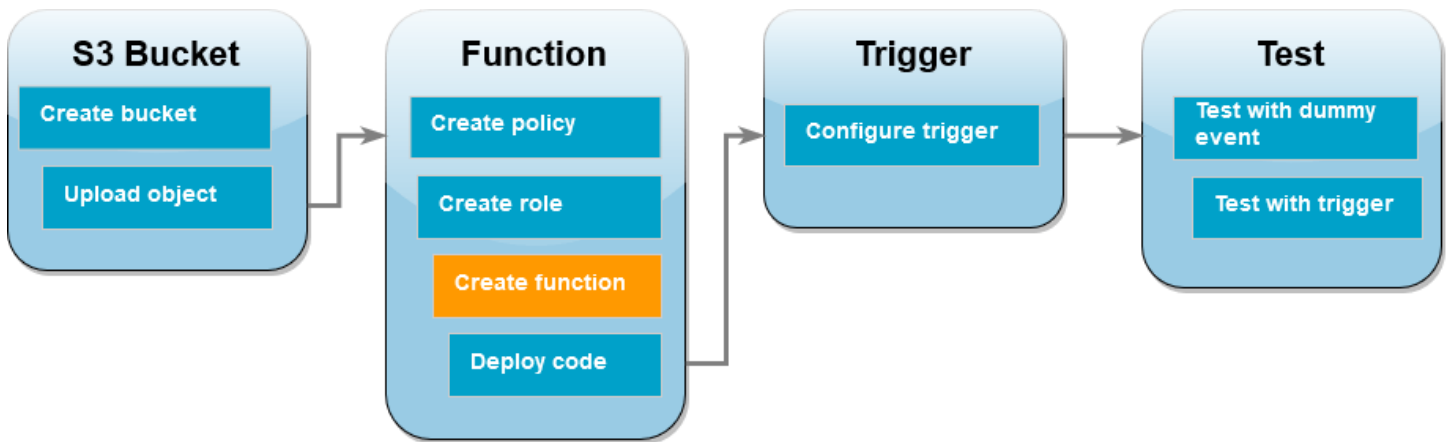

An [execution role](#) is an AWS Identity and Access Management (IAM) role that grants a Lambda function permission to access AWS services and resources. In this step, create an execution role using the permissions policy that you created in the previous step.

To create an execution role and attach your custom permissions policy

1. Open the [Roles page](#) of the IAM console.
2. Choose **Create role**.
3. For the type of trusted entity, choose **AWS service**, then for the use case, choose **Lambda**.
4. Choose **Next**.
5. In the policy search box, enter **s3-trigger-tutorial**.
6. In the search results, select the policy that you created (s3-trigger-tutorial), and then choose **Next**.
7. Under **Role details**, for the **Role name**, enter **lambda-s3-trigger-role**, then choose **Create role**.

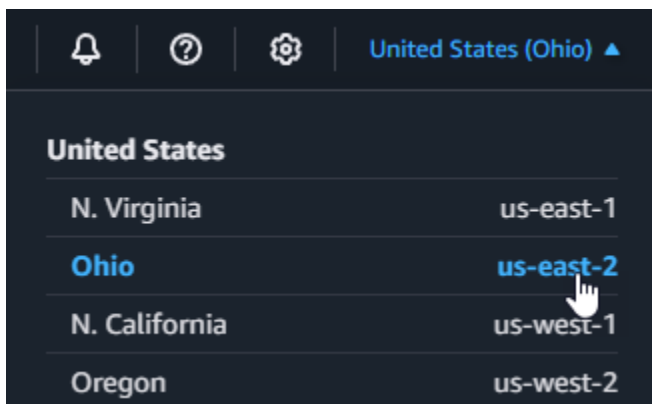

Create the Lambda function

Create a Lambda function in the console using the Python 3.14 runtime.

To create the Lambda function

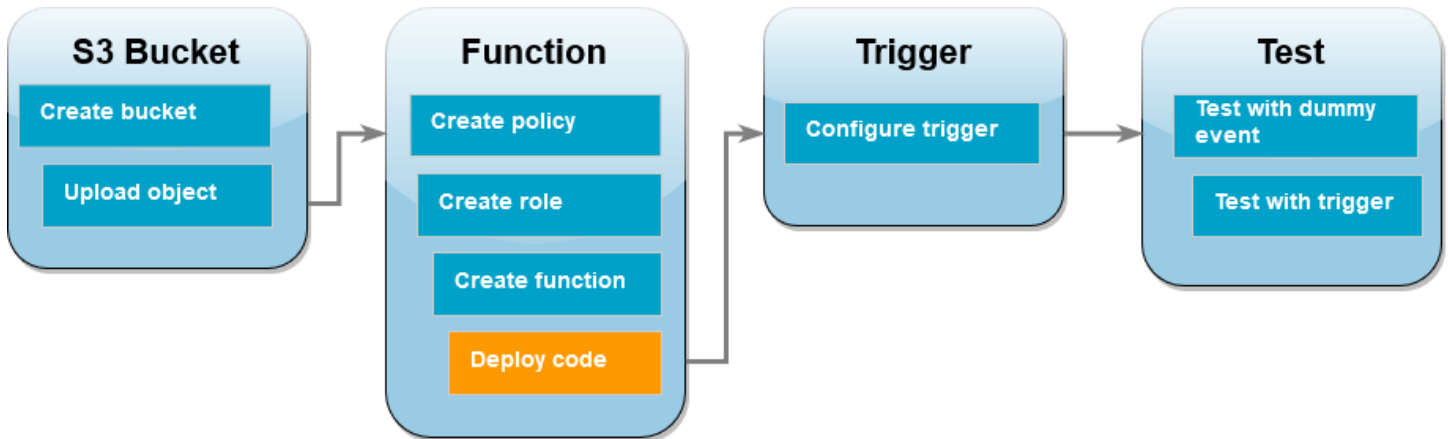

1. Open the [Functions page](#) of the Lambda console.
2. Make sure you're working in the same AWS Region you created your Amazon S3 bucket in. You can change your Region using the drop-down list at the top of the screen.

3. Choose **Create function**.
4. Choose **Author from scratch**
5. Under **Basic information**, do the following:
 - a. For **Function name**, enter `s3-trigger-tutorial`
 - b. For **Runtime**, choose **Python 3.14**.
 - c. For **Architecture**, choose **x86_64**.
6. In the **Change default execution role** tab, do the following:

- a. Expand the tab, then choose **Use an existing role**.
 - b. Select the `lambda-s3-trigger-role` you created earlier.
7. Choose **Create function**.

Deploy the function code

This tutorial uses the Python 3.14 runtime, but we've also provided example code files for other runtimes. You can select the tab in the following box to see the code for the runtime you're interested in.

The Lambda function retrieves the key name of the uploaded object and the name of the bucket from the event parameter it receives from Amazon S3. The function then uses the [get_object](#) method from the AWS SDK for Python (Boto3) to retrieve the object's metadata, including the content type (MIME type) of the uploaded object.

To deploy the function code

1. Choose the **Python** tab in the following box and copy the code.

contains a 'body' property of type ByteStream"),
        Err(_) => tracing::info!("Failure with S3 Get Object request")
    }

    Ok(())
}

```

2. In the **Code source** pane on the Lambda console, paste the code into the code editor, replacing the code that Lambda created.
3. In the **DEPLOY** section, choose **Deploy** to update your function's code:

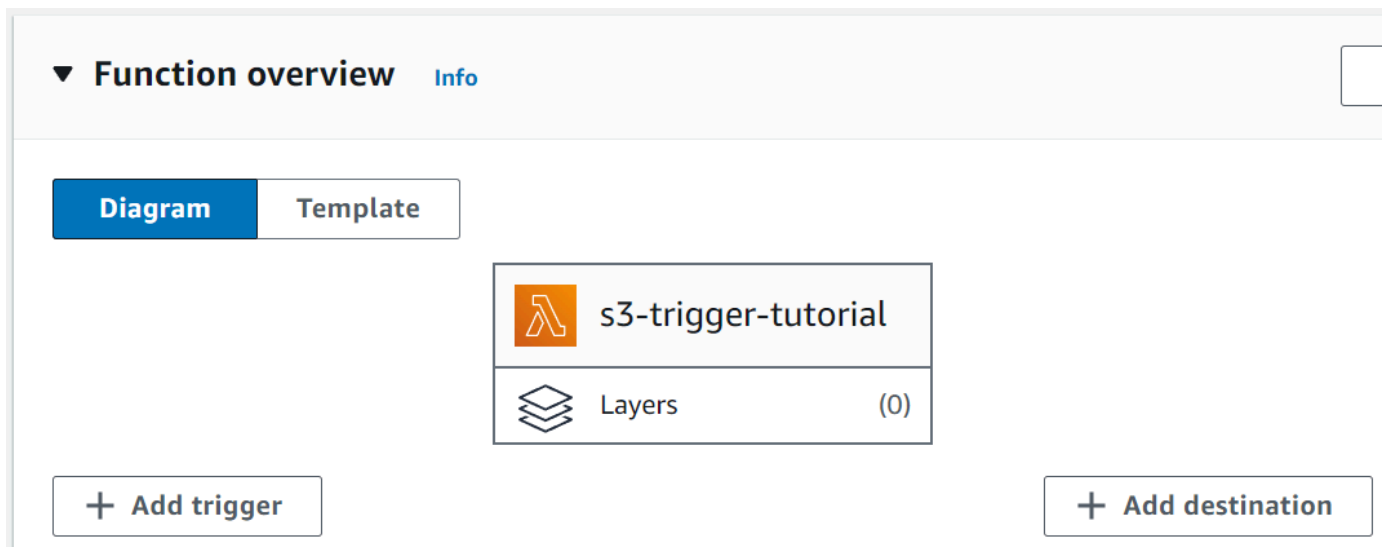

Create the Amazon S3 trigger

To create the Amazon S3 trigger

1. In the **Function overview** pane, choose **Add trigger**.

2. Select **S3**.
3. Under **Bucket**, select the bucket you created earlier in the tutorial.

4. Under **Event types**, be sure that **All object create events** is selected.
5. Under **Recursive invocation**, select the check box to acknowledge that using the same Amazon S3 bucket for input and output is not recommended.
6. Choose **Add**.

Note

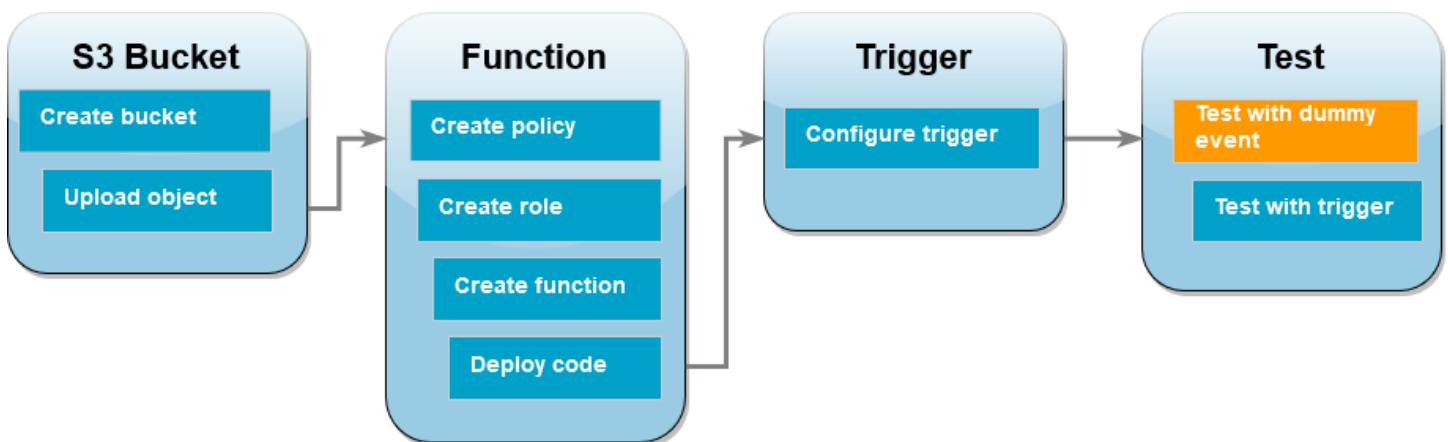

When you create an Amazon S3 trigger for a Lambda function using the Lambda console, Amazon S3 configures an [event notification](#) on the bucket you specify. Before configuring this event notification, Amazon S3 performs a series of checks to confirm that the event destination exists and has the required IAM policies. Amazon S3 also performs these tests on any other event notifications configured for that bucket.

Because of this check, if the bucket has previously configured event destinations for resources that no longer exist, or for resources that don't have the required permissions policies, Amazon S3 won't be able to create the new event notification. You'll see the following error message indicating that your trigger couldn't be created:

An error occurred when creating the trigger: Unable to validate the following destination configurations.

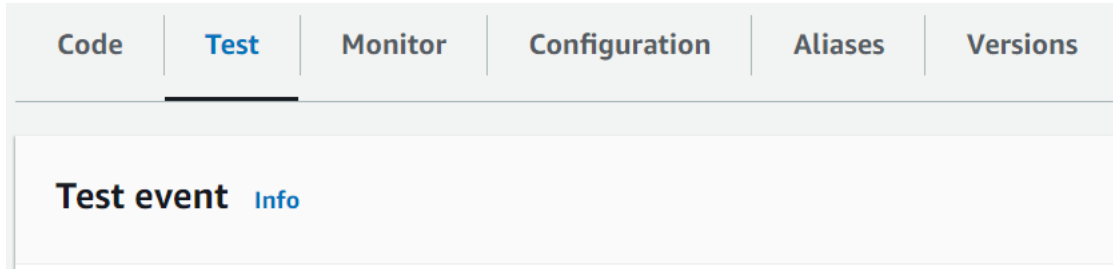

You can see this error if you previously configured a trigger for another Lambda function using the same bucket, and you have since deleted the function or modified its permissions policies.

Test your Lambda function with a dummy event

To test the Lambda function with a dummy event

1. In the Lambda console page for your function, choose the **Test** tab.

2. For **Event name**, enter MyTestEvent.
3. In the **Event JSON**, paste the following test event. Be sure to replace these values:
 - Replace `us-east-1` with the region you created your Amazon S3 bucket in.
 - Replace both instances of `amzn-s3-demo-bucket` with the name of your own Amazon S3 bucket.
 - Replace `test%2FKey` with the name of the test object you uploaded to your bucket earlier (for example, `HappyFace.jpg`).

```
{
  "Records": [
    {

Test the Lambda function with the Amazon S3 trigger

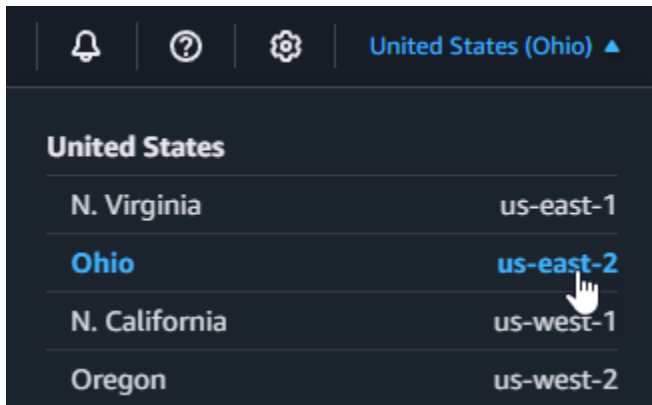

To test your function with the configured trigger, upload an object to your Amazon S3 bucket using the console. To verify that your Lambda function ran as expected, use CloudWatch Logs to view your function's output.

To upload an object to your Amazon S3 bucket

1. Open the [Buckets](#) page of the Amazon S3 console and choose the bucket that you created earlier.
2. Choose **Upload**.
3. Choose **Add files** and use the file selector to choose an object you want to upload. This object can be any file you choose.
4. Choose **Open**, then choose **Upload**.

To verify the function invocation using CloudWatch Logs

1. Open the [CloudWatch](#) console.
2. Make sure you're working in the same AWS Region you created your Lambda function in. You can change your Region using the drop-down list at the top of the screen.

3. Choose **Logs**, then choose **Log groups**.
4. Choose the log group for your function (`/aws/lambda/s3-trigger-tutorial`).
5. Under **Log streams**, choose the most recent log stream.
6. If your function was invoked correctly in response to your Amazon S3 trigger, you'll see output similar to the following. The `CONTENT TYPE` you see depends on the type of file you uploaded to your bucket.

```
2022-05-09T23:17:28.702Z 0cae7f5a-b0af-4c73-8563-a3430333cc10 INFO CONTENT
TYPE: image/jpeg
```

Clean up your resources

You can now delete the resources that you created for this tutorial, unless you want to retain them. By deleting AWS resources that you're no longer using, you prevent unnecessary charges to your AWS account.

To delete the Lambda function

1. Open the [Functions page](#) of the Lambda console.
2. Select the function that you created.
3. Choose **Actions**, **Delete**.
4. Type **confirm** in the text input field and choose **Delete**.

To delete the execution role

1. Open the [Roles page](#) of the IAM console.

2. Select the execution role that you created.
3. Choose **Delete**.
4. Enter the name of the role in the text input field and choose **Delete**.

To delete the S3 bucket

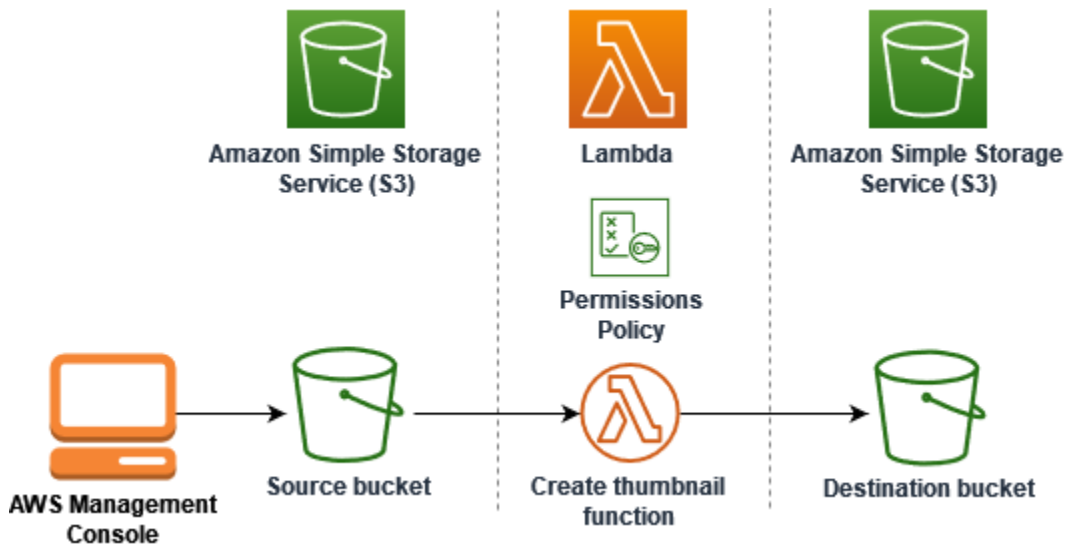

1. Open the [Amazon S3 console](#).
2. Select the bucket you created.
3. Choose **Delete**.
4. Enter the name of the bucket in the text input field.
5. Choose **Delete bucket**.

Next steps

In [Tutorial: Using an Amazon S3 trigger to create thumbnail images](#), the Amazon S3 trigger invokes a function that creates a thumbnail image for each image file that is uploaded to a bucket. This tutorial requires a moderate level of AWS and Lambda domain knowledge. It demonstrates how to create resources using the AWS Command Line Interface (AWS CLI) and how to create a .zip file archive deployment package for the function and its dependencies.

Tutorial: Using an Amazon S3 trigger to create thumbnail images

In this tutorial, you create and configure a Lambda function that resizes images added to an Amazon Simple Storage Service (Amazon S3) bucket. When you add an image file to your bucket, Amazon S3 invokes your Lambda function. The function then creates a thumbnail version of the image and outputs it to a different Amazon S3 bucket.

To complete this tutorial, you carry out the following steps:

1. Create source and destination Amazon S3 buckets and upload a sample image.
2. Create a Lambda function that resizes an image and outputs a thumbnail to an Amazon S3 bucket.
3. Configure a Lambda trigger that invokes your function when objects are uploaded to your source bucket.
4. Test your function, first with a dummy event, and then by uploading an image to your source bucket.

By completing these steps, you'll learn how to use Lambda to carry out a file processing task on objects added to an Amazon S3 bucket. You can complete this tutorial using the AWS Command Line Interface (AWS CLI) or the AWS Management Console.

If you're looking for a simpler example to learn how to configure an Amazon S3 trigger for Lambda, you can try [Tutorial: Using an Amazon S3 trigger to invoke a Lambda function](#).

Topics

- [Prerequisites](#)
- [Create two Amazon S3 buckets](#)
- [Upload a test image to your source bucket](#)
- [Create a permissions policy](#)
- [Create an execution role](#)

- [Create the function deployment package](#)
- [Create the Lambda function](#)
- [Configure Amazon S3 to invoke the function](#)
- [Test your Lambda function with a dummy event](#)
- [Test your function using the Amazon S3 trigger](#)
- [Clean up your resources](#)

Prerequisites

If you want to use the AWS CLI to complete the tutorial, install the [latest version of the AWS Command Line Interface](#).

For your Lambda function code, you can use Python or Node.js. Install the language support tools and a package manager for the language that you want to use.

Install the AWS Command Line Interface

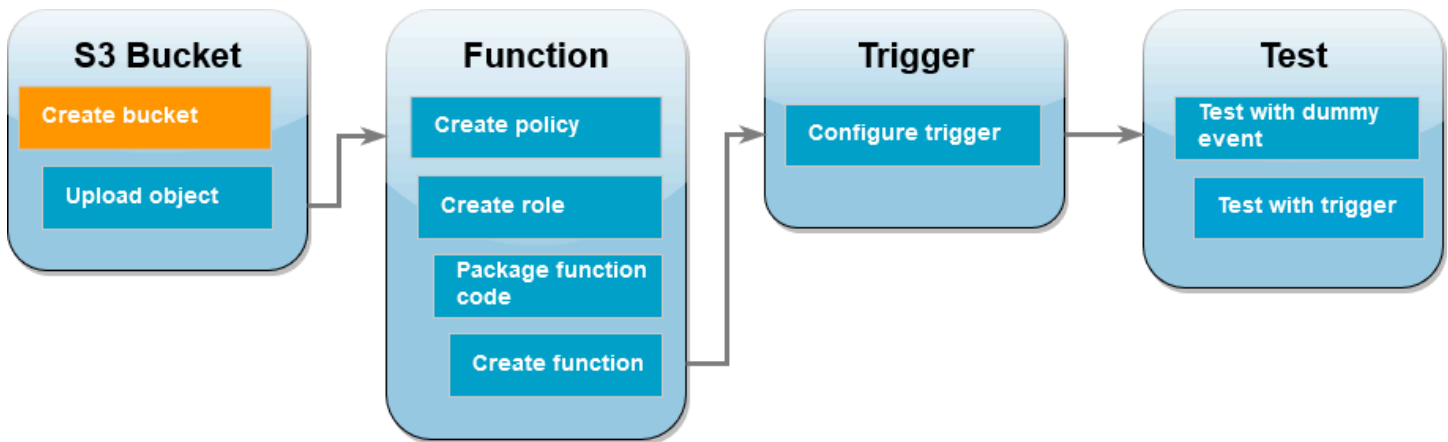

If you have not yet installed the AWS Command Line Interface, follow the steps at [Installing or updating the latest version of the AWS CLI](#) to install it.

The tutorial requires a command line terminal or shell to run commands. In Linux and macOS, use your preferred shell and package manager.

Note

In Windows, some Bash CLI commands that you commonly use with Lambda (such as `zip`) are not supported by the operating system's built-in terminals. To get a Windows-integrated version of Ubuntu and Bash, [install the Windows Subsystem for Linux](#).

Create two Amazon S3 buckets

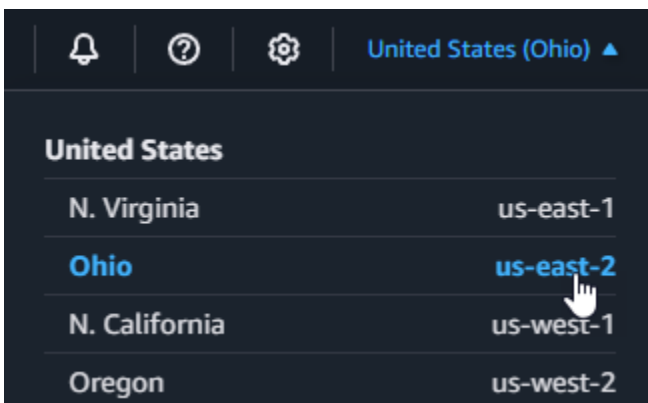

First create two Amazon S3 buckets. The first bucket is the source bucket you will upload your images to. The second bucket is used by Lambda to save the resized thumbnail when you invoke your function.

AWS Management Console

To create the Amazon S3 buckets (console)

1. Open the [Amazon S3 console](#) and select the **General purpose buckets** page.
2. Select the AWS Region closest to your geographical location. You can change your region using the drop-down list at the top of the screen. Later in the tutorial, you must create your Lambda function in the same Region.

3. Choose **Create bucket**.
4. Under **General configuration**, do the following:
 - a. For **Bucket type**, ensure **General purpose** is selected.

- b. For **Bucket name**, enter a globally unique name that meets the Amazon S3 [Bucket naming rules](#). Bucket names can contain only lower case letters, numbers, dots (.), and hyphens (-).
5. Leave all other options set to their default values and choose **Create bucket**.
6. Repeat steps 1 to 5 to create your destination bucket. For **Bucket name**, enter **amzn-s3-demo-source-bucket-resized**, where **amzn-s3-demo-source-bucket** is the name of the source bucket you just created.

AWS CLI

To create the Amazon S3 buckets (AWS CLI)

1. Run the following CLI command to create your source bucket. The name you choose for your bucket must be globally unique and follow the Amazon S3 [Bucket naming rules](#). Names can only contain lower case letters, numbers, dots (.), and hyphens (-). For region and LocationConstraint, choose the [AWS Region](#) closest to your geographical location.

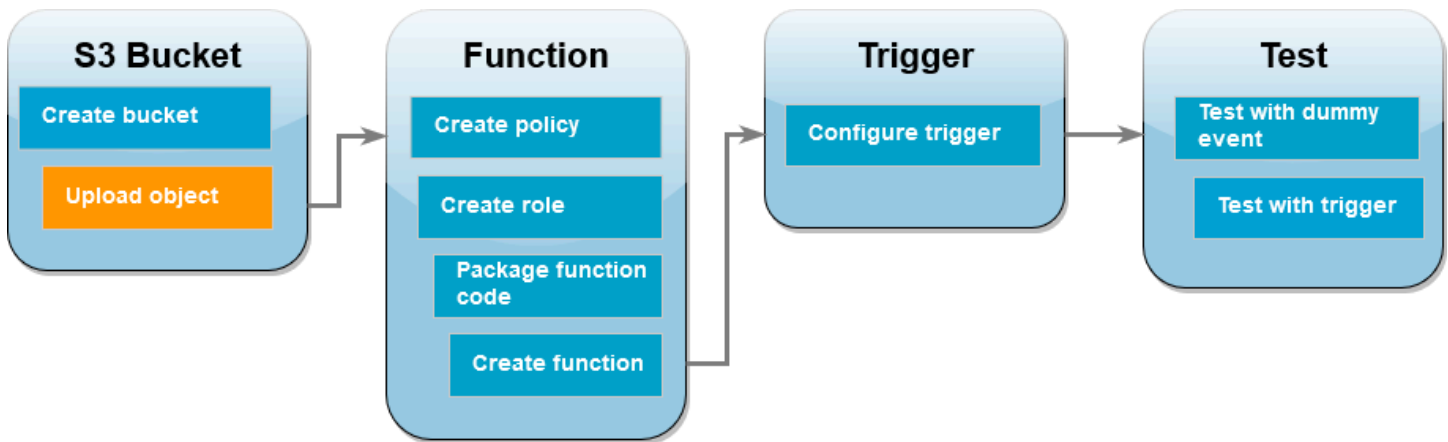

```
aws s3api create-bucket --bucket amzn-s3-demo-source-bucket --region us-east-1 \
--create-bucket-configuration LocationConstraint=us-east-1
```

Later in the tutorial, you must create your Lambda function in the same AWS Region as your source bucket, so make a note of the region you chose.

2. Run the following command to create your destination bucket. For the bucket name, you must use **amzn-s3-demo-source-bucket-resized**, where **amzn-s3-demo-source-bucket** is the name of the source bucket you created in step 1. For region and LocationConstraint, choose the same AWS Region you used to create your source bucket.

```
aws s3api create-bucket --bucket amzn-s3-demo-source-bucket-resized --region us-east-1 \
--create-bucket-configuration LocationConstraint=us-east-1
```

Upload a test image to your source bucket

Later in the tutorial, you'll test your Lambda function by invoking it using the AWS CLI or the Lambda console. To confirm that your function is operating correctly, your source bucket needs to contain a test image. This image can be any JPG or PNG file you choose.

AWS Management Console

To upload a test image to your source bucket (console)

1. Open the [Buckets](#) page of the Amazon S3 console.
2. Select the source bucket you created in the previous step.
3. Choose **Upload**.
4. Choose **Add files** and use the file selector to choose the object you want to upload.
5. Choose **Open**, then choose **Upload**.

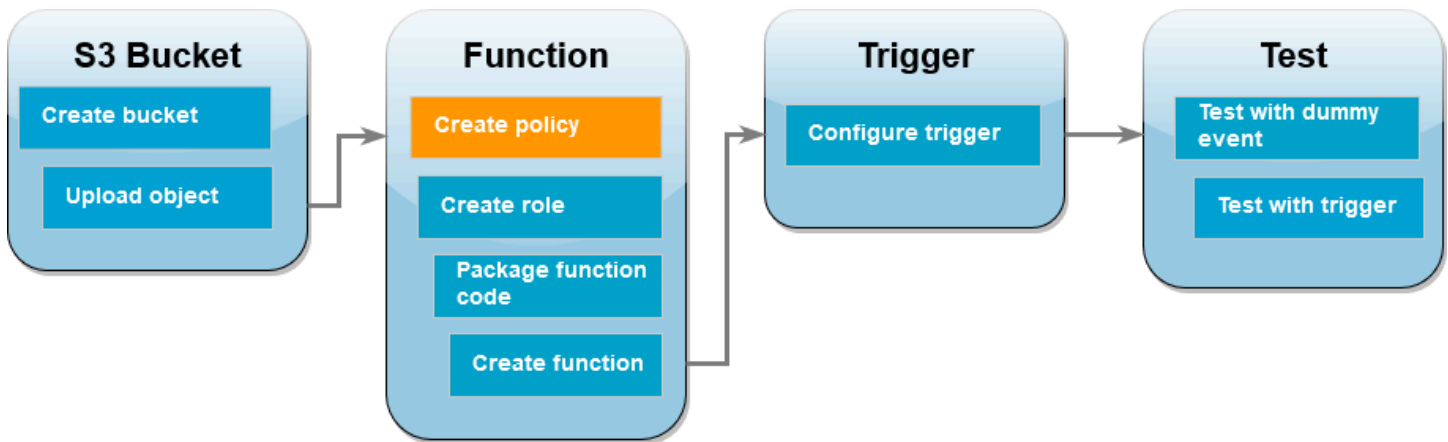

AWS CLI

To upload a test image to your source bucket (AWS CLI)

- From the directory containing the image you want to upload, run the following CLI command. Replace the `--bucket` parameter with the name of your source bucket. For the `--key` and `--body` parameters, use the filename of your test image.

```
aws s3api put-object --bucket amzn-s3-demo-source-bucket --key HappyFace.jpg --  
body ./HappyFace.jpg
```

Create a permissions policy

The first step in creating your Lambda function is to create a permissions policy. This policy gives your function the permissions it needs to access other AWS resources. For this tutorial, the policy gives Lambda read and write permissions for Amazon S3 buckets and allows it to write to Amazon CloudWatch Logs.

AWS Management Console

To create the policy (console)

1. Open the [Policies](#) page of the AWS Identity and Access Management (IAM) console.
2. Choose **Create policy**.
3. Choose the **JSON** tab, and then paste the following custom policy into the JSON editor.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "logs:PutLogEvents",
        "logs:CreateLogGroup",
        "logs:CreateLogStream"
      ],
      "Resource": "arn:aws:logs:*:*:*"
    },
    {
      "Effect": "Allow",
      "Action": [
```

```
        "s3:GetObject"
      ],
      "Resource": "arn:aws:s3:::*/*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:PutObject"
      ],
      "Resource": "arn:aws:s3:::*/*"
    }
  ]
}
```

4. Choose **Next**.
5. Under **Policy details**, for **Policy name**, enter **LambdaS3Policy**.
6. Choose **Create policy**.

AWS CLI

To create the policy (AWS CLI)

1. Save the following JSON in a file named `policy.json`.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "logs:PutLogEvents",
        "logs:CreateLogGroup",
        "logs:CreateLogStream"
      ],
      "Resource": "arn:aws:logs:*:*:*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject"
      ],

```

```

        "Resource": "arn:aws:s3:::*/**"
    },
    {
        "Effect": "Allow",
        "Action": [
            "s3:PutObject"
        ],
        "Resource": "arn:aws:s3:::*/**"
    }
]
}

```

- From the directory you saved the JSON policy document in, run the following CLI command.

```
aws iam create-policy --policy-name LambdaS3Policy --policy-document file://policy.json
```

Create an execution role

An execution role is an IAM role that grants a Lambda function permission to access AWS services and resources. To give your function read and write access to an Amazon S3 bucket, you attach the permissions policy you created in the previous step.

AWS Management Console

To create an execution role and attach your permissions policy (console)

- Open the [Roles](#) page of the (IAM) console.
- Choose **Create role**.

3. For **Trusted entity type**, select **AWS service**, and for **Use case**, select **Lambda**.
4. Choose **Next**.
5. Add the permissions policy you created in the previous step by doing the following:
 - a. In the policy search box, enter **LambdaS3Policy**.
 - b. In the search results, select the check box for LambdaS3Policy.
 - c. Choose **Next**.
6. Under **Role details**, for the **Role name** enter **LambdaS3Role**.
7. Choose **Create role**.

AWS CLI

To create an execution role and attach your permissions policy (AWS CLI)

1. Save the following JSON in a file named `trust-policy.json`. This trust policy allows Lambda to use the role's permissions by giving the service principal `lambda.amazonaws.com` permission to call the AWS Security Token Service (AWS STS) `AssumeRole` action.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "lambda.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

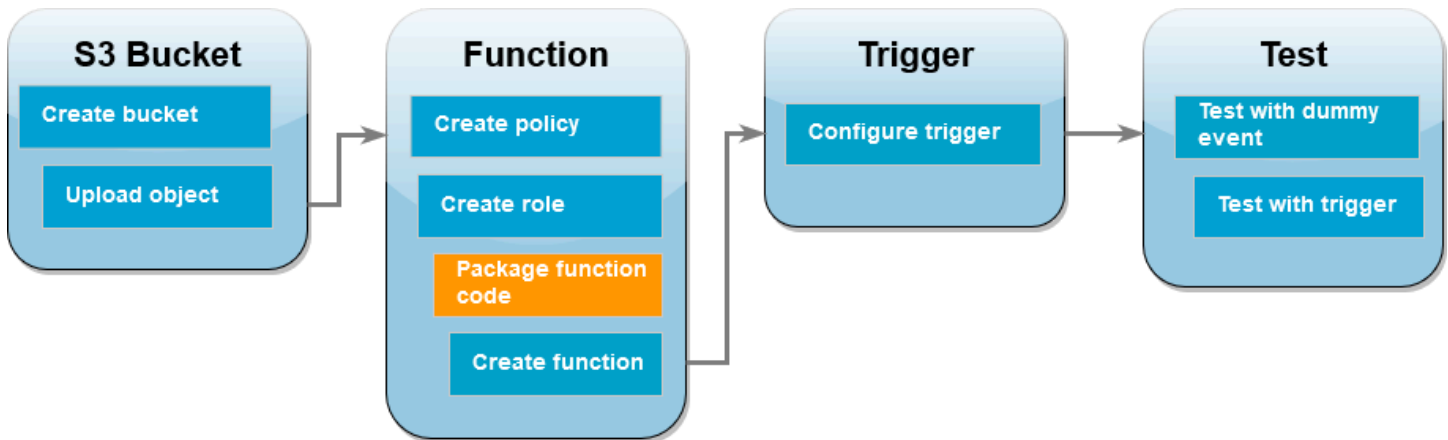

2. From the directory you saved the JSON trust policy document in, run the following CLI command to create the execution role.

```
aws iam create-role --role-name LambdaS3Role --assume-role-policy-document
file://trust-policy.json
```

3. To attach the permissions policy you created in the previous step, run the following CLI command. Replace the AWS account number in the policy's ARN with your own account number.

```
aws iam attach-role-policy --role-name LambdaS3Role --policy-arn
arn:aws:iam::123456789012:policy/LambdaS3Policy
```

Create the function deployment package

To create your function, you create a *deployment package* containing your function code and its dependencies. For this `CreateThumbnail` function, your function code uses a separate library for the image resizing. Follow the instructions for your chosen language to create a deployment package containing the required library.

Node.js

To create the deployment package (Node.js)

1. Create a directory named `lambda-s3` for your function code and dependencies and navigate into it.

```
mkdir lambda-s3
cd lambda-s3
```

2. Create a new Node.js project with npm. To accept the default options provided in the interactive experience, press Enter.

```
npm init
```

3. Save the following function code in a file named `index.mjs`. Make sure to replace `us-east-1` with the AWS Region in which you created your own source and destination buckets.

```
// dependencies
import { S3Client, GetObjectCommand, PutObjectCommand } from '@aws-sdk/client-s3';

import { Readable } from 'stream';

import sharp from 'sharp';
import util from 'util';

// create S3 client
const s3 = new S3Client({region: 'us-east-1'});

// define the handler function
export const handler = async (event, context) => {

// Read options from the event parameter and get the source bucket
console.log("Reading options from event:\n", util.inspect(event, {depth: 5}));
  const srcBucket = event.Records[0].s3.bucket.name;

// Object key may have spaces or unicode non-ASCII characters
const srcKey = decodeURIComponent(event.Records[0].s3.object.key.replace(/\/g, " "));
const dstBucket = srcBucket + "-resized";
const dstKey = "resized-" + srcKey;

// Infer the image type from the file suffix
const typeMatch = srcKey.match(/\.[^.]*$/);
if (!typeMatch) {
  console.log("Could not determine the image type.");
  return;
}

// Check that the image type is supported
const imageType = typeMatch[1].toLowerCase();
if (imageType !== "jpg" && imageType !== "png") {
  console.log(`Unsupported image type: ${imageType}`);
  return;
}
```

```
// Get the image from the source bucket. GetObjectCommand returns a stream.
try {
    const params = {
        Bucket: srcBucket,
        Key: srcKey
    };
    var response = await s3.send(new GetObjectCommand(params));
    var stream = response.Body;

    // Convert stream to buffer to pass to sharp resize function.
    if (stream instanceof Readable) {
        var content_buffer = Buffer.concat(await stream.toArray());

    } else {
        throw new Error('Unknown object stream type');
    }

} catch (error) {
    console.log(error);
    return;
}

// set thumbnail width. Resize will set the height automatically to maintain
// aspect ratio.
const width = 200;

// Use the sharp module to resize the image and save in a buffer.
try {
    var output_buffer = await sharp(content_buffer).resize(width).toBuffer();

} catch (error) {
    console.log(error);
    return;
}

// Upload the thumbnail image to the destination bucket
try {
    const destparams = {
        Bucket: dstBucket,
        Key: dstKey,
        Body: output_buffer,
```

```
        ContentType: "image"
    };

    const putResult = await s3.send(new PutObjectCommand(destparams));

    } catch (error) {
        console.log(error);
        return;
    }

    console.log('Successfully resized ' + srcBucket + '/' + srcKey +
        ' and uploaded to ' + dstBucket + '/' + dstKey);
};
```

4. In your `lambda-s3` directory, install the sharp library using npm. Note that the latest version of sharp (0.33) isn't compatible with Lambda. Install version 0.32.6 to complete this tutorial.

```
npm install sharp@0.32.6
```

The `npm install` command creates a `node_modules` directory for your modules. After this step, your directory structure should look like the following.

```
lambda-s3
|- index.mjs
|- node_modules
|  |- base64js
|  |- bl
|  |- buffer
|  ...
|- package-lock.json
|- package.json
```

5. Create a `.zip` deployment package containing your function code and its dependencies. In MacOS and Linux, run the following command.

```
zip -r function.zip .
```

In Windows, use your preferred zip utility to create a `.zip` file. Ensure that your `index.mjs`, `package.json`, and `package-lock.json` files and your `node_modules` directory are all at the root of your `.zip` file.

Python

To create the deployment package (Python)

1. Save the example code as a file named `lambda_function.py`.

```
import boto3
import os
import sys
import uuid
from urllib.parse import unquote_plus
from PIL import Image
import PIL.Image

s3_client = boto3.client('s3')

def resize_image(image_path, resized_path):
    with Image.open(image_path) as image:
        image.thumbnail(tuple(x / 2 for x in image.size))
        image.save(resized_path)

def lambda_handler(event, context):
    for record in event['Records']:
        bucket = record['s3']['bucket']['name']
        key = unquote_plus(record['s3']['object']['key'])
        tmpkey = key.replace('/', '')
        download_path = '/tmp/{}'.format(uuid.uuid4(), tmpkey)
        upload_path = '/tmp/resized-{}'.format(tmpkey)
        s3_client.download_file(bucket, key, download_path)
        resize_image(download_path, upload_path)
        s3_client.upload_file(upload_path, '{}-resized'.format(bucket), 'resized-{}'.format(key))
```

2. In the same directory in which you created your `lambda_function.py` file, create a new directory named `package` and install the [Pillow \(PIL\)](#) library and the AWS SDK for Python (Boto3). Although the Lambda Python runtime includes a version of the Boto3 SDK, we recommend that you add all of your function's dependencies to your deployment package, even if they are included in the runtime. For more information, see [Runtime dependencies in Python](#).

```
mkdir package
pip install \
```

```
--platform manylinux2014_x86_64 \  
--target=package \  
--implementation cp \  
--python-version 3.12 \  
--only-binary=:all: --upgrade \  
pillow boto3
```

The Pillow library contains C/C++ code. By using the `--platform manylinux_2014_x86_64` and `--only-binary=:all:` options, pip will download and install a version of Pillow that contains pre-compiled binaries compatible with the Amazon Linux 2 operating system. This ensures that your deployment package will work in the Lambda execution environment, regardless of the operating system and architecture of your local build machine.

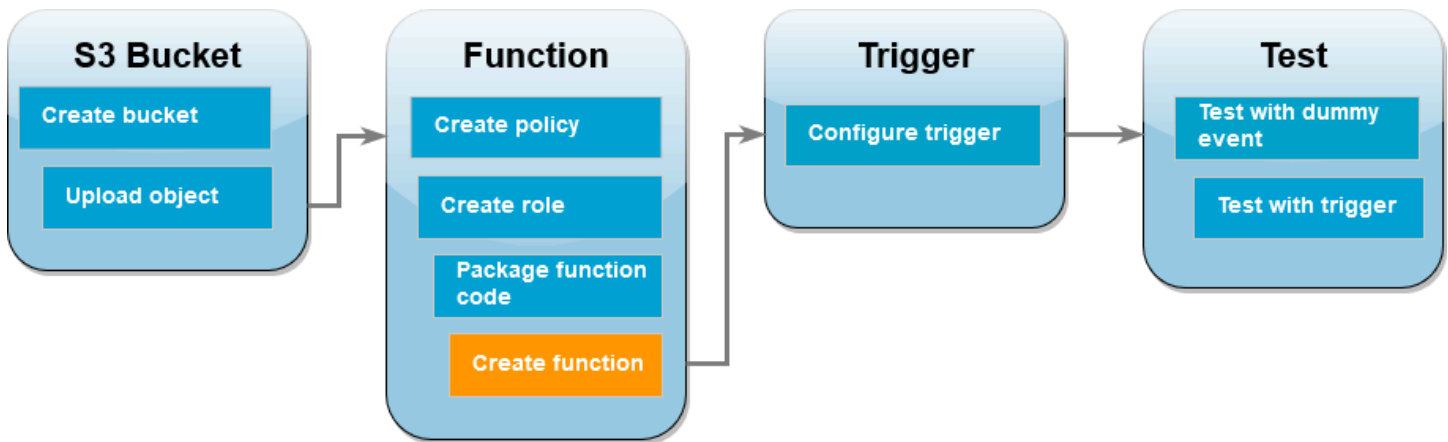

3. Create a .zip file containing your application code and the Pillow and Boto3 libraries. In Linux or MacOS, run the following commands from your command line interface.

```
cd package  
zip -r ../lambda_function.zip .  
cd ..  
zip lambda_function.zip lambda_function.py
```

In Windows, use your preferred zip tool to create the `lambda_function.zip` file. Make sure that your `lambda_function.py` file and the folders containing your dependencies are all at the root of the .zip file.

You can also create your deployment package using a Python virtual environment. See [Working with .zip file archives for Python Lambda functions](#)

Create the Lambda function

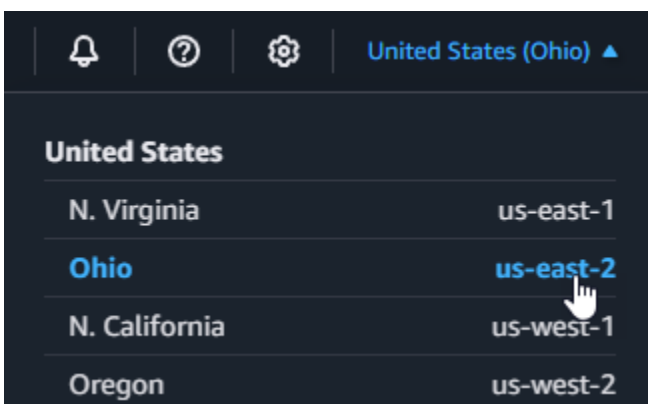

You can create your Lambda function using either the AWS CLI or the Lambda console. Follow the instructions for your chosen language to create the function.

AWS Management Console

To create the function (console)

To create your Lambda function using the console, you first create a basic function containing some 'Hello world' code. You then replace this code with your own function code by uploading the .zip or JAR file you created in the previous step.

1. Open the [Functions page](#) of the Lambda console.
2. Make sure you're working in the same AWS Region you created your Amazon S3 bucket in. You can change your region using the drop-down list at the top of the screen.

3. Choose **Create function**.
4. Choose **Author from scratch**.
5. Under **Basic information**, do the following:

- a. For **Function name**, enter **CreateThumbnail**.
 - b. For **Runtime**, choose either **Node.js 22.x** or **Python 3.12** according to the language you chose for your function.
 - c. For **Architecture**, choose **x86_64**.
6. In the **Change default execution role** tab, do the following:
 - a. Expand the tab, then choose **Use an existing role**.
 - b. Select the `LambdaS3Role` you created earlier.
7. Choose **Create function**.

To upload the function code (console)

1. In the **Code source** pane, choose **Upload from**.
2. Choose **.zip file**.
3. Choose **Upload**.
4. In the file selector, select your .zip file and choose **Open**.
5. Choose **Save**.

AWS CLI

To create the function (AWS CLI)

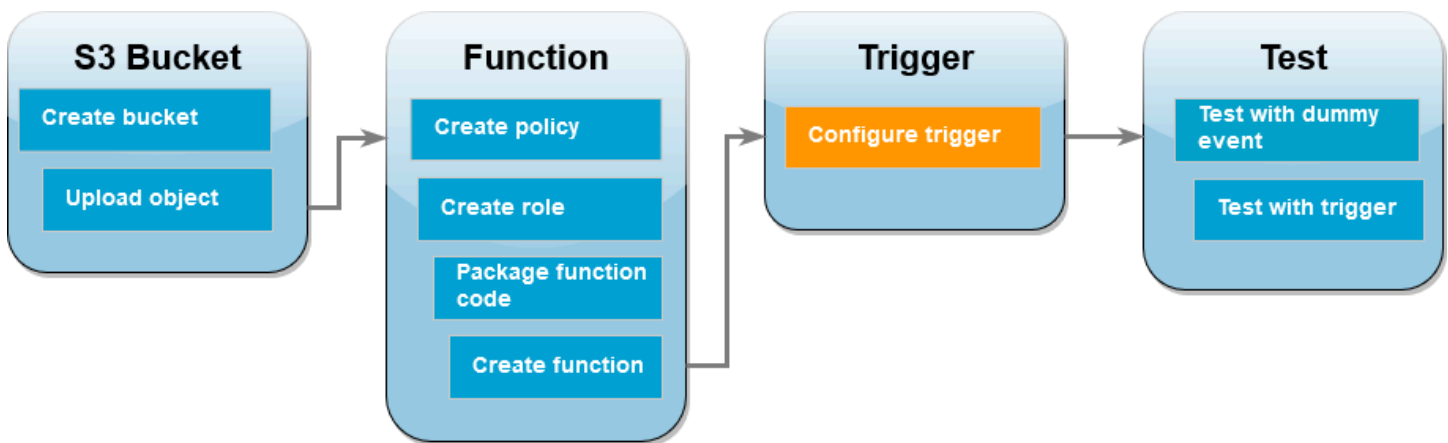

- Run the CLI command for the language you chose. For the `role` parameter, make sure to replace `123456789012` with your own AWS account ID. For the `region` parameter, replace `us-east-1` with the region you created your Amazon S3 buckets in.
- For **Node.js**, run the following command from the directory containing your `function.zip` file.

```
aws lambda create-function --function-name CreateThumbnail \  
--zip-file fileb://function.zip --handler index.handler --runtime nodejs24.x \  
--timeout 10 --memory-size 1024 \  
--role arn:aws:iam::123456789012:role/LambdaS3Role --region us-east-1
```

- For **Python**, run the following command from the directory containing your `lambda_function.zip` file.

```
aws lambda create-function --function-name CreateThumbnail \  
--zip-file fileb://lambda_function.zip --handler  
lambda_function.lambda_handler \  
--runtime python3.14 --timeout 10 --memory-size 1024 \  
--role arn:aws:iam::123456789012:role/LambdaS3Role --region us-east-1
```

Configure Amazon S3 to invoke the function

For your Lambda function to run when you upload an image to your source bucket, you need to configure a trigger for your function. You can configure the Amazon S3 trigger using either the console or the AWS CLI.

⚠ Important

This procedure configures the Amazon S3 bucket to invoke your function every time that an object is created in the bucket. Be sure to configure this only on the source bucket. If your Lambda function creates objects in the same bucket that invokes it, your function can be [invoked continuously in a loop](#). This can result in unexpected charges being billed to your AWS account.

AWS Management Console

To configure the Amazon S3 trigger (console)

1. Open the [Functions page](#) of the Lambda console and choose your function (CreateThumbnail).

2. Choose **Add trigger**.
3. Select **S3**.
4. Under **Bucket**, select your source bucket.
5. Under **Event types**, select **All object create events**.
6. Under **Recursive invocation**, select the check box to acknowledge that using the same Amazon S3 bucket for input and output is not recommended. You can learn more about recursive invocation patterns in Lambda by reading [Recursive patterns that cause run-away Lambda functions](#) in Serverless Land.
7. Choose **Add**.

When you create a trigger using the Lambda console, Lambda automatically creates a [resource based policy](#) to give the service you select permission to invoke your function.

AWS CLI

To configure the Amazon S3 trigger (AWS CLI)

1. For your Amazon S3 source bucket to invoke your function when you add an image file, you first need to configure permissions for your function using a [resource based policy](#). A resource-based policy statement gives other AWS services permission to invoke your function. To give Amazon S3 permission to invoke your function, run the following CLI command. Be sure to replace the `source-account` parameter with your own AWS account ID and to use your own source bucket name.

```
aws lambda add-permission --function-name CreateThumbnail \  
--principal s3.amazonaws.com --statement-id s3invoke --action \  
"lambda:InvokeFunction" \  
--source-arn arn:aws:s3:::amzn-s3-demo-source-bucket \  
--source-account 123456789012
```

The policy you define with this command allows Amazon S3 to invoke your function only when an action takes place on your source bucket.

Note

Although Amazon S3 bucket names are globally unique, when using resource-based policies it is best practice to specify that the bucket must belong to your account.

This is because if you delete a bucket, it is possible for another AWS account to create a bucket with the same Amazon Resource Name (ARN).

2. Save the following JSON in a file named `notification.json`. When applied to your source bucket, this JSON configures the bucket to send a notification to your Lambda function every time a new object is added. Replace the AWS account number and AWS Region in the Lambda function ARN with your own account number and region.

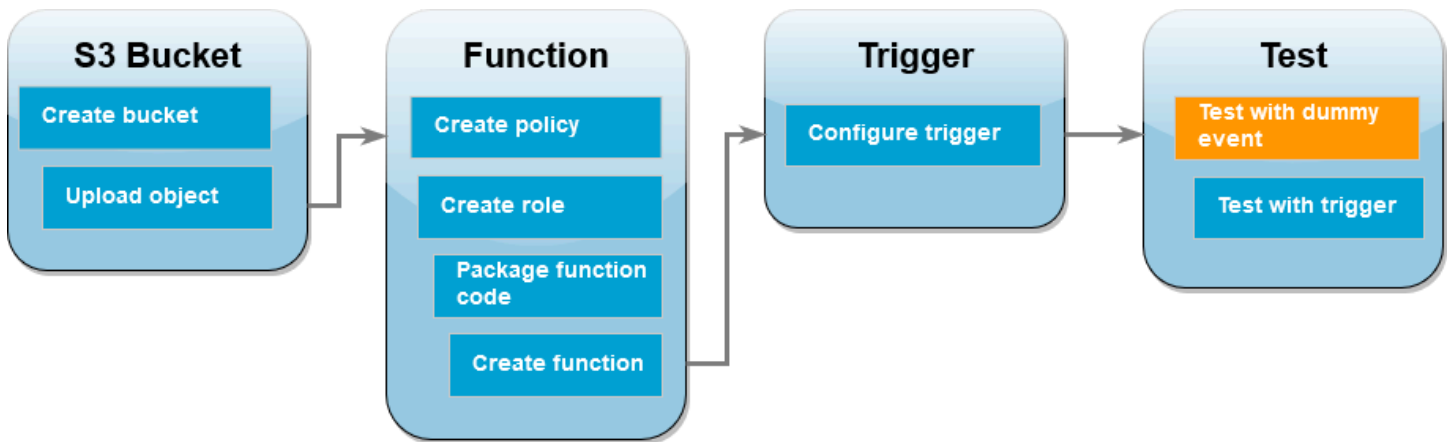

```
{
  "LambdaFunctionConfigurations": [
    {
      "Id": "CreateThumbnailEventConfiguration",
      "LambdaFunctionArn": "arn:aws:lambda:us-
east-1:123456789012:function:CreateThumbnail",
      "Events": [ "s3:ObjectCreated:Put" ]
    }
  ]
}
```

3. Run the following CLI command to apply the notification settings in the JSON file you created to your source bucket. Replace `amzn-s3-demo-source-bucket` with the name of your own source bucket.

```
aws s3api put-bucket-notification-configuration --bucket amzn-s3-demo-source-
bucket \
--notification-configuration file://notification.json
```

To learn more about the `put-bucket-notification-configuration` command and the `notification-configuration` option, see [put-bucket-notification-configuration](#) in the *AWS CLI Command Reference*.

Test your Lambda function with a dummy event

Before you test your whole setup by adding an image file to your Amazon S3 source bucket, you test that your Lambda function is working correctly by invoking it with a dummy event. An event in Lambda is a JSON-formatted document that contains data for your function to process. When your function is invoked by Amazon S3, the event sent to your function contains information such as the bucket name, bucket ARN, and object key.

AWS Management Console

To test your Lambda function with a dummy event (console)

1. Open the [Functions page](#) of the Lambda console and choose your function (CreateThumbnail).
2. Choose the **Test** tab.
3. To create your test event, in the **Test event** pane, do the following:
 - a. Under **Test event action**, select **Create new event**.
 - b. For **Event name**, enter **myTestEvent**.
 - c. For **Template**, select **S3 Put**.
 - d. Replace the values for the following parameters with your own values.
 - For **awsRegion**, replace **us-east-1** with the AWS Region you created your Amazon S3 buckets in.
 - For **name**, replace **amzn-s3-demo-bucket** with the name of your own Amazon S3 source bucket.

- For key, replace test%2Fkey with the filename of the test object you uploaded to your source bucket in the step [Upload a test image to your source bucket](#).

```
{
  "Records": [
    {
      "eventVersion": "2.0",
      "eventSource": "aws:s3",
      "awsRegion": "us-east-1",
      "eventTime": "1970-01-01T00:00:00.000Z",
      "eventName": "ObjectCreated:Put",
      "userIdentity": {
        "principalId": "EXAMPLE"
      },
      "requestParameters": {
        "sourceIPAddress": "127.0.0.1"
      },
      "responseElements": {
        "x-amz-request-id": "EXAMPLE123456789",
        "x-amz-id-2": "EXAMPLE123/5678abcdefghijklambdaisawesome/mnopqrstuvwxyzABCDEFGH"
      },
      "s3": {
        "s3SchemaVersion": "1.0",
        "configurationId": "testConfigRule",
        "bucket": {
          "name": "amzn-s3-demo-bucket",
          "ownerIdentity": {
            "principalId": "EXAMPLE"
          },
          "arn": "arn:aws:s3:::amzn-s3-demo-bucket"
        },
        "object": {
          "key": "test%2Fkey",
          "size": 1024,
          "eTag": "0123456789abcdef0123456789abcdef",
          "sequencer": "0A1B2C3D4E5F678901"
        }
      }
    }
  ]
}
```

- e. Choose **Save**.
4. In the **Test event** pane, choose **Test**.
5. To check the your function has created a resized verison of your image and stored it in your target Amazon S3 bucket, do the following:
 - a. Open the [Buckets page](#) of the Amazon S3 console.
 - b. Choose your target bucket and confirm that your resized file is listed in the **Objects** pane.

AWS CLI

To test your Lambda function with a dummy event (AWS CLI)

1. Save the following JSON in a file named `dummyS3Event.json`. Replace the values for the following parameters with your own values:
 - For `awsRegion`, replace `us-east-1` with the AWS Region you created your Amazon S3 buckets in.
 - For `name`, replace `amzn-s3-demo-bucket` with the name of your own Amazon S3 source bucket.
 - For `key`, replace `test%2Fkey` with the filename of the test object you uploaded to your source bucket in the step [Upload a test image to your source bucket](#).

```
{
  "Records": [
    {
      "eventVersion": "2.0",
      "eventSource": "aws:s3",
      "awsRegion": "us-east-1",
      "eventTime": "1970-01-01T00:00:00.000Z",
      "eventName": "ObjectCreated:Put",
      "userIdentity": {
        "principalId": "EXAMPLE"
      },
      "requestParameters": {
        "sourceIPAddress": "127.0.0.1"
      },
      "responseElements": {
```

```

        "x-amz-request-id": "EXAMPLE123456789",
        "x-amz-id-2": "EXAMPLE123/5678abcdefghijklambdaisawesome/
mnopqrstuvwxyzABCDEFGH"
    },
    "s3": {
        "s3SchemaVersion": "1.0",
        "configurationId": "testConfigRule",
        "bucket": {
            "name": "amzn-s3-demo-bucket",
            "ownerIdentity": {
                "principalId": "EXAMPLE"
            },
            "arn": "arn:aws:s3:::amzn-s3-demo-bucket"
        },
        "object": {
            "key": "test%2Fkey",
            "size": 1024,
            "eTag": "0123456789abcdef0123456789abcdef",
            "sequencer": "0A1B2C3D4E5F678901"
        }
    }
}
]
}

```

2. From the directory you saved your `dummyS3Event.json` file in, invoke the function by running the following CLI command. This command invokes your Lambda function synchronously by specifying `RequestResponse` as the value of the `invocation-type` parameter. To learn more about synchronous and asynchronous invocation, see [Invoking Lambda functions](#).

```

aws lambda invoke --function-name CreateThumbnail \
--invocation-type RequestResponse --cli-binary-format raw-in-base64-out \
--payload file://dummyS3Event.json outputfile.txt

```

The `cli-binary-format` option is required if you are using version 2 of the AWS CLI. To make this the default setting, run `aws configure set cli-binary-format raw-in-base64-out`. For more information, see [AWS CLI supported global command line options](#).

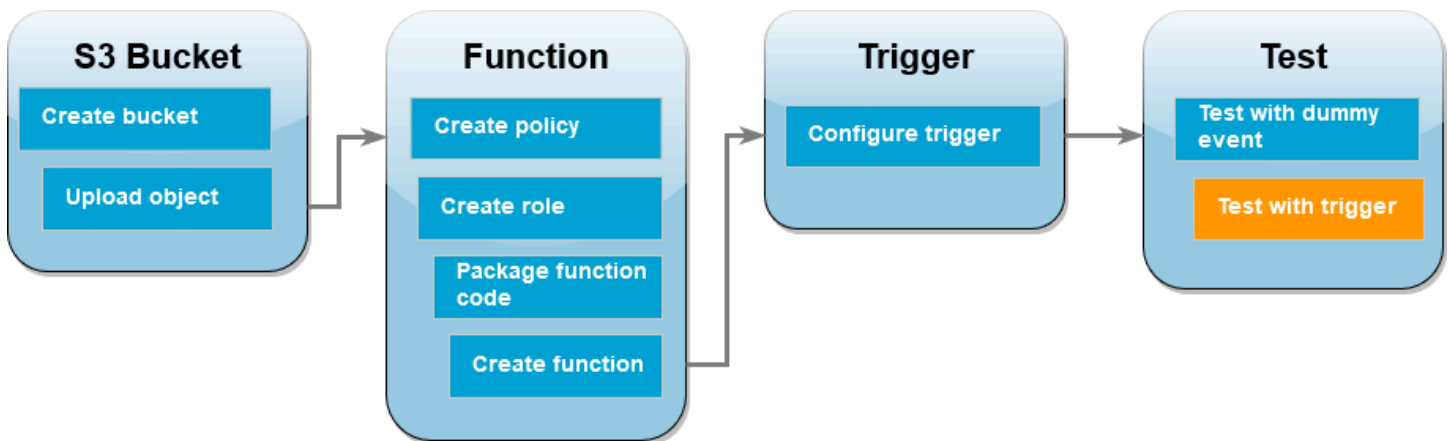

3. Verify that your function has created a thumbnail version of your image and saved it to your target Amazon S3 bucket. Run the following CLI command, replacing `amzn-s3-demo-source-bucket-resized` with the name of your own destination bucket.

```
aws s3api list-objects-v2 --bucket amzn-s3-demo-source-bucket-resized
```

You should see output similar to the following. The Key parameter shows the filename of your resized image file.

```
{
  "Contents": [
    {
      "Key": "resized-HappyFace.jpg",
      "LastModified": "2023-06-06T21:40:07+00:00",
      "ETag": "\"d8ca652ffe83ba6b721ffc20d9d7174a\"",
      "Size": 2633,
      "StorageClass": "STANDARD"
    }
  ]
}
```

Test your function using the Amazon S3 trigger

Now that you've confirmed your Lambda function is operating correctly, you're ready to test your complete setup by adding an image file to your Amazon S3 source bucket. When you add your image to the source bucket, your Lambda function should be automatically invoked. Your function creates a resized version of the file and stores it in your target bucket.

AWS Management Console

To test your Lambda function using the Amazon S3 trigger (console)

1. To upload an image to your Amazon S3 bucket, do the following:
 - a. Open the [Buckets](#) page of the Amazon S3 console and choose your source bucket.
 - b. Choose **Upload**.
 - c. Choose **Add files** and use the file selector to choose the image file you want to upload. Your image object can be any .jpg or .png file.
 - d. Choose **Open**, then choose **Upload**.
2. Verify that Lambda has saved a resized version of your image file in your target bucket by doing the following:
 - a. Navigate back to the [Buckets](#) page of the Amazon S3 console and choose your destination bucket.
 - b. In the **Objects** pane, you should now see two resized image files, one from each test of your Lambda function. To download your resized image, select the file, then choose **Download**.

AWS CLI

To test your Lambda function using the Amazon S3 trigger (AWS CLI)

1. From the directory containing the image you want to upload, run the following CLI command. Replace the `--bucket` parameter with the name of your source bucket. For the `--key` and `--body` parameters, use the filename of your test image. Your test image can be any .jpg or .png file.

```
aws s3api put-object --bucket amzn-s3-demo-source-bucket --key SmileyFace.jpg --  
body ./SmileyFace.jpg
```

2. Verify that your function has created a thumbnail version of your image and saved it to your target Amazon S3 bucket. Run the following CLI command, replacing `amzn-s3-demo-source-bucket-resized` with the name of your own destination bucket.

```
aws s3api list-objects-v2 --bucket amzn-s3-demo-source-bucket-resized
```

If your function runs successfully, you'll see output similar to the following. Your target bucket should now contain two resized files.

```
{
  "Contents": [
    {
      "Key": "resized-HappyFace.jpg",
      "LastModified": "2023-06-07T00:15:50+00:00",
      "ETag": "\"7781a43e765a8301713f533d70968a1e\"",
      "Size": 2763,
      "StorageClass": "STANDARD"
    },
    {
      "Key": "resized-SmileyFace.jpg",
      "LastModified": "2023-06-07T00:13:18+00:00",
      "ETag": "\"ca536e5a1b9e32b22cd549e18792cdbc\"",
      "Size": 1245,
      "StorageClass": "STANDARD"
    }
  ]
}
```

Clean up your resources

You can now delete the resources that you created for this tutorial, unless you want to retain them. By deleting AWS resources that you're no longer using, you prevent unnecessary charges to your AWS account.

To delete the Lambda function

1. Open the [Functions page](#) of the Lambda console.
2. Select the function that you created.
3. Choose **Actions, Delete**.
4. Type **confirm** in the text input field and choose **Delete**.

To delete the policy that you created

1. Open the [Policies page](#) of the IAM console.

2. Select the policy that you created (**AWSLambdaS3Policy**).
3. Choose **Policy actions, Delete**.
4. Choose **Delete**.

To delete the execution role

1. Open the [Roles page](#) of the IAM console.
2. Select the execution role that you created.
3. Choose **Delete**.
4. Enter the name of the role in the text input field and choose **Delete**.

To delete the S3 bucket

1. Open the [Amazon S3 console](#).
2. Select the bucket you created.
3. Choose **Delete**.
4. Enter the name of the bucket in the text input field.
5. Choose **Delete bucket**.

Use Secrets Manager secrets in Lambda functions

AWS Secrets Manager helps you manage credentials, API keys, and other secrets that your Lambda functions need. You have two main approaches for retrieving secrets in your Lambda functions, both offering better performance and lower costs compared to retrieving secrets directly using the AWS SDK:

- **AWS parameters and secrets Lambda extension** - A runtime-agnostic solution that provides a simple HTTP interface for retrieving secrets
- **Powertools for AWS Lambda parameters utility** - A code-integrated solution that supports multiple providers (Secrets Manager, Parameter Store, AppConfig) with built-in transformations

Both approaches maintain local caches of secrets, eliminating the need for your function to call Secrets Manager for every invocation. When your function requests a secret, the cache is checked first. If the secret is available and hasn't expired, it's returned immediately. Otherwise, it's retrieved from Secrets Manager, cached, and returned. This caching mechanism results in faster response times and reduced costs by minimizing API calls.

Choosing an approach

Consider these factors when choosing between the extension and PowerTools:

Use the AWS parameters and secrets Lambda extension when:

- You want a runtime-agnostic solution that works with any Lambda runtime
- You prefer not to add code dependencies to your function
- You only need to retrieve secrets from Secrets Manager or Parameter Store

Use Powertools for AWS Lambda parameters utility when:

- You want an integrated development experience with your application code
- You need support for multiple providers (Secrets Manager, Parameter Store, AppConfig)
- You want built-in data transformations (JSON parsing, base64 decoding)
- You're using Python, TypeScript, Java, or .NET runtimes

When to use Secrets Manager with Lambda

Common scenarios for using Secrets Manager with Lambda include:

- Storing database credentials that your function uses to connect to Amazon RDS or other databases
- Managing API keys for external services your function calls
- Storing encryption keys or other sensitive configuration data
- Rotating credentials automatically without needing to update your function code

Using the AWS parameters and secrets Lambda extension

The AWS parameters and secrets Lambda extension uses a simple HTTP interface compatible with any Lambda runtime. By default, it caches secrets for 300 seconds (5 minutes) and can hold up to 1,000 secrets. You can [customize these settings with environment variables](#).

Use Secrets Manager in a Lambda function

This section assumes that you already have a Secrets Manager secret. To create a secret, see [Create an AWS Secrets Manager secret](#).

Create the deployment package

Choose your preferred runtime and follow the steps to create a function that retrieves secrets from Secrets Manager. The example function retrieves a secret from Secrets Manager and can be used to access database credentials, API keys, or other sensitive configuration data in your applications.

Python

To create a Python function

1. Create and navigate to a new project directory. Example:

```
mkdir my_function
cd my_function
```

2. Create a file named `lambda_function.py` with the following code. For `secret_name`, use the name or Amazon Resource Name (ARN) of your secret.

```
import json
import os
import requests

def lambda_handler(event, context):
```

```

try:
    # Replace with the name or ARN of your secret
    secret_name = "arn:aws:secretsmanager:us-
east-1:111122223333:secret:SECRET_NAME"

    secrets_extension_endpoint = f"http://localhost:2773/secretsmanager/get?
secretId={secret_name}"
    headers = {"X-Aws-Parameters-Secrets-Token":
os.environ.get('AWS_SESSION_TOKEN')}

    response = requests.get(secrets_extension_endpoint, headers=headers)
    print(f"Response status code: {response.status_code}")

    secret = json.loads(response.text)["SecretString"]
    print(f"Retrieved secret: {secret}")

    return {
        'statusCode': response.status_code,
        'body': json.dumps({
            'message': 'Successfully retrieved secret',
            'secretRetrieved': True
        })
    }

except Exception as e:
    print(f"Error: {str(e)}")
    return {
        'statusCode': 500,
        'body': json.dumps({
            'message': 'Error retrieving secret',
            'error': str(e)
        })
    }
}

```

3. Create a file named `requirements.txt` with this content:

```
requests
```

4. Install the dependencies:

```
pip install -r requirements.txt -t .
```

5. Create a `.zip` file containing all files:

```
zip -r function.zip .
```

Node.js

To create a Node.js function

1. Create and navigate to a new project directory. Example:

```
mkdir my_function  
cd my_function
```

2. Create a file named `index.mjs` with the following code. For `secret_name`, use the name or Amazon Resource Name (ARN) of your secret.

```
import http from 'http';  
  
export const handler = async (event) => {  
  try {  
    // Replace with the name or ARN of your secret  
    const secretName = "arn:aws:secretsmanager:us-  
east-1:111122223333:secret:SECRET_NAME";  
    const options = {  
      hostname: 'localhost',  
      port: 2773,  
      path: `/secretsmanager/get?secretId=${secretName}`,  
      headers: {  
        'X-Aws-Parameters-Secrets-Token': process.env.AWS_SESSION_TOKEN  
      }  
    };  
  };  
  
  const response = await new Promise((resolve, reject) => {  
    http.get(options, (res) => {  
      let data = '';  
      res.on('data', (chunk) => { data += chunk; });  
      res.on('end', () => {  
        resolve({  
          statusCode: res.statusCode,  
          body: data  
        });  
      });  
    });  
  }).on('error', reject);
```

```
});

const secret = JSON.parse(response.body).SecretString;
console.log('Retrieved secret:', secret);

return {
  statusCode: response.statusCode,
  body: JSON.stringify({
    message: 'Successfully retrieved secret',
    secretRetrieved: true
  })
};
} catch (error) {
  console.error('Error:', error);
  return {
    statusCode: 500,
    body: JSON.stringify({
      message: 'Error retrieving secret',
      error: error.message
    })
  };
}
};
```

3. Create a .zip file containing the index.mjs file:

```
zip -r function.zip index.mjs
```

Java

To create a Java function

1. Create a Maven project:

```
mvn archetype:generate \
  -DgroupId=example \
  -DartifactId=lambda-secrets-demo \
  -DarchetypeArtifactId=maven-archetype-quickstart \
  -DarchetypeVersion=1.4 \
  -DinteractiveMode=false
```

2. Navigate to the project directory:

```
cd lambda-secrets-demo
```

3. Open the `pom.xml` and replace the contents with the following:

```
<project xmlns="http://maven.apache.org/POM/4.0.0"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 http://
maven.apache.org/xsd/maven-4.0.0.xsd">
  <modelVersion>4.0.0</modelVersion>

  <groupId>example</groupId>
  <artifactId>lambda-secrets-demo</artifactId>
  <version>1.0-SNAPSHOT</version>

  <properties>
    <maven.compiler.source>11</maven.compiler.source>
    <maven.compiler.target>11</maven.compiler.target>
  </properties>

  <dependencies>
    <dependency>
      <groupId>com.amazonaws</groupId>
      <artifactId>aws-lambda-java-core</artifactId>
      <version>1.2.1</version>
    </dependency>
  </dependencies>

  <build>
    <plugins>
      <plugin>
        <groupId>org.apache.maven.plugins</groupId>
        <artifactId>maven-shade-plugin</artifactId>
        <version>3.2.4</version>
        <executions>
          <execution>
            <phase>package</phase>
            <goals>
              <goal>shade</goal>
            </goals>
            <configuration>
              <createDependencyReducedPom>>false</
createDependencyReducedPom>
```

```

        <finalName>function</finalName>
    </configuration>
</execution>
</executions>
</plugin>
</plugins>
</build>
</project>

```

4. Rename the `/lambda-secrets-demo/src/main/java/example/App.java` to `Hello.java` to match Lambda's default Java handler name (`example.Hello::handleRequest`):

```
mv src/main/java/example/App.java src/main/java/example/Hello.java
```

5. Open the `Hello.java` file and replace its contents with the following. For `secretName`, use the name or Amazon Resource Name (ARN) of your secret.

```

package example;

import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;
import java.net.URI;
import java.net.http.HttpClient;
import java.net.http.HttpRequest;
import java.net.http.HttpResponse;

public class Hello implements RequestHandler<Object, String> {
    private final HttpClient client = HttpClient.newHttpClient();

    @Override
    public String handleRequest(Object input, Context context) {
        try {
            // Replace with the name or ARN of your secret
            String secretName = "arn:aws:secretsmanager:us-
east-1:111122223333:secret:SECRET_NAME";
            String endpoint = "http://localhost:2773/secretsmanager/get?
secretId=" + secretName;

            HttpRequest request = HttpRequest.newBuilder()
                .uri(URI.create(endpoint))
                .header("X-Aws-Parameters-Secrets-Token",
                    System.getenv("AWS_SESSION_TOKEN"))

```

```
        .GET()
        .build();

    HttpResponse<String> response = client.send(request,
        HttpResponse.BodyHandlers.ofString());

    String secret = response.body();
    secret = secret.substring(secret.indexOf("SecretString") + 15);
    secret = secret.substring(0, secret.indexOf("\\"));

    System.out.println("Retrieved secret: " + secret);
    return String.format(
        "{\\"statusCode\\": %d, \\"body\\": \\"%s\\"}",
        response.statusCode(), "Successfully retrieved secret"
    );

} catch (Exception e) {
    e.printStackTrace();
    return String.format(
        "{\\"body\\": \\"Error retrieving secret: %s\\"}",
        e.getMessage()
    );
}
}
```

6. Remove the test directory. Maven creates this by default, but we don't need it for this example.

```
rm -rf src/test
```

7. Build the project:

```
mvn package
```

8. Download the JAR file (target/function.jar) for later use.

Create the function

1. Open the [Functions page](#) of the Lambda console.
2. Choose **Create function**.
3. Select **Author from scratch**.

4. For **Function name**, enter **secret-retrieval-demo**.
5. Choose your preferred **Runtime**.
6. Choose **Create function**.

To upload the deployment package

1. In the function's **Code** tab, choose **Upload from** and select **.zip file** (for Python and Node.js) or **.jar file** (for Java).
2. Upload the deployment package you created earlier.
3. Choose **Save**.

Add the extension

To add the AWS Parameters and Secrets Lambda extension as a layer

1. In the function's **Code** tab, scroll down to **Layers**.
2. Choose **Add a layer**.
3. Select **AWS layers**.
4. Choose **AWS-Parameters-and-Secrets-Lambda-Extension**.
5. Select the latest version.
6. Choose **Add**.

Add permissions

To add Secrets Manager permissions to your execution role

1. Choose the **Configuration** tab, and then choose **Permissions**.
2. Under **Role name**, choose the link to your execution role. This link opens the role in the IAM console.

Execution role

Role name

secret-retrieval-demo-role- 

3. Choose **Add permissions**, and then choose **Create inline policy**.

Permissions policies (1) [Info](#)

You can attach up to 10 managed policies.

[Simulate](#) [Remove](#)[Add permissions](#)

Filter by Type

All types

Attach policies

Create inline policy

< 1 >

- Choose the **JSON** tab and add the following policy. For Resource, enter the ARN of your secret.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "secretsmanager:GetSecretValue",
      "Resource": "arn:aws:secretsmanager:us-east-1:111122223333:secret:SECRET_NAME"
    }
  ]
}
```

- Choose **Next**.
- Enter a name for the policy.
- Choose **Create policy**.

Test the function**To test the function**

- Return to the Lambda console.
- Select the **Test** tab.
- Choose **Test**. You should see the following response:

✔ Executing function: succeeded ([logs](#))

▼ Details

The area below shows the last 4 KB of the execution log.

```
{
  "statusCode": 200,
  "body": "{\"message\": \"Successfully retrieved secret\", \"secretRetrieved\": true}"
}
```

Environment variables

The AWS Parameters and Secrets Lambda extension uses the following default settings. You can override these settings by creating the corresponding [environment variables](#). To view the current settings for a function, set `PARAMETERS_SECRETS_EXTENSION_LOG_LEVEL` to `DEBUG`. The extension will log its configuration information to CloudWatch Logs at the start of each function invocation.

Setting	Default value	Valid values	Environment variable	Details
HTTP port	2773	1 - 65535	PARAMETERS_SECRETS_EXTENSION_HTTP_PORT	Port for the local HTTP server
Cache enabled	TRUE	TRUE FALSE	PARAMETERS_SECRETS_EXTENSION_CACHE_ENABLED	Enable or disable the cache
Cache size	1000	0 - 1000	PARAMETERS_SECRETS_EXTENSION_CACHE_SIZE	Set to 0 to disable caching
Secrets Manager TTL	300 seconds	0 - 300 seconds	SECRETS_MANAGER_TTL	Time-to-live for cached secrets. Set to 0 to disable caching. This variable is ignored if the value for <code>PARAMETER</code>

Setting	Default value	Valid values	Environment variable	Details
				S_SECRETS_EXTENSION_CACHE_SIZE is 0.
Parameter Store TTL	300 seconds	0 - 300 seconds	SSM_PARAMETER_STORE_TTL	Time-to-live for cached parameters. Set to 0 to disable caching. This variable is ignored if the value for PARAMETER_STORE_CACHE_SIZE is 0.
Log level	INFO	DEBUG INFO WARN ERROR NONE	PARAMETERS_SECRETS_EXTENSION_LOG_LEVEL	The level of detail reported in logs for the extension
Max connections	3	1 or greater	PARAMETERS_SECRETS_EXTENSION_MAX_CONNECTIONS	Maximum number of HTTP connections for requests to Parameter Store or Secrets Manager
Secrets Manager timeout	0 (no timeout)	All whole numbers	SECRETS_MANAGER_TIMEOUT_MILLIS	Timeout for requests to Secrets Manager (in milliseconds)
Parameter Store timeout	0 (no timeout)	All whole numbers	SSM_PARAMETER_STORE_TIMEOUT_MILLIS	Timeout for requests to Parameter Store (in milliseconds)

Working with secret rotation

If you rotate secrets frequently, the default 300-second cache duration might cause your function to use outdated secrets. You have two options to ensure your function uses the latest secret value:

- Reduce the cache TTL by setting the `SECRETS_MANAGER_TTL` environment variable to a lower value (in seconds). For example, setting it to 60 ensures your function will never use a secret that's more than one minute old.
- Use the `AWSCURRENT` or `AWSPREVIOUS` staging labels in your secret request to ensure you get the specific version you want:

```
secretsmanager/get?secretId=YOUR_SECRET_NAME&versionStage=AWSCURRENT
```

Choose the approach that best balances your needs for performance and freshness. A lower TTL means more frequent calls to Secrets Manager but ensures you're working with the most recent secret values.

Using the parameters utility from Powertools for AWS Lambda

The parameters utility from Powertools for AWS Lambda provides a unified interface for retrieving secrets from multiple providers including Secrets Manager, parameter store, and AppConfig. It handles caching, transformations, and provides a more integrated development experience compared to the extension approach.

Benefits of the parameters utility

- **Multiple providers** - Retrieve parameters from Secrets Manager, Parameter Store, and AppConfig using the same interface
- **Built-in transformations** - Automatic JSON parsing, base64 decoding, and other data transformations
- **Integrated caching** - Configurable caching with TTL support to reduce API calls
- **Type safety** - Strong typing support in TypeScript and other supported runtimes
- **Error handling** - Built-in retry logic and error handling

Code examples

The following examples show how to retrieve secrets using the Parameters utility in different runtimes:

Python

Note

For complete examples and setup instructions, see the [Parameters utility documentation](#).

Retrieving secrets from Secrets Manager with Powertools for AWS Lambda Parameters utility.

```
from aws_lambda_powertools import Logger
from aws_lambda_powertools.utilities import parameters

logger = Logger()

def lambda_handler(event, context):
    try:
        # Get secret with caching (default TTL: 5 seconds)
        secret_value = parameters.get_secret("my-secret-name")

        # Get secret with custom TTL
        secret_with_ttl = parameters.get_secret("my-secret-name", max_age=300)

        # Get secret and transform JSON
        secret_json = parameters.get_secret("my-json-secret", transform="json")

        logger.info("Successfully retrieved secrets")

        return {
            'statusCode': 200,
            'body': 'Successfully retrieved secrets'
        }

    except Exception as e:
        logger.error(f"Error retrieving secret: {str(e)}")
        return {
            'statusCode': 500,
            'body': f'Error: {str(e)}'
        }
```

TypeScript

Note

For complete examples and setup instructions, see the [Parameters utility documentation](#).

Retrieving secrets from Secrets Manager with Powertools for AWS Lambda Parameters utility.

```
import { Logger } from '@aws-lambda-powertools/logger';
import { getSecret } from '@aws-lambda-powertools/parameters/secrets';
import type { Context } from 'aws-lambda';

const logger = new Logger();

export const handler = async (event: any, context: Context) => {
  try {
    // Get secret with caching (default TTL: 5 seconds)
    const secretValue = await getSecret('my-secret-name');

    // Get secret with custom TTL
    const secretWithTtl = await getSecret('my-secret-name', { maxAge: 300 });

    // Get secret and transform JSON
    const secretJson = await getSecret('my-json-secret', { transform: 'json' });

    logger.info('Successfully retrieved secrets');

    return {
      statusCode: 200,
      body: 'Successfully retrieved secrets'
    };
  } catch (error) {
    logger.error('Error retrieving secret', { error });
    return {
      statusCode: 500,
      body: `Error: ${error}`
    };
  }
};
```

Java

For complete examples and setup instructions, see the [Parameters utility documentation](#).

Retrieving secrets from Secrets Manager with Powertools for AWS Lambda Parameters utility.

```
using AWS.Lambda.Powertools.Logging;
using AWS.Lambda.Powertools.Parameters;
using Amazon.Lambda.Core;

[assembly:
    LambdaSerializer(typeof(Amazon.Lambda.Serialization.SystemTextJson.DefaultLambdaJsonSerializer))]

public class Function
{
    private readonly ISecretsProvider _secretsProvider;

    public Function()
    {
        _secretsProvider = ParametersManager.SecretsProvider;
    }

    [Logging]
    public async Task<string> FunctionHandler(object input, ILambdaContext context)
    {
        try
        {
            // Get secret with caching (default TTL: 5 seconds)
            var secretValue = await _secretsProvider.GetAsync("my-secret-name");

            // Get secret with custom TTL
            var secretWithTtl = await
                _secretsProvider.WithMaxAge(TimeSpan.FromMinutes(5))
                    .GetAsync("my-secret-name");
        }
    }
}
```

```
        // Get secret and transform JSON
        var secretJson = await _secretsProvider.GetAsync<MySecret>("my-json-
secret");

        return "Successfully retrieved secrets";
    }
    catch (Exception e)
    {
        return $"Error retrieving secret: {e.Message}";
    }
}

public class MySecret
{
    // Define your secret structure here
}
}
```

Setup and permissions

To use the Parameters utility, you need to:

1. Install Powertools for AWS Lambda for your runtime. For details, see [Powertools for AWS Lambda](#).
2. Add the necessary IAM permissions to your function's execution role. Refer to [Managing permissions in AWS Lambda](#) for details.
3. Configure any optional settings through [environment variables](#).

The required IAM permissions are the same as for the extension approach. The utility will automatically handle caching and API calls to Secrets Manager based on your configuration.

Using Lambda with Amazon SQS

Note

If you want to send data to a target other than a Lambda function or enrich the data before sending it, see [Amazon EventBridge Pipes](#).

You can use a Lambda function to process messages in an Amazon Simple Queue Service (Amazon SQS) queue. Lambda supports both [standard queues](#) and [first-in, first-out \(FIFO\) queues](#) for [event source mappings](#). You can also use provisioned mode to allocate dedicated polling resources for your Amazon SQS event source mappings. The Lambda function and the Amazon SQS queue must be in the same AWS Region, although they can be in [different AWS accounts](#).

When processing Amazon SQS messages, you need to implement partial batch response logic to prevent successfully processed messages from being retried when some messages in a batch fail. The [Batch Processor utility](#) from Powertools for AWS Lambda simplifies this implementation by automatically handling partial batch response logic, reducing development time and improving reliability.

- [Tutorial: Using a cross-account Amazon SQS queue as an event source](#)

Understanding polling and batching behavior for Amazon SQS event source mappings

With Amazon SQS event source mappings, Lambda polls the queue and invokes your function [synchronously](#) with an event. Each event can contain a batch of multiple messages from the queue. Lambda receives these events one batch at a time, and invokes your function once for each batch. When your function successfully processes a batch, Lambda deletes its messages from the queue.

When Lambda receives a batch, the messages stay in the queue but are hidden for the length of the queue's [visibility timeout](#). If your function successfully processes all messages in the batch, Lambda deletes the messages from the queue. By default, if your function encounters an error while processing a batch, all messages in that batch become visible in the queue again after the visibility timeout expires. For this reason, your function code must be able to process the same message multiple times without unintended side effects.

Warning

Lambda event source mappings process each event at least once, and duplicate processing of records can occur. To avoid potential issues related to duplicate events, we strongly recommend that you make your function code idempotent. To learn more, see [How do I make my Lambda function idempotent](#) in the AWS Knowledge Center.

To prevent Lambda from processing a message multiple times, you can either configure your event source mapping to include [batch item failures](#) in your function response, or you can use the [DeleteMessage](#) API to remove messages from the queue as your Lambda function successfully processes them.

For more information about configuration parameters that Lambda supports for SQS event source mappings, see [the section called "Creating an SQS event source mapping"](#).

Using provisioned mode with Amazon SQS event source mappings

For workloads where you need to fine-tune the throughput of your event source mapping, you can use provisioned mode. In provisioned mode, you define minimum and maximum limits for the amount of provisioned event pollers. These provisioned event pollers are dedicated to your event source mapping, and can handle unexpected message spikes through responsive autoscaling. Amazon SQS event source mapping configured with Provisioned Mode scales 3x faster (up to 1,000

concurrent invokes per minute) and supports 16x higher concurrency (up to 20,000 concurrent invokes) than default Amazon SQS event source mapping capability. We recommend that you use provisioned mode for Amazon SQS event-driven workloads that have strict performance requirements, such as financial services firms processing market data feeds, e-commerce platforms providing real-time personalized recommendations, and gaming companies managing live player interactions. Using provisioned mode incurs additional costs. For detailed pricing, see [AWS Lambda pricing](#).

Each event poller in provisioned mode can handle up to 1 MB/s of throughput, up to 10 concurrent invokes, or up to 10 Amazon SQS polling API calls per second. The range of accepted values for the minimum number of event pollers (MinimumPollers) is between 2 and 200, with default of 2. The range of accepted values for the maximum number of event pollers (MaximumPollers) is between 2 and 2,000, with default of 200. MaximumPollers must be greater than or equal to MinimumPollers.

Determining required event pollers

To estimate the number of event pollers required to ensure optimal message processing performance when using provisioned mode for SQS ESM, gather the following metrics for your application: peak SQS events per second requiring low-latency processing, average SQS event payload size, average Lambda function duration, and configured batch size.

First you can estimate the number of SQS events per second (EPS) supported by an event poller for your workload using the following formula:

```
EPS per event poller =  
    minimum(  
        ceiling(1024 / average event size in KB),  
        ceiling(10 / average function duration in seconds) * batch size,  
        min(100, 10 * batch size)  
    )
```

Then, you can calculate the number of minimum pollers required using below formula. This calculation ensures you provision sufficient capacity to handle your peak traffic requirements.

```
Required event pollers = (Peak number of events per second in Queue) / EPS per event  
poller
```

Consider a workload with a default batch size of 10, average event size of 3 KB, average function duration of 100 ms, and a requirement to handle 1,000 events per second. In this scenario, each

event poller will support approximately 100 events per second (EPS). Therefore, you should set minimum pollers to 10 to adequately handle your peak traffic requirements. If your workload has the same characteristics but with average function duration of 1 second, each poller will support only 10 EPS, requiring you to configure 100 minimum pollers to support 1,000 events per second at low latency.

We recommend using default batch size of 10 or higher to maximize the efficiency of provisioned mode event pollers. Higher batch sizes allow each poller to process more events per invocation, for improved throughput and cost efficiency. When planning your event poller capacity, account for potential traffic spikes and consider setting your `minimumPollers` value slightly higher than the calculated minimum to provide a buffer. Additionally, monitor your workload characteristics over time, as changes in message size, function duration, or traffic patterns may necessitate adjustments to your event poller configuration to maintain optimal performance and cost efficiency. For precise capacity planning, we recommend testing your specific workload to determine the actual EPS each event poller can drive.

Configuring provisioned mode for Amazon SQS event source mapping

You can configure provisioned mode for your Amazon SQS event source mapping using the console or the Lambda API.

To configure provisioned mode for an existing Amazon SQS event source mapping (console)

1. Open the [Functions page](#) of the Lambda console.
2. Choose the function with the Amazon SQS event source mapping that you want to configure provisioned mode for.
3. Choose **Configuration**, then choose **Triggers**.
4. Choose the Amazon SQS event source mapping that you want to configure provisioned mode for, then choose **Edit**.
5. Under **Event source mapping configuration**, choose **Configure provisioned mode**.
 - For **Minimum event pollers**, enter a value between 2 and 200. If you don't specify a value, Lambda chooses a default value of 2.
 - For **Maximum event pollers**, enter a value between 2 and 2,000. This value must be greater than or equal to your value for **Minimum event pollers**. If you don't specify a value, Lambda chooses a default value of 200.
6. Choose **Save**.

You can configure provisioned mode programmatically using the `ProvisionedPollerConfig` object in your `EventSourceMappingConfiguration`. For example, the following `UpdateEventSourceMapping` CLI command configures a `MinimumPollers` value of 5, and a `MaximumPollers` value of 100.

```
aws lambda update-event-source-mapping \  
  --uuid a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 \  
  --provisioned-poller-config '{"MinimumPollers": 5, "MaximumPollers": 100}'
```

After configuring provisioned mode, you can observe the usage of event pollers for your workload by monitoring the `ProvisionedPollers` metric. For more information, see [Event source mapping metrics](#).

To disable provisioned mode and return to default (on-demand) mode, you can use the following `UpdateEventSourceMapping` CLI command:

```
aws lambda update-event-source-mapping \  
  --uuid a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 \  
  --provisioned-poller-config '{}'
```

Note

Provisioned mode cannot be used in conjunction with the maximum concurrency setting. When using provisioned mode, you control maximum concurrency through the maximum number of event pollers.

For more information on configuring provisioned mode, see [the section called “Create mapping”](#).

Example standard queue message event

Example Amazon SQS message event (standard queue)

```
{  
  "Records": [  
    {  
      "messageId": "059f36b4-87a3-44ab-83d2-661975830a7d",  
      "receiptHandle": "AQEBwJnKyrHigUMZj6rYigCgXlaS3SLy0a...",
```

```

    "body": "Test message.",
    "attributes": {
      "ApproximateReceiveCount": "1",
      "SentTimestamp": "1545082649183",
      "SenderId": "AIDAIENQZJOL023YVJ4V0",
      "ApproximateFirstReceiveTimestamp": "1545082649185"
    },
    "messageAttributes": {
      "myAttribute": {
        "stringValue": "myValue",
        "stringListValues": [],
        "binaryListValues": [],
        "dataType": "String"
      }
    },
    "md5fBody": "e4e68fb7bd0e697a0ae8f1bb342846b3",
    "eventSource": "aws:sqs",
    "eventSourceARN": "arn:aws:sqs:us-east-2:123456789012:my-queue",
    "awsRegion": "us-east-2"
  },
  {
    "messageId": "2e1424d4-f796-459a-8184-9c92662be6da",
    "receiptHandle": "AQEBzWwafTRI0KuVm4tP+/7q1rGgNqicHq...",
    "body": "Test message.",
    "attributes": {
      "ApproximateReceiveCount": "1",
      "SentTimestamp": "1545082650636",
      "SenderId": "AIDAIENQZJOL023YVJ4V0",
      "ApproximateFirstReceiveTimestamp": "1545082650649"
    },
    "messageAttributes": {},
    "md5fBody": "e4e68fb7bd0e697a0ae8f1bb342846b3",
    "eventSource": "aws:sqs",
    "eventSourceARN": "arn:aws:sqs:us-east-2:123456789012:my-queue",
    "awsRegion": "us-east-2"
  }
]
}

```

By default, Lambda polls up to 10 messages in your queue at once and sends that batch to your function. To avoid invoking the function with a small number of records, you can configure the event source to buffer records for up to 5 minutes by configuring a batch window. Before invoking the function, Lambda continues to poll messages from the standard queue until the batch window

expires, the [invocation payload size quota](#) is reached, or the configured maximum batch size is reached.

If you're using a batch window and your SQS queue contains very low traffic, Lambda might wait for up to 20 seconds before invoking your function. This is true even if you set a batch window lower than 20 seconds.

Note

In Java, you might experience null pointer errors when deserializing JSON. This could be due to how case of "Records" and "eventSourceARN" is converted by the JSON object mapper.

Example FIFO queue message event

For FIFO queues, records contain additional attributes that are related to deduplication and sequencing.

Example Amazon SQS message event (FIFO queue)

```
{
  "Records": [
    {
      "messageId": "11d6ee51-4cc7-4302-9e22-7cd8afdaadf5",
      "receiptHandle": "AQEBBX8nesZEXmkhsmZeyIE8iQAMig7qw...",
      "body": "Test message.",
      "attributes": {
        "ApproximateReceiveCount": "1",
        "SentTimestamp": "1573251510774",
        "SequenceNumber": "18849496460467696128",
        "MessageGroupId": "1",
        "SenderId": "AIDAI023YVJENQZJ0L4V0",
        "MessageDeduplicationId": "1",
        "ApproximateFirstReceiveTimestamp": "1573251510774"
      },
      "messageAttributes": {},
      "md5OfBody": "e4e68fb7bd0e697a0ae8f1bb342846b3",
      "eventSource": "aws:sqs",
      "eventSourceARN": "arn:aws:sqs:us-east-2:123456789012:fifo.fifo",
      "awsRegion": "us-east-2"
    }
  ]
}
```

```
}  
]  
}
```

Creating and configuring an Amazon SQS event source mapping

To process Amazon SQS messages with Lambda, configure your queue with the appropriate settings, then create a Lambda event source mapping.

Topics

- [Configuring a queue to use with Lambda](#)
- [Setting up Lambda execution role permissions](#)
- [Creating an SQS event source mapping](#)

Configuring a queue to use with Lambda

If you don't already have an existing Amazon SQS queue, [create one](#) to serve as an event source for your Lambda function. The Lambda function and the Amazon SQS queue must be in the same AWS Region, although they can be in [different AWS accounts](#).

To allow your function time to process each batch of records, set the source queue's [visibility timeout](#) to at least six times the [configuration timeout](#) on your function. The extra time allows Lambda to retry if your function is throttled while processing a previous batch.

Note

Your function's timeout must be less than or equal to the queue's visibility timeout. Lambda validates this requirement when you create or update an event source mapping and will return an error if the function timeout exceeds the queue's visibility timeout.

By default, if Lambda encounters an error at any point while processing a batch, all messages in that batch return to the queue. After the [visibility timeout](#), the messages become visible to Lambda again. You can configure your event source mapping to use [partial batch responses](#) to return only the failed messages back to the queue. In addition, if your function fails to process a message multiple times, Amazon SQS can send it to a [dead-letter queue](#). We recommend setting the `maxReceiveCount` on your source queue's [redrive policy](#) to at least 5. This gives Lambda a few chances to retry before sending failed messages directly to the dead-letter queue.

Setting up Lambda execution role permissions

The [AWSLambdaSQSQueueExecutionRole](#) AWS managed policy includes the permissions that Lambda needs to read from your Amazon SQS queue. You can add this managed policy to your function's [execution role](#).

Optionally, if you're using an encrypted queue, you also need to add the following permission to your execution role:

- [kms:Decrypt](#)

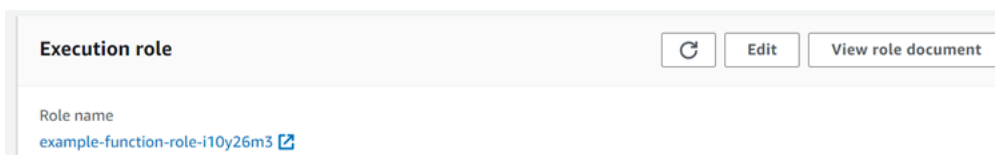

Creating an SQS event source mapping

Create an event source mapping to tell Lambda to send items from your queue to a Lambda function. You can create multiple event source mappings to process items from multiple queues with a single function. When Lambda invokes the target function, the event can contain multiple items, up to a configurable maximum *batch size*.

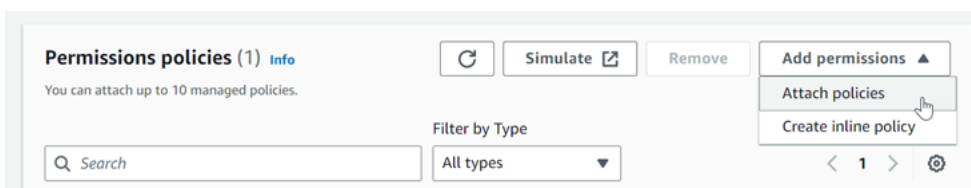

To configure your function to read from Amazon SQS, attach the [AWSLambdaSQSQueueExecutionRole](#) AWS managed policy to your execution role. Then, create an **SQS** event source mapping from the console using the following steps.

To add permissions and create a trigger

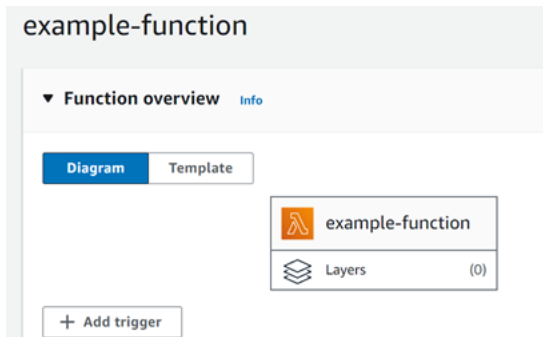

1. Open the [Functions page](#) of the Lambda console.
2. Choose the name of a function.
3. Choose the **Configuration** tab, and then choose **Permissions**.
4. Under **Role name**, choose the link to your execution role. This link opens the role in the IAM console.

5. Choose **Add permissions**, and then choose **Attach policies**.

6. In the search field, enter `AWSLambdaSQSQueueExecutionRole`. Add this policy to your execution role. This is an AWS managed policy that contains the permissions your function needs to read from an Amazon SQS queue. For more information about this policy, see [AWSLambdaSQSQueueExecutionRole](#) in the *AWS Managed Policy Reference*.
7. Go back to your function in the Lambda console. Under **Function overview**, choose **Add trigger**.

8. Choose a trigger type.
9. Configure the required options, and then choose **Add**.

Lambda supports the following configuration options for Amazon SQS event sources:

SQS queue

The Amazon SQS queue to read records from. The Lambda function and the Amazon SQS queue must be in the same AWS Region, although they can be in [different AWS accounts](#).

Enable trigger

The status of the event source mapping. **Enable trigger** is selected by default.

Batch size

The maximum number of records to send to the function in each batch. For a standard queue, this can be up to 10,000 records. For a FIFO queue, the maximum is 10. For a batch size over 10, you must also set the batch window (`MaximumBatchingWindowInSeconds`) to at least 1 second.

Configure your [function timeout](#) to allow enough time to process an entire batch of items. If items take a long time to process, choose a smaller batch size. A large batch size can improve efficiency for workloads that are very fast or have a lot of overhead. If you configure [reserved concurrency](#) on your function, set a minimum of five concurrent executions to reduce the chance of throttling errors when Lambda invokes your function.

Lambda passes all of the records in the batch to the function in a single call, as long as the total size of the events doesn't exceed the [invocation payload size quota](#) for synchronous invocation (6 MB). Both Lambda and Amazon SQS generate metadata for each record. This additional metadata is counted towards the total payload size and can cause the total number of records sent in a batch to be lower than your configured batch size. The metadata fields that Amazon SQS sends can be variable in length. For more information about the Amazon SQS metadata fields, see the [ReceiveMessage](#) API operation documentation in the *Amazon Simple Queue Service API Reference*.

Batch window

The maximum amount of time to gather records before invoking the function, in seconds. This applies only to standard queues.

If you're using a batch window greater than 0 seconds, you must account for the increased processing time in your queue's [visibility timeout](#). We recommend setting your queue's visibility timeout to six times your [function timeout](#), plus the value of `MaximumBatchingWindowInSeconds`. This allows time for your Lambda function to process each batch of events and to retry in the event of a throttling error.

When messages become available, Lambda starts processing messages in batches. Lambda starts processing five batches at a time with five concurrent invocations of your function. If messages are still available, Lambda adds up to 300 concurrent invokes of your function a minute, up to a maximum of 1,250 concurrent invokes. When using provisioned mode, each event poller can handle up to 1 MB/s of throughput, up to 10 concurrent invokes, or up to 10 Amazon SQS polling API calls per second. Lambda scales the number of event pollers between your configured minimum and maximum, quickly adding up to 1,000 concurrent invokes per minute to provide low-latency processing of your Amazon SQS events. You control scaling and concurrency through these minimum and maximum event poller settings. To learn more about function scaling and concurrency, see [Understanding Lambda function scaling](#).

To process more messages, you can optimize your Lambda function for higher throughput. For more information, see [Understanding how AWS Lambda scales with Amazon SQS standard queues](#).

Filter criteria

Add filter criteria to control which events Lambda sends to your function for processing. For more information, see [Control which events Lambda sends to your function](#).

Maximum concurrency

The maximum number of concurrent functions that the event source can invoke. Cannot be used with Provisioned Mode enabled. For more information, see [Configuring maximum concurrency for Amazon SQS event sources](#).

Provisioned Mode

When enabled, allocates dedicated polling resources for your event source mapping. You can configure the minimum (2-200) and maximum (2-2000) number of event pollers. Each event poller can handle up to 1 MB/sec of throughput, up to 10 concurrent invokes, or up to 10 Amazon SQS polling API calls per second.

Note

Note: You cannot use Provisioned Mode and Maximum concurrency together. When Provisioned Mode is enabled, use the maximum pollers setting to control concurrency.

Configuring scaling behavior for SQS event source mappings

You can control the scaling behavior of your Amazon SQS event source mappings either through maximum concurrency settings or by enabling provisioned mode. These are mutually exclusive options.

By default, Lambda automatically scales event pollers based on message volume. When you enable provisioned mode, you allocate a minimum and maximum number of dedicated polling resources that remain ready to handle expected traffic patterns. This allows you to optimize your event source mapping's performance in two ways:

- **Standard mode (Default):** Lambda automatically manages scaling, starting with a small number of pollers and scaling up or down based on workload.
- **Provisioned mode:** You configure dedicated polling resources with minimum and maximum limits, enabling 3 times faster scaling and up to 16 times higher processing capacity.

For standard queues, Lambda uses [long polling](#) to poll a queue until it becomes active. When messages are available, Lambda starts processing five batches at a time with five concurrent invocations of your function. If messages are still available, Lambda increases the number of processes that are reading batches by up to 300 more concurrent invokes per minute. The

maximum number of invokes that an event source mapping can process simultaneously is 1,250. When traffic is low, Lambda scales back the processing to five concurrent invokes, and can optimize to as few as 2 concurrent invokes to reduce the Amazon SQS calls and corresponding costs. However, this optimization is not available when you enable the maximum concurrency setting.

For FIFO queues, Lambda sends messages to your function in the order that it receives them. When you send a message to a FIFO queue, you specify a [message group ID](#). Amazon SQS ensures that messages in the same group are delivered to Lambda in order. When Lambda reads your messages into batches, each batch may contain messages from more than one message group, but the order of the messages is maintained. If your function returns an error, the function attempts all retries on the affected messages before Lambda receives additional messages from the same group.

When using provisioned mode, each event poller can handle up to 1 MB/sec of throughput, up to 10 concurrent invokes, or up to 10 Amazon SQS polling API calls per second. Lambda scales the number of event pollers between your configured minimum and maximum, quickly adding up to 1,000 concurrency per minute to provide consistent, low-latency processing of your Amazon SQS events. Using provisioned mode incurs additional costs. For detailed pricing, see [AWS Lambda pricing](#). Each event poller uses [long polling](#) to your SQS queue with up to 10 polls per second, which incur SQS API requests cost. See [Amazon SQS pricing](#) for details. You control scaling and concurrency through these minimum and maximum event poller settings, rather than using the maximum concurrency setting, as these options cannot be used together.

Note

You cannot use the maximum concurrency setting and provisioned mode at the same time. When provisioned mode is enabled, you control the scaling and concurrency of your Amazon SQS event source mapping through the minimum and maximum number of event pollers.

Configuring maximum concurrency for Amazon SQS event sources

You can use the maximum concurrency setting to control scaling behavior for your SQS event sources. Note that maximum concurrency cannot be used with provisioned mode enabled. The maximum concurrency setting limits the number of concurrent instances of the function that an Amazon SQS event source can invoke. Maximum concurrency is an event source-level setting. If you have multiple Amazon SQS event sources mapped to one function, each event source can have a separate maximum concurrency setting. You can use maximum concurrency to prevent one

queue from using all of the function's [reserved concurrency](#) or the rest of the [account's concurrency quota](#). There is no charge for configuring maximum concurrency on an Amazon SQS event source.

Importantly, maximum concurrency and reserved concurrency are two independent settings. Don't set maximum concurrency higher than the function's reserved concurrency. If you configure maximum concurrency, make sure that your function's reserved concurrency is greater than or equal to the total maximum concurrency for all Amazon SQS event sources on the function. Otherwise, Lambda may throttle your messages.

When your account's concurrency quota is set to the default value of 1,000, an Amazon SQS event source mapping can scale to invoke function instances up to this value, unless you specify a maximum concurrency.

If you receive an increase to your account's default concurrency quota, Lambda may not be able to invoke concurrent functions instances up to your new quota. By default, Lambda can scale to invoke up to 1,250 concurrent function instances for an Amazon SQS event source mapping. If this is insufficient for your use case, contact AWS support to discuss an increase to your account's Amazon SQS event source mapping concurrency.

Note

For FIFO queues, concurrent invocations are capped either by the number of [message group IDs](#) (messageGroupId) or the maximum concurrency setting—whichever is lower. For example, if you have six message group IDs and maximum concurrency is set to 10, your function can have a maximum of six concurrent invocations.

You can configure maximum concurrency on new and existing Amazon SQS event source mappings.

Configure maximum concurrency using the Lambda console

1. Open the [Functions page](#) of the Lambda console.
2. Choose the name of a function.
3. Under **Function overview**, choose **SQS**. This opens the **Configuration** tab.
4. Select the Amazon SQS trigger and choose **Edit**.
5. For **Maximum concurrency**, enter a number between 2 and 1,000. To turn off maximum concurrency, leave the box empty.
6. Choose **Save**.

Configure maximum concurrency using the AWS Command Line Interface (AWS CLI)

Use the [update-event-source-mapping](#) command with the `--scaling-config` option. Example:

```
aws lambda update-event-source-mapping \  
  --uuid "a1b2c3d4-5678-90ab-cdef-1111EXAMPLE" \  
  --scaling-config '{"MaximumConcurrency":5}'
```

To turn off maximum concurrency, enter an empty value for `--scaling-config`:

```
aws lambda update-event-source-mapping \  
  --uuid "a1b2c3d4-5678-90ab-cdef-1111EXAMPLE" \  
  --scaling-config "{}"
```

Configure maximum concurrency using the Lambda API

Use the [CreateEventSourceMapping](#) or [UpdateEventSourceMapping](#) action with a [ScalingConfig](#) object.

Handling errors for an SQS event source in Lambda

To handle errors related to an SQS event source, Lambda automatically uses a retry strategy with a backoff strategy. You can also customize error handling behavior by configuring your SQS event source mapping to return [partial batch responses](#).

Backoff strategy for failed invocations

When an invocation fails, Lambda attempts to retry the invocation while implementing a backoff strategy. The backoff strategy differs slightly depending on whether Lambda encountered the failure due to an error in your function code, or due to throttling.

- If your **function code** caused the error, Lambda will stop processing and retrying the invocation. In the meantime, Lambda gradually backs off, reducing the amount of concurrency allocated to your Amazon SQS event source mapping. After your queue's visibility timeout runs out, the message will again reappear in the queue.
- If the invocation fails due to **throttling**, Lambda gradually backs off retries by reducing the amount of concurrency allocated to your Amazon SQS event source mapping. Lambda continues to retry the message until the message's timestamp exceeds your queue's visibility timeout, at which point Lambda drops the message.

Implementing partial batch responses

When your Lambda function encounters an error while processing a batch, all messages in that batch become visible in the queue again by default, including messages that Lambda processed successfully. As a result, your function can end up processing the same message several times.

To avoid reprocessing successfully processed messages in a failed batch, you can configure your event source mapping to make only the failed messages visible again. This is called a partial batch response. To turn on partial batch responses, specify `ReportBatchItemFailures` for the [FunctionResponseTypes](#) action when configuring your event source mapping. This lets your function return a partial success, which can help reduce the number of unnecessary retries on records.

Note

The [Batch Processor utility](#) from Powertools for AWS Lambda handles all of the partial batch response logic automatically. This utility simplifies implementing batch processing patterns and reduces the custom code needed to handle batch item failures correctly. It is available for Python, Java, Typescript, and .NET.

When `ReportBatchItemFailures` is activated, Lambda doesn't [scale down message polling](#) when function invocations fail. If you expect some messages to fail—and you don't want those failures to impact the message processing rate—use `ReportBatchItemFailures`.

Note

Keep the following in mind when using partial batch responses:

- If your function throws an exception, the entire batch is considered a complete failure.
- If you're using this feature with a FIFO queue, your function should stop processing messages after the first failure and return all failed and unprocessed messages in `batchItemFailures`. This helps preserve the ordering of messages in your queue.

To activate partial batch reporting

1. Review the [Best practices for implementing partial batch responses](#).

2. Run the following command to activate `ReportBatchItemFailures` for your function. To retrieve your event source mapping's UUID, run the [list-event-source-mappings](#) AWS CLI command.

```
aws lambda update-event-source-mapping \  
--uuid "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE" \  
--function-response-types "ReportBatchItemFailures"
```

3. Update your function code to catch all exceptions and return failed messages in a `batchItemFailures` JSON response. The `batchItemFailures` response must include a list of message IDs, as `itemIdentifier` JSON values.

For example, suppose you have a batch of five messages, with message IDs `id1`, `id2`, `id3`, `id4`, and `id5`. Your function successfully processes `id1`, `id3`, and `id5`. To make messages `id2` and `id4` visible again in your queue, your function should return the following response:

```
{  
  "batchItemFailures": [  
    {  
      "itemIdentifier": "id2"  
    },  
    {  
      "itemIdentifier": "id4"  
    }  
  ]  
}
```

Here are some examples of function code that return the list of failed message IDs in the batch:

}
```

If the failed events do not return to the queue, see [How do I troubleshoot Lambda function SQS ReportBatchItemFailures?](#) in the AWS Knowledge Center.

Success and failure conditions

Lambda treats a batch as a complete success if your function returns any of the following:

- An empty `batchItemFailures` list
- A null `batchItemFailures` list
- An empty `EventResponse`
- A null `EventResponse`

Lambda treats a batch as a complete failure if your function returns any of the following:

- An invalid JSON response
- An empty string `itemIdentifier`
- A null `itemIdentifier`
- An `itemIdentifier` with a bad key name
- An `itemIdentifier` value with a message ID that doesn't exist

CloudWatch metrics

To determine whether your function is correctly reporting batch item failures, you can monitor the `NumberOfMessagesDeleted` and `ApproximateAgeOfOldestMessage` Amazon SQS metrics in Amazon CloudWatch.

- `NumberOfMessagesDeleted` tracks the number of messages removed from your queue. If this drops to 0, this is a sign that your function response is not correctly returning failed messages.
- `ApproximateAgeOfOldestMessage` tracks how long the oldest message has stayed in your queue. A sharp increase in this metric can indicate that your function is not correctly returning failed messages.

Using Powertools for AWS Lambda batch processor

The batch processor utility from Powertools for AWS Lambda automatically handles partial batch response logic, reducing the complexity of implementing batch failure reporting. Here are examples using the batch processor:

Python

Note

For complete examples and setup instructions, see the [batch processor documentation](#).

Processing Amazon SQS messages with AWS Lambda batch processor.

```
import json
from aws_lambda_powertools import Logger
from aws_lambda_powertools.utilities.batch import BatchProcessor, EventType,
    process_partial_response
from aws_lambda_powertools.utilities.data_classes import SQSEvent
from aws_lambda_powertools.utilities.typing import LambdaContext

processor = BatchProcessor(event_type=EventType.SQS)
logger = Logger()

def record_handler(record):
    logger.info(record)
    # Your business logic here
    # Raise an exception to mark this record as failed

def lambda_handler(event, context: LambdaContext):
    return process_partial_response(
        event=event,
        record_handler=record_handler,
```

```
        processor=processor,  
        context=context  
    )
```

TypeScript

Note

For complete examples and setup instructions, see the [batch processor documentation](#).

Processing Amazon SQS messages with AWS Lambda batch processor.

```
import { BatchProcessor, EventType, processPartialResponse } from '@aws-lambda-  
powertools/batch';  
import { Logger } from '@aws-lambda-powertools/logger';  
import type { SQSEvent, Context } from 'aws-lambda';  
  
const processor = new BatchProcessor(EventType.SQS);  
const logger = new Logger();  
  
const recordHandler = async (record: any): Promise<void> => {  
    logger.info('Processing record', { record });  
    // Your business logic here  
    // Throw an error to mark this record as failed  
};  
  
export const handler = async (event: SQSEvent, context: Context) => {  
    return processPartialResponse(event, recordHandler, processor, {  
        context,  
    });  
};
```

Lambda parameters for Amazon SQS event source mappings

All Lambda event source types share the same [CreateEventSourceMapping](#) and [UpdateEventSourceMapping](#) API operations. However, only some of the parameters apply to Amazon SQS.

Parameter	Required	Default	Notes
BatchSize	N	10	For standard queues, the maximum is 10,000. For FIFO queues, the maximum is 10.
Enabled	N	true	none
EventSourceArn	Y	N/A	The ARN of the data stream or a stream consumer
FunctionName	Y	N/A	none
FilterCriteria	N	N/A	Control which events Lambda sends to your function
FunctionResponseType	N	N/A	To let your function report specific failures in a batch, include the value <code>ReportBatchItemFailures</code> in <code>FunctionResponseTypes</code> . For more information, see Implementing partial batch responses .
MaximumBatchingWindowInSeconds	N	0	Batching window is not supported for FIFO queues

Parameter	Required	Default	Notes
ProvisionedPollerConfig	N	N/A	Configures the minimum (2-200) and maximum (2-2000) number of dedicated event pollers for the SQS event source mapping. Each poller can handle up to 1 MB/sec of throughput and 10 concurrent invokes.
ScalingConfig	N	N/A	Configuring maximum concurrency for Amazon SQS event sources

Using event filtering with an Amazon SQS event source

You can use event filtering to control which records from a stream or queue Lambda sends to your function. For general information about how event filtering works, see [the section called “Event filtering”](#).

This section focuses on event filtering for Amazon SQS event sources.

Note

Amazon SQS event source mappings only support filtering on the body key.

Topics

- [Amazon SQS event filtering basics](#)

Amazon SQS event filtering basics

Suppose your Amazon SQS queue contains messages in the following JSON format.

```
{
  "RecordNumber": 1234,
  "TimeStamp": "yyyy-mm-ddThh:mm:ss",
  "RequestCode": "AAAA"
}
```

An example record for this queue would look as follows.

```
{
  "messageId": "059f36b4-87a3-44ab-83d2-661975830a7d",
  "receiptHandle": "AQEBwJnKyrHigUMZj6rYigCgXlaS3SLy0a...",
  "body": "{\n  \"RecordNumber\": 1234,\n  \"TimeStamp\": \"yyyy-mm-ddThh:mm:ss\",\n  \"RequestCode\": \"AAAA\"\n}",
  "attributes": {
    "ApproximateReceiveCount": "1",
    "SentTimestamp": "1545082649183",
    "SenderId": "AIDAIENQZJOL023YVJ4V0",
    "ApproximateFirstReceiveTimestamp": "1545082649185"
  },
  "messageAttributes": {},
  "md5OfBody": "e4e68fb7bd0e697a0ae8f1bb342846b3",
  "eventSource": "aws:sqs",
  "eventSourceARN": "arn:aws:sqs:us-west-2:123456789012:my-queue",
  "awsRegion": "us-west-2"
}
```

To filter based on the contents of your Amazon SQS messages, use the `body` key in the Amazon SQS message record. Suppose you want to process only those records where the `RequestCode` in your Amazon SQS message is "BBBB." The `FilterCriteria` object would be as follows.

```
{
  "Filters": [
    {
      "Pattern": "{ \"body\" : { \"RequestCode\" : [ \"BBBB\" ] } }"
    }
  ]
}
```

For added clarity, here is the value of the filter's Pattern expanded in plain JSON.

```
{
  "body": {
    "RequestCode": [ "BBBB" ]
  }
}
```

You can add your filter using the console, AWS CLI or an AWS SAM template.

Console

To add this filter using the console, follow the instructions in [Attaching filter criteria to an event source mapping \(console\)](#) and enter the following string for the **Filter criteria**.

```
{ "body" : { "RequestCode" : [ "BBBB" ] } }
```

AWS CLI

To create a new event source mapping with these filter criteria using the AWS Command Line Interface (AWS CLI), run the following command.

```
aws lambda create-event-source-mapping \
  --function-name my-function \
  --event-source-arn arn:aws:sqs:us-east-2:123456789012:my-queue \
  --filter-criteria '{"Filters": [{"Pattern": "{ \"body\" : { \"RequestCode\" : [ \"BBBB\" ] } }"]}]'
```

To add these filter criteria to an existing event source mapping, run the following command.

```
aws lambda update-event-source-mapping \
  --uuid "a1b2c3d4-5678-90ab-cdef-1111EXAMPLE" \
  --filter-criteria '{"Filters": [{"Pattern": "{ \"body\" : { \"RequestCode\" : [ \"BBBB\" ] } }"]}]'
```

AWS SAM

To add this filter using AWS SAM, add the following snippet to the YAML template for your event source.

```
FilterCriteria:
  Filters:
```

```
- Pattern: '{ "body" : { "RequestCode" : [ "BBBB" ] } }'
```

Suppose you want your function to process only those records where `RecordNumber` is greater than 9999. The `FilterCriteria` object would be as follows.

```
{
  "Filters": [
    {
      "Pattern": "{ \"body\" : { \"RecordNumber\" : [ { \"numeric\": [ \">\",
9999 ] } ] } }"
    }
  ]
}
```

For added clarity, here is the value of the filter's `Pattern` expanded in plain JSON.

```
{
  "body": {
    "RecordNumber": [
      {
        "numeric": [ ">", 9999 ]
      }
    ]
  }
}
```

You can add your filter using the console, AWS CLI or an AWS SAM template.

Console

To add this filter using the console, follow the instructions in [Attaching filter criteria to an event source mapping \(console\)](#) and enter the following string for the **Filter criteria**.

```
{ "body" : { "RecordNumber" : [ { "numeric": [ ">", 9999 ] } ] } }
```

AWS CLI

To create a new event source mapping with these filter criteria using the AWS Command Line Interface (AWS CLI), run the following command.

```
aws lambda create-event-source-mapping \
```

```
--function-name my-function \
--event-source-arn arn:aws:sqs:us-east-2:123456789012:my-queue \
--filter-criteria '{"Filters": [{"Pattern": "{ \"body\" : { \"RecordNumber\" : [ { \"numeric\" : [ \">\", 9999 ] } ] } }"]}]'
```

To add these filter criteria to an existing event source mapping, run the following command.

```
aws lambda update-event-source-mapping \
--uuid "a1b2c3d4-5678-90ab-cdef-1111EXAMPLE" \
--filter-criteria '{"Filters": [{"Pattern": "{ \"body\" : { \"RecordNumber\" : [ { \"numeric\" : [ \">\", 9999 ] } ] } }"]}]'
```

AWS SAM

To add this filter using AWS SAM, add the following snippet to the YAML template for your event source.

```
FilterCriteria:
  Filters:
    - Pattern: '{ "body" : { "RecordNumber" : [ { "numeric": [ ">", 9999 ] } ] } }'
```

For Amazon SQS, the message body can be any string. However, this can be problematic if your `FilterCriteria` expect body to be in a valid JSON format. The reverse scenario is also true—if the incoming message body is in JSON format but your filter criteria expects body to be a plain string, this can lead to unintended behavior.

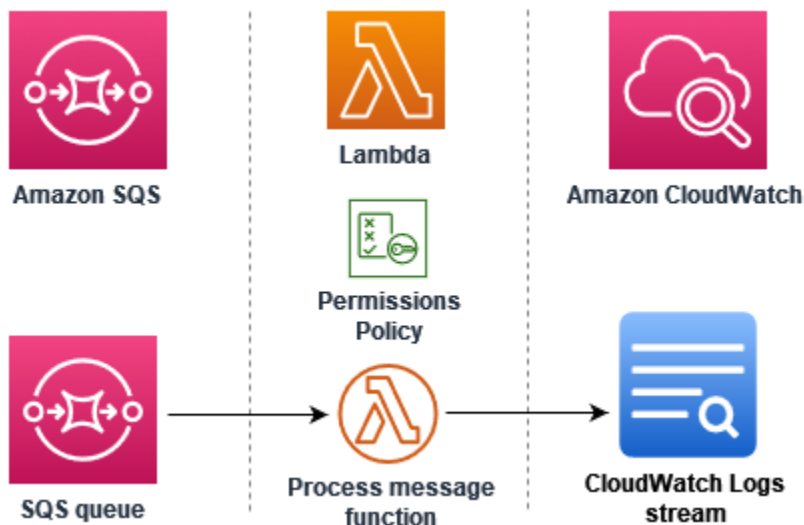

To avoid this issue, ensure that the format of body in your `FilterCriteria` matches the expected format of body in messages that you receive from your queue. Before filtering your messages, Lambda automatically evaluates the format of the incoming message body and of your filter pattern for body. If there is a mismatch, Lambda drops the message. The following table summarizes this evaluation:

Incoming message body format	Filter pattern body format	Resulting action
Plain string	Plain string	Lambda filters based on your filter criteria.

Incoming message body format	Filter pattern body format	Resulting action
Plain string	No filter pattern for data properties	Lambda filters (on the other metadata properties only) based on your filter criteria.
Plain string	Valid JSON	Lambda drops the message.
Valid JSON	Plain string	Lambda drops the message.
Valid JSON	No filter pattern for data properties	Lambda filters (on the other metadata properties only) based on your filter criteria.
Valid JSON	Valid JSON	Lambda filters based on your filter criteria.

Tutorial: Using Lambda with Amazon SQS

In this tutorial, you create a Lambda function that consumes messages from an [Amazon Simple Queue Service \(Amazon SQS\)](#) queue. The Lambda function runs whenever a new message is added to the queue. The function writes the messages to an Amazon CloudWatch Logs stream. The following diagram shows the AWS resources you use to complete the tutorial.

To complete this tutorial, you carry out the following steps:

1. Create a Lambda function that writes messages to CloudWatch Logs.
2. Create an Amazon SQS queue.
3. Create a Lambda event source mapping. The event source mapping reads the Amazon SQS queue and invokes your Lambda function when a new message is added.
4. Test the setup by adding messages to your queue and monitoring the results in CloudWatch Logs.

Prerequisites

Install the AWS Command Line Interface

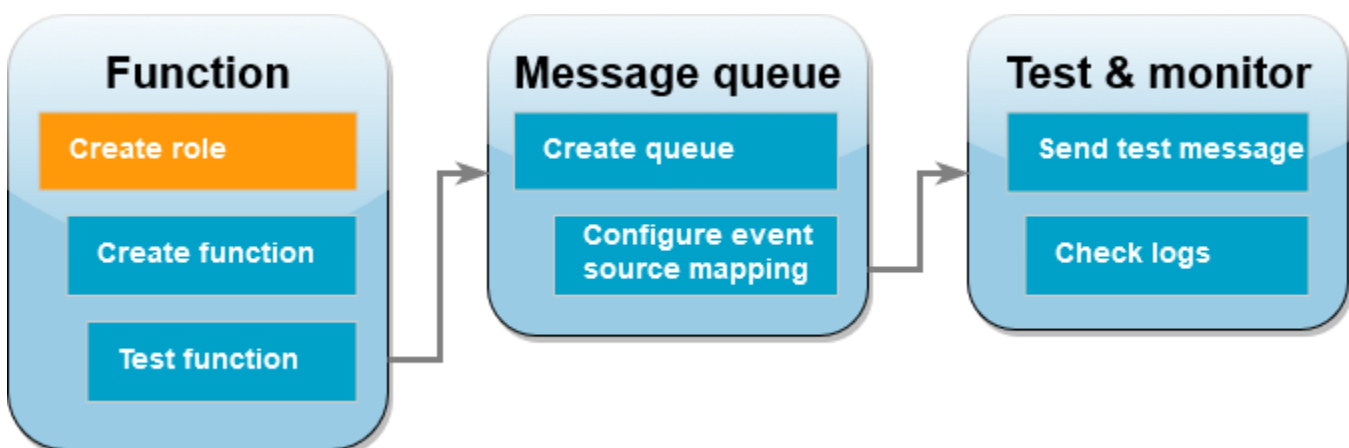

If you have not yet installed the AWS Command Line Interface, follow the steps at [Installing or updating the latest version of the AWS CLI](#) to install it.

The tutorial requires a command line terminal or shell to run commands. In Linux and macOS, use your preferred shell and package manager.

Note

In Windows, some Bash CLI commands that you commonly use with Lambda (such as `zip`) are not supported by the operating system's built-in terminals. To get a Windows-integrated version of Ubuntu and Bash, [install the Windows Subsystem for Linux](#).

Create the execution role

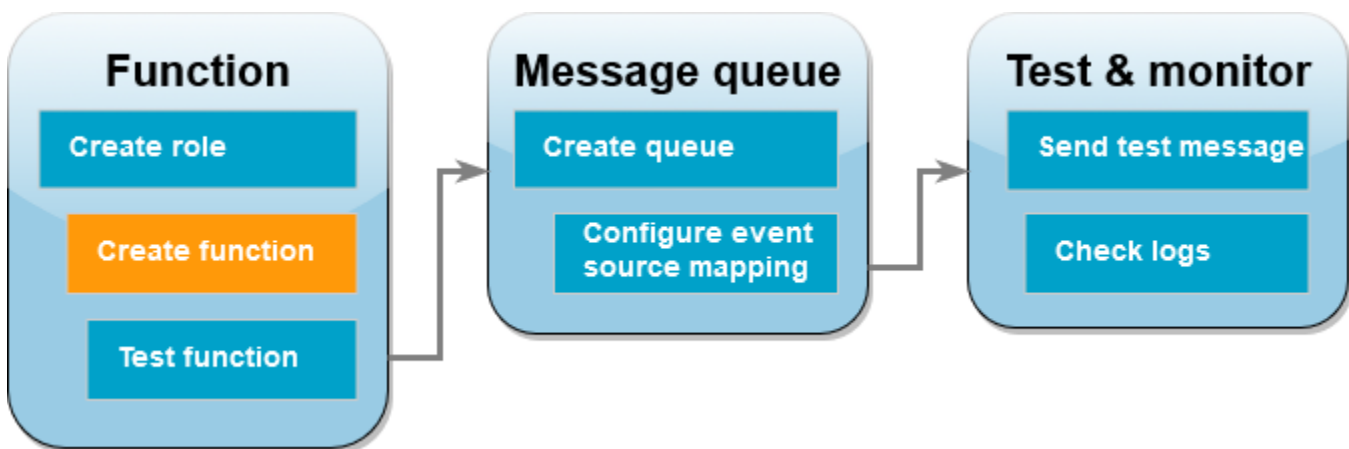

An [execution role](#) is an AWS Identity and Access Management (IAM) role that grants a Lambda function permission to access AWS services and resources. To allow your function to read items from Amazon SQS, attach the **AWSLambdaSQSQueueExecutionRole** permissions policy.

To create an execution role and attach an Amazon SQS permissions policy

1. Open the [Roles page](#) of the IAM console.
2. Choose **Create role**.
3. For **Trusted entity type**, choose **AWS service**.
4. For **Use case**, choose **Lambda**.
5. Choose **Next**.
6. In the **Permissions policies** search box, enter **AWSLambdaSQSQueueExecutionRole**.
7. Select the **AWSLambdaSQSQueueExecutionRole** policy, and then choose **Next**.
8. Under **Role details**, for **Role name**, enter **lambda-sqs-role**, then choose **Create role**.

After role creation, note down the Amazon Resource Name (ARN) of your execution role. You'll need it in later steps.

Create the function

Create a Lambda function that processes your Amazon SQS messages. The function code logs the body of the Amazon SQS message to CloudWatch Logs.

This tutorial uses the Node.js 24 runtime, but we've also provided example code in other runtime languages. You can select the tab in the following box to see code for the runtime you're interested in. The JavaScript code you'll use in this step is in the first example shown in the **JavaScript** tab.

Consuming an SQS event with Lambda using Rust.

```
// Copyright Amazon.com, Inc. or its affiliates. All Rights Reserved.
// SPDX-License-Identifier: Apache-2.0
use aws_lambda_events::event::sqs::SqsEvent;
use lambda_runtime::{run, service_fn, Error, LambdaEvent};

async fn function_handler(event: LambdaEvent<SqsEvent>) -> Result<(), Error> {
    event.payload.records.iter().for_each(|record| {
        // process the record
        tracing::info!("Message body: {}",
            record.body.as_deref().unwrap_or_default())
    });

    Ok(())
}

#[tokio::main]
async fn main() -> Result<(), Error> {
    tracing_subscriber::fmt()
        .with_max_level(tracing::Level::INFO)
        // disable printing the name of the module in every log line.
        .with_target(false)
        // disabling time is handy because CloudWatch will add the ingestion
        time.
        .without_time()
        .init();

    run(service_fn(function_handler)).await
}
```

To create a Node.js Lambda function

1. Create a directory for the project, and then switch to that directory.

```
mkdir sqs-tutorial
cd sqs-tutorial
```

2. Copy the sample JavaScript code into a new file named `index.js`.
3. Create a deployment package using the following `zip` command.

```
zip function.zip index.js
```

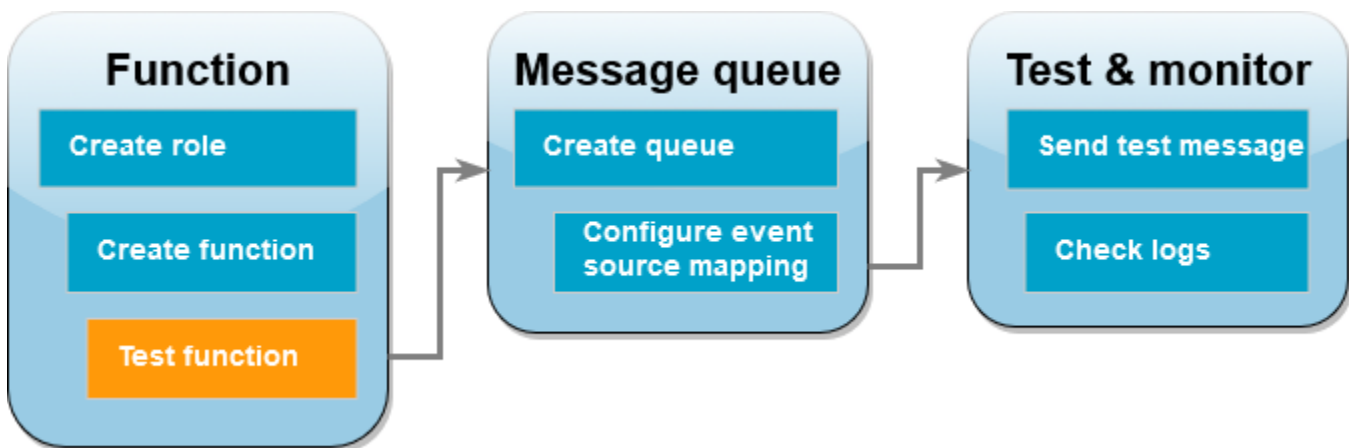

4. Create a Lambda function using the [create-function](#) AWS CLI command. For the `role` parameter, enter the ARN of the execution role that you created earlier.

Note

The Lambda function and the Amazon SQS queue must be in the same AWS Region.

```
aws lambda create-function --function-name ProcessSQSRecord \  
--zip-file fileb://function.zip --handler index.handler --runtime nodejs24.x \  
--role arn:aws:iam::111122223333:role/lambda-sqs-role
```

Test the function

Invoke your Lambda function manually using the `invoke` AWS CLI command and a sample Amazon SQS event.

To invoke the Lambda function with a sample event

1. Save the following JSON as a file named `input.json`. This JSON simulates an event that Amazon SQS might send to your Lambda function, where `"body"` contains the actual message from the queue. In this example, the message is `"test"`.

Example Amazon SQS event

This is a test event—you don't need to change the message or the account number.

```
{
  "Records": [
    {
      "messageId": "059f36b4-87a3-44ab-83d2-661975830a7d",
      "receiptHandle": "AQEBWJnKyrHigUMZj6rYigCgXlaS3SLy0a...",
      "body": "test",
      "attributes": {
        "ApproximateReceiveCount": "1",
        "SentTimestamp": "1545082649183",
        "SenderId": "AIDAIENQZJOL023YVJ4V0",
        "ApproximateFirstReceiveTimestamp": "1545082649185"
      },
      "messageAttributes": {},
      "md5OfBody": "098f6bcd4621d373cade4e832627b4f6",
      "eventSource": "aws:sqs",
      "eventSourceARN": "arn:aws:sqs:us-east-1:111122223333:my-queue",
      "awsRegion": "us-east-1"
    }
  ]
}
```

2. Run the following [invoke](#) AWS CLI command. This command returns CloudWatch logs in the response. For more information about retrieving logs, see [Access logs with the AWS CLI](#).

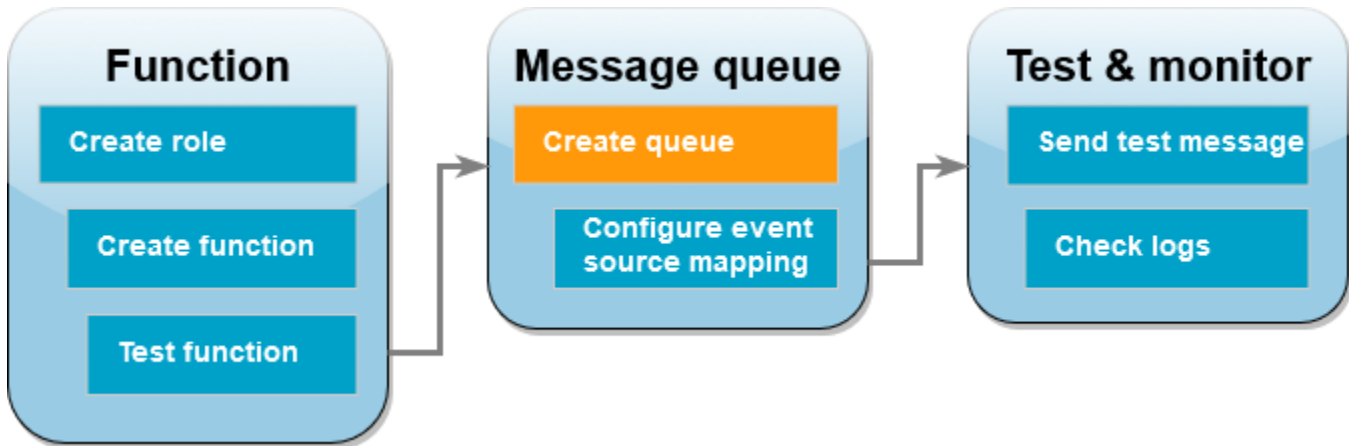

```
aws lambda invoke --function-name ProcessSQSRecord --payload file://input.json out
--log-type Tail \
--query 'LogResult' --output text --cli-binary-format raw-in-base64-out | base64 --
decode
```

The **cli-binary-format** option is required if you're using AWS CLI version 2. To make this the default setting, run `aws configure set cli-binary-format raw-in-base64-out`. For more information, see [AWS CLI supported global command line options](#) in the *AWS Command Line Interface User Guide for Version 2*.

3. Find the INFO log in the response. This is where the Lambda function logs the message body. You should see logs that look like this:

```
2023-09-11T22:45:04.271Z 348529ce-2211-4222-9099-59d07d837b60 INFO Processed
message test
2023-09-11T22:45:04.288Z 348529ce-2211-4222-9099-59d07d837b60 INFO done
```

Create an Amazon SQS queue

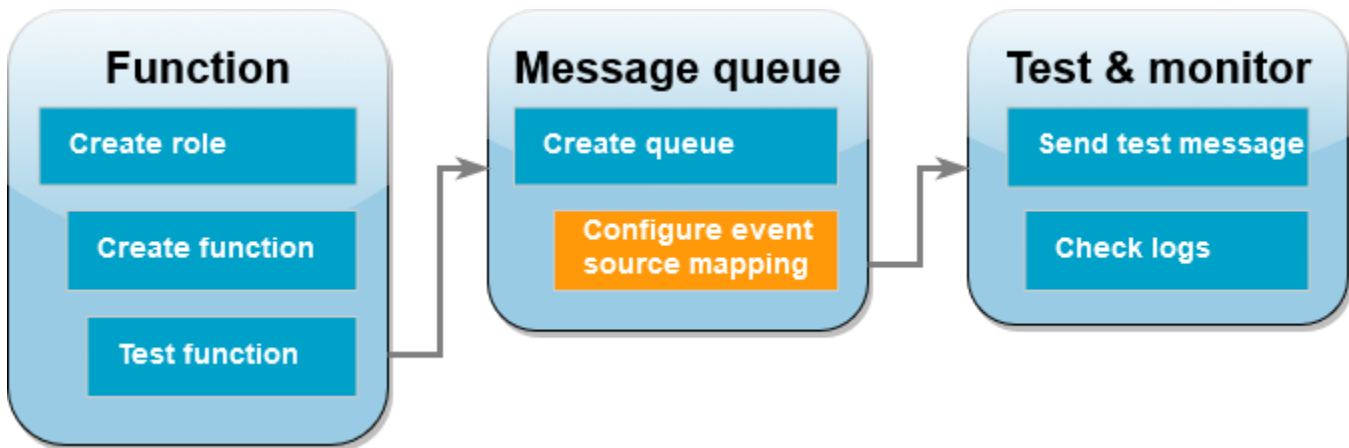

Create an Amazon SQS queue that the Lambda function can use as an event source. The Lambda function and the Amazon SQS queue must be in the same AWS Region.

To create a queue

1. Open the [Amazon SQS console](#).
2. Choose **Create queue**.
3. Enter a name for the queue. Leave all other options at the default settings.
4. Choose **Create queue**.

After creating the queue, note down its ARN. You need this in the next step when you associate the queue with your Lambda function.

Configure the event source

Connect the Amazon SQS queue to your Lambda function by creating an [event source mapping](#). The event source mapping reads the Amazon SQS queue and invokes your Lambda function when a new message is added.

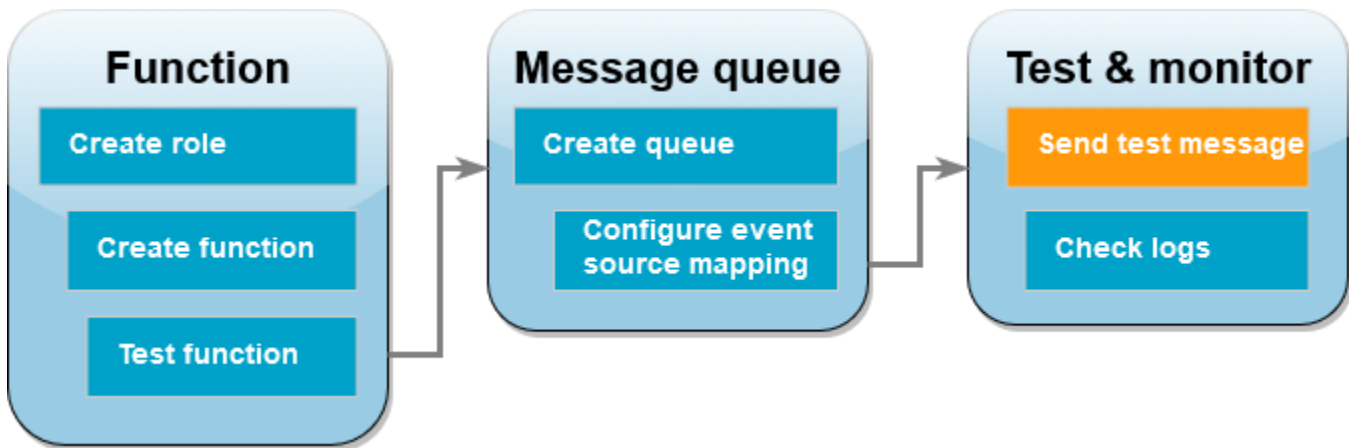

To create a mapping between your Amazon SQS queue and your Lambda function, use the [create-event-source-mapping](#) AWS CLI command. Example:

```
aws lambda create-event-source-mapping --function-name ProcessSQSRecord --batch-size 10 \
--event-source-arn arn:aws:sqs:us-east-1:111122223333:my-queue
```

To get a list of your event source mappings, use the [list-event-source-mappings](#) command. Example:

```
aws lambda list-event-source-mappings --function-name ProcessSQSRecord
```

Send a test message

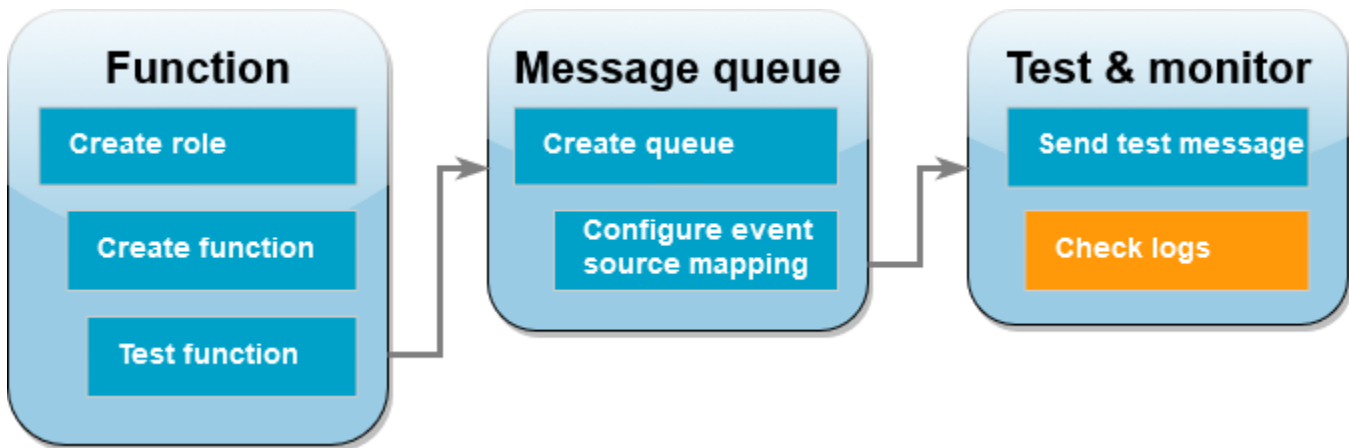

To send an Amazon SQS message to the Lambda function

1. Open the [Amazon SQS console](#).
2. Choose the queue that you created earlier.
3. Choose **Send and receive messages**.
4. Under **Message body**, enter a test message, such as "this is a test message."
5. Choose **Send message**.

Lambda polls the queue for updates. When there is a new message, Lambda invokes your function with this new event data from the queue. If the function handler returns without exceptions, Lambda considers the message successfully processed and begins reading new messages in the queue. After successfully processing a message, Lambda automatically deletes it from the queue. If the handler throws an exception, Lambda considers the batch of messages not successfully processed, and Lambda invokes the function with the same batch of messages.

Check the CloudWatch logs

To confirm that the function processed the message

1. Open the [Functions page](#) of the Lambda console.
2. Choose the **ProcessSQSRecord** function.
3. Choose **Monitor**.
4. Choose **View CloudWatch logs**.
5. In the CloudWatch console, choose the **Log stream** for the function.
6. Find the INFO log. This is where the Lambda function logs the message body. You should see the message that you sent from the Amazon SQS queue. Example:

```
2023-09-11T22:49:12.730Z b0c41e9c-0556-5a8b-af83-43e59efee71 INFO Processed  
message this is a test message.
```

Clean up your resources

You can now delete the resources that you created for this tutorial, unless you want to retain them. By deleting AWS resources that you're no longer using, you prevent unnecessary charges to your AWS account.

To delete the execution role

1. Open the [Roles page](#) of the IAM console.
2. Select the execution role that you created.
3. Choose **Delete**.

4. Enter the name of the role in the text input field and choose **Delete**.

To delete the Lambda function

1. Open the [Functions page](#) of the Lambda console.
2. Select the function that you created.
3. Choose **Actions, Delete**.
4. Type **confirm** in the text input field and choose **Delete**.

To delete the Amazon SQS queue

1. Sign in to the AWS Management Console and open the Amazon SQS console at <https://console.aws.amazon.com/sqs/>.
2. Select the queue you created.
3. Choose **Delete**.
4. Enter **confirm** in the text input field.
5. Choose **Delete**.

Tutorial: Using a cross-account Amazon SQS queue as an event source

In this tutorial, you create a Lambda function that consumes messages from an Amazon Simple Queue Service (Amazon SQS) queue in a different AWS account. This tutorial involves two AWS accounts: **Account A** refers to the account that contains your Lambda function, and **Account B** refers to the account that contains the Amazon SQS queue.

Prerequisites

Install the AWS Command Line Interface

If you have not yet installed the AWS Command Line Interface, follow the steps at [Installing or updating the latest version of the AWS CLI](#) to install it.

The tutorial requires a command line terminal or shell to run commands. In Linux and macOS, use your preferred shell and package manager.

Note

In Windows, some Bash CLI commands that you commonly use with Lambda (such as `zip`) are not supported by the operating system's built-in terminals. To get a Windows-integrated version of Ubuntu and Bash, [install the Windows Subsystem for Linux](#).

Create the execution role (Account A)

In **Account A**, create an [execution role](#) that gives your function permission to access the required AWS resources.

To create an execution role

1. Open the [Roles page](#) in the AWS Identity and Access Management (IAM) console.
2. Choose **Create role**.
3. Create a role with the following properties.
 - **Trusted entity** – AWS Lambda
 - **Permissions** – `AWSLambdaSQSQueueExecutionRole`
 - **Role name** – `cross-account-lambda-sqs-role`

The `AWSLambdaSQSQueueExecutionRole` policy has the permissions that the function needs to read items from Amazon SQS and to write logs to Amazon CloudWatch Logs.

Create the function (Account A)

In **Account A**, create a Lambda function that processes your Amazon SQS messages. The Lambda function and the Amazon SQS queue must be in the same AWS Region.

The following Node.js code example writes each message to a log in CloudWatch Logs.

Example `index.mjs`

```
export const handler = async function(event, context) {
  event.Records.forEach(record => {
    const { body } = record;
    console.log(body);
  });
  return {};
```

```
}
```

To create the function

Note

Following these steps creates a Node.js function. For other languages, the steps are similar, but some details are different.

1. Save the code example as a file named `index.mjs`.
2. Create a deployment package.

```
zip function.zip index.mjs
```

3. Create the function using the `create-function` AWS Command Line Interface (AWS CLI) command. Replace `arn:aws:iam::111122223333:role/cross-account-lambda-sqs-role` with the ARN of the execution role that you created earlier.

```
aws lambda create-function --function-name CrossAccountSQSExample \  
--zip-file fileb://function.zip --handler index.handler --runtime nodejs24.x \  
--role arn:aws:iam::111122223333:role/cross-account-lambda-sqs-role
```

Test the function (Account A)

In **Account A**, test your Lambda function manually using the `invoke` AWS CLI command and a sample Amazon SQS event.

If the handler returns normally without exceptions, Lambda considers the message to be successfully processed and begins reading new messages in the queue. After successfully processing a message, Lambda automatically deletes it from the queue. If the handler throws an exception, Lambda considers the batch of messages not successfully processed, and Lambda invokes the function with the same batch of messages.

1. Save the following JSON as a file named `input.txt`.

```
{  
  "Records": [  
    {
```

```

    "messageId": "059f36b4-87a3-44ab-83d2-661975830a7d",
    "receiptHandle": "AQEBwJnKyrHigUMZj6rYigCgXlaS3SLy0a...",
    "body": "test",
    "attributes": {
        "ApproximateReceiveCount": "1",
        "SentTimestamp": "1545082649183",
        "SenderId": "AIDAIENQZJOL023YVJ4V0",
        "ApproximateFirstReceiveTimestamp": "1545082649185"
    },
    "messageAttributes": {},
    "md5OfBody": "098f6bcd4621d373cade4e832627b4f6",
    "eventSource": "aws:sqs",
    "eventSourceARN": "arn:aws:sqs:us-east-1:111122223333:example-queue",
    "awsRegion": "us-east-1"
  }
]
}

```

The preceding JSON simulates an event that Amazon SQS might send to your Lambda function, where "body" contains the actual message from the queue.

2. Run the following invoke AWS CLI command.

```

aws lambda invoke --function-name CrossAccountSQSExample \
  --cli-binary-format raw-in-base64-out \
  --payload file://input.txt outputfile.txt

```

The **cli-binary-format** option is required if you're using AWS CLI version 2. To make this the default setting, run `aws configure set cli-binary-format raw-in-base64-out`. For more information, see [AWS CLI supported global command line options](#) in the *AWS Command Line Interface User Guide for Version 2*.

3. Verify the output in the file `outputfile.txt`.

Create an Amazon SQS queue (Account B)

In **Account B**, create an Amazon SQS queue that the Lambda function in **Account A** can use as an event source. The Lambda function and the Amazon SQS queue must be in the same AWS Region.

To create a queue

1. Open the [Amazon SQS console](#).

2. Choose **Create queue**.
3. Create a queue with the following properties.
 - **Type** – **Standard**
 - **Name** – **LambdaCrossAccountQueue**
 - **Configuration** – Keep the default settings.
 - **Access policy** – Choose **Advanced**. Paste in the following JSON policy. Replace the following values:
 - 111122223333: AWS account ID for **Account A**
 - 444455556666: AWS account ID for **Account B**

JSON

```
{
  "Version": "2012-10-17",
  "Id": "Queue1_Policy_UUID",
  "Statement": [
    {
      "Sid": "Queue1_AllActions",
      "Effect": "Allow",
      "Principal": {
        "AWS": [
          "arn:aws:iam::111122223333:role/cross-account-lambda-
sqs-role"
        ]
      },
      "Action": "sqs:*",
      "Resource": "arn:aws:sqs:us-
east-1:444455556666:LambdaCrossAccountQueue"
    }
  ]
}
```

This policy grants the Lambda execution role in **Account A** permissions to consume messages from this Amazon SQS queue.

4. After creating the queue, record its Amazon Resource Name (ARN). You need this in the next step when you associate the queue with your Lambda function.

Configure the event source (Account A)

In **Account A**, create an event source mapping between the Amazon SQS queue in **Account B** and your Lambda function by running the following `create-event-source-mapping` AWS CLI command. Replace `arn:aws:sqs:us-east-1:444455556666:LambdaCrossAccountQueue` with the ARN of the Amazon SQS queue that you created in the previous step.

```
aws lambda create-event-source-mapping --function-name CrossAccountSQSExample --batch-size 10 \
--event-source-arn arn:aws:sqs:us-east-1:444455556666:LambdaCrossAccountQueue
```

To get a list of your event source mappings, run the following command.

```
aws lambda list-event-source-mappings --function-name CrossAccountSQSExample \
--event-source-arn arn:aws:sqs:us-east-1:444455556666:LambdaCrossAccountQueue
```

Test the setup

You can now test the setup as follows:

1. In **Account B**, open the [Amazon SQS console](#).
2. Choose **LambdaCrossAccountQueue**, which you created earlier.
3. Choose **Send and receive messages**.
4. Under **Message body**, enter a test message.
5. Choose **Send message**.

Your Lambda function in **Account A** should receive the message. Lambda will continue to poll the queue for updates. When there is a new message, Lambda invokes your function with this new event data from the queue. Your function runs and creates logs in Amazon CloudWatch. You can view the logs in the [CloudWatch console](#).

Clean up your resources

You can now delete the resources that you created for this tutorial, unless you want to retain them. By deleting AWS resources that you're no longer using, you prevent unnecessary charges to your AWS account.

In **Account A**, clean up your execution role and Lambda function.

To delete the execution role

1. Open the [Roles page](#) of the IAM console.
2. Select the execution role that you created.
3. Choose **Delete**.
4. Enter the name of the role in the text input field and choose **Delete**.

To delete the Lambda function

1. Open the [Functions page](#) of the Lambda console.
2. Select the function that you created.
3. Choose **Actions, Delete**.
4. Type **confirm** in the text input field and choose **Delete**.

In **Account B**, clean up the Amazon SQS queue.

To delete the Amazon SQS queue

1. Sign in to the AWS Management Console and open the Amazon SQS console at <https://console.aws.amazon.com/sqs/>.
2. Select the queue you created.
3. Choose **Delete**.
4. Enter **confirm** in the text input field.
5. Choose **Delete**.

Orchestrating Lambda functions with Step Functions

AWS Step Functions provides visual workflow orchestration for coordinating Lambda functions with other AWS services. With native integrations to 220+ AWS services and fully managed, zero-maintenance infrastructure, Step Functions is ideal when you need visual workflow design and fully-managed service integrations.

For orchestration using standard programming languages within Lambda where workflow logic lives alongside business logic, consider [Lambda durable functions](#). For help choosing between these options, see [Durable functions or Step Functions](#).

For example, processing an order might require validating the order details, checking inventory levels, processing payment, and generating an invoice. Write separate Lambda functions for each task and use Step Functions to manage the workflow. Step Functions coordinates the flow of data between your functions and handles errors at each step. This separation makes your workflows easier to visualize, modify, and maintain as they grow more complex.

When to use Step Functions with Lambda

The following scenarios are good examples of when Step Functions is a particularly good fit for orchestrating Lambda-based applications.

- [Sequential processing](#)
- [Complex error handling](#)
- [Conditional workflows and human approvals](#)
- [Parallel processing](#)

Sequential processing

Sequential processing is when one task must complete before the next task can begin. For example, in an order processing system, payment processing can't begin until order validation is complete, and invoice generation must wait for payment confirmation. Write separate Lambda functions for each task and use Step Functions to manage the sequence and handle data flow between functions.

Anti-pattern example

A single Lambda function manages the entire order processing workflow by:

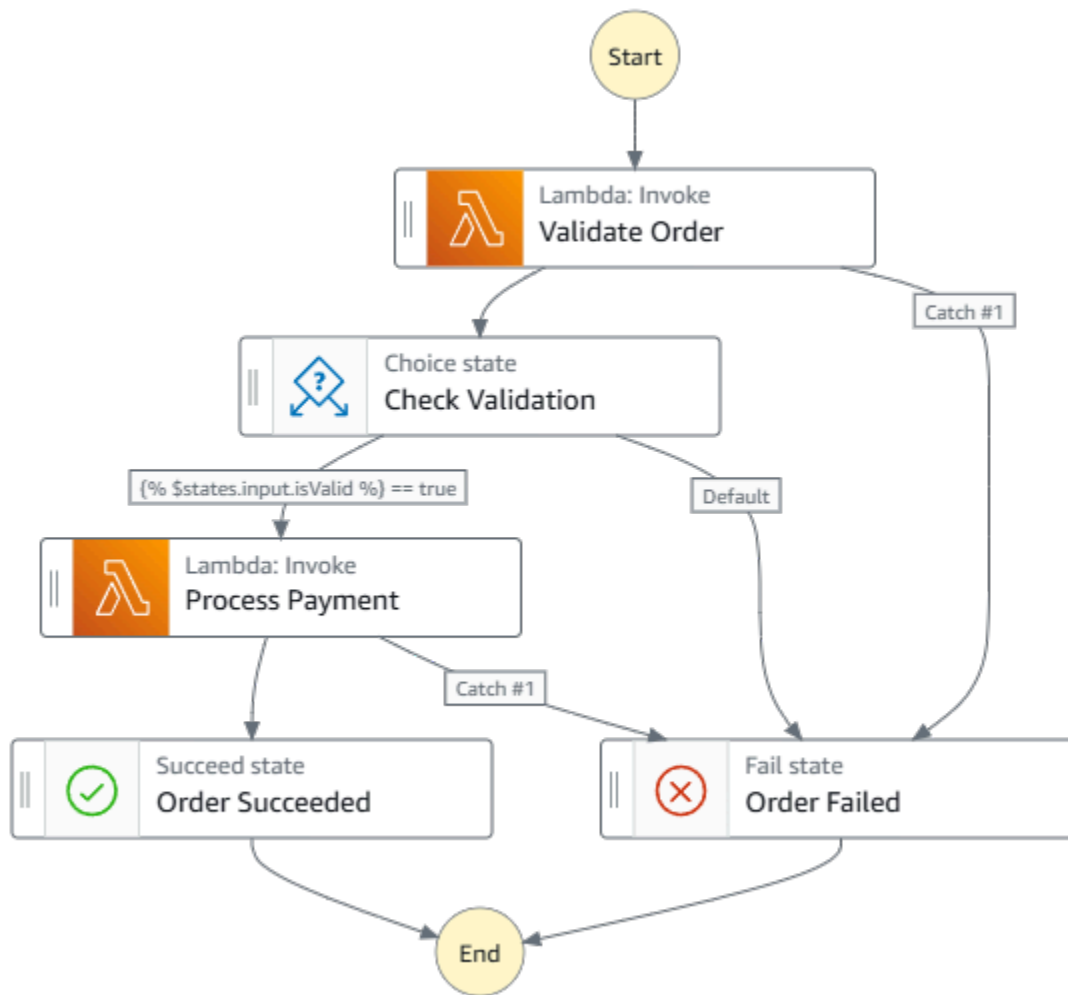

- Invoking other Lambda functions in sequence
- Parsing and validating responses from each function
- Implementing error handling and recovery logic
- Managing the flow of data between functions

Recommended approach

Use two Lambda functions: one to validate the order and one to process the payment. Step Functions coordinates these functions by:

- Running tasks in the correct sequence
- Passing data between functions
- Implementing error handling at each step
- Using [Choice](#) states to ensure only valid orders proceed to payment

Example workflow graph

Note

Code-first alternative: For sequential processing with code-based checkpointing and retry, see [Lambda durable functions steps](#).

Complex error handling

While Lambda provides [retry capabilities for asynchronous invocations and event source mappings](#), Step Functions offers more sophisticated error handling for complex workflows. You can [configure automatic retries](#) with exponential backoff and set different retry policies for different types of errors. When retries are exhausted, use Catch to route errors to a [fallback state](#). This is particularly

useful when you need workflow-level error handling that coordinates multiple functions and services.

To learn more about handling Lambda function errors in a state machine, see [Handling errors](#) in *The AWS Step Functions Workshop*.

Anti-pattern example

A single Lambda function handles all of the following:

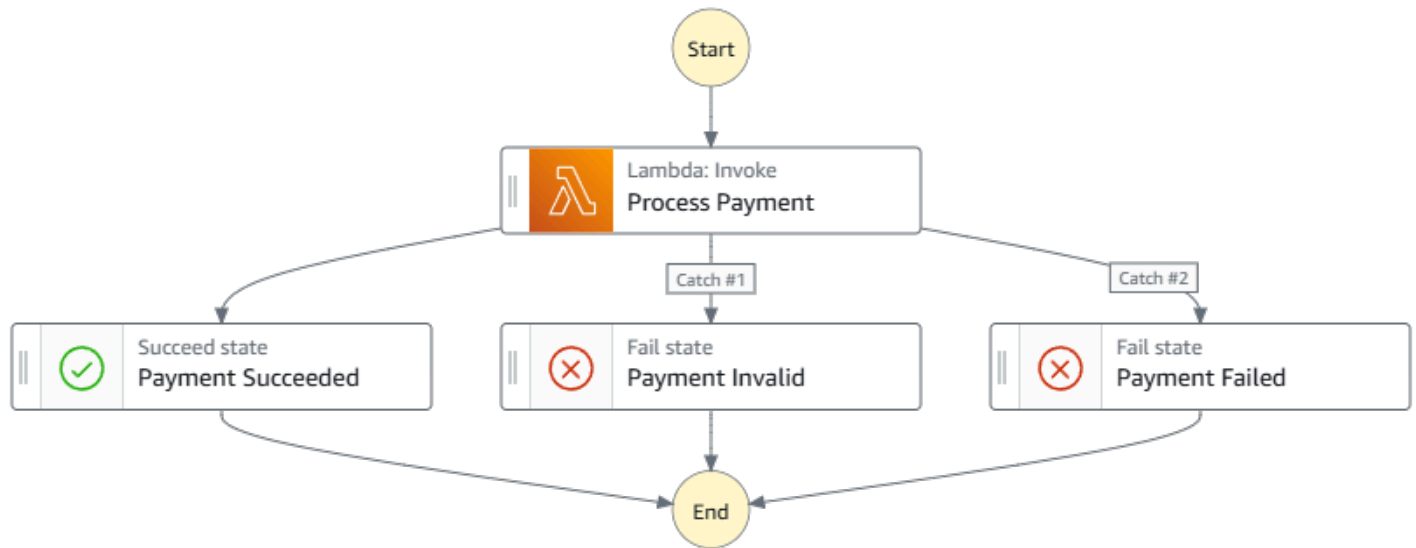

- Attempts to call a payment processing service
- If the payment service is unavailable, the function waits and tries again later.
- Implements a custom exponential backoff for the wait time
- After all attempts fail, catch the error and choose another flow

Recommended approach

Use a single Lambda function focused solely on payment processing. Step Functions manages error handling by:

- Automatically [retrying failed tasks with configurable backoff periods](#)
- Applying different retry policies based on error types
- Routing different types of errors to appropriate fallback states
- Maintaining error handling state and history

Example workflow graph

Note

Code-first alternative: Durable functions provide try-catch error handling with configurable retry strategies. See [Error handling in durable functions](#).

Conditional workflows and human approvals

Use the Step Functions [Choice state](#) to route workflows based on function output and the [waitForTaskToken suffix](#) to pause workflows for human decisions. For example, to process a credit limit increase request, use a Lambda function to evaluate risk factors. Then, use Step Functions to route high-risk requests to manual approval and low-risk requests to automatic approval.

To deploy an example workflow that uses a callback task token integration pattern, see [Callback with Task Token](#) in *The AWS Step Functions Workshop*.

Anti-pattern example

A single Lambda function manages a complex approval workflow by:

- Implementing nested conditional logic to evaluate credit requests
- Invoking different approval functions based on request amounts
- Managing multiple approval paths and decision points

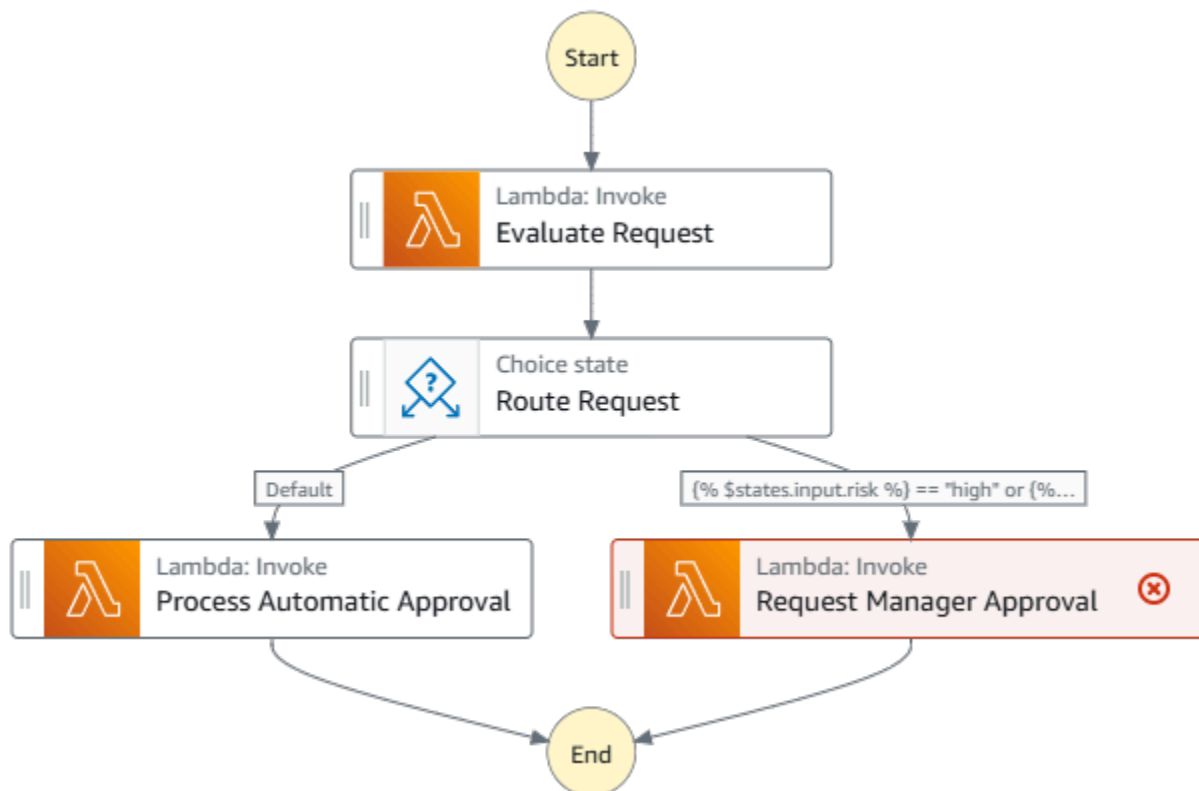

- Tracking the state of pending approvals
- Implementing timeout and notification logic for approvals

Recommended approach

Use three Lambda functions: one to evaluate the risk of each request, one to approve low-risk requests, and one to route high-risk requests to a manager for review. Step Functions manages the workflow by:

- Using [Choice](#) states to route requests based on amount and risk level
- Pausing execution while waiting for human approval
- Managing timeouts for pending approvals
- Providing visibility into the current state of each request

Example workflow graph

Note

Code-first alternative: Durable functions support callbacks for human-in-the-loop workflows. See [Callbacks in durable functions](#).

Parallel processing

Step Functions provides three ways to handle parallel processing:

- The [Parallel state](#) executes multiple branches of your workflow simultaneously. Use this when you need to run different functions in parallel, such as generating thumbnails while extracting image metadata.
- The [Inline Map state](#) processes arrays of data with up to 40 concurrent iterations. Use this for small to medium datasets where you need to perform the same operation on each item.
- The [Distributed Map state](#) handles large-scale parallel processing with up to 10,000 concurrent executions, supporting both JSON arrays and Amazon Simple Storage Service (Amazon S3) data sources. Use this when processing large datasets or when you need higher concurrency.

Anti-pattern example

A single Lambda function attempts to manage parallel processing by:

- Simultaneously invoking multiple image processing functions
- Implementing custom parallel execution logic
- Managing timeouts and error handling for each parallel task
- Collecting and aggregating results from all functions

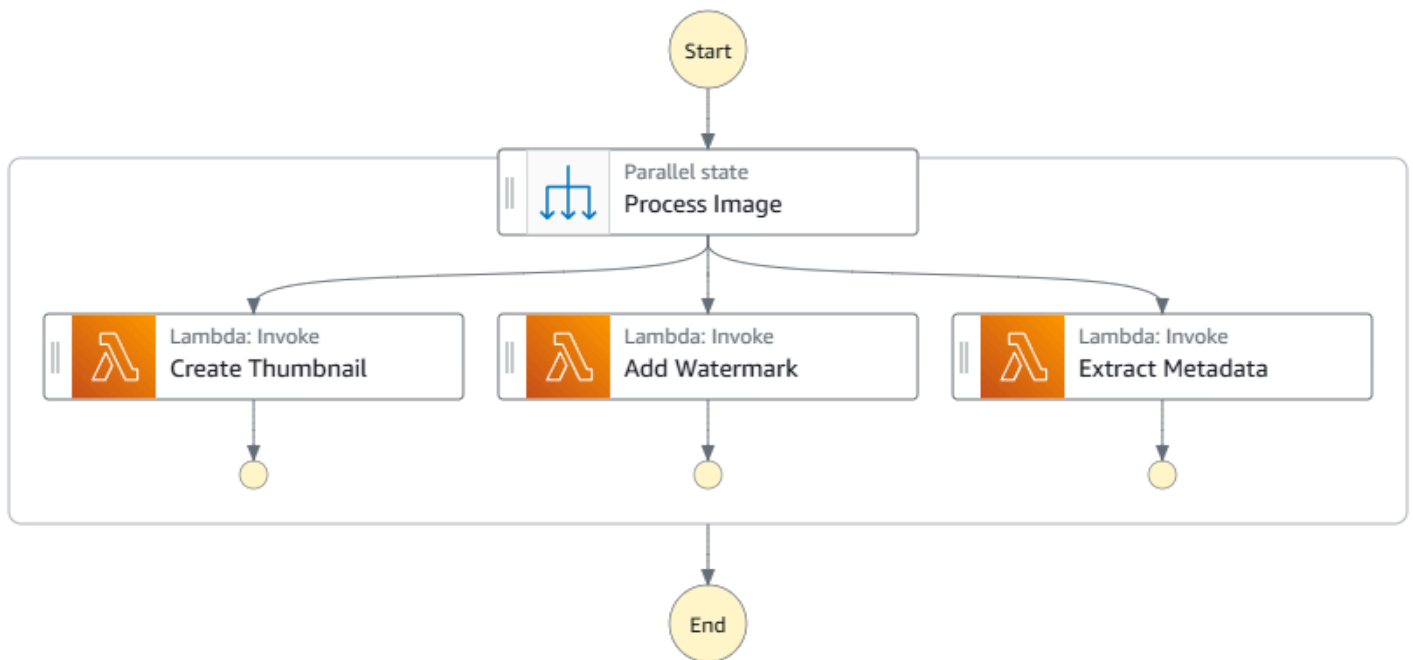

Recommended approach

Use three Lambda functions: one to create a thumbnail image, one to add a watermark, and one to extract the metadata. Step Functions manages these functions by:

- Running all functions simultaneously using the [Parallel](#) state
- Collecting results from each function into an ordered array
- Managing timeouts and error handling across all parallel executions

- Proceeding only when all parallel branches complete

Example workflow graph

Note

Code-first alternative: Durable functions provide `parallel()` and `map()` operations. See [Parallel execution](#).

When not to use Step Functions with Lambda

Not all Lambda-based applications benefit from using Step Functions. Consider these scenarios when choosing your application architecture.

- [Simple applications](#)
- [Complex data processing](#)
- [CPU-intensive workloads](#)

Simple applications

Note

For workflows that don't require visual design or extensive service integrations, [Lambda durable functions](#) may be a simpler alternative that keeps workflow logic in code within Lambda.

For applications that don't require complex orchestration, using Step Functions might add unnecessary complexity. For example, if you're simply processing messages from an Amazon SQS queue or responding to Amazon EventBridge events, you can configure these services to invoke your Lambda functions directly. Similarly, if your application consists of only one or two Lambda functions with straightforward error handling, direct Lambda invocation or event-driven architectures might be simpler to deploy and maintain.

Complex data processing

You can use the Step Functions [Distributed Map](#) state to concurrently process large Amazon S3 datasets with Lambda functions. This is effective for many large-scale parallel workloads, including processing semi-structured data like JSON or CSV files. However, for more complex data transformations or advanced analytics, consider these alternatives:

- **Data transformation pipelines:** Use AWS Glue for ETL jobs that process structured or semi-structured data from multiple sources. AWS Glue is particularly useful when you need built-in data catalog and schema management capabilities.
- **Data analytics:** Use Amazon EMR for petabyte-scale data analytics, especially when you need Apache Hadoop ecosystem tools or for machine learning workloads that exceed Lambda's [memory](#) limits.

CPU-intensive workloads

While Step Functions can orchestrate CPU-intensive tasks, Lambda functions may not be suitable for these workloads due to their limited CPU resources. For computationally intensive operations within your workflows, consider these alternatives:

- **Container orchestration:** Use Step Functions to manage Amazon Elastic Container Service (Amazon ECS) tasks for more consistent and scalable compute resources.

- **Batch processing:** Integrate AWS Batch with Step Functions for managing compute-intensive batch jobs that require sustained CPU usage.

Invoke a Lambda function with Amazon S3 batch events

You can use Amazon S3 batch operations to invoke a Lambda function on a large set of Amazon S3 objects. Amazon S3 tracks the progress of batch operations, sends notifications, and stores a completion report that shows the status of each action.

To run a batch operation, you create an Amazon S3 [batch operations job](#). When you create the job, you provide a manifest (the list of objects) and configure the action to perform on those objects.

When the batch job starts, Amazon S3 invokes the Lambda function [synchronously](#) for each object in the manifest. The event parameter includes the names of the bucket and the object.

The following example shows the event that Amazon S3 sends to the Lambda function for an object that is named **customerImage1.jpg** in the **amzn-s3-demo-bucket** bucket.

Example Amazon S3 batch request event

```
{
  "invocationSchemaVersion": "1.0",
  "invocationId": "YXNkbGZqYWRmaiBhc2RmdW9hZHNmZGpmaGFzbGtkaGZza2RmaAo",
  "job": {
    "id": "f3cc4f60-61f6-4a2b-8a21-d07600c373ce"
  },
  "tasks": [
    {
      "taskId": "dGFza2lkZ291c2h1cmUK",
      "s3Key": "customerImage1.jpg",
      "s3VersionId": "1",
      "s3BucketArn": "arn:aws:s3:::amzn-s3-demo-bucket"
    }
  ]
}
```

Your Lambda function must return a JSON object with the fields as shown in the following example. You can copy the `invocationId` and `taskId` from the event parameter. You can return a string in the `resultString`. Amazon S3 saves the `resultString` values in the completion report.

Example Amazon S3 batch request response

```
{
  "invocationSchemaVersion": "1.0",
  "treatMissingKeysAs" : "PermanentFailure",
  "invocationId" : "YXNkbGZqYWRmaiBhc2RmdW9hZHNmZGpmaGFzbGtkaGZza2RmaAo",
  "results": [
    {
      "taskId": "dGFza2lkZ29lc2hlcmUK",
      "resultCode": "Succeeded",
      "resultString": "[\"Alice\", \"Bob\"]"
    }
  ]
}
```

Invoking Lambda functions from Amazon S3 batch operations

You can invoke the Lambda function with an unqualified or qualified function ARN. If you want to use the same function version for the entire batch job, configure a specific function version in the `FunctionARN` parameter when you create your job. If you configure an alias or the `$LATEST` qualifier, the batch job immediately starts calling the new version of the function if the alias or `$LATEST` is updated during the job execution.

Note that you can't reuse an existing Amazon S3 event-based function for batch operations. This is because the Amazon S3 batch operation passes a different event parameter to the Lambda function and expects a return message with a specific JSON structure.

In the [resource-based policy](#) that you create for the Amazon S3 batch job, ensure that you set permission for the job to invoke your Lambda function.

In the execution role for the function, set a [trust policy for Amazon S3 to assume the role when it runs your function](#).

If your function uses the AWS SDK to manage Amazon S3 resources, you need to add Amazon S3 permissions in the execution role.

When the job runs, Amazon S3 starts multiple function instances to process the Amazon S3 objects in parallel, up to the [concurrency limit](#) of the function. Amazon S3 limits the initial ramp-up of instances to avoid excess cost for smaller jobs.

If the Lambda function returns a `TemporaryFailure` response code, Amazon S3 retries the operation.

For more information about Amazon S3 batch operations, see [Performing batch operations](#) in the *Amazon S3 Developer Guide*.

For an example of how to use a Lambda function in Amazon S3 batch operations, see [Invoking a Lambda function from Amazon S3 batch operations](#) in the *Amazon S3 Developer Guide*.

Invoking Lambda functions with Amazon SNS notifications

You can use a Lambda function to process Amazon Simple Notification Service (Amazon SNS) notifications. Amazon SNS supports Lambda functions as a target for messages sent to a topic. You can subscribe your function to topics in the same account or in other AWS accounts. For a detailed walkthrough, see [the section called “Tutorial”](#).

Lambda supports SNS triggers for standard SNS topics only. FIFO topics aren't supported.

Lambda processes SNS messages asynchronously by queuing the messages and handling retries. If Amazon SNS can't reach Lambda or the message is rejected, Amazon SNS retries at increasing intervals over several hours. For details, see [Reliability](#) in the Amazon SNS FAQs.

Warning

Lambda asynchronous invocations process each event at least once, and duplicate processing of records can occur. To avoid potential issues related to duplicate events, we strongly recommend that you make your function code idempotent. To learn more, see [How do I make my Lambda function idempotent](#) in the AWS Knowledge Center.

Idempotency utility from Powertools for AWS Lambda

The idempotency utility from Powertools for AWS Lambda makes your Lambda functions idempotent. It is available for Python, TypeScript, Java, and .NET. For more information, see [Idempotency utility](#) in the *Powertools for AWS Lambda (Python) documentation*, [Idempotency Utility](#) in the *Powertools for AWS Lambda (TypeScript) documentation*, [Idempotency Utility](#) in the *Powertools for AWS Lambda (Java) documentation*, and [Idempotency Utility](#) in the *Powertools for AWS Lambda (.NET) documentation*.

Topics

- [Adding an Amazon SNS topic trigger for a Lambda function using the console](#)
- [Manually adding an Amazon SNS topic trigger for a Lambda function](#)
- [Sample SNS event shape](#)
- [Tutorial: Using AWS Lambda with Amazon Simple Notification Service](#)

Adding an Amazon SNS topic trigger for a Lambda function using the console

To add an SNS topic as a trigger for a Lambda function, the easiest way is to use the Lambda console. When you add the trigger via the console, Lambda automatically sets up the necessary permissions and subscriptions to start receiving events from the SNS topic.

To add an SNS topic as a trigger for a Lambda function (console)

1. Open the [Functions page](#) of the Lambda console.
2. Choose the name of a function you want to add the trigger for.
3. Choose **Configuration**, and then choose **Triggers**.
4. Choose **Add trigger**.
5. Under **Trigger configuration**, in the dropdown menu, choose **SNS**.
6. For **SNS topic**, choose the SNS topic to subscribe to.

Manually adding an Amazon SNS topic trigger for a Lambda function

To set up an SNS trigger for a Lambda function manually, you need to complete the following steps:

- Define a resource-based policy for your function to allow SNS to invoke it.
- Subscribe your Lambda function to the Amazon SNS topic.

Note

If your SNS topic and your Lambda function are in different AWS accounts, you also need to grant extra permissions to allow cross-account subscriptions to the SNS topic. For more information, see [Grant cross-account permission for Amazon SNS subscription](#).

You can use the AWS Command Line Interface (AWS CLI) to complete both of these steps. First, to define a resource-based policy for a Lambda function that allows SNS invocations, use the following AWS CLI command. Be sure to replace the value of `--function-name` with your Lambda function name, and the value of `--source-arn` with your SNS topic ARN.

```
aws lambda add-permission --function-name example-function \  
  --source-arn arn:aws:sns:us-east-1:123456789012:sns-topic-for-lambda \  
  --statement-id function-with-sns --action "lambda:InvokeFunction" \  
  --principal sns.amazonaws.com
```

To subscribe your function to the SNS topic, use the following AWS CLI command. Replace the value of `--topic-arn` with your SNS topic ARN, and the value of `--notification-endpoint` with your Lambda function ARN.

```
aws sns subscribe --protocol lambda \  
  --region us-east-1 \  
  --topic-arn arn:aws:sns:us-east-1:123456789012:sns-topic-for-lambda \  
  --notification-endpoint arn:aws:lambda:us-east-1:123456789012:function:example-function
```

Sample SNS event shape

Amazon SNS invokes your function [asynchronously](#) with an event that contains a message and metadata.

Example Amazon SNS message event

```
{  
  "Records": [  
    {  
      "EventVersion": "1.0",  
      "EventSubscriptionArn": "arn:aws:sns:us-east-1:123456789012:sns-lambda:21be56ed-a058-49f5-8c98-aedd2564c486",  
      "EventSource": "aws:sns",  
      "Sns": {  
        "SignatureVersion": "1",  
        "Timestamp": "2019-01-02T12:45:07.000Z",  
        "Signature": "tcc6faL2yUC6dgZdmrwh1Y4cGa/ebXEKai6RibDsvpi+tE/1+82j...65r==",  
        "SigningCertURL": "https://sns.us-east-1.amazonaws.com/SimpleNotificationService-ac565b8b1a6c5d002d285f9598aa1d9b.pem",  
        "MessageId": "95df01b4-ee98-5cb9-9903-4c221d41eb5e",  
        "Message": "Hello from SNS!",  
        "MessageAttributes": {  
          "Test": {  
            "Type": "String",  
            "Value": "TestString"          }  
        }  
      }  
    }  
  ]  
}
```

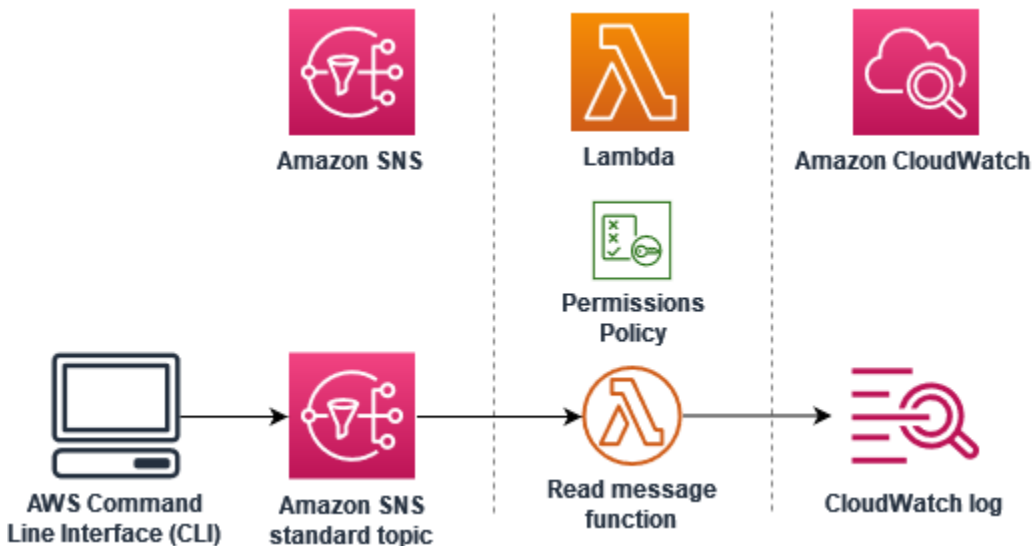

```

    },
    "TestBinary": {
      "Type": "Binary",
      "Value": "TestBinary"
    }
  },
  "Type": "Notification",
  "UnsubscribeUrl": "https://sns.us-east-1.amazonaws.com/?
Action=Unsubscribe&SubscriptionArn=arn:aws:sns:us-east-1:123456789012:test-
lambda:21be56ed-a058-49f5-8c98-aedd2564c486",
  "TopicArn": "arn:aws:sns:us-east-1:123456789012:sns-lambda",
  "Subject": "TestInvoke"
}
}
]
}

```

Tutorial: Using AWS Lambda with Amazon Simple Notification Service

In this tutorial, you use a Lambda function in one AWS account to subscribe to an Amazon Simple Notification Service (Amazon SNS) topic in a separate AWS account. When you publish messages to your Amazon SNS topic, your Lambda function reads the contents of the message and outputs it to Amazon CloudWatch Logs. To complete this tutorial, you use the AWS Command Line Interface (AWS CLI).

To complete this tutorial, you perform the following steps:

- In **account A**, create an Amazon SNS topic.

- In **account B**, create a Lambda function that will read messages from the topic.
- In **account B**, create a subscription to the topic.
- Publish messages to the Amazon SNS topic in **account A** and confirm that the Lambda function in **account B** outputs them to CloudWatch Logs.

By completing these steps, you will learn how to configure an Amazon SNS topic to invoke a Lambda function. You will also learn how to create an AWS Identity and Access Management (IAM) policy that gives permission for a resource in another AWS account to invoke Lambda.

In the tutorial, you use two separate AWS accounts. The AWS CLI commands illustrate this by using two named profiles called `accountA` and `accountB`, each configured for use with a different AWS account. To learn how to configure the AWS CLI to use different profiles, see [Configuration and credential file settings](#) in the *AWS Command Line Interface User Guide for Version 2*. Be sure to configure the same default AWS Region for both profiles.

If the AWS CLI profiles you create for the two AWS accounts use different names, or if you use the default profile and one named profile, modify the AWS CLI commands in the following steps as needed.

Prerequisites

Install the AWS Command Line Interface

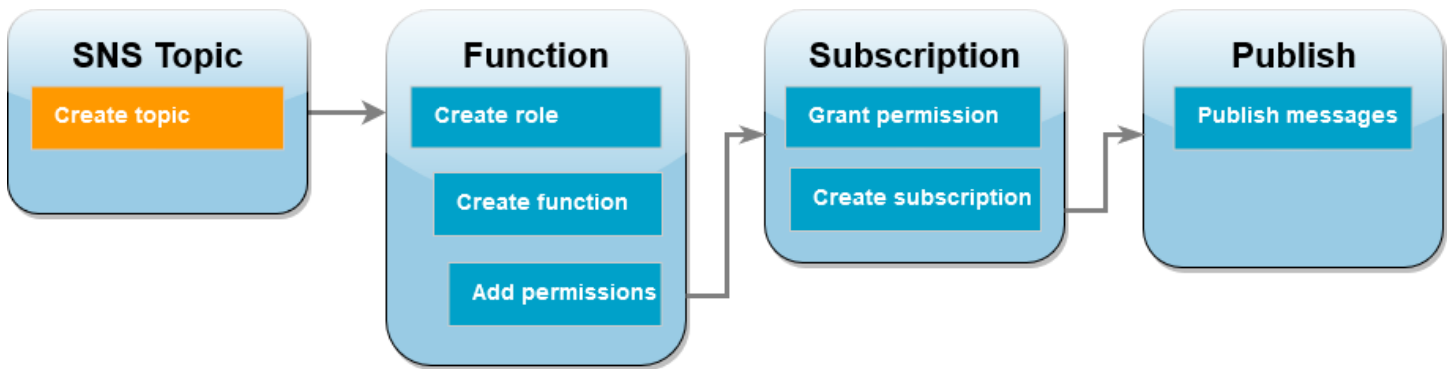

If you have not yet installed the AWS Command Line Interface, follow the steps at [Installing or updating the latest version of the AWS CLI](#) to install it.

The tutorial requires a command line terminal or shell to run commands. In Linux and macOS, use your preferred shell and package manager.

Note

In Windows, some Bash CLI commands that you commonly use with Lambda (such as `zip`) are not supported by the operating system's built-in terminals. To get a Windows-integrated version of Ubuntu and Bash, [install the Windows Subsystem for Linux](#).

Create an Amazon SNS topic (account A)

To create the topic

- In **account A**, create an Amazon SNS standard topic using the following AWS CLI command.

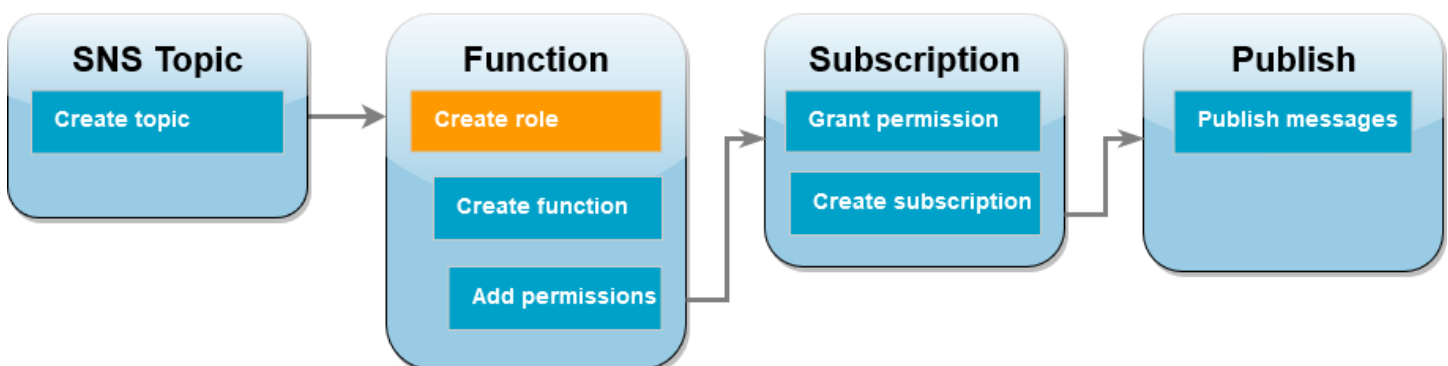

```
aws sns create-topic --name sns-topic-for-lambda --profile accountA
```

You should see output similar to the following.

```
{
  "TopicArn": "arn:aws:sns:us-west-2:123456789012:sns-topic-for-lambda"
}
```

Make a note of the Amazon Resource Name (ARN) of your topic. You'll need it later in the tutorial when you add permissions to your Lambda function to subscribe to the topic.

Create a function execution role (account B)

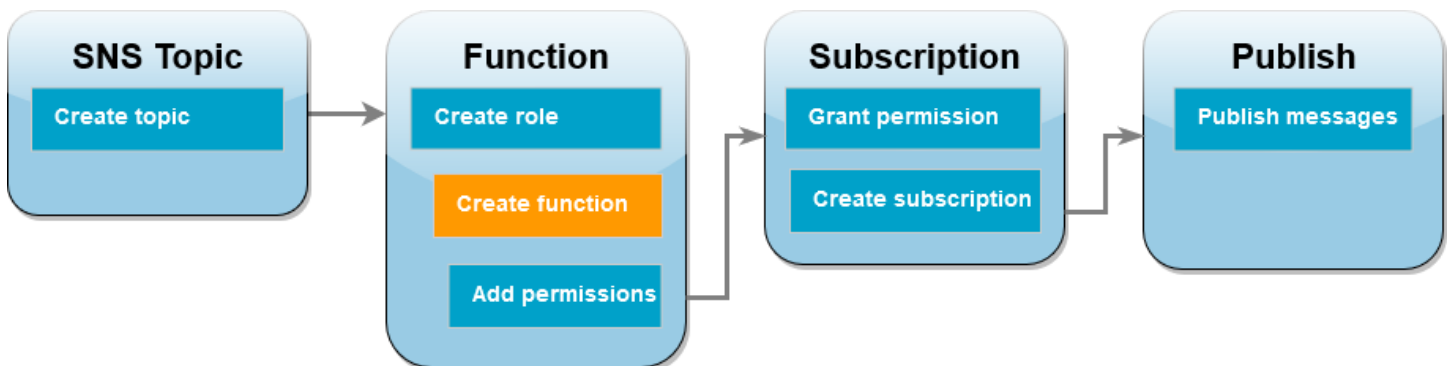

An execution role is an IAM role that grants a Lambda function permission to access AWS services and resources. Before you create your function in **account B**, you create a role that gives the

function basic permissions to write logs to CloudWatch Logs. We'll add the permissions to read from your Amazon SNS topic in a later step.

To create an execution role

1. In **account B** open the [roles page](#) in the IAM console.
2. Choose **Create role**.
3. For **Trusted entity type**, choose **AWS service**.
4. For **Use case**, choose **Lambda**.
5. Choose **Next**.
6. Add a basic permissions policy to the role by doing the following:
 - a. In the **Permissions policies** search box, enter **AWSLambdaBasicExecutionRole**.
 - b. Choose **Next**.
7. Finalize the role creation by doing the following:
 - a. Under **Role details**, enter **lambda-sns-role** for **Role name**.
 - b. Choose **Create role**.

Create a Lambda function (account B)

Create a Lambda function that processes your Amazon SNS messages. The function code logs the message contents of each record to Amazon CloudWatch Logs.

This tutorial uses the Node.js 24 runtime, but we've also provided example code in other runtime languages. You can select the tab in the following box to see code for the runtime you're interested in. The JavaScript code you'll use in this step is in the first example shown in the **JavaScript** tab.

.NET

Consuming an SNS event with Lambda using Rust.

```
// Copyright Amazon.com, Inc. or its affiliates. All Rights Reserved.
// SPDX-License-Identifier: Apache-2.0
use aws_lambda_events::event::sns::SnsEvent;
use aws_lambda_events::sns::SnsRecord;
use lambda_runtime::{run, service_fn, Error, LambdaEvent};
use tracing::info;

// Built with the following dependencies:
// aws_lambda_events = { version = "0.10.0", default-features = false, features
//   = ["sns"] }
// lambda_runtime = "0.8.1"
// tokio = { version = "1", features = ["macros"] }
// tracing = { version = "0.1", features = ["log"] }
// tracing-subscriber = { version = "0.3", default-features = false, features =
//   ["fmt"] }

async fn function_handler(event: LambdaEvent<SnsEvent>) -> Result<(), Error> {
    for event in event.payload.records {
        process_record(&event)?;
    }

    Ok(())
}

fn process_record(record: &SnsRecord) -> Result<(), Error> {
    info!("Processing SNS Message: {}", record.sns.message);

    // Implement your record handling code here.

    Ok(())
}
```

```
#[tokio::main]
async fn main() -> Result<(), Error> {
    tracing_subscriber::fmt()
        .with_max_level(tracing::Level::INFO)
        .with_target(false)
        .without_time()
        .init();

    run(service_fn(function_handler)).await
}
```

To create the function

1. Create a directory for the project, and then switch to that directory.

```
mkdir sns-tutorial
cd sns-tutorial
```

2. Copy the sample JavaScript code into a new file named `index.js`.
3. Create a deployment package using the following `zip` command.

```
zip function.zip index.js
```

4. Run the following AWS CLI command to create your Lambda function in **account B**.

```
aws lambda create-function --function-name Function-With-SNS \
    --zip-file fileb://function.zip --handler index.handler --runtime nodejs24.x \
    --role arn:aws:iam::<AccountB_ID>:role/lambda-sns-role \
    --timeout 60 --profile accountB
```

You should see output similar to the following.

```
{
  "FunctionName": "Function-With-SNS",
  "FunctionArn": "arn:aws:lambda:us-west-2:123456789012:function:Function-With-SNS",
  "Runtime": "nodejs24.x",
  "Role": "arn:aws:iam::123456789012:role/lambda_basic_role",
  "Handler": "index.handler",
  ...
}
```

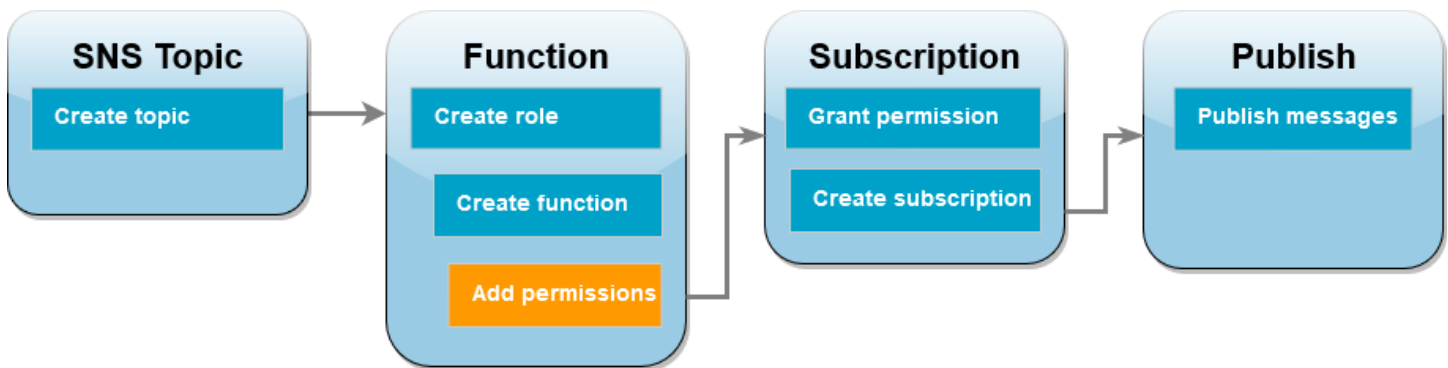

```

"RuntimeVersionConfig": {
  "RuntimeVersionArn": "arn:aws:lambda:us-
west-2::runtime:7d5f06b69c951da8a48b926ce280a9daf2e8bb1a74fc4a2672580c787d608206"
}
}

```

- Record the Amazon Resource Name (ARN) of your function. You'll need it later in the tutorial when you add permissions to allow Amazon SNS to invoke your function.

Add permissions to function (account B)

For Amazon SNS to invoke your function, you need to grant it permission in a statement on a [resource-based policy](#). You add this statement using the AWS CLI `add-permission` command.

To grant Amazon SNS permission to invoke your function

- In **account B**, run the following AWS CLI command using the ARN for your Amazon SNS topic you recorded earlier.

```

aws lambda add-permission --function-name Function-With-SNS \
  --source-arn arn:aws:sns:us-east-1:<AccountA_ID>:sns-topic-for-lambda \
  --statement-id function-with-sns --action "lambda:InvokeFunction" \
  --principal sns.amazonaws.com --profile accountB

```

You should see output similar to the following.

```

{
  "Statement": "{ \"Condition\": { \"ArnLike\": { \"AWS:SourceArn\": \"arn:aws:sns:us-east-1:<AccountA_ID>:sns-topic-for-lambda\" } }, \"Action\": [ \"lambda:InvokeFunction\" ], \"Resource\": \"arn:aws:lambda:us-east-1:<AccountB_ID>:function:Function-With-SNS\" },

```

```

    \"Effect\": \"Allow\", \"Principal\": { \"Service\": \"sns.amazonaws.com\" },
    \"Sid\": \"function-with-sns\" }
  }
}

```

Note

If the account with the Amazon SNS topic is hosted in an [opt-in AWS Region](#), you need to specify the region in the principal. For example, if you're working with an Amazon SNS topic in the Asia Pacific (Hong Kong) region, you need to specify `sns.ap-east-1.amazonaws.com` instead of `sns.amazonaws.com` for the principal.

Grant cross-account permission for Amazon SNS subscription (account A)

For your Lambda function in **account B** to subscribe to the Amazon SNS topic you created in **account A**, you need to grant permission for **account B** to subscribe to your topic. You grant this permission using the AWS CLI `add-permission` command.

To grant permission for account B to subscribe to the topic

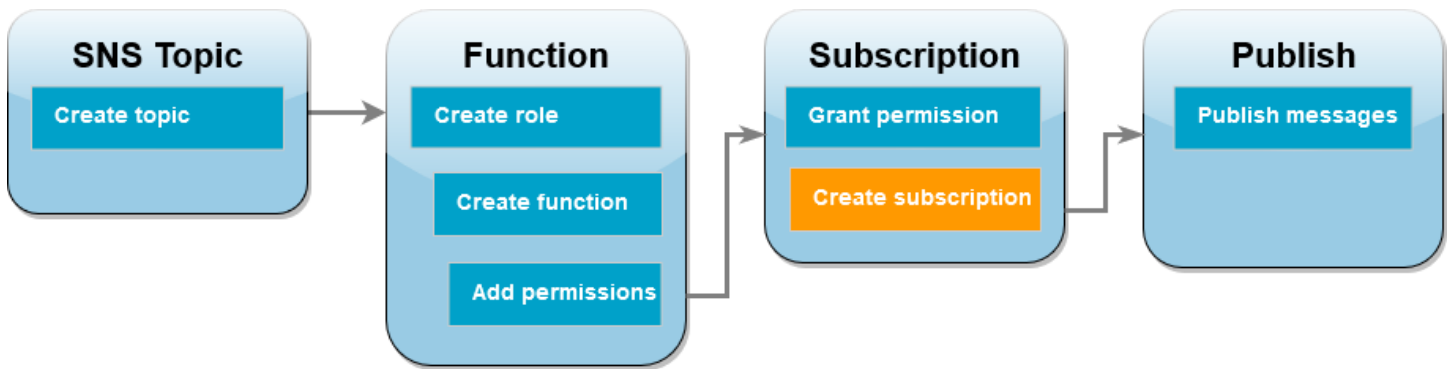

- In **account A**, run the following AWS CLI command. Use the ARN for the Amazon SNS topic you recorded earlier.

```

aws sns add-permission --label lambda-access --aws-account-id <AccountB_ID> \
  --topic-arn arn:aws:sns:us-east-1:<AccountA_ID>:sns-topic-for-lambda \
  --action-name Subscribe ListSubscriptionsByTopic --profile accountA

```

Create a subscription (account B)

In **account B**, you now subscribe your Lambda function to the Amazon SNS topic you created at the beginning of the tutorial in **account A**. When a message is sent to this topic (sns-topic-for-lambda), Amazon SNS invokes your Lambda function Function-With-SNS in **account B**.

To create a subscription

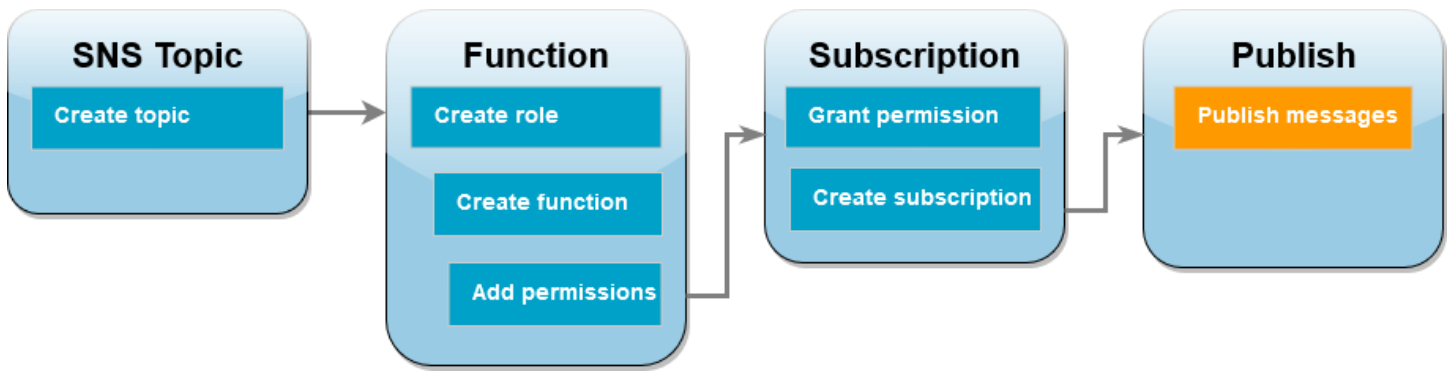

- In **account B**, run the following AWS CLI command. Use your default region you created your topic in and the ARNs for your topic and Lambda function.

```
aws sns subscribe --protocol lambda \
  --region us-east-1 \
  --topic-arn arn:aws:sns:us-east-1:<AccountA_ID>:sns-topic-for-lambda \
  --notification-endpoint arn:aws:lambda:us-east-1:<AccountB_ID>:function:Function-With-SNS \
  --profile accountB
```

You should see output similar to the following.

```
{
  "SubscriptionArn": "arn:aws:sns:us-east-1:<AccountA_ID>:sns-topic-for-lambda:5d906xxxx-7c8x-45dx-a9dx-0484e31c98xx"
}
```

Publish messages to topic (account A and account B)

Now that your Lambda function in **account B** is subscribed to your Amazon SNS topic in **account A**, it's time to test your setup by publishing messages to your topic. To confirm that Amazon SNS has invoked your Lambda function, you use CloudWatch Logs to view your function's output.

To publish a message to your topic and view your function's output

1. Enter `Hello World` into a text file and save it as `message.txt`.
2. From the same directory you saved your text file in, run the following AWS CLI command in **account A**. Use the ARN for your own topic.

```
aws sns publish --message file://message.txt --subject Test \
  --topic-arn arn:aws:sns:us-east-1:<AccountA_ID>:sns-topic-for-lambda \
  --profile accountA
```

This will return a message ID with a unique identifier, indicating that Amazon SNS has accepted the message. Amazon SNS then attempts to deliver the message to the topic's subscribers. To confirm that Amazon SNS has invoked your Lambda function, use CloudWatch Logs to view your function's output:

3. In **account B**, open the [Log groups](#) page of the Amazon CloudWatch console.
4. Choose the log group for your function (`/aws/lambda/Function-With-SNS`).
5. Choose the most recent log stream.
6. If your function was correctly invoked, you'll see output similar to the following showing the contents of the message you published to your topic.

```
2023-07-31T21:42:51.250Z c1cba6b8-ade9-4380-aa32-d1a225da0e48 INFO Processed
message Hello World
2023-07-31T21:42:51.250Z c1cba6b8-ade9-4380-aa32-d1a225da0e48 INFO done
```

Clean up your resources

You can now delete the resources that you created for this tutorial, unless you want to retain them. By deleting AWS resources that you're no longer using, you prevent unnecessary charges to your AWS account.

In **Account A**, clean up your Amazon SNS topic.

To delete the Amazon SNS topic

1. Open the [Topics page](#) of the Amazon SNS console.
2. Select the topic you created.
3. Choose **Delete**.
4. Enter **delete me** in the text input field.
5. Choose **Delete**.

In **Account B**, clean up your execution role, Lambda function, and Amazon SNS subscription.

To delete the execution role

1. Open the [Roles page](#) of the IAM console.
2. Select the execution role that you created.
3. Choose **Delete**.
4. Enter the name of the role in the text input field and choose **Delete**.

To delete the Lambda function

1. Open the [Functions page](#) of the Lambda console.
2. Select the function that you created.
3. Choose **Actions, Delete**.
4. Type **confirm** in the text input field and choose **Delete**.

To delete the Amazon SNS subscription

1. Open the [Subscriptions page](#) of the Amazon SNS console.
2. Select the subscription you created.

3. Choose **Delete, Delete**.

Managing permissions in AWS Lambda

You can use AWS Identity and Access Management (IAM) to manage permissions in AWS Lambda. There are two main categories of permissions that you need to consider when working with Lambda functions:

- Permissions that your Lambda functions need to perform API actions and access other AWS resources
- Permissions that other AWS users and entities need to access your Lambda functions

Lambda functions often need to access other AWS resources, and perform various API operations on those resources. For example, you might have a Lambda function that responds to an event by updating entries in an Amazon DynamoDB database. In this case, your function needs permissions to access the database, as well as permissions to put or update items in that database.

You define the permissions that your Lambda function needs in a special IAM role called an [execution role](#). In this role, you can attach a policy that defines every permission your function needs to access other AWS resources, and read from event sources. Every Lambda function must have an execution role. At a minimum, your execution role must have access to Amazon CloudWatch because Lambda functions log to CloudWatch Logs by default. You can attach the [AWSLambdaBasicExecutionRole managed policy](#) to your execution role to satisfy this requirement.

To give other AWS accounts, organizations, and services permissions to access your Lambda resources, you have a few options:

- You can use [identity-based policies](#) to grant other users access to your Lambda resources. Identity-based policies can apply to users directly, or to groups and roles that are associated with a user.
- You can use [resource-based policies](#) to give other accounts and AWS services permissions to access your Lambda resources. When a user tries to access a Lambda resource, Lambda considers both the user's identity-based policies and the resource's resource-based policy. When an AWS service such as Amazon Simple Storage Service (Amazon S3) calls your Lambda function, Lambda considers only the resource-based policy.
- You can use an [attribute-based access control \(ABAC\)](#) model to control access to your Lambda functions. With ABAC, you can attach tags to a Lambda function, pass them in certain API

requests, or attach them to the IAM principal making the request. Specify the same tags in the condition element of an IAM policy to control function access.

In AWS, it's a best practice to grant only the permissions required to perform a task ([least-privilege permissions](#)). To implement this in Lambda, we recommend starting with an [AWS managed policy](#). You can use these managed policies as-is, or as a starting point for writing your own more restrictive policies.

To help you fine-tune your permissions for least-privilege access, Lambda provides some additional conditions you can include in your policies. For more information, see [the section called "Resources and Conditions"](#).

For more information about IAM, see the [IAM User Guide](#).

Defining Lambda function permissions with an execution role

A Lambda function's execution role is an AWS Identity and Access Management (IAM) role that grants the function permission to access AWS services and resources. For example, you might create an execution role that has permission to send logs to Amazon CloudWatch and upload trace data to AWS X-Ray. This page provides information on how to create, view, and manage a Lambda function's execution role.

Lambda automatically assumes your execution role when you invoke your function. You should avoid manually calling `sts:AssumeRole` to assume the execution role in your function code. If your use case requires that the role assumes itself, you must include the role itself as a trusted principal in your role's trust policy. For more information on how to modify a role trust policy, see [Modifying a role trust policy \(console\)](#) in the IAM User Guide.

In order for Lambda to properly assume your execution role, the role's [trust policy](#) must specify the Lambda service principal (`lambda.amazonaws.com`) as a trusted service.

Topics

- [Creating an execution role in the IAM console](#)
- [Creating and managing roles with the AWS CLI](#)
- [Grant least privilege access to your Lambda execution role](#)
- [Viewing and updating permissions in the execution role](#)
- [Working with AWS managed policies in the execution role](#)
- [Using source function ARN to control function access behavior](#)

Creating an execution role in the IAM console

By default, Lambda creates an execution role with minimal permissions when you [create a function in the Lambda console](#). Specifically, this execution role includes the [AWSLambdaBasicExecutionRole managed policy](#), which gives your function basic permissions to log events to Amazon CloudWatch Logs.

Your functions typically need additional permissions to perform more meaningful tasks. For example, you might have a Lambda function that responds to an event by updating entries in an Amazon DynamoDB database. You can create an execution role with the necessary permissions using the IAM console.

To create an execution role in the IAM console

1. Open the [Roles page](#) in the IAM console.
2. Choose **Create role**.
3. Under **Trusted entity type**, choose **AWS service**.
4. Under **Use case**, choose **Lambda**.
5. Choose **Next**.
6. Select the AWS managed policies that you want to attach to your role. For example, if your function needs to access DynamoDB, select the **AWSLambdaDynamoDBExecutionRole** managed policy.
7. Choose **Next**.
8. Enter a **Role name** and then choose **Create role**.

For detailed instructions, see [Creating a role for an AWS service \(console\)](#) in the *IAM User Guide*.

After you create your execution role, attach it to your function. When you [create a function in the Lambda console](#), you can attach any execution role that you previously created to the function. If you want to attach a new execution role to an existing function, follow the steps in [the section called "Updating a function's execution role"](#).

Creating and managing roles with the AWS CLI

To create an execution role with the AWS Command Line Interface (AWS CLI), use the **create-role** command. When using this command, you can specify the trust policy inline. A role's trust policy gives the specified principals permission to assume the role. In the following example, you grant the Lambda service principal permission to assume your role. Note that requirements for escaping quotes in the JSON string may vary depending on your shell.

```
aws iam create-role \
  --role-name lambda-ex \
  --assume-role-policy-document '{"Version": "2012-10-17", "Statement":
  [{"Effect": "Allow", "Principal": {"Service": "lambda.amazonaws.com"}, "Action":
  "sts:AssumeRole"}]}'
```

You can also define the trust policy for the role using a separate JSON file. In the following example, `trust-policy.json` is a file in the current directory.

Example trust-policy.json

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "lambda.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

```
aws iam create-role \
  --role-name lambda-ex \
  --assume-role-policy-document file://trust-policy.json
```

To add permissions to the role, use the **attach-policy-to-role** command. The following command adds the `AWSLambdaBasicExecutionRole` managed policy to the `lambda-ex` execution role.

```
aws iam attach-role-policy --role-name lambda-ex --policy-arn arn:aws:iam::aws:policy/
service-role/AWSLambdaBasicExecutionRole
```

After you create your execution role, attach it to your function. When you [create a function in the Lambda console](#), you can attach any execution role that you previously created to the function. If you want to attach a new execution role to an existing function, follow the steps in [the section called "Updating a function's execution role"](#).

Grant least privilege access to your Lambda execution role

When you first create an IAM role for your Lambda function during the development phase, you might sometimes grant permissions beyond what is required. Before publishing your function in the production environment, as a best practice, adjust the policy to include only the required permissions. For more information, see [Apply least-privilege permissions](#) in the *IAM User Guide*.

Use IAM Access Analyzer to help identify the required permissions for the IAM execution role policy. IAM Access Analyzer reviews your AWS CloudTrail logs over the date range that you specify and generates a policy template with only the permissions that the function used during that time. You can use the template to create a managed policy with fine-grained permissions, and then attach it to the IAM role. That way, you grant only the permissions that the role needs to interact with AWS resources for your specific use case.

For more information, see [Generate policies based on access activity](#) in the *IAM User Guide*.

Viewing and updating permissions in the execution role

This topic covers how you can view and update your function's [execution role](#).

Topics

- [Viewing a function's execution role](#)
- [Updating a function's execution role](#)

Viewing a function's execution role

To view a function's execution role, use the Lambda console.

To view a function's execution role (console)

1. Open the [Functions page](#) of the Lambda console.
2. Choose the name of a function.
3. Choose **Configuration**, and then choose **Permissions**.
4. Under **Execution role**, you can view the role that's currently being used as the function's execution role. For convenience, you can view all the resources and actions that the function can access under the **Resource summary** section. You can also choose a service from the dropdown list to see all permissions related to that service.

Updating a function's execution role

You can add or remove permissions from a function's execution role at any time, or configure your function to use a different role. If your function needs access to any other services or resources, you must add the necessary permissions to the execution role.

When you add permissions to your function, perform a trivial update to its code or configuration as well. This forces running instances of your function, which have outdated credentials, to stop and be replaced.

To update a function's execution role, you can use the Lambda console.

To update a function's execution role (console)

1. Open the [Functions page](#) of the Lambda console.
2. Choose the name of a function.
3. Choose **Configuration**, and then choose **Permissions**.
4. Under **Execution role**, choose **Edit**.
5. If you want to update your function to use a different role as the execution role, choose the new role in the dropdown menu under **Existing role**.

Note

If you want to update the permissions within an existing execution role, you can only do so in the AWS Identity and Access Management (IAM) console.

If you want to create a new role to use as the execution role, choose **Create a new role from AWS policy templates** under **Execution role**. Then, enter a name for your new role under **Role name**, and specify any policies you want to attach to the new role under **Policy templates**.

6. Choose **Save**.

Working with AWS managed policies in the execution role

The following AWS managed policies provide permissions that are required to use Lambda features.

Change	Description	Date
AWSLambdaMSKExecutionRole – Lambda added the kafka:DescribeClusterV2 permission to this policy.	AWSLambdaMSKExecutionRole grants permissions to read and access records from an Amazon Managed	June 17, 2022

Change	Description	Date
	Streaming for Apache Kafka (Amazon MSK) cluster, manage elastic network interfaces (ENIs), and write to CloudWatch Logs.	
<u>AWSLambdaBasicExecutionRole</u> – Lambda started tracking changes to this policy.	AWSLambdaBasicExecutionRole grants permissions to upload logs to CloudWatch.	February 14, 2022
<u>AWSLambdaDynamoDBExecutionRole</u> – Lambda started tracking changes to this policy.	AWSLambdaDynamoDBExecutionRole grants permissions to read records from an Amazon DynamoDB stream and write to CloudWatch Logs.	February 14, 2022
<u>AWSLambdaKinesisExecutionRole</u> – Lambda started tracking changes to this policy.	AWSLambdaKinesisExecutionRole grants permissions to read events from an Amazon Kinesis data stream and write to CloudWatch Logs.	February 14, 2022
<u>AWSLambdaMSKExecutionRole</u> – Lambda started tracking changes to this policy.	AWSLambdaMSKExecutionRole grants permissions to read and access records from an Amazon Managed Streaming for Apache Kafka (Amazon MSK) cluster, manage elastic network interfaces (ENIs), and write to CloudWatch Logs.	February 14, 2022

Change	Description	Date
<u>AWSLambdaSQSQueueExecutionRole</u> – Lambda started tracking changes to this policy.	AWSLambdaSQSQueueExecutionRole grants permissions to read a message from an Amazon Simple Queue Service (Amazon SQS) queue and write to CloudWatch Logs.	February 14, 2022
<u>AWSLambdaVPCAccessExecutionRole</u> – Lambda started tracking changes to this policy.	AWSLambdaVPCAccessExecutionRole grants permissions to manage ENIs within an Amazon VPC and write to CloudWatch Logs.	February 14, 2022
<u>AWSXRayDaemonWriteAccess</u> – Lambda started tracking changes to this policy.	AWSXRayDaemonWriteAccess grants permissions to upload trace data to X-Ray.	February 14, 2022
<u>CloudWatchLambdaInsightsExecutionRolePolicy</u> – Lambda started tracking changes to this policy.	CloudWatchLambdaInsightsExecutionRolePolicy grants permissions to write runtime metrics to CloudWatch Lambda Insights.	February 14, 2022
<u>AmazonS3ObjectLambdaExecutionRolePolicy</u> – Lambda started tracking changes to this policy.	AmazonS3ObjectLambdaExecutionRolePolicy grants permissions to interact with Amazon Simple Storage Service (Amazon S3) object Lambda and to write to CloudWatch Logs.	February 14, 2022

For some features, the Lambda console attempts to add missing permissions to your execution role in a customer managed policy. These policies can become numerous. To avoid creating extra policies, add the relevant AWS managed policies to your execution role before enabling features.

When you use an [event source mapping](#) to invoke your function, Lambda uses the execution role to read event data. For example, an event source mapping for Kinesis reads events from a data stream and sends them to your function in batches.

When a service assumes a role in your account, you can include the `aws:SourceAccount` and `aws:SourceArn` global condition context keys in your role trust policy to limit access to the role to only requests that are generated by expected resources. For more information, see [Cross-service confused deputy prevention for AWS Security Token Service](#).

In addition to the AWS managed policies, the Lambda console provides templates for creating a custom policy with permissions for additional use cases. When you create a function in the Lambda console, you can choose to create a new execution role with permissions from one or more templates. These templates are also applied automatically when you create a function from a blueprint, or when you configure options that require access to other services. Example templates are available in this guide's [GitHub repository](#).

Using source function ARN to control function access behavior

It's common for your Lambda function code to make API requests to other AWS services. To make these requests, Lambda generates an ephemeral set of credentials by assuming your function's execution role. These credentials are available as environment variables during your function's invocation. When working with AWS SDKs, you don't need to provide credentials for the SDK directly in code. By default, the credential provider chain sequentially checks each place where you can set credentials and selects the first one available—usually the environment variables (`AWS_ACCESS_KEY_ID`, `AWS_SECRET_ACCESS_KEY`, and `AWS_SESSION_TOKEN`).

Lambda injects the source function ARN into the credentials context if the request is an AWS API request that comes from within your execution environment. Lambda also injects the source function ARN for the following AWS API requests that Lambda makes on your behalf outside of your execution environment:

Service	Action	Reason
CloudWatch Logs	CreateLogGroup , CreateLogStream , PutLogEvents	To store logs into a CloudWatch Logs log group
X-Ray	PutTraceSegments	To send trace data to X-Ray
Amazon EFS	ClientMount	To connect your function to an Amazon Elastic File System (Amazon EFS) file system

Other AWS API calls that Lambda makes outside of your execution environment on your behalf using the same execution role don't contain the source function ARN. Examples of such API calls outside the execution environment include:

- Calls to AWS Key Management Service (AWS KMS) to automatically encrypt and decrypt your environment variables.
- Calls to Amazon Elastic Compute Cloud (Amazon EC2) to create elastic network interfaces (ENIs) for a VPC-enabled function.
- Calls to AWS services, such as Amazon Simple Queue Service (Amazon SQS), to read from an event source that's set up as an [event source mapping](#).

With the source function ARN in the credentials context, you can verify whether a call to your resource came from a specific Lambda function's code. To verify this, use the `lambda:SourceFunctionArn` condition key in an IAM identity-based policy or [service control policy \(SCP\)](#).

Note

You cannot use the `lambda:SourceFunctionArn` condition key in resource-based policies.

With this condition key in your identity-based policies or SCPs, you can implement security controls for the API actions that your function code makes to other AWS services. This has a few key security applications, such as helping you identify the source of a credential leak.

Note

The `lambda:SourceFunctionArn` condition key is different from the `lambda:FunctionArn` and `aws:SourceArn` condition keys. The `lambda:FunctionArn` condition key applies only to [event source mappings](#) and helps define which functions your event source can invoke. The `aws:SourceArn` condition key applies only to policies where your Lambda function is the target resource, and helps define which other AWS services and resources can invoke that function. The `lambda:SourceFunctionArn` condition key can apply to any identity-based policy or SCP to define the specific Lambda functions that have permissions to make specific AWS API calls to other resources.

To use `lambda:SourceFunctionArn` in your policy, include it as a condition with any of the [ARN condition operators](#). The value of the key must be a valid ARN.

For example, suppose your Lambda function code makes an `s3:PutObject` call that targets a specific Amazon S3 bucket. You might want to allow only one specific Lambda function to have `s3:PutObject` access that bucket. In this case, your function's execution role should have a policy attached that looks like this:

Example policy granting a specific Lambda function access to an Amazon S3 resource

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ExampleSourceFunctionArn",
      "Effect": "Allow",
      "Action": "s3:PutObject",
      "Resource": "arn:aws:s3:::lambda_bucket/*",
      "Condition": {
        "ArnEquals": {
          "lambda:SourceFunctionArn": "arn:aws:lambda:us-east-1:123456789012:function:source_lambda"
        }
      }
    }
  ]
}
```

```

    }
  }
}

```

This policy allows only `s3:PutObject` access if the source is the Lambda function with ARN `arn:aws:lambda:us-east-1:123456789012:function:source_lambda`. This policy doesn't allow `s3:PutObject` access to any other calling identity. This is true even if a different function or entity makes an `s3:PutObject` call with the same execution role.

Note

The `lambda:SourceFunctionARN` condition key doesn't support Lambda function versions or function aliases. If you use the ARN for a particular function version or alias, your function won't have permission to take the action you specify. Be sure to use the unqualified ARN for your function without a version or alias suffix.

You can also use `lambda:SourceFunctionArn` in SCPs. For example, suppose you want to restrict access to your bucket to either a single Lambda function's code or to calls from a specific Amazon Virtual Private Cloud (VPC). The following SCP illustrates this.

Example policy denying access to Amazon S3 under specific conditions

JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "s3:*"
      ],
      "Resource": "arn:aws:s3:::lambda_bucket/*",
      "Effect": "Deny",
      "Condition": {
        "StringNotEqualsIfExists": {
          "aws:SourceVpc": [

```

```

        "vpc-12345678"
    ]
}
},
{
    "Action": [
        "s3:*"
    ],
    "Resource": "arn:aws:s3:::lambda_bucket/*",
    "Effect": "Deny",
    "Condition": {
        "ArnNotEqualsIfExists": {
            "lambda:SourceFunctionArn": "arn:aws:lambda:us-
east-1:123456789012:function:source_lambda"
        }
    }
}
]
}

```

This policy denies all S3 actions unless they come from a specific Lambda function with ARN `arn:aws:lambda:*:123456789012:function:source_lambda`, or unless they come from the specified VPC. The `StringNotEqualsIfExists` operator tells IAM to process this condition only if the `aws:SourceVpc` key is present in the request. Similarly, IAM considers the `ArnNotEqualsIfExists` operator only if the `lambda:SourceFunctionArn` exists.

Granting other AWS entities access to your Lambda functions

To give other AWS accounts, organizations, and services permissions to access your Lambda resources, you have a few options:

- You can use [identity-based policies](#) to grant other users access to your Lambda resources. Identity-based policies can apply to users directly, or to groups and roles that are associated with a user.
- You can use [resource-based policies](#) to give other accounts and AWS services permissions to access your Lambda resources. When a user tries to access a Lambda resource, Lambda considers both the user's identity-based policies and the resource's resource-based policy. When an AWS service such as Amazon Simple Storage Service (Amazon S3) calls your Lambda function, Lambda considers only the resource-based policy.
- You can use an [attribute-based access control \(ABAC\)](#) model to control access to your Lambda functions. With ABAC, you can attach tags to a Lambda function, pass them in certain API requests, or attach them to the IAM principal making the request. Specify the same tags in the condition element of an IAM policy to control function access.

To help you fine-tune your permissions for least-privilege access, Lambda provides some additional conditions you can include in your policies. For more information, see [the section called “Resources and Conditions”](#).

Identity-based IAM policies for Lambda

You can use identity-based policies in AWS Identity and Access Management (IAM) to grant users in your account access to Lambda. Identity-based policies can apply to users, user groups, or roles. You can also grant users in another account permission to assume a role in your account and access your Lambda resources.

Lambda provides AWS managed policies that grant access to Lambda API actions and, in some cases, access to other AWS services used to develop and manage Lambda resources. Lambda updates these managed policies as needed to ensure that your users have access to new features when they're released.

- [AWSLambda_FullAccess](#) – Grants full access to Lambda actions and other AWS services used to develop and maintain Lambda resources.
- [AWSLambda_ReadOnlyAccess](#) – Grants read-only access to Lambda resources.

- [AWSLambdaRole](#) – Grants permissions to invoke Lambda functions.

AWS managed policies grant permission to API actions without restricting the Lambda functions or layers that a user can modify. For finer-grained control, you can create your own policies that limit the scope of a user's permissions.

Topics

- [Granting users access to a Lambda function](#)
- [Granting users access to a Lambda layer](#)

Granting users access to a Lambda function

Use [identity-based policies](#) to allow users, user groups, or roles to perform operations on Lambda functions.

Note

For a function defined as a container image, the user permission to access the image must be configured in Amazon Elastic Container Registry (Amazon ECR). For an example, see [Amazon ECR repository policies](#).

The following shows an example of a permissions policy with limited scope. It allows a user to create and manage Lambda functions named with a designated prefix (intern-), and configured with a designated execution role.

Example Function development policy

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ReadOnlyPermissions",
      "Effect": "Allow",
      "Action": [
        "lambda:GetAccountSettings",
```

```

        "lambda:GetEventSourceMapping",
        "lambda:GetFunction",
        "lambda:GetFunctionConfiguration",
        "lambda:GetFunctionCodeSigningConfig",
        "lambda:GetFunctionConcurrency",
        "lambda:ListEventSourceMappings",
        "lambda:ListFunctions",
        "lambda:ListTags",
        "iam:ListRoles"
    ],
    "Resource": "*"
},
{
    "Sid": "DevelopFunctions",
    "Effect": "Allow",
    "NotAction": [
        "lambda:AddPermission",
        "lambda:PutFunctionConcurrency"
    ],
    "Resource": "arn:aws:lambda:*:*:function:intern-*"
},
{
    "Sid": "DevelopEventSourceMappings",
    "Effect": "Allow",
    "Action": [
        "lambda>DeleteEventSourceMapping",
        "lambda:UpdateEventSourceMapping",
        "lambda>CreateEventSourceMapping"
    ],
    "Resource": "*",
    "Condition": {
        "ArnLike": {
            "lambda:FunctionArn": "arn:aws:lambda:*:*:function:intern-*"
        }
    }
},
{
    "Sid": "PassExecutionRole",
    "Effect": "Allow",
    "Action": [
        "iam:ListRolePolicies",
        "iam:ListAttachedRolePolicies",
        "iam:GetRole",
        "iam:GetRolePolicy",

```

```

        "iam:PassRole",
        "iam:SimulatePrincipalPolicy"
    ],
    "Resource": "arn:aws:iam::*:role/intern-lambda-execution-role"
},
{
    "Sid": "ViewLogs",
    "Effect": "Allow",
    "Action": [
        "logs:*"
    ],
    "Resource": "arn:aws:logs:*:*:log-group:/aws/lambda/intern-*"
}
]
}

```

The permissions in the policy are organized into statements based on the [resources and conditions](#) that they support.

- **ReadOnlyPermissions** – The Lambda console uses these permissions when you browse and view functions. They don't support resource patterns or conditions.

```

    "Action": [
        "lambda:GetAccountSettings",
        "lambda:GetEventSourceMapping",
        "lambda:GetFunction",
        "lambda:GetFunctionConfiguration",
        "lambda:GetFunctionCodeSigningConfig",
        "lambda:GetFunctionConcurrency",
        "lambda:ListEventSourceMappings",
        "lambda:ListFunctions",
        "lambda:ListTags",
        "iam:ListRoles"
    ],
    "Resource": "*"

```

- **DevelopFunctions** – Use any Lambda action that operates on functions prefixed with `intern-`, except `AddPermission` and `PutFunctionConcurrency`. `AddPermission` modifies the [resource-based policy](#) on the function and can have security implications.

PutFunctionConcurrency reserves scaling capacity for a function and can take capacity away from other functions.

```
"NotAction": [
    "lambda:AddPermission",
    "lambda:PutFunctionConcurrency"
],
"Resource": "arn:aws:lambda:*:*:function:intern-*
```

- **DevelopEventSourceMappings** – Manage event source mappings on functions that are prefixed with `intern-`. These actions operate on event source mappings, but you can restrict them by function with a *condition*.

```
"Action": [
    "lambda:DeleteEventSourceMapping",
    "lambda:UpdateEventSourceMapping",
    "lambda:CreateEventSourceMapping"
],
"Resource": "*",
"Condition": {
    "StringLike": {
        "lambda:FunctionArn": "arn:aws:lambda:*:*:function:intern-*"
    }
}
```

- **PassExecutionRole** – View and pass only a role named `intern-lambda-execution-role`, which must be created and managed by a user with IAM permissions. `PassRole` is used when you assign an execution role to a function.

```
"Action": [
    "iam:ListRolePolicies",
    "iam:ListAttachedRolePolicies",
    "iam:GetRole",
    "iam:GetRolePolicy",
    "iam:PassRole",
    "iam:SimulatePrincipalPolicy"
],
"Resource": "arn:aws:iam:*:*:role/intern-lambda-execution-role"
```

- **ViewLogs** – Use CloudWatch Logs to view logs for functions that are prefixed with `intern-`.

```
"Action": [  
    "logs:*"  
],  
"Resource": "arn:aws:logs:*:*:log-group:/aws/lambda/intern-*
```

This policy allows a user to get started with Lambda, without putting other users' resources at risk. It doesn't allow a user to configure a function to be triggered by or call other AWS services, which requires broader IAM permissions. It also doesn't include permission to services that don't support limited-scope policies, like CloudWatch and X-Ray. Use the read-only policies for these services to give the user access to metrics and trace data.

When you configure triggers for your function, you need access to use the AWS service that invokes your function. For example, to configure an Amazon S3 trigger, you need permission to use the Amazon S3 actions that manage bucket notifications. Many of these permissions are included in the [AWSLambda_FullAccess](#) managed policy.

Granting users access to a Lambda layer

Use [identity-based policies](#) to allow users, user groups, or roles to perform operations on Lambda layers. The following policy grants a user permission to create layers and use them with functions. The resource patterns allow the user to work in any AWS Region and with any layer version, as long as the name of the layer starts with `test-`.

Example layer development policy

JSON

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "PublishLayers",  
            "Effect": "Allow",  
            "Action": [  
                "lambda:PublishLayerVersion"  
            ],  
            "Resource": "arn:aws:lambda:*:*:layer:*/*"
```

```

        "Resource": "arn:aws:lambda:*:*:layer:test-*"
    },
    {
        "Sid": "ManageLayerVersions",
        "Effect": "Allow",
        "Action": [
            "lambda:GetLayerVersion",
            "lambda:DeleteLayerVersion"
        ],
        "Resource": "arn:aws:lambda:*:*:layer:test-*:*"
    }
]
}

```

You can also enforce layer use during function creation and configuration with the `lambda:Layer` condition. For example, you can prevent users from using layers published by other accounts. The following policy adds a condition to the `CreateFunction` and `UpdateFunctionConfiguration` actions to require that any layers specified come from account 123456789012.

JSON

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ConfigureFunctions",
            "Effect": "Allow",
            "Action": [
                "lambda:CreateFunction",
                "lambda:UpdateFunctionConfiguration"
            ],
            "Resource": "*",
            "Condition": {
                "ForAllValues:StringLike": {
                    "lambda:Layer": [
                        "arn:aws:lambda:*:123456789012:layer:*:*"
                    ]
                }
            }
        }
    ]
}

```

```
]
}
```

To ensure that the condition applies, verify that no other statements grant the user permission to these actions.

Viewing resource-based IAM policies in Lambda

Lambda supports resource-based permissions policies for Lambda functions and layers. You can use resource-based policies to grant access to other [AWS accounts](#), [organizations](#), or [services](#). Resource-based policies apply to a single function, version, alias, or layer version.

Console

To view a function's resource-based policy

1. Open the [Functions page](#) of the Lambda console.
2. Choose a function.
3. Choose **Configuration** and then choose **Permissions**.
4. Scroll down to **Resource-based policy** and then choose **View policy document**. The resource-based policy shows the permissions that are applied when another account or AWS service attempts to access the function. The following example shows a statement that allows Amazon S3 to invoke a function named `my-function` for a bucket named `amzn-s3-demo-bucket` in account `123456789012`.

Example resource-based policy

```
{
  "Version": "2012-10-17",
  "Id": "default",
  "Statement": [
    {
      "Sid": "lambda-allow-s3-my-function",
      "Effect": "Allow",
      "Principal": {
        "Service": "s3.amazonaws.com"
      },
      "Action": "lambda:InvokeFunction",
```

```

        "Resource": "arn:aws:lambda:us-east-2:123456789012:function:my-
function",
        "Condition": {
            "StringEquals": {
                "AWS:SourceAccount": "123456789012"
            },
            "ArnLike": {
                "AWS:SourceArn": "arn:aws:s3:::amzn-s3-demo-bucket"
            }
        }
    }
]
}

```

AWS CLI

To view a function's resource-based policy, use the `get-policy` command.

```

aws lambda get-policy \
  --function-name my-function \
  --output text

```

You should see the following output:

```

{"Version":"2012-10-17",      "Id":"default","Statement":
[{"Sid":"sns","Effect":"Allow","Principal":
{"Service":"s3.amazonaws.com"},"Action":"lambda:InvokeFunction","Resource":"arn:aws:lambda:us-east-2:123456789012:function:my-function","Condition":{"ArnLike":{"AWS:SourceArn":"arn:aws:sns:us-east-2:123456789012:lambda*"}}}]

```

For versions and aliases, append the version number or alias to the function name.

```

aws lambda get-policy --function-name my-function:PROD

```

To remove permissions from your function, use `remove-permission`.

```

aws lambda remove-permission \
  --function-name example \

```

```
--statement-id sns
```

Use the `get-layer-version-policy` command to view the permissions on a layer.

```
aws lambda get-layer-version-policy \  
  --layer-name my-layer \  
  --version-number 3 \  
  --output text
```

You should see the following output:

```
b0cd9796-d4eb-4564-939f-de7fe0b42236    {"Sid":"engineering-  
org","Effect":"Allow","Principal":"*","Action":"lambda:GetLayerVersion","Resource":"arn:aws:  
west-2:123456789012:layer:my-layer:3","Condition":{"StringEquals":  
{"aws:PrincipalOrgID":"o-t194hfs8cz"}}}"
```

Use `remove-layer-version-permission` to remove statements from the policy.

```
aws lambda remove-layer-version-permission --layer-name my-layer --version-number 3  
  --statement-id engineering-org
```

Supported API actions

The following Lambda API actions support resource-based policies:

- [CreateAlias](#)
- [DeleteAlias](#)
- [DeleteFunction](#)
- [DeleteFunctionConcurrency](#)
- [DeleteFunctionEventInvokeConfig](#)
- [DeleteProvisionedConcurrencyConfig](#)
- [GetAlias](#)
- [GetFunction](#)
- [GetFunctionConcurrency](#)
- [GetFunctionConfiguration](#)

- [GetFunctionEventInvokeConfig](#)
- [GetPolicy](#)
- [GetProvisionedConcurrencyConfig](#)
- [Invoke](#)
- [InvokeFunctionUrl](#) (permission only)
- [ListAliases](#)
- [ListFunctionEventInvokeConfigs](#)
- [ListProvisionedConcurrencyConfigs](#)
- [ListTags](#)
- [ListVersionsByFunction](#)
- [PublishVersion](#)
- [PutFunctionConcurrency](#)
- [PutFunctionEventInvokeConfig](#)
- [PutProvisionedConcurrencyConfig](#)
- [TagResource](#)
- [UntagResource](#)
- [UpdateAlias](#)
- [UpdateFunctionCode](#)
- [UpdateFunctionEventInvokeConfig](#)

Granting Lambda function access to AWS services

When you [use an AWS service to invoke your function](#), you grant permission in a statement on a resource-based policy. You can apply the statement to the entire function, or limit the statement to a single version or alias.

Note

When you add a trigger to your function with the Lambda console, the console updates the function's resource-based policy to allow the service to invoke it. To grant permissions to other accounts or services that aren't available in the Lambda console, you can use the AWS CLI.

Add a statement with the [add-permission](#) command. The simplest resource-based policy statement allows a service to invoke a function. The following command grants Amazon Simple Notification Service permission to invoke a function named `my-function`.

```
aws lambda add-permission \  
  --function-name my-function \  
  --action lambda:InvokeFunction \  
  --statement-id sns \  
  --principal sns.amazonaws.com \  
  --output text
```

You should see the following output:

```
{"Sid":"sns","Effect":"Allow","Principal":  
{"Service":"sns.amazonaws.com"},"Action":"lambda:InvokeFunction","Resource":"arn:aws:lambda:us-  
east-2:123456789012:function:my-function"}
```

This lets Amazon SNS call the [Invoke](#) API action on the function, but it doesn't restrict the Amazon SNS topic that triggers the invocation. To ensure that your function is only invoked by a specific resource, specify the Amazon Resource Name (ARN) of the resource with the `source-arn` option. The following command only allows Amazon SNS to invoke the function for subscriptions to a topic named `my-topic`.

```
aws lambda add-permission \  
  --function-name my-function \  
  --action lambda:InvokeFunction \  
  --statement-id sns-my-topic \  
  --principal sns.amazonaws.com \  
  --source-arn arn:aws:sns:us-east-2:123456789012:my-topic
```

Some services can invoke functions in other accounts. If you specify a source ARN that has your account ID in it, that isn't an issue. For Amazon S3, however, the source is a bucket whose ARN doesn't have an account ID in it. It's possible that you could delete the bucket and another account could create a bucket with the same name. Use the `source-account` option with your account ID to ensure that only resources in your account can invoke the function.

```
aws lambda add-permission \  
  --function-name my-function \  
  --action lambda:InvokeFunction \  
  --statement-id s3-account \  
  --source-account 123456789012
```

```
--principal s3.amazonaws.com \  
--source-arn arn:aws:s3:::amzn-s3-demo-bucket \  
--source-account 123456789012
```

Granting function access to an organization

To grant permissions to an organization in [AWS Organizations](#), specify the organization ID as the `principal-org-id`. The following [add-permission](#) command grants invocation access to all users in organization o-a1b2c3d4e5f.

```
aws lambda add-permission \  
  --function-name example \  
  --statement-id PrincipalOrgIDExample \  
  --action lambda:InvokeFunction \  
  --principal * \  
  --principal-org-id o-a1b2c3d4e5f
```

Note

In this command, `Principal` is `*`. This means that all users in the organization o-a1b2c3d4e5f get function invocation permissions. If you specify an AWS account or role as the `Principal`, then only that principal gets function invocation permissions, but only if they are also part of the o-a1b2c3d4e5f organization.

This command creates a resource-based policy that looks like the following:

JSON

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Sid": "PrincipalOrgIDExample",  
      "Effect": "Allow",  
      "Principal": "*",  
      "Action": "lambda:InvokeFunction",  
      "Resource": "arn:aws:lambda:us-east-2:123456789012:function:example",  
      "Condition": {  
        "StringEquals": {
```

```

    "aws:PrincipalOrgID": "o-a1b2c3d4e5f"
  }
}
]
}

```

For more information, see [aws:PrincipalOrgID](#) in the *IAM user guide*.

Granting Lambda function access to other accounts

To share a function with another AWS account, add a cross-account permissions statement to the function's [resource-based policy](#). Run the [add-permission](#) command and specify the account ID as the principal. The following example grants account 111122223333 permission to invoke my-function with the prod alias.

```

aws lambda add-permission \
  --function-name my-function:prod \
  --statement-id xaccount \
  --action lambda:InvokeFunction \
  --principal 111122223333 \
  --output text

```

You should see the following output:

```

{"Sid":"xaccount","Effect":"Allow","Principal":
{"AWS":"arn:aws:iam::111122223333:root"},"Action":"lambda:InvokeFunction","Resource":"arn:aws:lambda:us-east-1:123456789012:function:my-function"}

```

The resource-based policy grants permission for the other account to access the function, but doesn't allow users in that account to exceed their permissions. Users in the other account must have the corresponding [user permissions](#) to use the Lambda API.

To limit access to a user or role in another account, specify the full ARN of the identity as the principal. For example, `arn:aws:iam::123456789012:user/developer`.

The [alias](#) limits which version the other account can invoke. It requires the other account to include the alias in the function ARN.

```

aws lambda invoke \

```

```
--function-name arn:aws:lambda:us-east-2:123456789012:function:my-function:prod out
```

You should see the following output:

```
{
  "StatusCode": 200,
  "ExecutedVersion": "1"
}
```

The function owner can then update the alias to point to a new version without the caller needing to change the way they invoke your function. This ensures that the other account doesn't need to change its code to use the new version, and it only has permission to invoke the version of the function associated with the alias.

You can grant cross-account access for most API actions that operate on an existing function. For example, you could grant access to `lambda:ListAliases` to let an account get a list of aliases, or `lambda:GetFunction` to let them download your function code. Add each permission separately, or use `lambda:*` to grant access to all actions for the specified function.

To grant other accounts permission for multiple functions, or for actions that don't operate on a function, we recommend that you use [IAM roles](#).

Granting Lambda layer access to other accounts

To share a layer with another AWS account, add a cross-account permissions statement to the layer's [resource-based policy](#). Run the [add-layer-version-permission](#) command and specify the account ID as the principal. In each statement, you can grant permission to a single account, all accounts, or an organization in [AWS Organizations](#).

The following example grants account 111122223333 access to version 2 of the `bash-runtime` layer.

```
aws lambda add-layer-version-permission \
  --layer-name bash-runtime \
  --version-number 2 \
  --statement-id xaccount \
  --action lambda:GetLayerVersion \
  --principal 111122223333 \
  --output text
```

You should see output similar to the following:

```
{
  "Sid": "xaccount",
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:root"
  },
  "Action": "lambda:GetLayerVersion",
  "Resource": "arn:aws:lambda:us-east-1:123456789012:layer:bash-runtime:2"
}
```

Permissions apply only to a single layer version. Repeat the process each time that you create a new layer version.

To grant permission to all accounts in an [AWS Organizations](#) organization, use the `organization-id` option. The following example grants all accounts in organization `o-t194hfs8cz` permission to use version 3 of `my-layer`.

```
aws lambda add-layer-version-permission \
  --layer-name my-layer \
  --version-number 3 \
  --statement-id engineering-org \
  --principal '*' \
  --action lambda:GetLayerVersion \
  --organization-id o-t194hfs8cz \
  --output text
```

You should see the following output:

```
{
  "Sid": "engineering-org",
  "Effect": "Allow",
  "Principal": "*",
  "Action": "lambda:GetLayerVersion",
  "Resource": "arn:aws:lambda:us-east-2:123456789012:layer:my-layer:3",
  "Condition": {
    "StringEquals": {
      "aws:PrincipalOrgID": "o-t194hfs8cz"
    }
  }
}
```

To grant permission to multiple accounts or organizations, you must add multiple statements.

Using attribute-based access control in Lambda

With [attribute-based access control \(ABAC\)](#), you can use tags to control access to your Lambda resources. You can attach tags to certain Lambda resources, attach them to certain API requests, or attach them to the AWS Identity and Access Management (IAM) principal making the request. For more information about how AWS grants attribute-based access, see [Controlling access to AWS resources using tags](#) in the *IAM User Guide*.

You can use ABAC to [grant least privilege](#) without specifying an Amazon Resource Name (ARN) or ARN pattern in the IAM policy. Instead, you can specify a tag in the [condition element](#) of an IAM

policy to control access. Scaling is easier with ABAC because you don't have to update your IAM policies when you create new resources. Instead, add tags to the new resources to control access.

In Lambda, tags work on the following resources:

- Functions—For more information on tagging functions see, [the section called “Tags”](#).
- Code signing configurations—For more information on tagging code signing configurations, see [the section called “Code signing configuration tags”](#).
- Event source mappings—For more information on tagging event source mappings, see [the section called “Event source mapping tags”](#).

Tags aren't supported for layers.

You can use the following condition keys to write IAM policy rules based on tags:

- [aws:ResourceTag/tag-key](#): Control access based on the tags that are attached to a Lambda resource.
- [aws:RequestTag/tag-key](#): Require tags to be present in a request, such as when creating a new function.
- [aws:PrincipalTag/tag-key](#): Control what the IAM principal (the person making the request) is allowed to do based on the tags that are attached to their IAM [user](#) or [role](#).
- [aws:TagKeys](#): Control whether specific tag keys can be used in a request.

You can only specify conditions for actions that support them. For a list of conditions supported by each Lambda action, see [Actions, resources, and condition keys for AWS Lambda](#) in the Service Authorization Reference. For **aws:ResourceTag/tag-key** support, refer to "Resource types defined by AWS Lambda." For **aws:RequestTag/tag-key** and **aws:TagKeys** support, refer to "Actions defined by AWS Lambda."

Topics

- [Secure your functions by tag](#)

Secure your functions by tag

The following steps demonstrate one way to set up permissions for functions using ABAC. In this example scenario, you'll create four IAM permissions policies. Then, you'll attach these policies to

a new IAM role. Finally, you'll create an IAM user and give that user permission to assume the new role.

Topics

- [Prerequisites](#)
- [Step 1: Require tags on new functions](#)
- [Step 2: Allow actions based on tags attached to a Lambda function and IAM principal](#)
- [Step 3: Grant list permissions](#)
- [Step 4: Grant IAM permissions](#)
- [Step 5: Create the IAM role](#)
- [Step 6: Create the IAM user](#)
- [Step 7: Test the permissions](#)
- [Step 8: Clean up your resources](#)

Prerequisites

Make sure that you have a [Lambda execution role](#). You'll use this role when you grant IAM permissions and when you create a Lambda function.

Step 1: Require tags on new functions

When using ABAC with Lambda, it's a best practice to require that all functions have tags. This helps ensure that your ABAC permissions policies work as expected.

[Create an IAM policy](#) similar to the following example. This policy uses the [aws:RequestTag/tag-key](#), [aws:ResourceTag/tag-key](#), and [aws:TagKeys](#) condition keys to require that new functions and the IAM principal creating the functions both have the project tag. The `ForAllValues` modifier ensures that project is the only allowed tag. If you don't include the `ForAllValues` modifier, users can add other tags to the function as long as they also pass project.

Example– Require tags on new functions

JSON

```
{  
  "Version": "2012-10-17",
```

```

    "Statement": {
      "Effect": "Allow",
      "Action": [
        "lambda:CreateFunction",
        "lambda:TagResource"
      ],
      "Resource": "arn:aws:lambda:*:*:function:*",
      "Condition": {
        "StringEquals": {
          "aws:RequestTag/project": "${aws:PrincipalTag/project}",
          "aws:ResourceTag/project": "${aws:PrincipalTag/project}"
        },
        "ForAllValues:StringEquals": {
          "aws:TagKeys": "project"
        }
      }
    }
  }
}

```

Step 2: Allow actions based on tags attached to a Lambda function and IAM principal

Create a second IAM policy using the [aws:ResourceTag/tag-key](#) condition key to require the principal's tag to match the tag that's attached to the function. The following example policy allows principals with the `project` tag to invoke functions with the `project` tag. If a function has any other tags, the action is denied.

Example– Require matching tags on function and IAM principal

JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "lambda:InvokeFunction",
        "lambda:GetFunction"
      ],
      "Resource": "arn:aws:lambda:*:*:function:*",
      "Condition": {

```

```

        "StringEquals": {
            "aws:ResourceTag/project": "${aws:PrincipalTag/project}"
        }
    }
}
]
}

```

Step 3: Grant list permissions

Create a policy that allows the principal to list Lambda functions and IAM roles. This allows the principal to see all Lambda functions and IAM roles on the console and when calling the API actions.

Example– Grant Lambda and IAM list permissions

JSON

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllResourcesLambdaNoTags",
            "Effect": "Allow",
            "Action": [
                "lambda:GetAccountSettings",
                "lambda:ListFunctions",
                "iam:ListRoles"
            ],
            "Resource": "*"
        }
    ]
}

```

Step 4: Grant IAM permissions

Create a policy that allows **iam:PassRole**. This permission is required when you assign an execution role to a function. In the following example policy, replace the example ARN with the ARN of your Lambda execution role.

Note

Do not use the `ResourceTag` condition key in a policy with the `iam:PassRole` action. You cannot use the tag on an IAM role to control access to who can pass that role. For more information about permissions required to pass a role to a service, see [Granting a user permissions to pass a role to an AWS service](#).

Example– Grant permission to pass the execution role

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": [
        "iam:PassRole"
      ],
      "Resource": "arn:aws:iam::111122223333:role/lambda-ex"
    }
  ]
}
```

Step 5: Create the IAM role

It's a best practice to [use roles to delegate permissions](#). [Create an IAM role](#) called `abac-project-role`:

- On **Step 1: Select trusted entity**: Choose **AWS account** and then choose **This account**.
- On **Step 2: Add permissions**: Attach the four IAM policies that you created in the previous steps.
- On **Step 3: Name, review, and create**: Choose **Add tag**. For **Key**, enter `project`. Don't enter a **Value**.

Step 6: Create the IAM user

[Create an IAM user](#) called `abac-test-user`. In the **Set permissions** section, choose **Attach existing policies directly** and then choose **Create policy**. Enter the following policy definition. Replace `111122223333` with your [AWS account ID](#). This policy allows `abac-test-user` to assume `abac-project-role`.

Example– Allow IAM user to assume ABAC role

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "sts:AssumeRole",
      "Resource": "arn:aws:iam::111122223333:role/abac-project-role"
    }
  ]
}
```

Step 7: Test the permissions

1. Sign in to the AWS console as `abac-test-user`. For more information, see [Sign in as an IAM user](#).
2. Switch to the `abac-project-role` role. For more information, see [Switching to a role \(console\)](#).
3. [Create a Lambda function](#):
 - Under **Permissions**, choose **Change default execution role**, and then for **Execution role**, choose **Use an existing role**. Choose the same execution role that you used in [Step 4: Grant IAM permissions](#).
 - Under **Advanced settings**, choose **Enable tags** and then choose **Add new tag**. For **Key**, enter `project`. Don't enter a **Value**.
4. [Test the function](#).
5. Create a second Lambda function and add a different tag, such as `environment`. This operation should fail because the ABAC policy that you created in [Step 1: Require tags on new functions](#) only allows the principal to create functions with the `project` tag.

6. Create a third function without tags. This operation should fail because the ABAC policy that you created in [Step 1: Require tags on new functions](#) doesn't allow the principal to create functions without tags.

This authorization strategy allows you to control access without creating new policies for each new user. To grant access to new users, simply give them permission to assume the role that corresponds to their assigned project.

Step 8: Clean up your resources

To delete the IAM role

1. Open the [Roles page](#) of the IAM console.
2. Select the role that you created in [step 5](#).
3. Choose **Delete**.
4. To confirm deletion, enter the role name in the text input field.
5. Choose **Delete**.

To delete the IAM user

1. Open the [Users page](#) of the IAM console.
2. Select the IAM user that you created in [step 6](#).
3. Choose **Delete**.
4. To confirm deletion, enter the user name in the text input field.
5. Choose **Delete user**.

To delete the Lambda function

1. Open the [Functions page](#) of the Lambda console.
2. Select the function that you created.
3. Choose **Actions, Delete**.
4. Type **confirm** in the text input field and choose **Delete**.

Fine-tuning the Resources and Conditions sections of policies

You can restrict the scope of a user's permissions by specifying resources and conditions in an AWS Identity and Access Management (IAM) policy. Each action in a policy supports a combination of resource and condition types that varies depending on the behavior of the action.

Every IAM policy statement grants permission to an action that's performed on a resource. When the action doesn't act on a named resource, or when you grant permission to perform the action on all resources, the value of the resource in the policy is a wildcard (*). For many actions, you can restrict the resources that a user can modify by specifying the Amazon Resource Name (ARN) of a resource, or an ARN pattern that matches multiple resources.

By resource type, the general design of how to restrict the scope of an action is the following:

- **Functions**—Actions that operate on a function can be restricted to a specific function by function, version, or alias ARN.
- **Event source mappings**—Actions can be restricted to specific event source mapping resources by ARN. Event source mappings are always associated with a function. You can also use the `lambda:FunctionArn` condition to restrict actions by associated function.
- **Layers**—Actions related to layer usage and permissions act on a version of a layer.
- **Code signing configuration**—Actions can be restricted to specific code signing configuration resources by ARN.
- **Tags**—Use standard tag conditions. For more information, see [the section called "Attribute-based access control"](#).

To restrict permissions by resource, specify the resource by ARN.

Lambda resource ARN format

- **Function** – `arn:aws:lambda:us-west-2:123456789012:function:my-function`
- **Function version** – `arn:aws:lambda:us-west-2:123456789012:function:my-function:1`
- **Function alias** – `arn:aws:lambda:us-west-2:123456789012:function:my-function:TEST`
- **Event source mapping** – `arn:aws:lambda:us-west-2:123456789012:event-source-mapping:fa123456-14a1-4fd2-9fec-83de64ad683de6d47`

- Layer – `arn:aws:lambda:us-west-2:123456789012:layer:my-layer`
- Layer version – `arn:aws:lambda:us-west-2:123456789012:layer:my-layer:1`
- Code signing configuration – `arn:aws:lambda:us-west-2:123456789012:code-signing-config:my-csc`

For example, the following policy allows a user in AWS account 123456789012 to invoke a function named `my-function` in the US West (Oregon) AWS Region.

Example invoke function policy

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Invoke",
      "Effect": "Allow",
      "Action": [
        "lambda:InvokeFunction"
      ],
      "Resource": "arn:aws:lambda:us-west-2:123456789012:function:my-  
function"
    }
  ]
}
```

This is a special case where the action identifier (`lambda:InvokeFunction`) differs from the API operation ([Invoke](#)). For other actions, the action identifier is the operation name prefixed by `lambda:`.

Sections

- [Understanding the Condition section in policies](#)
- [Referencing functions in the Resource section of policies](#)
- [Supported IAM actions and function behaviors](#)

Understanding the Condition section in policies

Conditions are an optional policy element that applies additional logic to determine if an action is allowed. In addition to common [conditions](#) that all actions support, Lambda defines condition types that you can use to restrict the values of additional parameters on some actions.

For example, the `lambda:Principal` condition lets you restrict the service or account that a user can grant invocation access to on a function's [resource-based policy](#). The following policy lets a user grant permission to Amazon Simple Notification Service (Amazon SNS) topics to invoke a function named `test`.

Example manage function policy permissions

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ManageFunctionPolicy",
      "Effect": "Allow",
      "Action": [
        "lambda:AddPermission",
        "lambda:RemovePermission"
      ],
      "Resource": "arn:aws:lambda:us-west-2:123456789012:function:test:*",
      "Condition": {
        "StringEquals": {
          "lambda:Principal": "sns.amazonaws.com"
        }
      }
    }
  ]
}
```

The condition requires that the principal is Amazon SNS and not another service or account. The resource pattern requires that the function name is `test` and includes a version number or alias. For example, `test:v1`.

For more information on resources and conditions for Lambda and other AWS services, see [Actions, resources, and condition keys for AWS services](#) in the *Service Authorization Reference*.

Referencing functions in the Resource section of policies

You reference a Lambda function in a policy statement using an Amazon Resource Name (ARN). The format of a function ARN depends on whether you are referencing the whole function (unqualified) or a function [version](#) or [alias](#) (qualified).

When making Lambda API calls, users can specify a version or alias by passing a version ARN or alias ARN in the [GetFunction](#) `FunctionName` parameter, or by setting a value in the [GetFunction](#) `Qualifier` parameter. Lambda makes authorization decisions by comparing the resource element in the IAM policy with both the `FunctionName` and `Qualifier` passed in API calls. If there is a mismatch, Lambda denies the request.

Whether you are allowing or denying an action on your function, you must use the correct function ARN types in your policy statement to achieve the results that you expect. For example, if your policy references the unqualified ARN, Lambda accepts requests that reference the unqualified ARN but denies requests that reference a qualified ARN.

Note

You can't use a wildcard character (*) to match the account ID. For more information on accepted syntax, see [IAM JSON policy reference](#) in the *IAM User Guide*.

Example allowing invocation of an unqualified ARN

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "lambda:InvokeFunction",
      "Resource": "arn:aws:lambda:us-west-2:123456789012:function:myFunction"
    }
  ]
}
```

```
}
```

If your policy references a specific qualified ARN, Lambda accepts requests that reference that ARN but denies requests that reference the unqualified ARN or a different qualified ARN, for example, `myFunction:2`.

Example allowing invocation of a specific qualified ARN

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "lambda:InvokeFunction",
      "Resource": "arn:aws:lambda:us-west-2:123456789012:function:myFunction:1"
    }
  ]
}
```

If your policy references any qualified ARN using `:*`, Lambda accepts any qualified ARN but denies requests that reference the unqualified ARN.

Example allowing invocation of any qualified ARN

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "lambda:InvokeFunction",
      "Resource": "arn:aws:lambda:us-west-2:123456789012:function:myFunction:*"
    }
  ]
}
```

```
}
```

If your policy references any ARN using *, Lambda accepts any qualified or unqualified ARN.

Example allowing invocation of any qualified or unqualified ARN

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "lambda:InvokeFunction",
      "Resource": "arn:aws:lambda:us-west-2:123456789012:function:myFunction*"
    }
  ]
}
```

Supported IAM actions and function behaviors

Actions define what can be permitted through IAM policies. For a list of actions supported in Lambda, see [Actions, resources, and condition keys for AWS Lambda](#) in the Service Authorization Reference. In most cases, when an IAM action permits an Lambda API action, the name of the IAM action is the same as the name of the Lambda API action, with the following exceptions:

API action	IAM action
Invoke	lambda:InvokeFunction
GetLayerVersion	lambda:GetLayerVersion
GetLayerVersionByArn	

In addition to the resources and conditions defined in the [Service Authorization Reference](#), Lambda supports the following resources and conditions for certain actions. Many of these are related to

referencing functions in the resource section of policies. Actions that operate on a function can be restricted to a specific function by function, version, or alias ARN, as described in the following table.

Action	Resource	Condition
AddPermission	Function version	N/A
RemovePermission	Function alias	
Invoke (Permission: <code>lambda:InvokeFunction</code>)		
UpdateFunctionConfiguration	N/A	<code>lambda:CodeSigningConfigArn</code>
CreateFunctionUrlConfig	Function alias	N/A
DeleteFunctionUrlConfig		
GetFunctionUrlConfig		
UpdateFunctionUrlConfig		

Security in AWS Lambda

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The [shared responsibility model](#) describes this as security *of* the cloud and security *in* the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the [AWS compliance programs](#). To learn about the compliance programs that apply to AWS Lambda, see [AWS services in Scope by Compliance Program](#).
- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your company's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Lambda. The following topics show you how to configure Lambda to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your Lambda resources.

For more information about applying security principles to Lambda applications, see [Security](#) in Serverless Land.

- [Using code signing to verify code integrity with Lambda](#)

Data protection in AWS Lambda

The AWS [shared responsibility model](#) applies to data protection in AWS Lambda. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the [Data Privacy FAQ](#). For information about data protection in Europe, see the [AWS Shared Responsibility Model and GDPR](#) blog post on the *AWS Security Blog*.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual users with AWS IAM Identity Center or AWS Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with AWS CloudTrail. For information about using CloudTrail trails to capture AWS activities, see [Working with CloudTrail trails](#) in the *AWS CloudTrail User Guide*.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-3 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see [Federal Information Processing Standard \(FIPS\) 140-3](#).

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a **Name** field. This includes when you work with Lambda or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Sections

- [Encryption in transit](#)
- [Data encryption at rest for AWS Lambda](#)

Encryption in transit

Lambda API endpoints only support secure connections over HTTPS. When you manage Lambda resources with the AWS Management Console, AWS SDK, or the Lambda API, all communication is encrypted with Transport Layer Security (TLS). For a full list of API endpoints, see [AWS Regions and endpoints](#) in the AWS General Reference.

When you [connect your function to a file system](#), Lambda uses encryption in transit for all connections. For more information, see [Data encryption in Amazon EFS](#) in the *Amazon Elastic File System User Guide*.

When you use [environment variables](#), you can enable console encryption helpers to use client-side encryption to protect the environment variables in transit. For more information, see [Securing Lambda environment variables](#).

Data encryption at rest for AWS Lambda

Lambda always provides at-rest encryption for the following resources using an [AWS owned key](#) or an [AWS managed key](#):

- Environment variables
- Files that you upload to Lambda, including deployment packages and layer archives
- Event source mapping filter criteria objects

You can optionally configure Lambda to use a customer managed key to encrypt your [environment variables](#), [.zip deployment packages](#), and [filter criteria objects](#).

Amazon CloudWatch Logs and AWS X-Ray also encrypt data by default, and can be configured to use a customer managed key. For details, see [Encrypt log data in CloudWatch Logs](#) and [Data protection in AWS X-Ray](#).

Monitoring your encryption keys for Lambda

When you use an AWS KMS customer managed key with Lambda, you can use [AWS CloudTrail](#). The following examples are CloudTrail events for Decrypt, DescribeKey, and GenerateDataKey calls made by Lambda to access data encrypted by your customer managed key.

Decrypt

If you used a AWS KMS customer managed key to encrypt your [filter criteria](#) object, Lambda sends a Decrypt request on your behalf when you try to access it in plaintext (for example, from a `ListEventSourceMappings` call). The following example event records the Decrypt operation:

```
{
  "eventVersion": "1.09",
  "userIdentity": {
    "type": "AssumedRole",
    "principalId": "AROAI23456789EXAMPLE:example",
    "arn": "arn:aws:sts::123456789012:assumed-role/role-name/example",
    "accountId": "123456789012",
    "accessKeyId": "ASIAIOSFODNN7EXAMPLE",
    "sessionContext": {
      "sessionIssuer": {
        "type": "Role",
        "principalId": "AROAI23456789EXAMPLE",
        "arn": "arn:aws:iam::123456789012:role/role-name",
        "accountId": "123456789012",
        "userName": "role-name"
      },
      "attributes": {
        "creationDate": "2024-05-30T00:45:23Z",
        "mfaAuthenticated": "false"
      }
    },
    "invokedBy": "lambda.amazonaws.com"
  },
  "eventTime": "2024-05-30T01:05:46Z",
  "eventSource": "kms.amazonaws.com",
  "eventName": "Decrypt",
  "awsRegion": "eu-west-1",
  "sourceIPAddress": "lambda.amazonaws.com",
  "userAgent": "lambda.amazonaws.com",
  "requestParameters": {
```

```

    "keyId": "arn:aws:kms:eu-west-1:123456789012:key/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
    "encryptionContext": {
        "aws-crypto-public-key": "ABCD
+7876787678+CDEFGHIJKL/888666888999888555444111555222888333111==",
        "aws:lambda:EventSourceArn": "arn:aws:sqs:eu-west-1:123456789012:sample-
source",
        "aws:lambda:FunctionArn": "arn:aws:lambda:eu-
west-1:123456789012:function:sample-function"
    },

"readOnly": true,
"resources": [
    {
        "accountId": "AWS Internal",
        "type": "AWS::KMS::Key",
        "ARN": "arn:aws:kms:eu-west-1:123456789012:key/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
    }
],
"eventType": "AwsApiCall",
"managementEvent": true,
"recipientAccountId": "123456789012",
"eventCategory": "Management",
"sessionCredentialFromConsole": "true"
}

```

DescribeKey

If you used a AWS KMS customer managed key to encrypt your [filter criteria](#) object, Lambda sends a DescribeKey request on your behalf when you try to access it (for example, from a GetEventSourceMapping call). The following example event records the DescribeKey operation:

```

{
    "eventVersion": "1.09",
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "AROAI23456789EXAMPLE:example",

```

```

    "arn": "arn:aws:sts::123456789012:assumed-role/role-name/example",
    "accountId": "123456789012",
    "accessKeyId": "ASIAIOSFODNN7EXAMPLE",
    "sessionContext": {
      "sessionIssuer": {
        "type": "Role",
        "principalId": "AROAI23456789EXAMPLE",
        "arn": "arn:aws:iam::123456789012:role/role-name",
        "accountId": "123456789012",
        "userName": "role-name"
      },
      "attributes": {
        "creationDate": "2024-05-30T00:45:23Z",
        "mfaAuthenticated": "false"
      }
    },
    "eventTime": "2024-05-30T01:09:40Z",
    "eventSource": "kms.amazonaws.com",
    "eventName": "DescribeKey",
    "awsRegion": "eu-west-1",
    "sourceIPAddress": "54.240.197.238",
    "userAgent": "Mozilla/5.0 (Macintosh; Intel Mac OS X 10_15_7) AppleWebKit/537.36
(KHTML, like Gecko) Chrome/125.0.0.0 Safari/537.36",
    "requestParameters": {
      "keyId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
    },
    "responseElements": null,
    "requestID": "a1b2c3d4-5678-90ab-cdef-EXAMPLEEaaaaa",
    "eventID": "a1b2c3d4-5678-90ab-cdef-EXAMPLEebbbb",
    "readOnly": true,
    "resources": [
      {
        "accountId": "AWS Internal",
        "type": "AWS::KMS::Key",
        "ARN": "arn:aws:kms:eu-west-1:123456789012:key/a1b2c3d4-5678-90ab-cdef-
EXAMPLE11111"
      }
    ],
    "eventType": "AwsApiCall",
    "managementEvent": true,
    "recipientAccountId": "123456789012",
    "eventCategory": "Management",
    "tlsDetails": {

```

```

        "tlsVersion": "TLSv1.3",
        "cipherSuite": "TLS_AES_256_GCM_SHA384",
        "clientProvidedHostHeader": "kms.eu-west-1.amazonaws.com"
    },
    "sessionCredentialFromConsole": "true"
}

```

GenerateDataKey

When you use a AWS KMS customer managed key to encrypt your [filter criteria](#) object in a `CreateEventSourceMapping` or `UpdateEventSourceMapping` call, Lambda sends a `GenerateDataKey` request on your behalf to generate a data key to encrypt the filter criteria ([envelope encryption](#)). The following example event records the `GenerateDataKey` operation:

```

{
  "eventVersion": "1.09",
  "userIdentity": {
    "type": "AssumedRole",
    "principalId": "AROAI23456789EXAMPLE:example",
    "arn": "arn:aws:sts::123456789012:assumed-role/role-name/example",
    "accountId": "123456789012",
    "accessKeyId": "ASIAIOSFODNN7EXAMPLE",
    "sessionContext": {
      "sessionIssuer": {
        "type": "Role",
        "principalId": "AROAI23456789EXAMPLE",
        "arn": "arn:aws:iam::123456789012:role/role-name",
        "accountId": "123456789012",
        "userName": "role-name"
      },
      "attributes": {
        "creationDate": "2024-05-30T00:06:07Z",
        "mfaAuthenticated": "false"
      }
    },
    "invokedBy": "lambda.amazonaws.com"
  },
  "eventTime": "2024-05-30T01:04:18Z",
  "eventSource": "kms.amazonaws.com",
  "eventName": "GenerateDataKey",
  "awsRegion": "eu-west-1",
  "sourceIPAddress": "lambda.amazonaws.com",
  "userAgent": "lambda.amazonaws.com",

```

```

    "requestParameters": {
      "numberOfBytes": 32,
      "keyId": "arn:aws:kms:eu-west-1:123456789012:key/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
      "encryptionContext": {
        "aws-crypto-public-key": "ABCD
+7876787678+CDEFGHIJKL/888666888999888555444111555222888333111==",
        "aws:lambda:EventSourceArn": "arn:aws:sqs:eu-west-1:123456789012:sample-
source",
        "aws:lambda:FunctionArn": "arn:aws:lambda:eu-
west-1:123456789012:function:sample-function"
      },
    },

```

Using service-linked roles for Lambda

Lambda uses AWS Identity and Access Management (IAM) [service-linked roles](#). A service-linked role is a unique type of IAM role that is linked directly to Lambda. Service-linked roles are predefined by Lambda and include permissions that the service requires to call other AWS services on your behalf.

Lambda defines the permissions of its service-linked roles, and only Lambda can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete a service-linked role only after first deleting their related resources. This protects your Lambda resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see [AWS services that work with IAM](#) and look for the services that have **Yes** in the **Service-linked roles** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Lambda

Lambda uses the service-linked role named **AWSServiceRoleForLambda**. The service-linked role trusts the following services to assume the role:

- `lambda.amazonaws.com`

The role permissions policy named **AWSLambdaServiceRolePolicy** allows Lambda to complete the following actions on the specified resources:

- Action: `ec2:TerminateInstances` on `arn:aws:ec2:*:*:instance/*` with the condition that `ec2:ManagedResourceOperator` equals `scaler.lambda.amazonaws.com`
- Action: `ec2:DescribeInstanceStatus` and `ec2:DescribeInstances` on `*`

You must configure permissions to allow your users, groups, or roles to create, edit, or delete a service-linked role. For more information, see [Service-linked role permissions](#) in the *IAM User Guide*.

For managed policy updates, see [Lambda managed policies](#).

Creating a service-linked role for Lambda

You don't need to manually create a service-linked role. When you create a Lambda capacity provider in the AWS Management Console, the AWS CLI, or the AWS API, Lambda creates the service-linked role for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a Lambda capacity provider, Lambda creates the service-linked role for you again.

You can also use the IAM console to create a service-linked role with the **AWSServiceRoleForLambda** use case. In the AWS CLI or the AWS API, create a service-linked role with the `lambda.amazonaws.com` service name. For more information, see [Creating a service-](#)

[linked role](#) in the *IAM User Guide*. If you delete this service-linked role, you can use this same process to create the role again.

Editing a service-linked role for Lambda

Lambda does not allow you to edit the `AWSServiceRoleForLambda` service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see [Editing a service-linked role](#) in the *IAM User Guide*.

Deleting a service-linked role for Lambda

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up the resources for your service-linked role before you can manually delete it.

Note

If the Lambda service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete Lambda resources used by the `AWSServiceRoleForLambda`

1. Remove all Lambda capacity providers from your account. You can do this using the Lambda console, CLI, or API.
2. Verify that no Lambda capacity providers remain in your account before attempting to delete the service-linked role.

To manually delete the service-linked role using IAM

Use the IAM console, the AWS CLI, or the AWS API to delete the `AWSServiceRoleForLambda` service-linked role. For more information, see [Deleting a service-linked role](#) in the *IAM User Guide*.

Supported Regions for Lambda service-linked roles

Lambda does not support using service-linked roles in every Region where the service is available. `AWSServiceRoleForLambda` is supported in the following Regions.

Region name	Region identity	Support in Lambda
US East (N. Virginia)	us-east-1	Yes
US East (Ohio)	us-east-2	Yes
US West (N. California)	us-west-1	Yes
US West (Oregon)	us-west-2	Yes
Africa (Cape Town)	af-south-1	No
Asia Pacific (Hong Kong)	ap-east-1	Yes
Asia Pacific (Jakarta)	ap-southeast-3	Yes
Asia Pacific (Bangkok)	ap-southeast-7	Yes
Asia Pacific (Mumbai)	ap-south-1	Yes
Asia Pacific (Osaka)	ap-northeast-3	No
Asia Pacific (Seoul)	ap-northeast-2	No
Asia Pacific (Singapore)	ap-southeast-1	Yes
Asia Pacific (Sydney)	ap-southeast-2	Yes
Asia Pacific (Tokyo)	ap-northeast-1	Yes
Canada (Central)	ca-central-1	No
Europe (Frankfurt)	eu-central-1	Yes
Europe (Ireland)	eu-west-1	Yes
Europe (London)	eu-west-2	Yes
Europe (Milan)	eu-south-1	No
Europe (Paris)	eu-west-3	No

Region name	Region identity	Support in Lambda
Europe (Stockholm)	eu-north-1	No
Middle East (Bahrain)	me-south-1	No
Middle East (UAE)	me-central-1	No
South America (São Paulo)	sa-east-1	No
AWS GovCloud (US-East)	us-gov-east-1	No
AWS GovCloud (US-West)	us-gov-west-1	No

Identity and Access Management for AWS Lambda

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Lambda resources. IAM is an AWS service that you can use with no additional charge.

Topics

- [Audience](#)
- [Authenticating with identities](#)
- [Managing access using policies](#)
- [How AWS Lambda works with IAM](#)
- [Identity-based policy examples for AWS Lambda](#)
- [AWS managed policies for AWS Lambda](#)
- [Troubleshooting AWS Lambda identity and access](#)

Audience

How you use AWS Identity and Access Management (IAM) differs based on your role:

- **Service user** - request permissions from your administrator if you cannot access features (see [Troubleshooting AWS Lambda identity and access](#))
- **Service administrator** - determine user access and submit permission requests (see [How AWS Lambda works with IAM](#))
- **IAM administrator** - write policies to manage access (see [Identity-based policy examples for AWS Lambda](#))

Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. You must be authenticated as the AWS account root user, an IAM user, or by assuming an IAM role.

You can sign in as a federated identity using credentials from an identity source like AWS IAM Identity Center (IAM Identity Center), single sign-on authentication, or Google/Facebook credentials. For more information about signing in, see [How to sign in to your AWS account](#) in the *AWS Sign-In User Guide*.

For programmatic access, AWS provides an SDK and CLI to cryptographically sign requests. For more information, see [AWS Signature Version 4 for API requests](#) in the *IAM User Guide*.

AWS account root user

When you create an AWS account, you begin with one sign-in identity called the AWS account *root user* that has complete access to all AWS services and resources. We strongly recommend that you don't use the root user for everyday tasks. For tasks that require root user credentials, see [Tasks that require root user credentials](#) in the *IAM User Guide*.

Federated identity

As a best practice, require human users to use federation with an identity provider to access AWS services using temporary credentials.

A *federated identity* is a user from your enterprise directory, web identity provider, or Directory Service that accesses AWS services using credentials from an identity source. Federated identities assume roles that provide temporary credentials.

For centralized access management, we recommend AWS IAM Identity Center. For more information, see [What is IAM Identity Center?](#) in the *AWS IAM Identity Center User Guide*.

IAM users and groups

An [IAM user](#) is an identity with specific permissions for a single person or application. We recommend using temporary credentials instead of IAM users with long-term credentials. For more information, see [Require human users to use federation with an identity provider to access AWS using temporary credentials](#) in the *IAM User Guide*.

An [IAM group](#) specifies a collection of IAM users and makes permissions easier to manage for large sets of users. For more information, see [Use cases for IAM users](#) in the *IAM User Guide*.

IAM roles

An [IAM role](#) is an identity with specific permissions that provides temporary credentials. You can assume a role by [switching from a user to an IAM role \(console\)](#) or by calling an AWS CLI or AWS API operation. For more information, see [Methods to assume a role](#) in the *IAM User Guide*.

IAM roles are useful for federated user access, temporary IAM user permissions, cross-account access, cross-service access, and applications running on Amazon EC2. For more information, see [Cross account resource access in IAM](#) in the *IAM User Guide*.

Managing access using policies

You control access in AWS by creating policies and attaching them to AWS identities or resources. A policy defines permissions when associated with an identity or resource. AWS evaluates these policies when a principal makes a request. Most policies are stored in AWS as JSON documents. For more information about JSON policy documents, see [Overview of JSON policies](#) in the *IAM User Guide*.

Using policies, administrators specify who has access to what by defining which **principal** can perform **actions** on what **resources**, and under what **conditions**.

By default, users and roles have no permissions. An IAM administrator creates IAM policies and adds them to roles, which users can then assume. IAM policies define permissions regardless of the method used to perform the operation.

Identity-based policies

Identity-based policies are JSON permissions policy documents that you attach to an identity (user, group, or role). These policies control what actions identities can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Define custom IAM permissions with customer managed policies](#) in the *IAM User Guide*.

Identity-based policies can be *inline policies* (embedded directly into a single identity) or *managed policies* (standalone policies attached to multiple identities). To learn how to choose between managed and inline policies, see [Choose between managed policies and inline policies](#) in the *IAM User Guide*.

Resource-based policies

Resource-based policies are JSON policy documents that you attach to a resource. Examples include IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. You must [specify a principal](#) in a resource-based policy.

Resource-based policies are inline policies that are located in that service. You can't use AWS managed policies from IAM in a resource-based policy.

Other policy types

AWS supports additional policy types that can set the maximum permissions granted by more common policy types:

- **Permissions boundaries** – Set the maximum permissions that an identity-based policy can grant to an IAM entity. For more information, see [Permissions boundaries for IAM entities](#) in the *IAM User Guide*.
- **Service control policies (SCPs)** – Specify the maximum permissions for an organization or organizational unit in AWS Organizations. For more information, see [Service control policies](#) in the *AWS Organizations User Guide*.
- **Resource control policies (RCPs)** – Set the maximum available permissions for resources in your accounts. For more information, see [Resource control policies \(RCPs\)](#) in the *AWS Organizations User Guide*.
- **Session policies** – Advanced policies passed as a parameter when creating a temporary session for a role or federated user. For more information, see [Session policies](#) in the *IAM User Guide*.

Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see [Policy evaluation logic](#) in the *IAM User Guide*.

How AWS Lambda works with IAM

Before you use IAM to manage access to Lambda, learn what IAM features are available to use with Lambda.

IAM feature	Lambda support
Identity-based policies	Yes
Resource-based policies	Yes
Policy actions	Yes
Policy resources	Yes
Policy condition keys (service-specific)	Yes
ACLs	No
ABAC (tags in policies)	Partial
Temporary credentials	Yes
Forward access sessions (FAS)	No
Service roles	Yes
Service-linked roles	Partial

To get a high-level view of how Lambda and other AWS services work with most IAM features, see [AWS services that work with IAM](#) in the *IAM User Guide*.

Identity-based policies for Lambda

Supports identity-based policies: Yes

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Define custom IAM permissions with customer managed policies](#) in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. To learn about all of the elements that you can use in a JSON policy, see [IAM JSON policy elements reference](#) in the *IAM User Guide*.

Identity-based policy examples for Lambda

To view examples of Lambda identity-based policies, see [Identity-based policy examples for AWS Lambda](#).

Resource-based policies within Lambda

Supports resource-based policies: Yes

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must [specify a principal](#) in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. For more information, see [Cross account resource access in IAM](#) in the *IAM User Guide*.

You can attach a resource-based policy to a Lambda function or layer. This policy defines which principals can perform actions on the function or layer.

To learn how to attach a resource-based policy to a function or layer, see [Viewing resource-based IAM policies in Lambda](#).

Policy actions for Lambda

Supports policy actions: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The **Action** element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Include actions in a policy to grant permissions to perform the associated operation.

To see a list of Lambda actions, see [Actions defined by AWS Lambda](#) in the *Service Authorization Reference*.

Policy actions in Lambda use the following prefix before the action:

```
lambda
```

To specify multiple actions in a single statement, separate them with commas.

```
"Action": [  
    "lambda:action1",  
    "lambda:action2"  
]
```

To view examples of Lambda identity-based policies, see [Identity-based policy examples for AWS Lambda](#).

Policy resources for Lambda

Supports policy resources: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The Resource JSON policy element specifies the object or objects to which the action applies. As a best practice, specify a resource using its [Amazon Resource Name \(ARN\)](#). For actions that don't support resource-level permissions, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

To see a list of Lambda resource types and their ARNs, see [Resource types defined by AWS Lambda](#) in the *Service Authorization Reference*. To learn with which actions you can specify the ARN of each resource, see [Actions defined by AWS Lambda](#).

To view examples of Lambda identity-based policies, see [Identity-based policy examples for AWS Lambda](#).

Policy condition keys for Lambda

Supports service-specific policy condition keys: Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Condition` element specifies when statements execute based on defined criteria. You can create conditional expressions that use [condition operators](#), such as equals or less than, to match the condition in the policy with values in the request. To see all AWS global condition keys, see [AWS global condition context keys](#) in the *IAM User Guide*.

To see a list of Lambda condition keys, see [Condition keys for AWS Lambda](#) in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see [Actions defined by AWS Lambda](#).

To view examples of Lambda identity-based policies, see [Identity-based policy examples for AWS Lambda](#).

ACLs in Lambda

Supports ACLs: No

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

ABAC with Lambda

Supports ABAC (tags in policies): Partial

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes called tags. You can attach tags to IAM entities and AWS resources, then design ABAC policies to allow operations when the principal's tag matches the tag on the resource.

To control access based on tags, you provide tag information in the [condition element](#) of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see [Define permissions with ABAC authorization](#) in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see [Use attribute-based access control \(ABAC\)](#) in the *IAM User Guide*.

For more information about tagging Lambda resources, see [Using attribute-based access control in Lambda](#).

Using temporary credentials with Lambda

Supports temporary credentials: Yes

Temporary credentials provide short-term access to AWS resources and are automatically created when you use federation or switch roles. AWS recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see [Temporary security credentials in IAM](#) and [AWS services that work with IAM](#) in the *IAM User Guide*.

Forward access sessions for Lambda

Supports forward access sessions (FAS): No

Forward access sessions (FAS) use the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. For policy details when making FAS requests, see [Forward access sessions](#).

Service roles for Lambda

Supports service roles: Yes

A service role is an [IAM role](#) that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see [Create a role to delegate permissions to an AWS service](#) in the *IAM User Guide*.

In Lambda, a service role is known as an [execution role](#).

Warning

Changing the permissions for an execution role might break Lambda functionality.

Service-linked roles for Lambda

Supports service-linked roles: Partial

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

Lambda doesn't have service-linked roles, but Lambda@Edge does. For more information, see [Service-Linked Roles for Lambda@Edge](#) in the *Amazon CloudFront Developer Guide*.

For details about creating or managing service-linked roles, see [AWS services that work with IAM](#). Find a service in the table that includes a Yes in the **Service-linked role** column. Choose the **Yes** link to view the service-linked role documentation for that service.

Identity-based policy examples for AWS Lambda

By default, users and roles don't have permission to create or modify Lambda resources. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies.

To learn how to create an IAM identity-based policy by using these example JSON policy documents, see [Create IAM policies \(console\)](#) in the *IAM User Guide*.

For details about actions and resource types defined by Lambda, including the format of the ARNs for each of the resource types, see [Actions, resources, and condition keys for AWS Lambda](#) in the *Service Authorization Reference*.

Topics

- [Policy best practices](#)
- [Using the Lambda console](#)
- [Allow users to view their own permissions](#)

Policy best practices

Identity-based policies determine whether someone can create, access, or delete Lambda resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with AWS managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *AWS managed policies* that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see [AWS managed policies](#) or [AWS managed policies for job functions](#) in the *IAM User Guide*.
- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see [Policies and permissions in IAM](#) in the *IAM User Guide*.
- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as CloudFormation. For more information, see [IAM JSON policy elements: Condition](#) in the *IAM User Guide*.
- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see [Validate policies with IAM Access Analyzer](#) in the *IAM User Guide*.
- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your AWS account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see [Secure API access with MFA](#) in the *IAM User Guide*.

For more information about best practices in IAM, see [Security best practices in IAM](#) in the *IAM User Guide*.

Using the Lambda console

To access the AWS Lambda console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the Lambda resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for entities (users or roles) with that policy.

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that they're trying to perform.

For an example policy that grants minimal access for function development, see [Granting users access to a Lambda function](#). In addition to Lambda APIs, the Lambda console uses other services to display trigger configuration and let you add new triggers. If your users use Lambda with other services, they need access to those services as well. For details on configuring other services with Lambda, see [Invoking Lambda with events from other AWS services](#).

Allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ViewOwnUserInfo",
      "Effect": "Allow",
      "Action": [
        "iam:GetUserPolicy",
        "iam:ListGroupsForUser",
        "iam:ListAttachedUserPolicies",
        "iam:ListUserPolicies",
        "iam:GetUser"
      ],
      "Resource": ["arn:aws:iam::*:user/${aws:username}"]
    },
    {
      "Sid": "NavigateInConsole",
      "Effect": "Allow",
      "Action": [
        "iam:GetGroupPolicy",
        "iam:GetPolicyVersion",
        "iam:GetPolicy",
        "iam:ListAttachedGroupPolicies",
        "iam:ListGroupPolicies",
        "iam:ListPolicyVersions",
        "iam:ListPolicies",

```

```
        "iam:ListUsers"
      ],
      "Resource": "*"
    }
  ]
}
```

AWS managed policies for AWS Lambda

An AWS managed policy is a standalone policy that is created and administered by AWS. AWS managed policies are designed to provide permissions for many common use cases so that you can start assigning permissions to users, groups, and roles.

Keep in mind that AWS managed policies might not grant least-privilege permissions for your specific use cases because they're available for all AWS customers to use. We recommend that you reduce permissions further by defining [customer managed policies](#) that are specific to your use cases.

You cannot change the permissions defined in AWS managed policies. If AWS updates the permissions defined in an AWS managed policy, the update affects all principal identities (users, groups, and roles) that the policy is attached to. AWS is most likely to update an AWS managed policy when a new AWS service is launched or new API operations become available for existing services.

For more information, see [AWS managed policies](#) in the *IAM User Guide*.

AWS managed policy: AWSLambda_FullAccess

This policy grants full access to Lambda actions. It also grants permissions to other AWS services that are used to develop and maintain Lambda resources.

You can attach the AWSLambda_FullAccess policy to your users, groups, and roles.

Permissions details

This policy includes the following permissions:

- `lambda` – Allows principals full access to Lambda.
- `cloudformation` – Allows principals to describe AWS CloudFormation stacks and list the resources in those stacks.
- `cloudwatch` – Allows principals to list Amazon CloudWatch metrics and get metric data.
- `ec2` – Allows principals to describe security groups, subnets, and VPCs.
- `iam` – Allows principals to get policies, policy versions, roles, role policies, attached role policies, and the list of roles. This policy also allows principals to pass roles to Lambda. The `PassRole` permission is used when you assign an execution role to a function. The `CreateServiceLinkedRole` permission is used when creating a service-linked role.
- `kms` – Allows principals to list aliases and describe key for volume encryption.
- `logs` – Allows principals to describe log streams, get log events, filter log events, and to start and stop Live Tail sessions.
- `states` – Allows principals to describe and list AWS Step Functions state machines.

- `tag` – Allows principals to get resources based on their tags.
- `xray` – Allows principals to get AWS X-Ray trace summaries and retrieve a list of traces specified by ID.

For more information about this policy, including the JSON policy document and policy versions, see [AWSLambda_FullAccess](#) in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AWSLambda_ReadOnlyAccess

This policy grants read-only access to Lambda resources and to other AWS services that are used to develop and maintain Lambda resources.

You can attach the `AWSLambda_ReadOnlyAccess` policy to your users, groups, and roles.

Permissions details

This policy includes the following permissions:

- `lambda` – Allows principals to get and list all resources.
- `cloudformation` – Allows principals to describe and list AWS CloudFormation stacks and list the resources in those stacks.
- `cloudwatch` – Allows principals to list Amazon CloudWatch metrics and get metric data.
- `ec2` – Allows principals to describe security groups, subnets, and VPCs.
- `iam` – Allows principals to get policies, policy versions, roles, role policies, attached role policies, and the list of roles.
- `kms` – Allows principals to list aliases.
- `logs` – Allows principals to describe log streams, get log events, filter log events, and to start and stop Live Tail sessions.
- `states` – Allows principals to describe and list AWS Step Functions state machines.
- `tag` – Allows principals to get resources based on their tags.
- `xray` – Allows principals to get AWS X-Ray trace summaries and retrieve a list of traces specified by ID.

For more information about this policy, including the JSON policy document and policy versions, see [AWSLambda_ReadOnlyAccess](#) in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AWSLambdaBasicExecutionRole

This policy grants permissions to upload logs to CloudWatch Logs.

You can attach the `AWSLambdaBasicExecutionRole` policy to your users, groups, and roles.

For more information about this policy, including the JSON policy document and policy versions, see [AWSLambdaBasicExecutionRole](#) in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AWSLambdaBasicDurableExecutionRolePolicy

This policy provides write permissions to CloudWatch Logs and read/write permissions to durable execution APIs used by Lambda durable functions. This policy provides the essential permissions required for Lambda durable functions, which use durable execution APIs to persist progress and maintain state across function invocations.

You can attach the `AWSLambdaBasicDurableExecutionRolePolicy` policy to your users, groups, and roles.

Permissions details

This policy includes the following permissions:

- `logs` – Allows principals to create log groups and log streams, and write log events to CloudWatch Logs.
- `lambda` – Allows principals to checkpoint durable execution state and retrieve durable execution state for Lambda durable functions.

To view more details about the policy, including the latest version of the JSON policy document, see [AWSLambdaBasicDurableExecutionRolePolicy](#) in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AWSLambdaDynamoDBExecutionRole

This policy grants permissions to read records from an Amazon DynamoDB stream and write to CloudWatch Logs.

You can attach the `AWSLambdaDynamoDBExecutionRole` policy to your users, groups, and roles.

For more information about this policy, including the JSON policy document and policy versions, see [AWSLambdaDynamoDBExecutionRole](#) in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AWSLambdaENIManagementAccess

This policy grants permissions to create, describe, and delete elastic network interfaces used by a VPC-enabled Lambda function.

You can attach the AWSLambdaENIManagementAccess policy to your users, groups, and roles.

For more information about this policy, including the JSON policy document and policy versions, see [AWSLambdaENIManagementAccess](#) in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AWSLambdaInvocation-DynamoDB

This policy grants read access to Amazon DynamoDB Streams.

You can attach the AWSLambdaInvocation-DynamoDB policy to your users, groups, and roles.

For more information about this policy, including the JSON policy document and policy versions, see [AWSLambdaInvocation-DynamoDB](#) in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AWSLambdaKinesisExecutionRole

This policy grants permissions to read events from an Amazon Kinesis data stream and write to CloudWatch Logs.

You can attach the AWSLambdaKinesisExecutionRole policy to your users, groups, and roles.

For more information about this policy, including the JSON policy document and policy versions, see [AWSLambdaKinesisExecutionRole](#) in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AWSLambdaMSKExecutionRole

This policy grants permissions to read and access records from an Amazon Managed Streaming for Apache Kafka cluster, manage elastic network interfaces, and write to CloudWatch Logs.

You can attach the AWSLambdaMSKExecutionRole policy to your users, groups, and roles.

For more information about this policy, including the JSON policy document and policy versions, see [AWSLambdaMSKExecutionRole](#) in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AWSLambdaRole

This policy grants permissions to invoke Lambda functions.

You can attach the AWSLambdaRole policy to your users, groups, and roles.

For more information about this policy, including the JSON policy document and policy versions, see [AWSLambdaRole](#) in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AWSLambdaSQSQueueExecutionRole

This policy grants permissions to read and delete messages from an Amazon Simple Queue Service queue, and grants write permissions to CloudWatch Logs.

You can attach the `AWSLambdaSQSQueueExecutionRole` policy to your users, groups, and roles.

For more information about this policy, including the JSON policy document and policy versions, see [AWSLambdaSQSQueueExecutionRole](#) in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AWSLambdaVPCAccessExecutionRole

This policy grants permissions to manage elastic network interfaces within an Amazon Virtual Private Cloud and write to CloudWatch Logs.

You can attach the `AWSLambdaVPCAccessExecutionRole` policy to your users, groups, and roles.

For more information about this policy, including the JSON policy document and policy versions, see [AWSLambdaVPCAccessExecutionRole](#) in the *AWS Managed Policy Reference Guide*.

AWS managed policy: AWSLambdaManagedEC2ResourceOperator

This policy enables automated Amazon Elastic Compute Cloud instance management for Lambda capacity providers. It grants permissions to the Lambda scaler service to perform instance lifecycle operations on your behalf.

You can attach the `AWSLambdaManagedEC2ResourceOperator` policy to your users, groups, and roles.

Permissions details

This policy includes the following permissions:

- `ec2:RunInstances` – Allows Lambda to launch new Amazon EC2 instances with the condition that `ec2:ManagedResourceOperator` equals `scaler.lambda.amazonaws.com` and restricts AMI usage to Amazon-owned images only.
- `ec2:DescribeInstances` and `ec2:DescribeInstanceStatus` – Allows Lambda to monitor instance status and retrieve instance information.

- `ec2:CreateTags` – Allows Lambda to tag Amazon EC2 resources for management and identification purposes.
- `ec2:DescribeAvailabilityZones` – Allows Lambda to view available zones for instance placement decisions.
- `ec2:DescribeCapacityReservations` – Allows Lambda to check capacity reservations for optimal instance placement.
- `ec2:DescribeInstanceTypes` and `ec2:DescribeInstanceTypeOfferings` – Allows Lambda to review available instance types and their offerings.
- `ec2:DescribeSubnets` – Allows Lambda to examine subnet configurations for network planning.
- `ec2:DescribeSecurityGroups` – Allows Lambda to retrieve security group information for network interface configuration.
- `ec2:CreateNetworkInterface` – Allows Lambda to create network interfaces and manage subnet and security group associations.
- `ec2:AttachNetworkInterface` – Allows Lambda to attach network interfaces to Amazon EC2 instances with the condition that `ec2:ManagedResourceOperator` equals scaler.lambda.amazonaws.com.

For more information about this policy, including the JSON policy document and policy versions, see [AWSLambdaManagedEC2ResourceOperator](#) in the *AWS Managed Policy Reference Guide*.

AWS managed policy: `AWSLambdaServiceRolePolicy`

This policy is attached to the service-linked role named `AWSServiceRoleForLambda` to allow Lambda to terminate instances managed as part of Lambda capacity providers.

Permissions details

This policy includes the following permissions:

- `ec2:TerminateInstances` – Allows Lambda to terminate EC2 instances with the condition that `ec2:ManagedResourceOperator` equals `scaler.lambda.amazonaws.com`.
- `ec2:DescribeInstanceStatus` and `ec2:DescribeInstances` – Allows Lambda to describe EC2 instances.

For more information about this policy, see [Using service-linked roles for Lambda](#).

Lambda updates to AWS managed policies

Change	Description	Date
AWSLambdaManagedEC2ResourceOperator – New policy	Lambda added a new managed policy to enable automated Amazon EC2 instance management for Lambda capacity providers , allowing the scaler service to perform instance lifecycle operations.	November 30, 2025
AWSLambdaServiceRolePolicy – New policy	Lambda added a new managed policy for the service-linked role to allow Lambda to terminate instances managed as part of Lambda capacity providers.	November 30, 2025
AWSLambda_FullAccess – Change	Lambda updated the <code>AWSLambda_FullAccess</code> policy to allow the <code>kms:DescribeKey</code> and <code>iam:CreateServiceLinkedRole</code> actions.	November 30, 2025
AWSLambdaBasicDurableExecutionRolePolicy – New managed policy	Lambda released a new managed policy <code>AWSLambdaBasicDurableExecutionRolePolicy</code> that provides write permissions to CloudWatch Logs and read/write permissions to durable execution APIs used by Lambda durable functions.	December 1, 2025

Change	Description	Date
AWSLambda_ReadOnlyAccess and AWSLambda_FullAccess – Change	Lambda updated the <code>AWSLambda_ReadOnlyAccess</code> and <code>AWSLambda_FullAccess</code> policies to allow the <code>logs:StartLiveTail</code> and <code>logs:StopLiveTail</code> actions.	March 17, 2025
AWSLambdaVPCAccessExecutionRole – Change	Lambda updated the <code>AWSLambdaVPCAccessExecutionRole</code> policy to allow the action <code>ec2:DescribeSubnets</code> .	January 5, 2024
AWSLambda_ReadOnlyAccess – Change	Lambda updated the <code>AWSLambda_ReadOnlyAccess</code> policy to allow principals to list CloudFormation stacks.	July 27, 2023
AWS Lambda started tracking changes	AWS Lambda started tracking changes for its AWS managed policies.	July 27, 2023

Troubleshooting AWS Lambda identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with Lambda and IAM.

Topics

- [I am not authorized to perform an action in Lambda](#)
- [I am not authorized to perform iam:PassRole](#)
- [I want to allow people outside of my AWS account to access my Lambda resources](#)

I am not authorized to perform an action in Lambda

If you receive an error that you're not authorized to perform an action, your policies must be updated to allow you to perform the action.

The following example error occurs when the `mateojackson` IAM user tries to use the console to view details about a fictional `my-example-widget` resource but doesn't have the fictional `lambda:GetWidget` permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:
lambda:GetWidget on resource: my-example-widget
```

In this case, the policy for the `mateojackson` user must be updated to allow access to the `my-example-widget` resource by using the `lambda:GetWidget` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I am not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, your policies must be updated to allow you to pass a role to Lambda.

Some AWS services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named `marymajor` tries to use the console to perform an action in Lambda. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform:
iam:PassRole
```

In this case, Mary's policies must be updated to allow her to perform the `iam:PassRole` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I want to allow people outside of my AWS account to access my Lambda resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Lambda supports these features, see [How AWS Lambda works with IAM](#).
- To learn how to provide access to your resources across AWS accounts that you own, see [Providing access to an IAM user in another AWS account that you own](#) in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see [Providing access to AWS accounts owned by third parties](#) in the *IAM User Guide*.
- To learn how to provide access through identity federation, see [Providing access to externally authenticated users \(identity federation\)](#) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see [Cross account resource access in IAM](#) in the *IAM User Guide*.

Create a governance strategy for Lambda functions and layers

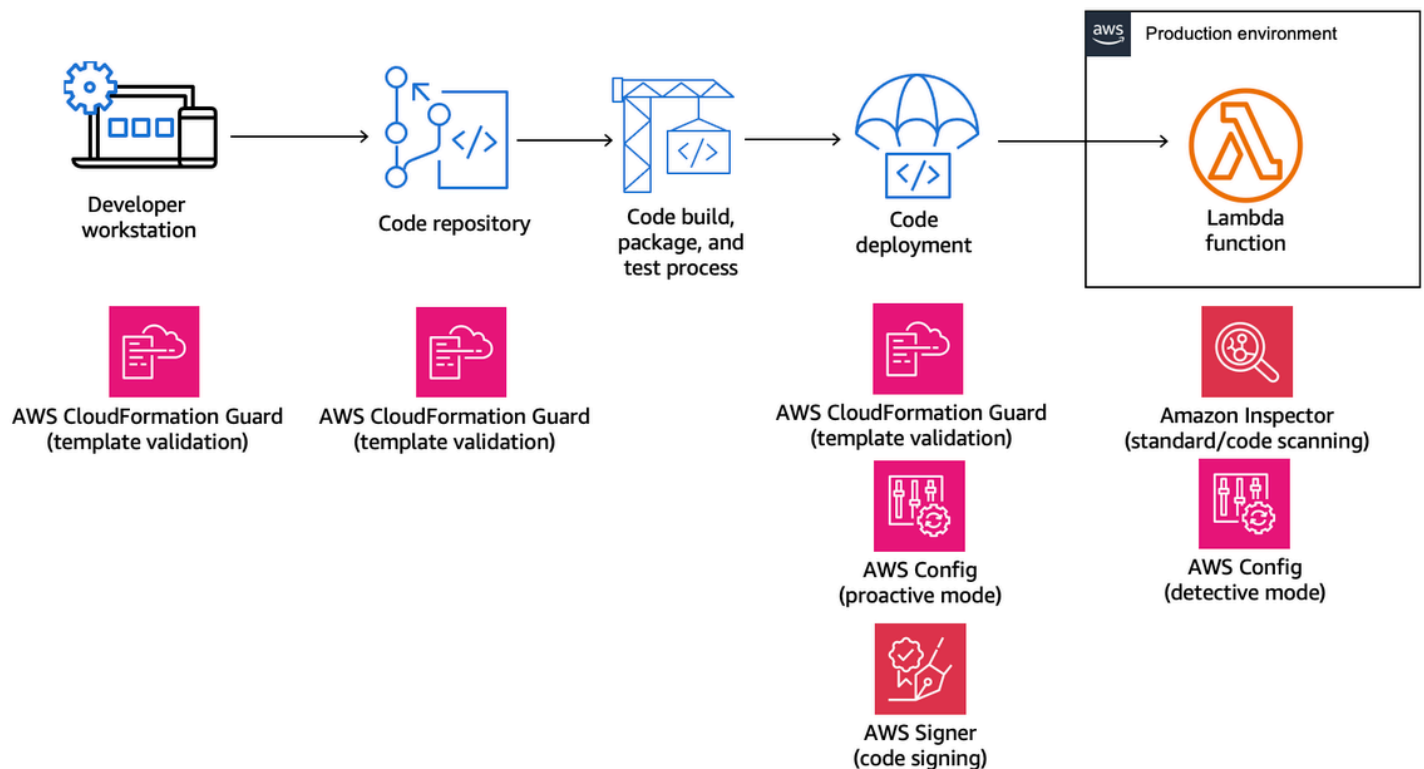

To build and deploy serverless, cloud-native applications, you must allow for agility and speed to market with appropriate governance and guardrails. You set business-level priorities, maybe emphasizing agility as the top priority, or alternatively emphasizing risk aversion via governance, guardrails, and controls. Realistically, you won't have an "either/or" strategy but an "and" strategy that balances both agility and guardrails in your software development lifecycle. No matter where these requirements fall in your company's lifecycle, governance capabilities are likely to become an implementation requirement in your processes and toolchains.

Here are a few examples of governance controls that an organization might implement for Lambda:

- Lambda functions must not be publicly accessible.
- Lambda functions must be attached to a VPC.
- Lambda functions should not use deprecated runtimes.
- Lambda functions must be tagged with a set of required tags.

- Lambda layers must not be accessible outside of the organization.
- Lambda functions with an attached security group must have matching tags between the function and security group.
- Lambda functions with an attached layer must use an approved version
- Lambda environment variables must be encrypted at rest with a customer managed key.

The following diagram is an example of an in-depth governance strategy that implements controls and policy throughout the software development and deployment process:

The following topics explain how to implement controls for developing and deploying Lambda functions in your organization, both for the startup and the enterprise. Your organization might already have tools in place. The following topics take a modular approach to these controls, so that you can pick and choose the components you actually need.

Topics

- [Proactive controls for Lambda with AWS CloudFormation Guard](#)
- [Implement preventative controls for Lambda with AWS Config](#)
- [Detect non-compliant Lambda deployments and configurations with AWS Config](#)

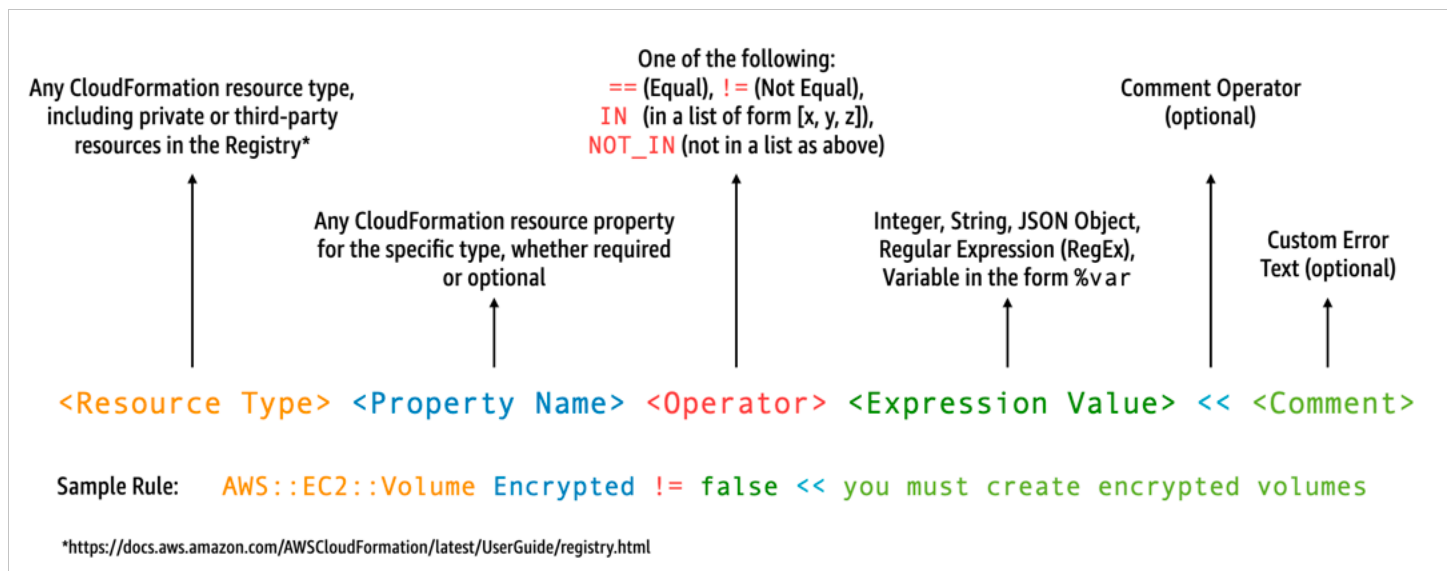

- [Lambda code signing with AWS Signer](#)
- [Automate security assessments for Lambda with Amazon Inspector](#)
- [Implement observability for Lambda security and compliance](#)

Proactive controls for Lambda with AWS CloudFormation Guard

[AWS CloudFormation Guard](#) is an open-source, general-purpose, policy-as-code evaluation tool. This can be used for preventative governance and compliance by validating Infrastructure as Code (IaC) templates and service compositions against policy rules. These rules can be customized based on your team or organizational requirements. For Lambda functions, the Guard rules can be used to control resource creation and configuration updates by defining the required property settings needed while creating or updating a Lambda function.

Compliance administrators define the list of controls and governance policies that are required for deploying and updating Lambda functions. Platform administrators implement the controls in CI/CD pipelines, as pre-commit validation webhooks with code repositories, and provide developers with command line tools for validating templates and code on local workstations. Developers author code, validate templates with command line tools, and then commit code to repositories, which are then automatically validated via the CI/CD pipelines prior to deployment into an AWS environment.

Guard allows you to [write your rules](#) and implement your controls with a domain-specific language as follows.

For example, suppose you want to ensure that developers choose only the latest runtimes. You could specify two different policies, one to identify [runtimes](#) that are already deprecated and another to identify runtimes that are to be deprecated soon. To do this, you might write the following `etc/rules.guard` file:

```

let lambda_functions = Resources.*[
  Type == "AWS::Lambda::Function"
]

rule lambda_already_deprecated_runtime when %lambda_functions !empty {
  %lambda_functions {
    Properties {
      when Runtime exists {
        Runtime !in ["dotnetcore3.1", "nodejs12.x", "python3.6", "python2.7",
"dotnet5.0", "dotnetcore2.1", "ruby2.5", "nodejs10.x", "nodejs8.10", "nodejs4.3",
"nodejs6.10", "dotnetcore1.0", "dotnetcore2.0", "nodejs4.3-edge", "nodejs"] <<Lambda
function is using a deprecated runtime.>>
      }
    }
  }
}

rule lambda_soon_to_be_deprecated_runtime when %lambda_functions !empty {
  %lambda_functions {
    Properties {
      when Runtime exists {
        Runtime !in ["nodejs16.x", "nodejs14.x", "python3.7", "java8",
"dotnet7", "go1.x", "ruby2.7", "provided"] <<Lambda function is using a runtime that
is targeted for deprecation.>>
      }
    }
  }
}

```

Now suppose you write the following `iac/lambda.yaml` CloudFormation template that defines a Lambda function:

```

Fn:
  Type: AWS::Lambda::Function
  Properties:
    Runtime: python3.7
    CodeUri: src
    Handler: fn.handler
    Role: !GetAtt FnRole.Arn
    Layers:
      - arn:aws:lambda:us-east-1:111122223333:layer:LambdaInsightsExtension:35

```

After [installing](#) the Guard utility, validate your template:

```
cfn-guard validate --rules etc/rules.guard --data iac/lambda.yaml
```

The output looks like this:

```
lambda.yaml Status = FAIL
FAILED rules
rules.guard/lambda_soon_to_be_deprecated_runtime
---
Evaluating data lambda.yaml against rules rules.guard
Number of non-compliant resources 1
Resource = Fn {
  Type      = AWS::Lambda::Function
  Rule = lambda_soon_to_be_deprecated_runtime {
    ALL {
      Check = Runtime not IN
["nodejs16.x","nodejs14.x","python3.7","java8","dotnet7","go1.x","ruby2.7","provided"]
{
      ComparisonError {
        Message      = Lambda function is using a runtime that is targeted for
deprecation.
        Error         = Check was not compliant as property [/Resources/
Fn/Properties/Runtime[L:88,C:15]] was not present in [(resolved, Path=[L:0,C:0]
Value=["nodejs16.x","nodejs14.x","python3.7","java8","dotnet7","go1.x","ruby2.7","provided"])]
      }
      PropertyPath    = /Resources/Fn/Properties/Runtime[L:88,C:15]
      Operator        = NOT IN
      Value           = "python3.7"
      ComparedWith    =
["nodejs16.x","nodejs14.x","python3.7","java8","dotnet7","go1.x","ruby2.7","provided"]]
      Code:
        86. Fn:
        87.   Type: AWS::Lambda::Function
        88.   Properties:
        89.     Runtime: python3.7
        90.     CodeUri: src
        91.     Handler: fn.handler
    }
  }
}
```

Guard allows your developers to see from their local developer workstations that they need to update the template to use a runtime that is allowed by the organization. This happens prior to committing to a code repository and subsequently failing checks within a CI/CD pipeline. As a result, your developers get this feedback on how to develop compliant templates and shift their time to writing code that delivers business value. This control can be applied on the local developer workstation, in a pre-commit validation webhook, and/or in the CI/CD pipeline prior to deployment.

Caveats

If you're using AWS Serverless Application Model (AWS SAM) templates to define Lambda functions, be aware that you need to update the Guard rule to search for the `AWS::Serverless::Function` resource type as follows.

```
let lambda_functions = Resources.*[
    Type == "AWS::Serverless::Function"
]
```

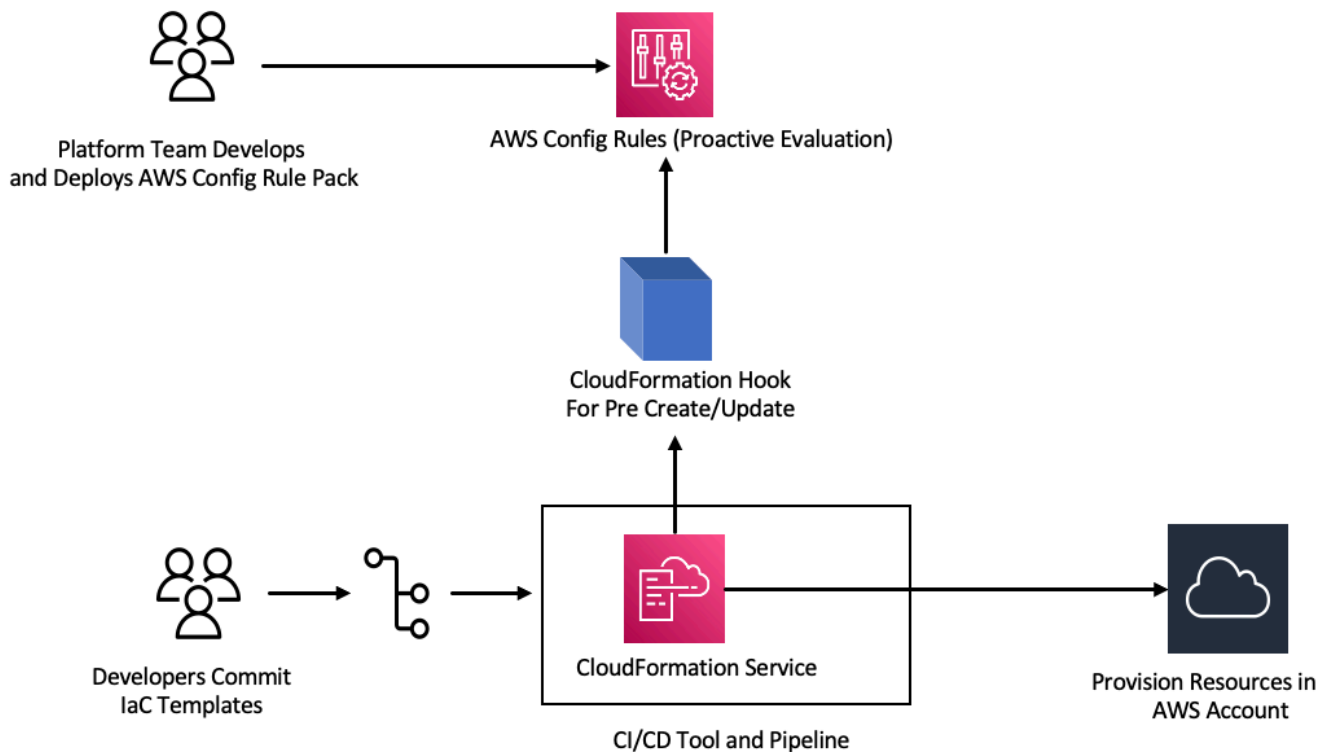

Guard also expects the properties to be included within the resource definition. Meanwhile, AWS SAM templates allow for properties to be specified in a separate [Globals](#) section. Properties that are defined in the Globals section are not validated with your Guard rules.

As outlined in the Guard troubleshooting [documentation](#), be aware that Guard doesn't support short-form intrinsics like `!GetAtt` or `!Sub` and instead requires using the expanded forms: `Fn::GetAtt` and `Fn::Sub`. (The [earlier example](#) doesn't evaluate the Role property, so the short-form intrinsic was used for simplicity.)

Implement preventative controls for Lambda with AWS Config

It is essential to ensure compliance in your serverless applications as early in the development process as possible. In this topic, we cover how to implement preventative controls using [AWS Config](#). This allows you to implement compliance checks earlier in the development process and enables you to implement the same controls in your CI/CD pipelines. This also standardizes your controls in a centrally managed repository of rules so that you can apply your controls consistently across your AWS accounts.

For example, suppose your compliance administrators defined a requirement to ensure that all Lambda functions include AWS X-Ray tracing. With AWS Config's proactive mode, you can run compliance checks on your Lambda function resources before deployment, reducing the risk of deploying improperly configured Lambda functions and saving developers time by giving them faster feedback on infrastructure as code templates. The following is a visualization of the flow for preventative controls with AWS Config:

Consider a requirement that all Lambda functions must have tracing enabled. In response, the platform team identifies the need for a specific AWS Config rule to run proactively across all

accounts. This rule flags any Lambda function that lacks a configured X-Ray tracing configuration as a non-compliant resource. The team develops a rule, packages it in a [conformance pack](#), and deploys the conformance pack across all AWS accounts to ensure that all accounts in the organization uniformly apply these controls. You can write the rule in AWS CloudFormation Guard 2.x.x syntax, which takes the following form:

```
rule name when condition { assertion }
```

The following is a sample Guard rule that checks to ensure Lambda functions has tracing enabled:

```
rule lambda_tracing_check {  
  when configuration.tracingConfig exists {  
    configuration.tracingConfig.mode == "Active"  
  }  
}
```

The platform team takes further action by mandating that every AWS CloudFormation deployment invokes a pre-create/update [hook](#). They assume full responsibility for developing this hook and configuring the pipeline, strengthening the centralized control of compliance rules and sustaining their consistent application across all deployments. To develop, package, and register a hook, see [Developing AWS CloudFormation Hooks](#) in the CloudFormation Command Line Interface (CFN-CLI) documentation. You can use the [CloudFormation CLI](#) to create the hook project:

```
cfn init
```

This command asks you for some basic information about your hook project and creates a project with following files in it:

```
README.md  
<hook-name>.json  
rpd.log  
src/handler.py  
template.yml  
hook-role.yaml
```

As a hook developer, you need to add the desired target resource type in the `<hook-name>.json` configuration file. In the configuration below, a hook is configured to execute before any Lambda function is created using CloudFormation. You can add similar handlers for `preUpdate` and `preDelete` actions as well.

```

"handlers": {
  "preCreate": {
    "targetNames": [
      "AWS::Lambda::Function"
    ],
    "permissions": []
  }
}

```

You also need to ensure that the CloudFormation hook has appropriate permissions to call the AWS Config APIs. You can do that by updating the role definition file named `hook-role.yaml`. The role definition file has the following trust policy by default, which allows CloudFormation to assume the role.

```

AssumeRolePolicyDocument:
  Version: '2012-10-17'
  Statement:
    - Effect: Allow
      Principal:
        Service:
          - hooks.cloudformation.amazonaws.com
          - resources.cloudformation.amazonaws.com

```

To allow this hook to call config APIs, you must add following permissions to the Policy statement. Then you submit the hook project using the `cfn submit` command, where CloudFormation creates a role for you with the required permissions.

```

Policies:
  - PolicyName: HookTypePolicy
    PolicyDocument:
      Version: '2012-10-17'
      Statement:
        - Effect: Allow
          Action:
            - "config:Describe*"
            - "config:Get*"
            - "config:List*"
            - "config:SelectResourceConfig"
          Resource: "*"

```

Next, you need to write a Lambda function in a `src/handler.py` file. Within this file, you find methods named `preCreate`, `preUpdate`, and `preDelete` already created when you initiated the project. You aim to write a common, reusable function that calls the AWS Config `StartResourceEvaluation` API in proactive mode using the AWS SDK for Python (Boto3). This API call takes resource properties as input and evaluates the resource against the rule definition.

```
def validate_lambda_tracing_config(resource_type, function_properties:
    MutableMapping[str, Any]) -> ProgressEvent:
    LOG.info("Fetching proactive data")
    config_client = boto3.client('config')
    resource_specs = {
        'ResourceId': 'MyFunction',
        'ResourceType': resource_type,
        'ResourceConfiguration': json.dumps(function_properties),
        'ResourceConfigurationSchemaType': 'CFN_RESOURCE_SCHEMA'
    }
    LOG.info("Resource Specifications:", resource_specs)
    eval_response = config_client.start_resource_evaluation(EvaluationMode='PROACTIVE',
        ResourceDetails=resource_specs, EvaluationTimeout=60)
    ResourceEvaluationId = eval_response.ResourceEvaluationId
    compliance_response =
    config_client.get_compliance_details_by_resource(ResourceEvaluationId=ResourceEvaluationId)
    LOG.info("Compliance Verification:",
        compliance_response.EvaluationResults[0].ComplianceType)
    if "NON_COMPLIANT" == compliance_response.EvaluationResults[0].ComplianceType:
        return ProgressEvent(status=OperationStatus.FAILED, message="Lambda function
        found with no tracing enabled : FAILED", errorCode=HandlerErrorCode.NonCompliant)
    else:
        return ProgressEvent(status=OperationStatus.SUCCESS, message="Lambda function
        found with tracing enabled : PASS.")
```

Now you can call the common function from the handler for the pre-create hook. Here's an example of the handler:

```
@hook.handler(HookInvocationPoint.CREATE_PRE_PROVISION)
def pre_create_handler(
    session: Optional[SessionProxy],
    request: HookHandlerRequest,
    callback_context: MutableMapping[str, Any],
    type_configuration: TypeConfigurationModel
) -> ProgressEvent:
    LOG.info("Starting execution of the hook")
```

```

target_name = request.hookContext.targetName
LOG.info("Target Name:", target_name)
if "AWS::Lambda::Function" == target_name:
    return validate_lambda_tracing_config(target_name,
        request.hookContext.targetModel.get("resourceProperties")
    )
else:
    raise exceptions.InvalidRequest(f"Unknown target type: {target_name}")

```

After this step you can register the hook and configure it to listen to all AWS Lambda function creation events.

A developer prepares the infrastructure as code (IaC) template for a serverless microservice using Lambda. This preparation includes adherence to internal standards, followed by locally testing and committing the template to the repository. Here's an example IaC template:

```

MyLambdaFunction:
  Type: 'AWS::Lambda::Function'
  Properties:
    Handler: index.handler
    Role: !GetAtt LambdaExecutionRole.Arn
    FunctionName: MyLambdaFunction
    Code:
      ZipFile: |
        import json

        def handler(event, context):
            return {
                'statusCode': 200,
                'body': json.dumps('Hello World!')
            }
    Runtime: python3.14
    TracingConfig:
      Mode: PassThrough
    MemorySize: 256
    Timeout: 10

```

As part of the CI/CD process, when the CloudFormation template is deployed, the CloudFormation service invokes the pre-create/update hook right before provisioning `AWS::Lambda::Function` resource type. The hook utilizes AWS Config rules running in proactive mode to verify that the Lambda function configuration includes the mandated tracing configuration. The response from the hook determines the next step. If compliant, the hook signals success, and CloudFormation

proceeds to provision the resources. If not, the CloudFormation stack deployment fails, the pipeline comes to an immediate halt, and the system records the details for subsequent review. Compliance notifications are sent to the relevant stakeholders.

You can find the hook success/fail information in the CloudFormation console:

In this way, you can implement preventative controls with AWS Config in proactive mode when developing and deploying serverless resources in your AWS accounts. By integrating AWS Config rules into the CI/CD pipeline, you can identify and optionally block non-compliant resource deployments, such as Lambda functions that lack an active tracing configuration. This ensures that only resources that comply with the latest governance policies are deployed into your AWS environments.

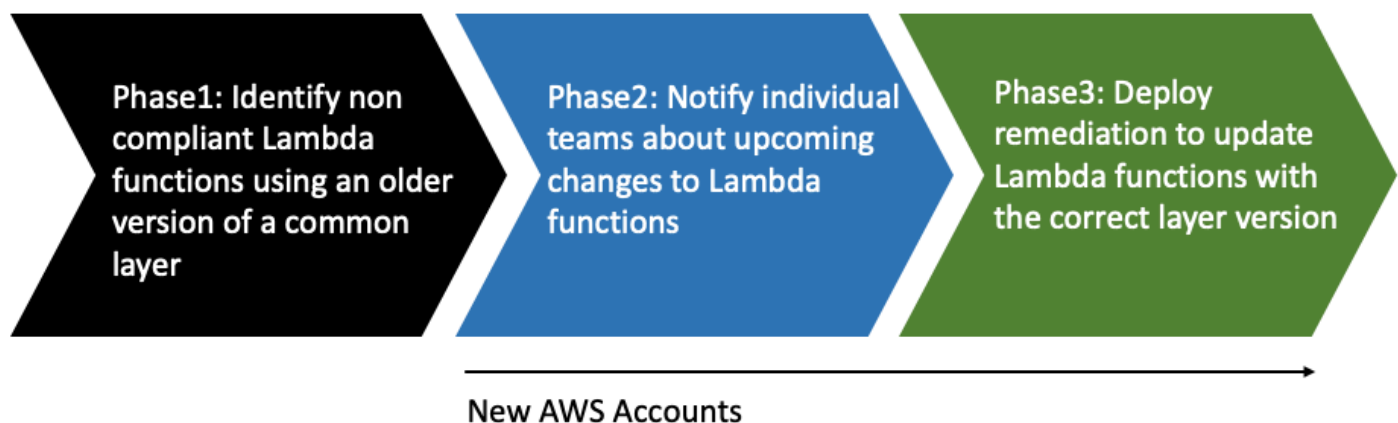

Detect non-compliant Lambda deployments and configurations with AWS Config

In addition to [proactive evaluation](#), AWS Config can also reactively detect resource deployments and configurations that do not comply with your governance policies. This is important because governance policies evolve as your organization learns and implements new best practices.

Consider a scenario where you set a brand new policy when deploying or updating Lambda functions: All Lambda functions must always use a specific, approved Lambda layer version. You can configure AWS Config to monitor new or updated functions for layer configurations. If AWS Config detects a function that is not using an approved layer version, it flags the function as a non-compliant resource. You can optionally configure AWS Config to automatically remediate the resource by specifying a remediation action using an AWS Systems Manager automation document. For example, you could write an automation document in Python using the AWS SDK for Python (Boto3), which updates the non-compliant function to point to the approved layer version. Thus, AWS Config serves as both a detective and corrective control, automating compliance management.

Let's break down this process into three important implementation phases:

Existing AWS Accounts

Phase 1: Identify access resources

Start by activating AWS Config across your accounts and configuring it to record AWS Lambda functions. This allows AWS Config to observe when Lambda functions are created or updated. You can then configure [custom policy rules](#) to check for specific policy violations, which use AWS CloudFormation Guard syntax. Guard rules take the following general form:

```
rule name when condition { assertion }
```

Below is a sample rule that checks to ensure that a layer is not set to an old layer version:

```
rule desiredlayer when configuration.layers != empty {  
    some configuration.layers[*].arn != CONFIG_RULE_PARAMETERS.OldLayerArn  
}
```

Let's understand the rule syntax and structure:

- **Rule name:** The name of the rule in the provided example is `desiredlayer`.
- **Condition:** This clause specifies the condition under which the rule should be checked. In the provided example, the condition is `configuration.layers != empty`. This means the resource should be evaluated only when the `layers` property in the configuration isn't empty.
- **Assertion:** After the `when` clause, an assertion determines what the rule checks. The assertion `some configuration.layers[*].arn != CONFIG_RULE_PARAMETERS.OldLayerArn` checks if any of the Lambda layer ARNs do not match the `OldLayerArn` value. If they do not match, the assertion is true and the rule passes; otherwise, it fails.

`CONFIG_RULE_PARAMETERS` is a special set of parameters that is configured with the AWS Config rule. In this case, `OldLayerArn` is a parameter inside `CONFIG_RULE_PARAMETERS`. This allows users to provide a specific ARN value that they consider old or deprecated, and then the rule checks if any Lambda functions are using this old ARN.

Phase 2: Visualize and design

AWS Config gathers configuration data and stores that data in Amazon Simple Storage Service (Amazon S3) buckets. You can use [Amazon Athena](#) to query this data directly from your S3 buckets. With Athena, you can aggregate this data at the organizational level, generating a holistic view of your resource configurations across all your accounts. To set up aggregation of resource configuration data, see [Visualizing AWS Config data using Athena and Amazon Quick Suite](#) on the AWS Cloud Operations and Management blog.

The following is a sample Athena query to identify all Lambda functions using a particular layer ARN:

```
WITH unnested AS (
```

```

SELECT
    item.awsaccountid AS account_id,
    item.awsregion AS region,
    item.configuration AS lambda_configuration,
    item.resourceid AS resourceid,
    item.resourcename AS resourcename,
    item.configuration AS configuration,
    json_parse(item.configuration) AS lambda_json
FROM
    default.aws_config_configuration_snapshot,
    UNNEST(configurationitems) as t(item)
WHERE
    "dt" = 'latest'
    AND item.resourcetype = 'AWS::Lambda::Function'
)

SELECT DISTINCT
    region as Region,
    resourcename as FunctionName,
    json_extract_scalar(lambda_json, '$.memorySize') AS memory_size,
    json_extract_scalar(lambda_json, '$.timeout') AS timeout,
    json_extract_scalar(lambda_json, '$.version') AS version
FROM
    unnested
WHERE
    lambda_configuration LIKE '%arn:aws:lambda:us-
east-1:111122223333:layer:AnyGovernanceLayer:24%'

```

Here are results from the query:

9	us-east-1	my_functions_function25	128	3	\$LATEST

With the AWS Config data aggregated across the organization, you can then create a dashboard using [Amazon Quick Suite](#). By importing your Athena results into Quick Suite, you can visualize how well your Lambda functions adhere to the layer version rule. This dashboard can highlight compliant and non-compliant resources, which helps you to determine your enforcement policy, as outlined in the [next section](#). The following image is an example dashboard that reports on the distribution of layer versions applied to functions within the organization.

Phase 3: Implement and enforce

You can now optionally pair your layer version rule that you created in [phase 1](#) with a remediation action via a Systems Manager automation document, which you author as a Python script written with AWS SDK for Python (Boto3). The script calls the [UpdateFunctionConfiguration](#) API action for each Lambda function, updating the function configuration with the new layer ARN. Alternatively, you could have the script submit a pull request to the code repository to update the layer ARN. This way future code deployments are also updated with the correct layer ARN.

Lambda code signing with AWS Signer

[AWS Signer](#) is a fully managed code-signing service that allows you to validate your code against a digital signature to confirm that code is unaltered and from a trusted publisher. AWS Signer can be used in conjunction with AWS Lambda to verify that functions and layers are unaltered prior to deployment into your AWS environments. This protects your organization from malicious actors who might have gained credentials to create new or update existing functions.

To set up code signing for your Lambda functions, start by creating an S3 bucket with versioning enabled. After that, create a signing profile with AWS Signer, specify Lambda as the platform and then specify a period of days in which the signing profile is valid. Example:

```
Signer:
  Type: AWS::Signer::SigningProfile
  Properties:
    PlatformId: AWSLambda-SHA384-ECDSA
    SignatureValidityPeriod:
      Type: DAYS
      Value: !Ref pValidDays
```

Then use the signing profile and create a signing configuration with Lambda. You have to specify what to do when the signing configuration sees an artifact that does not match a digital signature that it expected: warn (but allow the deployment) or enforce (and block the deployment). The example below is configured to enforce and block deployments.

```
SigningConfig:
  Type: AWS::Lambda::CodeSigningConfig
  Properties:
    AllowedPublishers:
      SigningProfileVersionArns:
        - !GetAtt Signer.ProfileVersionArn
    CodeSigningPolicies:
      UntrustedArtifactOnDeployment: Enforce
```

You now have AWS Signer configured with Lambda to block untrusted deployments. Let's assume you've finished coding a feature request and are now ready to deploy the function. The first step is to zip the code up with the appropriate dependencies and then sign the artifact using the signing profile that you created. You can do this by uploading the zip artifact to the S3 bucket and then starting a signing job.

```
aws signer start-signing-job \
--source 's3={bucketName=your-versioned-bucket,key=your-prefix/your-zip-artifact.zip,version=QyaJ3c4qa50LXV.9VaZgXHlsGbvCXpT}' \
--destination 's3={bucketName=your-versioned-bucket,prefix=your-prefix/}' \
--profile-name your-signer-id
```

You get an output as follows, where the `jobId` is the object that is created in the destination bucket and `prefix` and `jobOwner` is the 12-digit AWS account ID where the job was run.

```
{
  "jobId": "87a3522b-5c0b-4d7d-b4e0-4255a8e05388",
  "jobOwner": "111122223333"
}
```

And now you can deploy your function using the signed S3 object and the code signing configuration that you created.

```
Fn:
  Type: AWS::Serverless::Function
  Properties:
    CodeUri: s3://your-versioned-bucket/your-prefix/87a3522b-5c0b-4d7d-
b4e0-4255a8e05388.zip
    Handler: fn.handler
    Role: !GetAtt FnRole.Arn
    CodeSigningConfigArn: !Ref pSigningConfigArn
```

You can alternatively test a function deployment with the original unsigned source zip artifact. The deployment should fail with the following message:

```
Lambda cannot deploy the function. The function or layer might be signed using a
signature that the client is not configured to accept. Check the provided signature
for unsigned.
```

If you are building and deploying your functions using the AWS Serverless Application Model (AWS SAM), the `package` command handles uploading the zip artifact to S3 and also starts the signing job and gets the signed artifact. You can do this with the following command and parameters:

```
sam package -t your-template.yaml \
--output-template-file your-output.yaml \
--s3-bucket your-versioned-bucket \
```

```
--s3-prefix your-prefix \  
--signing-profiles your-signer-id
```

AWS Signer helps you verify that zip artifacts that are deployed into your accounts are trusted for deployment. You can include the process above in your CI/CD pipelines and require that all functions have a code signing configuration attached using the techniques outlined in previous topics. By using code signing with your Lambda function deployments, you prevent malicious actors who might have gotten credentials to create or update functions from injecting malicious code in your functions.

Automate security assessments for Lambda with Amazon Inspector

[Amazon Inspector](#) is a vulnerability management service that continually scans workloads for known software vulnerabilities and unintended network exposure. Amazon Inspector creates a finding that describes the vulnerability, identifies the affected resource, rates the severity of the vulnerability, and provides remediation guidance.

Amazon Inspector support provides continuous, automated security vulnerability assessments for Lambda functions and layers. Amazon Inspector provides two scan types for Lambda:

- **Lambda standard scanning (default):** Scans application dependencies within a Lambda function and its layers for [package vulnerabilities](#).
- **Lambda code scanning:** Scans the custom application code in your functions and layers for [code vulnerabilities](#). You can either activate Lambda standard scanning or activate Lambda standard scanning together with Lambda code scanning.

To enable Amazon Inspector, navigate to the [Amazon Inspector console](#), expand the **Settings** section, and choose **Account Management**. On the **Accounts** tab, choose **Activate**, and then select one of the scan options.

You can enable Amazon Inspector for multiple accounts and delegate permissions to manage Amazon Inspector for the organization to specific accounts while setting up Amazon Inspector. While enabling, you need to grant Amazon Inspector permissions by creating the role: `AWSServiceRoleForAmazonInspector2`. The Amazon Inspector console allows you to create this role using a one-click option.

For Lambda standard scanning, Amazon Inspector initiates vulnerability scans of Lambda functions in the following situations:

- As soon as Amazon Inspector discovers an existing Lambda function.
- When you deploy a new Lambda function.
- When you deploy an update to the application code or dependencies of an existing Lambda function or its layers.
- Whenever Amazon Inspector adds a new common vulnerabilities and exposures (CVE) item to its database, and that CVE is relevant to your function.

For Lambda code scanning, Amazon Inspector evaluates your Lambda function application code using automated reasoning and machine learning that analyzes your application code for overall security compliance. If Amazon Inspector detects a vulnerability in your Lambda function application code, Amazon Inspector produces a detailed **Code Vulnerability** finding. For a list of possible detections, see the [Amazon CodeGuru Detector Library](#).

To view the findings, go to the [Amazon Inspector console](#). On the **Findings** menu, choose **By Lambda function** to display the security scan results that were performed on Lambda functions.

To exclude a Lambda function from standard scanning, tag the function with the following key-value pair:

- Key:InspectorExclusion
- Value:LambdaStandardScanning

To exclude a Lambda function from code scans, tag the function with the following key-value pair:

- Key:InspectorCodeExclusion
- Value:LambdaCodeScanning

For example, as shown in following image, Amazon Inspector automatically detects vulnerabilities and categorizes the findings of type **Code Vulnerability**, which indicates that the vulnerability is in the code of the function, and not in one of the code-dependent libraries. You can check these details for a specific function or multiple functions at once.

13     s.bind(('',0))
```

Suggested remediation

Your code attempts to override an environment variable that is reserved by the Lambda runtime environment. This can lead to unexpected behavior and might break the execution of your Lambda function.

While working with your Lambda functions, ensure that you comply with the naming conventions for your Lambda functions. For more information, see [Working with Lambda environment variables](#).

You are responsible for the remediation suggestions that you accept. Always review remediation suggestions before accepting them. You might need to make edits to remediation suggestions to ensure that your code does what you intended.

Implement observability for Lambda security and compliance

AWS Config is a useful tool to find and fix non-compliant AWS Serverless resources. Every change you make to your serverless resources is recorded in AWS Config. Additionally, AWS Config allows you to store configuration snapshot data on S3. You can use Amazon Athena and Amazon Quick Suite to make dashboards and see AWS Config data. In [Detect non-compliant Lambda deployments and configurations with AWS Config](#), we discussed how we can visualize a certain configuration like Lambda layers. This topic expands on these concepts.

Visibility into Lambda configurations

You can use queries to pull important configurations like AWS account ID, Region, AWS X-Ray tracing configuration, VPC configuration, memory size, runtime, and tags. Here is a sample query you can use to pull this information from Athena:

```
WITH unnested AS (
  SELECT
    item.awsaccountid AS account_id,
    item.awsregion AS region,
    item.configuration AS lambda_configuration,
    item.resourceid AS resourceid,
    item.resourcename AS resourcename,
    item.configuration AS configuration,
    json_parse(item.configuration) AS lambda_json
  FROM
    default.aws_config_configuration_snapshot,
    UNNEST(configurationitems) as t(item)
  WHERE
    "dt" = 'latest'
    AND item.resourcetype = 'AWS::Lambda::Function'
)

SELECT DISTINCT
  account_id,
  tags,
  region as Region,
  resourcename as FunctionName,
  json_extract_scalar(lambda_json, '$.memorySize') AS memory_size,
  json_extract_scalar(lambda_json, '$.timeout') AS timeout,
  json_extract_scalar(lambda_json, '$.runtime') AS version
  json_extract_scalar(lambda_json, '$.vpcConfig.SubnetIds') AS vpcConfig
  json_extract_scalar(lambda_json, '$.tracingConfig.mode') AS tracingConfig
```

FROM
unnested

You can use the query to build an Quick Suite dashboard and visualize the data. To aggregate AWS resource configuration data, create tables in Athena, and build Quick Suite dashboards on the data from Athena, see [Visualizing AWS Config data using Athena and Amazon Quick Suite](#) on the AWS Cloud Operations and Management blog. Notably, this query also retrieves tag information for the functions. This allows for deeper insights into your workloads and environments, especially if you employ custom tags.

For more information on actions that you can take, see the [Addressing the observability findings](#) section later in this topic.

Visibility into Lambda compliance

With the data generated by AWS Config, you can create organization-level dashboards to monitor compliance. This allows for consistent tracking and monitoring of:

- Compliance packs by compliance score
- Rules by non-compliant resources

- Compliance status

AWS Config

- Dashboard
- Conformance packs

For more information on actions that you can take, see the [Addressing the observability findings](#) section below.

Visibility into Lambda function boundaries using Security Hub CSPM

To ensure that AWS services including Lambda are used securely, AWS introduced the Foundational Security Best Practices v1.0.0. This set of best practices provides clear guidelines for securing resources and data in the AWS environment, emphasizing the importance of maintaining a strong security posture. The AWS Security Hub CSPM complements this by offering a unified security and compliance center. It aggregates, organizes, and prioritizes security findings from multiple

AWS services like Amazon Inspector, AWS Identity and Access Management Access Analyzer, and Amazon GuardDuty.

If you have Security Hub CSPM, Amazon Inspector, IAM Access Analyzer, and GuardDuty enabled within your AWS organization, Security Hub CSPM automatically aggregates findings from these services. For instance, let's consider Amazon Inspector. Using Security Hub CSPM, you can efficiently identify code and package vulnerabilities in Lambda functions. In the Security Hub CSPM console, navigate to the bottom section labeled **Latest findings from AWS integrations**. Here, you can view and analyze findings sourced from various integrated AWS services.

Latest findings from AWS integrations		
Amazon GuardDuty		No findings
Open the GuardDuty console		
Amazon Inspector		23 minutes ago
Open the Inspector console	See findings	
Amazon Macie		No findings
Open the Macie console		
AWS Health		No findings
Open the Personal Health Dashboard		
AWS IAM Access Analyzer		No findings
Open the IAM Access Analyzer console		
AWS Systems Manager Patch Manager		No findings
Open the Systems Manager Patch Manager console		
AWS Firewall Manager		No findings
Open the Firewall Manager console		

To see details, choose the **See findings** link in the second column. This displays a list of findings filtered by product, such as Amazon Inspector. To limit your search to Lambda functions, set `ResourceType` to `AwsLambdaFunction`. This displays findings from Amazon Inspector related to Lambda functions.

<input type="checkbox"/>	■ HIGH	NEW	ACTIVE	us-east-1	218	Amazon	Inspector	CWE-117 - Log injection	Lambda Function \$LATEST		27 minutes ago
<input type="checkbox"/>	■ HIGH	NEW	ACTIVE	us-east-1	218	Amazon	Inspector	CWE-117 - Log injection	Lambda Function \$LATEST		27 minutes ago

For GuardDuty, you can identify suspicious network traffic patterns. Such anomalies might suggest the existence of potentially malicious code within your Lambda function.

With IAM Access Analyzer, you can check policies, especially those with condition statements that grant function access to external entities. Moreover, IAM Access Analyzer evaluates permissions set when using the [AddPermission](#) operation in the Lambda API alongside an EventSourceToken.

Addressing the observability findings

Given the wide-ranging configurations possible for Lambda functions and their distinct requirements, a standardized automation solution for remediation might not suit every situation. Additionally, changes are implemented differently across various environments. If you encounter any configuration that seems non-compliant, consider the following guidelines:

1. Tagging strategy

We recommend implementing a comprehensive tagging strategy. Each Lambda function should be tagged with key information such as:

- **Owner:** The person or team responsible for the function.
- **Environment:** Production, staging, development, or sandbox.
- **Application:** The broader context to which this function belongs, if applicable.

2. Owner outreach

Instead of automating the breaking changes (like VPC configuration adjustment), proactively contact the owners of non-compliant functions (identified by the owner tag) providing them sufficient time to either:

- Adjust non-compliant configurations on Lambda functions.
- Provide an explanation and request an exception, or refine the compliance standards.

3. **Maintain a configuration management database (CMDB)**

While tags can provide immediate context, maintaining a centralized CMDB can provide deeper insights. It can hold more granular information about each Lambda function, its dependencies, and other critical metadata. A CMDB is an invaluable resource for auditing, compliance checks, and identifying function owners.

As the landscape of serverless infrastructure continually evolves, it's essential to adopt a proactive stance towards monitoring. With tools like AWS Config, Security Hub CSPM, and Amazon Inspector, potential anomalies or non-compliant configurations can be swiftly identified. However, tools alone cannot ensure total compliance or optimal configurations. It's crucial to pair these tools with well-documented processes and best practices.

- **Feedback loop:** Once remediation steps are undertaken, ensure there's a feedback loop. This means periodically revisiting non-compliant resources to confirm if they've been updated or are still running with the same issues.
- **Documentation:** Always document the observations, actions taken, and any exceptions granted. Proper documentation not only helps during audits but also aids in enhancing the process for better compliance and security in the future.
- **Training and awareness:** Ensure that all stakeholders, especially Lambda function owners, are regularly trained and made aware of best practices, organizational policies, and compliance mandates. Regular workshops, webinars, or training sessions can go a long way in ensuring everyone is on the same page when it comes to security and compliance.

In conclusion, while tools and technologies provide robust capabilities to detect and flag potential issues, the human element—understanding, communication, training, and documentation—remains pivotal. Together, they form a potent combination to ensure that your Lambda functions and broader infrastructure remain compliant, secure, and optimized for your business needs.

Compliance validation for AWS Lambda

Third-party auditors assess the security and compliance of AWS Lambda as part of multiple AWS compliance programs. These include SOC, PCI, FedRAMP, HIPAA, and others.

For a list of AWS services in scope of specific compliance programs, see [AWS services in scope by compliance program](#). For general information, see [AWS compliance programs](#).

You can download third-party audit reports using AWS Artifact. For more information, see [Downloading reports in AWS artifact](#).

Your compliance responsibility when using Lambda is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. You can implement governance controls to ensure that your company's Lambda functions meet your compliance requirements. For more information, see [Create a governance strategy for Lambda functions and layers](#).

Resilience in AWS Lambda

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see [AWS global infrastructure](#).

In addition to the AWS global infrastructure, Lambda offers several features to help support your data resiliency and backup needs.

- **Versioning** – You can use versioning in Lambda to save your function's code and configuration as you develop it. Together with aliases, you can use versioning to perform blue/green and rolling deployments. For details, see [Manage Lambda function versions](#).
- **Scaling** – When your function receives a request while it's processing a previous request, Lambda launches another instance of your function to handle the increased load. Lambda automatically scales to handle 1,000 concurrent executions per Region, a [quota](#) that can be increased if needed. For details, see [Understanding Lambda function scaling](#).

- **High availability** – Lambda runs your function in multiple Availability Zones to ensure that it is available to process events in case of a service interruption in a single zone. If you configure your function to connect to a virtual private cloud (VPC) in your account, specify subnets in multiple Availability Zones to ensure high availability. For details, see [Giving Lambda functions access to resources in an Amazon VPC](#).
- **Reserved concurrency** – To make sure that your function can always scale to handle additional requests, you can reserve concurrency for it. Setting reserved concurrency for a function ensures that it can scale to, but not exceed, a specified number of concurrent invocations. This ensures that you don't lose requests due to other functions consuming all of the available concurrency. For details, see [Configuring reserved concurrency for a function](#).
- **Retries** – For asynchronous invocations and a subset of invocations triggered by other services, Lambda automatically retries on error with delays between retries. Other clients and AWS services that invoke functions synchronously are responsible for performing retries. For details, see [Understanding retry behavior in Lambda](#).
- **Dead-letter queue** – For asynchronous invocations, you can configure Lambda to send requests to a dead-letter queue if all retries fail. A dead-letter queue is an Amazon SNS topic or Amazon SQS queue that receives events for troubleshooting or reprocessing. For details, see [Adding a dead-letter queue](#).

Infrastructure security in AWS Lambda

As a managed service, AWS Lambda is protected by AWS global network security. For information about AWS security services and how AWS protects infrastructure, see [AWS Cloud Security](#). To design your AWS environment using the best practices for infrastructure security, see [Infrastructure Protection](#) in *Security Pillar AWS Well-Architected Framework*.

You use AWS published API calls to access Lambda through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Securing workloads with public endpoints

For workloads that are accessible publicly, AWS provides a number of features and services that can help mitigate certain risks. This section covers authentication and authorization of application users and protecting API endpoints.

Authentication and authorization

Authentication relates to identity and authorization refers to actions. Use authentication to control who can invoke a Lambda function, and then use authorization to control what they can do. For many applications, IAM is sufficient for managing both control mechanisms.

For applications with external users, such as web or mobile applications, it is common to use [JSON Web Tokens](#) (JWTs) to manage authentication and authorization. Unlike traditional, server-based password management, JWTs are passed from the client on every request. They are a cryptographically secure way to verify identity and claims using data passed from the client. For Lambda-based applications, this allows you to secure every call to each API endpoint without relying on a central server for authentication.

You can [implement JWTs with Amazon Cognito](#), a user directory service that can handle registration, authentication, account recovery, and other common account management operations. [Amplify Framework](#) provides libraries to simplify integrating this service into your frontend application. You can also consider third-party partner services like [Auth0](#).

Given the critical security role of an identity provider service, it's important to use professional tooling to safeguard your application. It's not recommended that you write your own services to handle authentication or authorization. Any vulnerabilities in custom libraries may have significant implications for the security of your workload and its data.

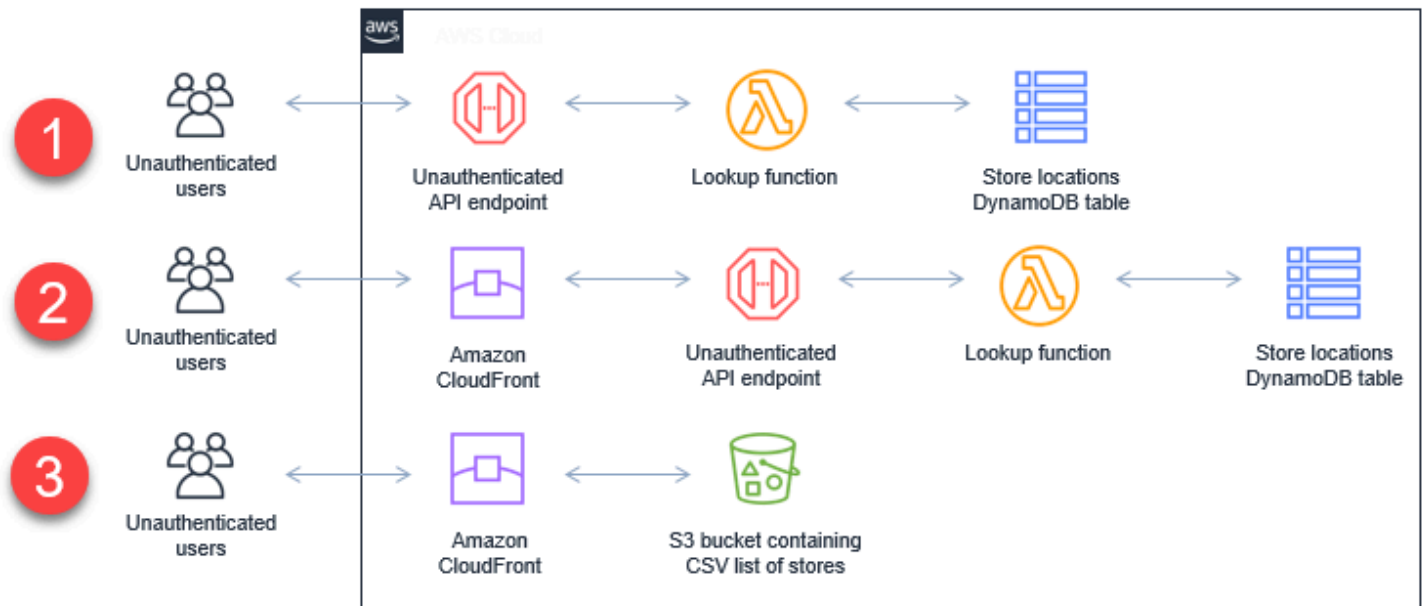

Protecting API endpoints

For serverless applications, the preferred way to serve a backend application publicly is to use Amazon API Gateway. This can help you protect an API from malicious users or spikes in traffic.

API Gateway offers two endpoint types for serverless developers: [REST APIs](#) and [HTTP APIs](#). Both support [authorization using AWS Lambda](#), IAM, or Amazon Cognito. When using IAM or Amazon Cognito, incoming requests are evaluated and if they are missing a required token or contain invalid authentication, the request is rejected. You are not charged for these requests and they do not count towards any throttling quotas.

Unauthenticated API routes may be accessed by anyone on the public internet so it's recommended that you limit the use of unauthenticated APIs. If you must use unauthenticated APIs, it's important to protect these against common risks, such as [denial-of-service](#) (DoS) attacks. [Applying AWS WAF](#) to these APIs can help protect your application from SQL injection and cross-site scripting (XSS) attacks. API Gateway also implements [throttling](#) at the AWS account-level and per-client level when API keys are used.

In many cases, the functionality provided by unauthenticated API can be achieved with an alternative approach. For example, a web application may provide a list of customer retail stores from a DynamoDB table to users who are not logged in. This request may originate from a frontend web application or from any other source that calls the URL endpoint. This diagram compares three solutions:

1. This unauthenticated API can be called by anyone on the internet. In a denial of service attack, it's possible to exhaust API throttling limits, Lambda concurrency, or DynamoDB provisioned read capacity on an underlying table.
2. A CloudFront distribution in front of the API endpoint with an appropriate [time-to-live](#) (TTL) configuration would absorb most of the traffic in a DoS attack, without changing the underlying solution for fetching the data.
3. Alternatively, for static data that rarely changes, the CloudFront distribution could serve the data from an Amazon S3 bucket.

Using code signing to verify code integrity with Lambda

Code signing helps ensure that only trusted code is deployed to your Lambda functions. Using AWS Signer, you can create digitally signed code packages for your functions. When you [add a code signing configuration to a function](#), Lambda verifies that all new code deployments are signed by a trusted source. Because code signing validation checks run at deployment time, there is no impact on function execution.

Important

Code signing configurations only prevent new deployments of unsigned code. If you add a code signing configuration to an existing function that has unsigned code, that code keeps running until you deploy a new code package.

When you enable code signing for a function, any [layers](#) that you add to the function must also be signed by an allowed signing profile.

There is no additional charge for using AWS Signer or code signing for AWS Lambda.

Signature validation

Lambda performs the following validation checks when you deploy a signed code package to your function:

1. **Integrity:** Validates that the code package has not been modified since it was signed. Lambda compares the hash of the package with the hash from the signature.
2. **Expiry:** Validates that the signature of the code package has not expired.
3. **Mismatch:** Validates that the code package is signed with an allowed signing profile
4. **Revocation:** Validates that the signature of the code package has not been revoked.

When you create a code signing configuration, you can use the [UntrustedArtifactOnDeployment](#) parameter to specify how Lambda should respond if the expiry, mismatch, or revocation checks fail. You can choose one of these actions:

- **Warn:** This is the default setting. Lambda allows the deployment of the code package, but issues a warning. Lambda issues a new Amazon CloudWatch metric (`SignatureValidationErrors`) and also stores the warning in the CloudTrail log.

- Enforce Lambda issues a warning (the same as for the Warn action) and blocks the deployment of the code package.

Topics

- [Creating code signing configurations for Lambda](#)
- [Configuring IAM policies for Lambda code signing configurations](#)
- [Using tags on code signing configurations](#)

Creating code signing configurations for Lambda

To enable code signing for a function, you create a *code signing configuration* and attach it to the function. A code signing configuration defines a list of allowed signing profiles and the policy action to take if any of the validation checks fail.

Note

Functions defined as container images do not support code signing.

Sections

- [Configuration prerequisites](#)
- [Creating code signing configurations](#)
- [Enabling code signing for a function](#)

Configuration prerequisites

Before you can configure code signing for a Lambda function, use AWS Signer to do the following:

- Create one or more [signing profiles](#).
- Use a signing profile to [create a signed code package for your function](#).

Creating code signing configurations

A code signing configuration defines a list of allowed signing profiles and the signature validation policy.

To create a code signing configuration (console)

1. Open the [Code signing configurations page](#) of the Lambda console.
2. Choose **Create configuration**.
3. For **Description**, enter a descriptive name for the configuration.
4. Under **Signing profiles**, add up to 20 signing profiles to the configuration.
 - a. For **Signing profile version ARN**, choose a profile version's Amazon Resource Name (ARN), or enter the ARN.
 - b. To add an additional signing profile, choose **Add signing profiles**.
5. Under **Signature validation policy**, choose **Warn** or **Enforce**.
6. Choose **Create configuration**.

Enabling code signing for a function

To enable code signing for a function, add a code signing configuration to the function.

Important

Code signing configurations only prevent new deployments of unsigned code. If you add a code signing configuration to an existing function that has unsigned code, that code keeps running until you deploy a new code package.

To associate a code signing configuration with a function (console)

1. Open the [Functions page](#) of the Lambda console.
2. Choose the function for which you want to enable code signing.
3. Open the **Configuration** tab.
4. Scroll down and choose **Code signing**.
5. Choose **Edit**.
6. In **Edit code signing**, choose a code signing configuration for this function.
7. Choose **Save**.

Configuring IAM policies for Lambda code signing configurations

To grant permission for a user to access Lambda code signing API operations, attach one or more policy statements to the user policy. For more information about user policies, see [Identity-based IAM policies for Lambda](#).

The following example policy statement grants permission to create, update, and retrieve code signing configurations.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "lambda:CreateCodeSigningConfig",
        "lambda:UpdateCodeSigningConfig",
        "lambda:GetCodeSigningConfig"
      ],
      "Resource": "*"
    }
  ]
}
```

Administrators can use the `CodeSigningConfigArn` condition key to specify the code signing configurations that developers must use to create or update your functions.

The following example policy statement grants permission to create a function. The policy statement includes a `lambda:CodeSigningConfigArn` condition to specify the allowed code signing configuration. Lambda blocks `CreateFunction` API requests if the [CodeSigningConfigArn](#) parameter is missing or does not match the value in the condition.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
```

```
{
  "Sid": "AllowReferencingCodeSigningConfig",
  "Effect": "Allow",
  "Action": [
    "lambda:CreateFunction"
  ],
  "Resource": "*",
  "Condition": {
    "StringEquals": {
      "lambda:CodeSigningConfigArn": "arn:aws:lambda:us-east-1:111122223333:code-signing-config:csc-0d4518bd353a0a7c6"
    }
  }
}
```

Using tags on code signing configurations

You can tag code signing configurations to organize and manage your resources. Tags are free-form key-value pairs associated with your resources that are supported across AWS services. For more information about use cases for tags, see [Common tagging strategies](#) in the *Tagging AWS Resources and Tag Editor Guide*.

You can use the AWS Lambda API to view and update tags. You can also view and update tags while managing a specific code signing configuration in the Lambda console.

Sections

- [Permissions required for working with tags](#)
- [Using tags with the Lambda console](#)
- [Using tags with the AWS CLI](#)

Permissions required for working with tags

To allow an AWS Identity and Access Management (IAM) identity (user, group, or role) to read or set tags on a resource, grant it the corresponding permissions:

- **lambda:ListTags**—When a resource has tags, grant this permission to anyone who needs to call `ListTags` on it. For tagged functions, this permission is also necessary for `GetFunction`.

- **lambda:TagResource**—Grant this permission to anyone who needs to call TagResource or perform a tag on create.

Optionally, consider granting the **lambda:UntagResource** permission as well to allow UntagResource calls to the resource.

For more information, see [Identity-based IAM policies for Lambda](#).

Using tags with the Lambda console

You can use the Lambda console to create code signing configurations that have tags, add tags to existing code signing configurations, and filter code signing configurations by tag.

To add a tag when you create a code signing configuration

1. Open [Code signing configurations](#) in the Lambda console.
2. From the header of the content pane, Choose **Create configuration**.
3. In the section at the top of the content pane, set up your code signing configuration. For more information about configuring code signing configurations, see [the section called “Code signing”](#).
4. In the **Tags** section, choose **Add new tag**.
5. In the **Key** field, enter your tag key. For information about tagging restrictions, see [Tag naming limits and requirements](#) in the *Tagging AWS Resources and Tag Editor Guide*.
6. Choose **Create configuration**.

To add a tag to an existing code signing configuration

1. Open [Code signing configurations](#) in the Lambda console.
2. Choose the name of your code signing configuration.
3. In the tabs below the **Detail** pane, choose **Tags**.
4. Choose **Manage tags**.
5. Choose **Add new tag**.
6. In the **Key** field, enter your tag key. For information about tagging restrictions, see [Tag naming limits and requirements](#) in the *Tagging AWS Resources and Tag Editor Guide*.
7. Choose **Save**.

To filter code signing configurations by tag

1. Open [Code signing configurations](#) in the Lambda console.
2. Choose the search box.
3. From the dropdown list, select your tag from below the **Tags** subheading.
4. Select **Use: "tag-name"** to see all code signing configurations tagged with this key, or choose an **Operator** to further filter by value.
5. Select your tag value to filter by a combination of tag key and value.

The search box also supports searching for tag keys. Enter the name of a key to find it in the list.

Using tags with the AWS CLI

You can add and remove tags on existing Lambda resources, including code signing configurations, with the Lambda API. You can also add tags when creating an code signing configuration, which allows you to keep a resource tagged through its entire lifecycle.

Updating tags with the Lambda tag APIs

You can add and remove tags for supported Lambda resources through the [TagResource](#) and [UntagResource](#) API operations.

You can call these operations using the AWS CLI. To add tags to an existing resource, use the `tag-resource` command. This example adds two tags, one with the key *Department* and one with the key *CostCenter*.

```
aws lambda tag-resource \  
--resource arn:aws:lambda:us-east-2:123456789012:resource-type:my-resource \  
--tags Department=Marketing, CostCenter=1234ABCD
```

To remove tags, use the `untag-resource` command. This example removes the tag with the key *Department*.

```
aws lambda untag-resource --resource arn:aws:lambda:us-east-1:123456789012:resource-  
type:resource-identifier \  
--tag-keys Department
```

Adding tags when creating a code signing configuration

To create a new Lambda code signing configuration with tags, use the [CreateCodeSigningConfig](#) API operation. Specify the `Tags` parameter. You can call this operation with the `create-code-signing-config` AWS CLI command and the `--tags` option. For more information about the CLI command, see [create-code-signing-config](#) in the *AWS CLI Command Reference*.

Before using the `Tags` parameter with `CreateCodeSigningConfig`, ensure that your role has permission to tag resources alongside the usual permissions needed for this operation. For more information about permissions for tagging, see [the section called "Permissions required for working with tags"](#).

Viewing tags with the Lambda tag APIs

To view the tags that are applied to a specific Lambda resource, use the `ListTags` API operation. For more information, see [ListTags](#).

You can call this operation with the `list-tags` AWS CLI command by providing an ARN (Amazon Resource Name).

```
aws lambda list-tags --resource arn:aws:lambda:us-east-1:123456789012:resource-  
type:resource-identifier
```

Filtering resources by tag

You can use the AWS Resource Groups Tagging API [GetResources](#) API operation to filter your resources by tags. The `GetResources` operation receives up to 10 filters, with each filter containing a tag key and up to 10 tag values. You provide `GetResources` with a `ResourceType` to filter by specific resource types.

You can call this operation using the `get-resources` AWS CLI command. For examples of using `get-resources`, see [get-resources](#) in the *AWS CLI Command Reference*.

Monitoring, debugging, and troubleshooting Lambda functions

AWS Lambda integrates with other AWS services to help you monitor and troubleshoot your Lambda functions. Lambda automatically monitors Lambda functions on your behalf and reports metrics through Amazon CloudWatch. To help you monitor your code when it runs, Lambda automatically tracks the number of requests, the invocation duration per request, and the number of requests that result in an error.

You can use other AWS services to troubleshoot your Lambda functions. This section describes how to use these AWS services to monitor, trace, debug, and troubleshoot your Lambda functions and applications. For details about function logging and errors in each runtime, see individual runtime sections.

Pricing

CloudWatch has a perpetual free tier. Beyond the free tier threshold, CloudWatch charges for metrics, dashboards, alarms, logs, and insights. For more information, see [Amazon CloudWatch pricing](#).

Using CloudWatch metrics with Lambda

When your AWS Lambda function finishes processing an event, Lambda automatically sends metrics about the invocation to Amazon CloudWatch. You don't need to grant any additional permissions to your execution role to receive function metrics, and there's no additional charge for these metrics.

There are many types of metrics associated with Lambda functions. These include invocation metrics, performance metrics, concurrency metrics, asynchronous invocation metrics, and event source mapping metrics. For more information, see [the section called "Metric types"](#).

In the CloudWatch console, you can [view these metrics](#) and build graphs and dashboards with them. You can also set alarms to respond to changes in utilization, performance, or error rates. Lambda sends metric data to CloudWatch in 1-minute intervals. For more immediate insight into your Lambda function, you can create [high-resolution custom metrics](#). Charges apply for custom metrics and CloudWatch alarms. For more information, see [Amazon CloudWatch Pricing](#).

Viewing metrics for Lambda functions

Use the CloudWatch console to view metrics for your Lambda functions. In the console, you can filter and sort function metrics by function name, alias, version, or event source mapping UUID.

To view metrics on the CloudWatch console

1. Open the [Metrics page](#) (AWS/Lambda namespace) of the CloudWatch console.
2. On the **Browse** tab, under **Metrics**, choose any of the following dimensions:
 - **By Function Name** (FunctionName) – View aggregate metrics for all versions and aliases of a function.
 - **By Resource** (Resource) – View metrics for a version or alias of a function.
 - **By Executed Version** (ExecutedVersion) – View metrics for a combination of alias and version. Use the ExecutedVersion dimension to compare error rates for two versions of a function that are both targets of a [weighted alias](#).
 - **By Event Source Mapping UUID** (EventSourceMappingUUID) – View metrics for an event source mapping.
 - **Across All Functions** (none) – View aggregate metrics for all functions in the current AWS Region.

3. Choose a metric. The metric should automatically appear in the visual graph, as well as under the **Graphed metrics** tab.

By default, graphs use the Sum statistic for all metrics. To choose a different statistic and customize the graph, use the options on the **Graphed metrics** tab.

Note

The timestamp on a metric reflects when the function was invoked. Depending on the duration of the invocation, this can be several minutes before the metric is emitted. For example, if your function has a 10-minute timeout, then look more than 10 minutes in the past for accurate metrics.

For more information about CloudWatch, see the [Amazon CloudWatch User Guide](#).

Types of metrics for Lambda functions

This section describes the types of Lambda metrics available in the CloudWatch console.

Topics

- [Invocation metrics](#)
- [Deployment metrics](#)
- [Performance metrics](#)
- [Concurrency metrics](#)
- [Asynchronous invocation metrics](#)
- [Event source mapping metrics](#)

Invocation metrics

Invocation metrics are binary indicators of the outcome of a Lambda function invocation. View these metrics with the Sum statistic. For example, if the function returns an error, then Lambda sends the `Errors` metric with a value of 1. To get a count of the number of function errors that occurred each minute, view the Sum of the `Errors` metric with a period of 1 minute.

- **Invocations** – The number of times that your function code is invoked, including successful invocations and invocations that result in a function error. Invocations aren't recorded if

the invocation request is throttled or otherwise results in an invocation error. The value of `Invocations` equals the number of requests billed.

- **Errors** – The number of invocations that result in a function error. Function errors include exceptions that your code throws and exceptions that the Lambda runtime throws. The runtime returns errors for issues such as timeouts and configuration errors. To calculate the error rate, divide the value of `Errors` by the value of `Invocations`. Note that the timestamp on an error metric reflects when the function was invoked, not when the error occurred.
- **DeadLetterErrors** – For [asynchronous invocation](#), the number of times that Lambda attempts to send an event to a dead-letter queue (DLQ) but fails. Dead-letter errors can occur due to incorrectly set resources or size limits.
- **DestinationDeliveryFailures** – For asynchronous invocation and supported [event source mappings](#), the number of times that Lambda attempts to send an event to a [destination](#) but fails. For event source mappings, Lambda supports destinations for stream sources (DynamoDB and Kinesis). Delivery errors can occur due to permissions errors, incorrectly configured resources, or size limits. Errors can also occur if the destination you have configured is an unsupported type such as an Amazon SQS FIFO queue or an Amazon SNS FIFO topic.
- **Throttles** – The number of invocation requests that are throttled. When all function instances are processing requests and no concurrency is available to scale up, Lambda rejects additional requests with a `TooManyRequestsException` error. Throttled requests and other invocation errors don't count as either `Invocations` or `Errors`.
- **OversizedRecordCount** – For Amazon DocumentDB event sources, the number of events your function receives from your change stream that are over 6 MB in size. Lambda drops the message and emits this metric.
- **ProvisionedConcurrencyInvocations** – The number of times that your function code is invoked using [provisioned concurrency](#).
- **ProvisionedConcurrencySpilloverInvocations** – The number of times that your function code is invoked using standard concurrency when all provisioned concurrency is in use.
- **RecursiveInvocationsDropped** – The number of times that Lambda has stopped invocation of your function because it has detected that your function is part of an infinite recursive loop. Recursive loop detection monitors how many times a function is invoked as part of a chain of requests by tracking metadata added by supported AWS SDKs. By default, if your function is invoked as part of a chain of requests approximately 16 times, Lambda drops the next invocation. If you disable recursive loop detection, this metric is not emitted. For more information about this feature, see [Use Lambda recursive loop detection to prevent infinite loops](#).

Deployment metrics

Deployment metrics provide information about Lambda function deployment events and related validation processes.

- **SignatureValidationErrors** – The number of times a code package deployment has occurred with signature validation failures when the code signing configuration policy is set to Warn. This metric is emitted when the expiry, mismatch, or revocation checks fail but the deployment is still allowed due to the Warn policy setting. For more information about code signing, see [Using code signing to verify code integrity with Lambda](#).

Performance metrics

Performance metrics provide performance details about a single function invocation. For example, the **Duration** metric indicates the amount of time in milliseconds that your function spends processing an event. To get a sense of how fast your function processes events, view these metrics with the Average or Max statistic.

- **Duration** – The amount of time that your function code spends processing an event. The billed duration for an invocation is the value of **Duration** rounded up to the nearest millisecond. **Duration** does not include cold start time.
- **PostRuntimeExtensionsDuration** – The cumulative amount of time that the runtime spends running code for extensions after the function code has completed.
- **IteratorAge** – For DynamoDB, Kinesis, and Amazon DocumentDB event sources, the age of the last record in the event in milliseconds. This metric measures the time between when a stream receives the record and when the event source mapping sends the event to the function.
- **OffsetLag** – For self-managed Apache Kafka and Amazon Managed Streaming for Apache Kafka (Amazon MSK) event sources, the difference in offset between the last record written to a topic and the last record that your function's consumer group processed. Though a Kafka topic can have multiple partitions, this metric measures the offset lag at the topic level.

Duration also supports percentile (p) statistics. Use percentiles to exclude outlier values that skew Average and Maximum statistics. For example, the p95 statistic shows the maximum duration of 95 percent of invocations, excluding the slowest 5 percent. For more information, see [Percentiles](#) in the *Amazon CloudWatch User Guide*.

Concurrency metrics

Lambda reports concurrency metrics as an aggregate count of the number of instances processing events across a function, version, alias, or AWS Region. To see how close you are to hitting [concurrency limits](#), view these metrics with the Max statistic.

- **ConcurrentExecutions** – The number of function instances that are processing events. If this number reaches your [concurrent executions quota](#) for the Region, or the [reserved concurrency](#) limit on the function, then Lambda throttles additional invocation requests.
- **ProvisionedConcurrentExecutions** – The number of function instances that are processing events using [provisioned concurrency](#). For each invocation of an alias or version with provisioned concurrency, Lambda emits the current count. If your function is inactive or not receiving requests, Lambda doesn't emit this metric.
- **ProvisionedConcurrencyUtilization** – For a version or alias, the value of **ProvisionedConcurrentExecutions** divided by the total amount of provisioned concurrency configured. For example, if you configure a provisioned concurrency of 10 for your function, and your **ProvisionedConcurrentExecutions** is 7, then your **ProvisionedConcurrencyUtilization** is 0.7.

If your function is inactive or not receiving requests, Lambda doesn't emit this metric because it is based on **ProvisionedConcurrentExecutions**. Keep this in mind if you use **ProvisionedConcurrencyUtilization** as the basis for CloudWatch alarms.

- **UnreservedConcurrentExecutions** – For a Region, the number of events that functions without reserved concurrency are processing.
- **ClaimedAccountConcurrency** – For a Region, the amount of concurrency that is unavailable for on-demand invocations. **ClaimedAccountConcurrency** is equal to **UnreservedConcurrentExecutions** plus the amount of allocated concurrency (i.e. the total reserved concurrency plus total provisioned concurrency). For more information, see [Working with the ClaimedAccountConcurrency metric](#).

Asynchronous invocation metrics

Asynchronous invocation metrics provide details about asynchronous invocations from event sources and direct invocations. You can set thresholds and alarms to notify you of certain changes. For example, when there's an undesired increase in the number of events queued for processing

(AsyncEventsReceived). Or, when an event has been waiting a long time to be processed (AsyncEventAge).

- **AsyncEventsReceived** – The number of events that Lambda successfully queues for processing. This metric provides insight into the number of events that a Lambda function receives. Monitor this metric and set alarms for thresholds to check for issues. For example, to detect an undesirable number of events sent to Lambda, and to quickly diagnose issues resulting from incorrect trigger or function configurations. Mismatches between AsyncEventsReceived and Invocations can indicate a disparity in processing, events being dropped, or a potential queue backlog.
- **AsyncEventAge** – The time between when Lambda successfully queues the event and when the function is invoked. The value of this metric increases when events are being retried due to invocation failures or throttling. Monitor this metric and set alarms for thresholds on different statistics for when a queue buildup occurs. To troubleshoot an increase in this metric, look at the **Errors** metric to identify function errors and the **Throttles** metric to identify concurrency issues.
- **AsyncEventsDropped** – The number of events that are dropped without successfully executing the function. If you configure a dead-letter queue (DLQ) or **OnFailure** destination, then events are sent there before they're dropped. Events are dropped for various reasons. For example, events can exceed the maximum event age or exhaust the maximum retry attempts, or reserved concurrency might be set to 0. To troubleshoot why events are dropped, look at the **Errors** metric to identify function errors and the **Throttles** metric to identify concurrency issues.

Event source mapping metrics

Event source mapping metrics provide insights into the processing behavior of your event source mapping.

Currently, event source mapping metrics are available for Amazon SQS, Kinesis, DynamoDB, Amazon MSK and self-managed Apache Kafka event sources.

For event source mapping with metrics config, you can also check all the ESM related metrics in the **Monitor** tab from the page Console **Lambda** > **Additional resources** > **event source mappings** now.

To enable metrics or an event source mapping (console)

1. Open the [Functions page](#) of the Lambda console.

2. Choose the function you want to enable metrics for.
3. Choose **Configuration**, then choose **Triggers**.
4. Choose the event source mapping that you want to enable metrics for, then choose **Edit**.
5. Under **Event source mapping configuration**, choose **Enable metrics** or select from the **Metrics** dropdown list.
6. Choose **Save**.

Alternatively, you can enable metrics for your event source mapping programmatically using the [EventSourceMappingMetricsConfig](#) object in your [EventSourceMappingConfiguration](#). For example, the following [UpdateEventSourceMapping](#) CLI command enables metrics for an event source mapping:

```
aws lambda update-event-source-mapping \
  --uuid a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 \
  --metrics-config Metrics=EventCount
```

There are 3 metric groups: `EventCount`, `ErrorCount` and `KafkaMetrics`, and each group has multiple metrics. Not every metric is available for each event source. The following table summarizes the supported metrics for each type of event source.

You must opt-in the metric group to receive metrics related metrics. For example, set `EventCount` in metrics config to have: (`PolledEventCount`, `FilteredOutEventCount`, `InvokedEventCount`, `FailedInvokeEventCount`, `DroppedEventCount`, `OnFailureDestinationDeliveredEventCount`, and `DeletedEventCount`).

Event source mapping metric	Metric group	Amazon SQS	Kinesis and DynamoDB streams	Amazon MSK and self-managed Apache Kafka
PolledEventCount	EventCount	Yes	Yes	Yes
FilteredOutEventCount	EventCount	Yes	Yes	Yes

Event source mapping metric	Metric group	Amazon SQS	Kinesis and DynamoDB streams	Amazon MSK and self-managed Apache Kafka
InvokedEventCount	EventCount	Yes	Yes	Yes
FailedInvokeEventCount	EventCount	Yes	Yes	Yes
DroppedEventCount	EventCount	No	Yes	Yes
OnFailureDestinationDeliveredEventCount	EventCount	No	Yes	Yes
DeletedEventCount	EventCount	Yes	No	No
CommittedEventCount	EventCount	No	No	Yes
PollingErrorCount	ErrorCount	No	No	Yes
InvokeErrorCount	ErrorCount	No	No	Yes
OnFailureDestinationDeliveryErrorCount	ErrorCount	No	No	Yes

Event source mapping metric	Metric group	Amazon SQS	Kinesis and DynamoDB streams	Amazon MSK and self-managed Apache Kafka
SchemaRegistryErrorCount	ErrorCount	No	No	Yes
CommitErrorCount	ErrorCount	No	No	Yes
MaxOffsetLag	KafkaMetrics	No	No	Yes
SumOffsetLag	KafkaMetrics	No	No	Yes

In addition, if your event source mapping is in [provisioned mode](#), Lambda provides the following metric:

- **ProvisionedPollers** – For event source mappings in provisioned mode, the number of event pollers that are actively running. View this metric using the MAX math.
- (Amazon MSK and self-managed Apache Kafka event sources only) **EventPollerUnit** – For event source mappings in provisioned mode, the number of event poller units that are actively running. View this metric using the SUM math.
- (Amazon MSK and self-managed Apache Kafka event sources) **EventPollerThroughputInBytes** – For event source mappings in provisioned mode, the total record size of event pollers polled from the event source. It can tell you the current polling throughput. View this metric using the SUM math.

Here is more detail about each of the metric:

- **PolledEventCount** – The number of events that Lambda reads successfully from the event source. If Lambda polls for events but receives an empty poll (no new records), Lambda emits a

0 value for this metric. Use this metric to detect whether your event source mapping is correctly polling for new events.

- **FilteredOutEventCount** – For event source mapping with a [filter criteria](#), the number of events filtered out by that filter criteria. Use this metric to detect whether your event source mapping is properly filtering out events. For events that match the filter criteria, Lambda emits a 0 metric.
- **InvokedEventCount** – The number of events that invoked your Lambda function. Use this metric to verify that events are properly invoking your function. If an event results in a function error or throttling, **InvokedEventCount** may count multiple times for the same polled event due to automatic retries.

Warning

Lambda event source mappings process each event at least once, and duplicate processing of records can occur. Because of this, events may be counted multiple times in metrics that involve event counts.

- **FailedInvokeEventCount** – The number of events that Lambda tried to invoke your function with, but failed. Invocations can fail due to reasons such as network configuration issues, incorrect permissions, or a deleted Lambda function, version, or alias. If your event source mapping has [partial batch responses](#) enabled, **FailedInvokeEventCount** includes any event with a non-empty **BatchItemFailures** in the response.

Note

The timestamp for the **FailedInvokeEventCount** metric represents the end of the function invocation. This behavior differs from other Lambda invocation error metrics, which are timestamped at the start of the function invocation.

- **DroppedEventCount** – The number of events that Lambda dropped due to expiry or retry exhaustion. Specifically, this is the number of records that exceed your configured values for **MaximumRecordAgeInSeconds** or **MaximumRetryAttempts**. Importantly, this doesn't include the number of records that expire due to exceeding your event source's retention settings. Dropped events also excludes events that you send to an [on-failure destination](#). Use this metric to detect an increasing backlog of events.
- **OnFailureDestinationDeliveredEventCount** – For event source mappings with an [on-failure destination](#) configured, the number of events sent to that destination. Use this metric

to monitor for function errors related to invocations from this event source. If delivery to the destination fails, Lambda handles metrics as follows:

- Lambda doesn't emit the `OnFailureDestinationDeliveredEventCount` metric.
- For the `DestinationDeliveryFailures` metric, Lambda emits a 1.
- For the `DroppedEventCount` metric, Lambda emits a number equal to the number of events that failed delivery.
- `DeletedEventCount` – The number of events that Lambda successfully deletes after processing. If Lambda tries to delete an event but fails, Lambda emits a 0 metric. Use this metric to ensure that successfully processed events are deleted from your event source.
- `CommittedEventCount` – The number of events that Lambda successfully committed after processing. It's a sum of the deltas of last and current committed offset from each partition in the Kafka event source mapping.
- `PollingErrorCount` – The number of errors that Lambda failed to poll requests from event source. Lambda only emits this metric data when error happened.
- `InvokeErrorCount` – The number of errors that Lambda failed to invoke your function. Notice the invocation is records in batch. The number is on batch level, not on record count level. Lambda only emits this metric data when error happened.
- `SchemaRegistryErrorCount` – The number of errors that Lambda failed to fetch the schema or deserialize with the scheme. Lambda only emits this metric data when error happened.
- `CommitErrorCount` – The number of errors that Lambda failed to commit to Kafka cluster. Lambda only emits this metric data when error happened.
- `MaxOffsetLag` – The max of offset lags (difference between latest and committed offsets) accross all partitions in the event source mapping.
- `SumOffsetLag` – The sum of the offset lags across all partitions in the event source mapping.

If your event source mapping is disabled, you won't receive event source mapping metrics. You may also see missing metrics if CloudWatch or Lambda is experiencing degraded availability.

Working with Lambda function logs

To help you troubleshoot failures, AWS Lambda automatically monitors Lambda functions on your behalf. You can view logs for Lambda functions using the Lambda console, the CloudWatch console, the AWS Command Line Interface (AWS CLI), the CloudWatch API. You can also configure Lambda to send logs to Amazon S3 and Firehose.

As long as your function's [execution role](#) has the necessary permissions, Lambda captures logs for all requests handled by your function and sends them to Amazon CloudWatch Logs, which is the default destination. You can also use the Lambda console to configure Amazon S3 or Firehose as logging destinations.

- **CloudWatch Logs** is the default logging destination for Lambda functions. CloudWatch Logs provides real-time log viewing and analysis capabilities, with support for creating metrics and alarms based on your log data.
- **Amazon S3** is economical for long-term storage, and services like Athena can be used to analyze logs. Latency is typically higher.
- **Firehose** offers managed streaming of logs to various destinations. If you need to send logs to other AWS services (for example, OpenSearch Service or Redshift Data API) or third-party platforms (like Datadog, New Relic, or Splunk), Firehose simplifies that process by providing pre-built integrations. You can also stream to custom HTTP endpoints without setting up additional infrastructure.

Choosing a service destination to send logs to

Consider the following key factors when choosing a service a destination for function logs:

- **Cost management varies by service.** Amazon S3 typically provides the most economical option for long-term storage, while CloudWatch Logs allows you to view logs, process logs, and set up alerts in real time. Firehose costs include both the streaming service and cost associated with what you configure it to stream to.
- **Analysis capabilities differ across services.** CloudWatch Logs excels at real-time monitoring and integrates natively with other CloudWatch features, such as Logs Insights and Live Tail. Amazon S3 works well with analysis tools like Athena and can integrate with various services, though it may require additional setup. Firehose simplifies direct streaming to specific AWS services (like OpenSearch Service and Redshift Data API) and supported third-party platforms (such as

Datadog and Splunk) by providing pre-built integrations, potentially reducing configuration work.

- **Setup and ease of use vary by service.** CloudWatch Logs is the default log destination - it works immediately with no additional configuration and provides straightforward log viewing and analysis through the CloudWatch console. If you need logs sent to Amazon S3, you'll need to do some initial setup in the Lambda console and configure bucket permissions. If you need logs sent directly to services like OpenSearch Service or third-party analytics platforms, Firehose can simplify that process.

Configuring log destinations

AWS Lambda supports multiple destinations for your function logs. This guide explains the available logging destinations and helps you choose the right option for your needs. Regardless of your chosen destination, Lambda provides options to control log format, filtering, and delivery.

Lambda supports both JSON and plain text formats for your function's logs. JSON structured logs provide enhanced searchability and enable automated analysis, while plain text logs offer simplicity and potentially reduced storage costs. You can control which logs Lambda sends to your chosen destination by configuring log levels for both system and application logs. Filtering helps you manage storage costs and makes it easier to find relevant log entries during debugging.

For detailed setup instructions for each destination, refer to the following sections:

- [Sending Lambda function logs to CloudWatch Logs](#)
- [Sending Lambda function logs to Firehose](#)
- [Sending Lambda function logs to Amazon S3](#)

Configuring advanced logging controls for Lambda functions

To give you more control over how your function logs are captured, processed, and consumed, Lambda offers the following logging configuration options:

- **Log format** - select between plain text and structured JSON format for your function's logs.
- **Log level** - for JSON structured logs, choose the detail level of the logs Lambda sends to CloudWatch, such as FATAL, ERROR, WARN, INFO, DEBUG, and TRACE.
- **Log group** - choose the CloudWatch log group your function sends logs to.

To learn more about configuring advanced logging controls, refer to the following sections:

- [Configuring JSON and plain text log formats](#)
- [Log-level filtering](#)
- [Configuring CloudWatch log groups](#)

Configuring JSON and plain text log formats

Capturing your log outputs as JSON key value pairs makes it easier to search and filter when debugging your functions. With JSON formatted logs, you can also add tags and contextual information to your logs. This can help you to perform automated analysis of large volumes of log data. Unless your development workflow relies on existing tooling that consumes Lambda logs in plain text, we recommend that you select JSON for your log format.

Lambda Managed Instances

Lambda Managed Instances only support JSON log format. When you create a Managed Instances function, Lambda automatically configures the log format to JSON and you cannot change it to plain text. For more information about Managed Instances, see [Lambda Managed Instances](#).

For all Lambda managed runtimes, you can choose whether your function's system logs are sent to CloudWatch Logs in unstructured plain text or JSON format. System logs are the logs that Lambda generates and are sometimes known as platform event logs.

For [supported runtimes](#), when you use one of the supported built-in logging methods, Lambda can also output your function's application logs (the logs your function code generates) in structured JSON format. When you configure your function's log format for these runtimes, the configuration you choose applies to both system and application logs.

For supported runtimes, if your function uses a supported logging library or method, you don't need to make any changes to your existing code for Lambda to capture logs in structured JSON.

Note

Using JSON log formatting adds additional metadata and encodes log messages as JSON objects containing a series of key value pairs. Because of this, the size of your function's log messages can increase.

Supported runtimes and logging methods

Lambda currently supports the option to output JSON structured application logs for the following runtimes.

Language	Supported versions
Java	All Java runtimes except Java 8 on Amazon Linux 1
.NET	.NET 8 and later
Node.js	Node.js 16 and later
Python	Python 3.8 and later
Rust	n/a

For Lambda to send your function's application logs to CloudWatch in structured JSON format, your function must use the following built-in logging tools to output logs:

- **Java:** The `LambdaLogger` logger or `Log4j2`. For more information, see [the section called “Logging”](#).
- **.NET:** The `ILambdaLogger` instance on the context object. For more information, see [Log and monitor C# Lambda functions](#).
- **Node.js** - The console methods `console.trace`, `console.debug`, `console.log`, `console.info`, `console.error`, and `console.warn`. For more information, see [the section called “Logging”](#).
- **Python:** The standard Python logging library. For more information, see [the section called “Logging”](#).

- **Rust:** The `tracing` crate. For more information, see [the section called “Logging”](#).

For other managed Lambda runtimes, Lambda currently only natively supports capturing system logs in structured JSON format. However, you can still capture application logs in structured JSON format in any runtime by using logging tools such as Powertools for AWS Lambda that output JSON formatted log outputs.

Default log formats

Currently, the default log format for all Lambda runtimes is plain text. For Lambda Managed Instances, the log format is always JSON and cannot be changed.

If you're already using logging libraries like Powertools for AWS Lambda to generate your function logs in JSON structured format, you don't need to change your code if you select JSON log formatting. Lambda doesn't double-encode any logs that are already JSON encoded, so your function's application logs will continue to be captured as before.

JSON format for system logs

When you configure your function's log format as JSON, each system log item (platform event) is captured as a JSON object that contains key value pairs with the following keys:

- `"time"` - the time the log message was generated
- `"type"` - the type of event being logged
- `"record"` - the contents of the log output

The format of the `"record"` value varies according to the type of event being logged. For more information see [the section called “Telemetry API Event object types”](#). For more information about the log levels assigned to system log events, see [the section called “System log level event mapping”](#).

For comparison, the following two examples show the same log output in both plain text and structured JSON formats. Note that in most cases, system log events contain more information when output in JSON format than when output in plain text.

Example plain text:

```
2024-03-13 18:56:24.046000 fbe8c1 INIT_START Runtime Version:
python:3.12.v18 Runtime Version ARN: arn:aws:lambda:eu-
west-1::runtime:edb5a058bfa782cb9cedc6d534ac8b8c193bc28e9a9879d9f5ebaaf619cd0fc0
```

Example structured JSON:

```
{
  "time": "2024-03-13T18:56:24.046Z",
  "type": "platform.initStart",
  "record": {
    "initializationType": "on-demand",
    "phase": "init",
    "runtimeVersion": "python:3.12.v18",
    "runtimeVersionArn": "arn:aws:lambda:eu-
west-1::runtime:edb5a058bfa782cb9cedc6d534ac8b8c193bc28e9a9879d9f5ebaaf619cd0fc0"
  }
}
```

Note

The [the section called “Telemetry API”](#) always emits platform events such as START and REPORT in JSON format. Configuring the format of the system logs Lambda sends to CloudWatch doesn't affect Lambda Telemetry API behavior.

JSON format for application logs

When you configure your function's log format as JSON, application log outputs written using supported logging libraries and methods are captured as a JSON object that contains key value pairs with the following keys.

- "timestamp" - the time the log message was generated
- "level" - the log level assigned to the message
- "message" - the contents of the log message
- "requestId" (Python, .NET, and Node.js) or "AWSrequestId" (Java) - the unique request ID for the function invocation

Depending on the runtime and logging method that your function uses, this JSON object may also contain additional key pairs. For example, in Node.js, if your function uses `console` methods to log error objects using multiple arguments, The JSON object will contain extra key value pairs with the keys `errorMessage`, `errorType`, and `stackTrace`. To learn more about JSON formatted logs in different Lambda runtimes, see [the section called “Logging”](#), [the section called “Logging”](#), and [the section called “Logging”](#).

Note

The key Lambda uses for the timestamp value is different for system logs and application logs. For system logs, Lambda uses the key `"time"` to maintain consistency with Telemetry API. For application logs, Lambda follows the conventions of the supported runtimes and uses `"timestamp"`.

For comparison, the following two examples show the same log output in both plain text and structured JSON formats.

Example plain text:

```
2024-10-27T19:17:45.586Z 79b4f56e-95b1-4643-9700-2807f4e68189 INFO some log message
```

Example structured JSON:

```
{
  "timestamp": "2024-10-27T19:17:45.586Z",
  "level": "INFO",
  "message": "some log message",
  "requestId": "79b4f56e-95b1-4643-9700-2807f4e68189"
}
```

Setting your function's log format

To configure the log format for your function, you can use the Lambda console or the AWS Command Line Interface (AWS CLI). You can also configure a function's log format using the [CreateFunction](#) and [UpdateFunctionConfiguration](#) Lambda API commands, the AWS Serverless Application Model (AWS SAM) [AWS::Serverless::Function](#) resource, and the CloudFormation [AWS::Lambda::Function](#) resource.

Changing your function's log format doesn't affect existing logs stored in CloudWatch Logs. Only new logs will use the updated format.

If you change your function's log format to JSON and do not set log level, then Lambda automatically sets your function's application log level and system log level to INFO. This means that Lambda sends only log outputs of level INFO and lower to CloudWatch Logs. To learn more about application and system log-level filtering see [the section called "Log-level filtering"](#)

Note

For Python runtimes, when your function's log format is set to plain text, the default log-level setting is WARN. This means that Lambda only sends log outputs of level WARN and lower to CloudWatch Logs. Changing your function's log format to JSON changes this default behavior. To learn more about logging in Python, see [the section called "Logging"](#).

For Node.js functions that emit embedded metric format (EMF) logs, changing your function's log format to JSON could result in CloudWatch being unable to recognize your metrics.

Important

If your function uses Powertools for AWS Lambda (TypeScript) or the open-sourced EMF client libraries to emit EMF logs, update your [Powertools](#) and [EMF](#) libraries to the latest versions to ensure that CloudWatch can continue to parse your logs correctly. If you switch to the JSON log format, we also recommend that you carry out testing to ensure compatibility with your function's embedded metrics. For further advice about node.js functions that emit EMF logs, see [the section called "Using embedded metric format \(EMF\) client libraries with structured JSON logs"](#).

To configure a function's log format (console)

1. Open the [Functions page](#) of the Lambda console.
2. Choose a function
3. On the function configuration page, choose **Monitoring and operations tools**.
4. In the **Logging configuration** pane, choose **Edit**.
5. Under **Log content**, for **Log format** select either **Text** or **JSON**.

6. Choose **Save**.

To change the log format of an existing function (AWS CLI)

- To change the log format of an existing function, use the [update-function-configuration](#) command. Set the LogFormat option in LoggingConfig to either JSON or Text.

```
aws lambda update-function-configuration \  
  --function-name myFunction \  
  --logging-config LogFormat=JSON
```

To set log format when you create a function (AWS CLI)

- To configure log format when you create a new function, use the `--logging-config` option in the [create-function](#) command. Set LogFormat to either JSON or Text. The following example command creates a Node.js function that outputs logs in structured JSON.

If you don't specify a log format when you create a function, Lambda will use the default log format for the runtime version you select. For information about default logging formats, see [the section called "Default log formats"](#).

```
aws lambda create-function \  
  --function-name myFunction \  
  --runtime nodejs24.x \  
  --handler index.handler \  
  --zip-file fileb://function.zip \  
  --role arn:aws:iam::123456789012:role/LambdaRole \  
  --logging-config LogFormat=JSON
```

Log-level filtering

Lambda can filter your function's logs so that only logs of a certain detail level or lower are sent to CloudWatch Logs. You can configure log-level filtering separately for your function's system logs (the logs that Lambda generates) and application logs (the logs that your function code generates).

For [the section called "Supported runtimes and logging methods"](#), you don't need to make any changes to your function code for Lambda to filter your function's application logs.

For all other runtimes and logging methods , your function code must output log events to `stdout` or `stderr` as JSON formatted objects that contain a key value pair with the key `"level"`. For example, Lambda interprets the following output to `stdout` as a `DEBUG` level log.

```
print({'level': 'debug', 'msg': 'my debug log', 'timestamp':
      '2024-11-02T16:51:31.587199Z'})
```

If the `"level"` value field is invalid or missing, Lambda will assign the log output the level `INFO`. For Lambda to use the `timestamp` field, you must specify the time in valid [RFC 3339](#) timestamp format. If you don't supply a valid timestamp, Lambda will assign the log the level `INFO` and add a timestamp for you.

When naming the `timestamp` key, follow the conventions of the runtime you are using. Lambda supports most common naming conventions used by the managed runtimes.

 **Note**

To use log-level filtering, your function must be configured to use the JSON log format. The default log format for all Lambda managed runtimes is currently plain text. To learn how to configure your function's log format to JSON, see [the section called “Setting your function's log format”](#).

For application logs (the logs generated by your function code), you can choose between the following log levels.

Log level	Standard usage
TRACE (most detail)	The most fine-grained information used to trace the path of your code's execution
DEBUG	Detailed information for system debugging
INFO	Messages that record the normal operation of your function
WARN	Messages about potential errors that may lead to unexpected behavior if unaddressed

Log level	Standard usage
ERROR	Messages about problems that prevent the code from performing as expected
FATAL (least detail)	Messages about serious errors that cause the application to stop functioning

When you select a log level, Lambda sends logs at that level and lower to CloudWatch Logs. For example, if you set a function's application log level to WARN, Lambda doesn't send log outputs at the INFO and DEBUG levels. The default application log level for log filtering is INFO.

When Lambda filters your function's application logs, log messages with no level will be assigned the log level INFO.

For system logs (the logs generated by the Lambda service), you can choose between the following log levels.

Log level	Usage
DEBUG (most detail)	Detailed information for system debugging
INFO	Messages that record the normal operation of your function
WARN (least detail)	Messages about potential errors that may lead to unexpected behavior if unaddressed

When you select a log level, Lambda sends logs at that level and lower. For example, if you set a function's system log level to INFO, Lambda doesn't send log outputs at the DEBUG level.

By default, Lambda sets the system log level to INFO. With this setting, Lambda automatically sends "start" and "report" log messages to CloudWatch. To receive more or less detailed system logs, change the log level to DEBUG or WARN. To see a list of the log levels that Lambda maps different system log events to, see [the section called "System log level event mapping"](#).

Configuring log-level filtering

To configure application and system log-level filtering for your function, you can use the Lambda console or the AWS Command Line Interface (AWS CLI). You can also configure a function's log level using the [CreateFunction](#) and [UpdateFunctionConfiguration](#) Lambda API commands, the AWS Serverless Application Model (AWS SAM) [AWS::Serverless::Function](#) resource, and the CloudFormation [AWS::Lambda::Function](#) resource.

Note that if you set your function's log level in your code, this setting takes precedence over any other log level settings you configure. For example, if you use the Python `logging.setLevel()` method to set your function's logging level to INFO, this setting takes precedence over a setting of WARN that you configure using the Lambda console.

To configure an existing function's application or system log level (console)

1. Open the [Functions page](#) of the Lambda console.
2. Choose a function.
3. On the function configuration page, choose **Monitoring and operations tools**.
4. In the **Logging configuration** pane, choose **Edit**.
5. Under **Log content**, for **Log format** ensure **JSON** is selected.
6. Using the radio buttons, select your desired **Application log level** and **System log level** for your function.
7. Choose **Save**.

To configure an existing function's application or system log level (AWS CLI)

- To change the application or system log level of an existing function, use the [update-function-configuration](#) command. Use `--logging-config` to set `SystemLogLevel` to one of DEBUG, INFO, or WARN. Set `ApplicationLogLevel` to one of DEBUG, INFO, WARN, ERROR, or FATAL.

```
aws lambda update-function-configuration \  
  --function-name myFunction \  
  --logging-config LogFormat=JSON,ApplicationLogLevel=ERROR,SystemLogLevel=WARN
```

To configure log-level filtering when you create a function

- To configure log-level filtering when you create a new function, use `--logging-config` to set the `SystemLogLevel` and `ApplicationLogLevel` keys in the [create-function](#) command. Set `SystemLogLevel` to one of `DEBUG`, `INFO`, or `WARN`. Set `ApplicationLogLevel` to one of `DEBUG`, `INFO`, `WARN`, `ERROR`, or `FATAL`.

```
aws lambda create-function \
  --function-name myFunction \
  --runtime nodejs24.x \
  --handler index.handler \
  --zip-file fileb://function.zip \
  --role arn:aws:iam::123456789012:role/LambdaRole \
  --logging-config LogFormat=JSON,ApplicationLogLevel=ERROR,SystemLogLevel=WARN
```

System log level event mapping

For system level log events generated by Lambda, the following table defines the log level assigned to each event. To learn more about the events listed in the table, see [the section called “Event schema reference”](#)

Event name	Condition	Assigned log level
initStart	runtimeVersion is set	INFO
initStart	runtimeVersion is not set	DEBUG
initRuntimeDone	status=success	DEBUG
initRuntimeDone	status!=success	WARN
initReport	initializationType!=on-demand	INFO
initReport	initializationType=on-demand	DEBUG
initReport	status!=success	WARN
restoreStart	runtimeVersion is set	INFO

Event name	Condition	Assigned log level
restoreStart	runtimeVersion is not set	DEBUG
restoreRuntimeDone	status=success	DEBUG
restoreRuntimeDone	status!=success	WARN
restoreReport	status=success	INFO
restoreReport	status!=success	WARN
start	-	INFO
runtimeDone	status=success	DEBUG
runtimeDone	status!=success	WARN
report	status=success	INFO
report	status!=success	WARN
extension	state=success	INFO
extension	state!=success	WARN
logSubscription	-	INFO
telemetrySubscription	-	INFO
logsDropped	-	WARN

Note

The [the section called “Telemetry API”](#) always emits the complete set of platform events. Configuring the level of the system logs Lambda sends to CloudWatch doesn’t affect Lambda Telemetry API behavior.

Application log-level filtering with custom runtimes

When you configure application log-level filtering for your function, behind the scenes Lambda sets the application log level in the runtime using the `AWS_LAMBDA_LOG_LEVEL` environment variable. Lambda also sets your function's log format using the `AWS_LAMBDA_LOG_FORMAT` environment variable. You can use these variables to integrate Lambda advanced logging controls into a [custom runtime](#).

For the ability to configure logging settings for a function using a custom runtime with the Lambda console, AWS CLI, and Lambda APIs, configure your custom runtime to check the value of these environment variables. You can then configure your runtime's loggers in accordance with the log format and log levels you select.

Sending Lambda function logs to CloudWatch Logs

By default, Lambda automatically captures logs for all function invocations and sends them to CloudWatch Logs, provided your function's execution role has the necessary permissions. These logs are, by default, stored in a log group named `/aws/lambda/<function-name>`. To enhance debugging, you can insert custom logging statements into your code, which Lambda will seamlessly integrate with CloudWatch Logs. If needed, you can configure your function to send logs to a different group using the Lambda console, AWS CLI, or Lambda API. See [the section called "Configure CloudWatch function logs"](#) to learn more.

You can view logs for Lambda functions using the Lambda console, the CloudWatch console, the AWS Command Line Interface (AWS CLI), or the CloudWatch API. For more information, see [Viewing CloudWatch logs for Lambda functions](#).

Note

It may take 5 to 10 minutes for logs to show up after a function invocation.

Required IAM permissions

Your [execution role](#) needs the following permissions to upload logs to CloudWatch Logs:

- `logs:CreateLogGroup`
- `logs:CreateLogStream`
- `logs:PutLogEvents`

To learn more, see [Using identity-based policies \(IAM policies\) for CloudWatch Logs](#) in the *Amazon CloudWatch User Guide*.

You can add these CloudWatch Logs permissions using the `AWSLambdaBasicExecutionRole` AWS managed policy provided by Lambda. To add this policy to your role, run the following command:

```
aws iam attach-role-policy --role-name your-role --policy-arn arn:aws:iam::aws:policy/service-role/AWSLambdaBasicExecutionRole
```

For more information, see [the section called “AWS managed policies”](#).

Pricing

There is no additional charge for using Lambda logs; however, standard CloudWatch Logs charges apply. For more information, see [CloudWatch pricing](#).

Configuring CloudWatch log groups

By default, CloudWatch automatically creates a log group named `/aws/lambda/<function name>` for your function when it's first invoked. To configure your function to send logs to an existing log group, or to create a new log group for your function, you can use the Lambda console or the AWS CLI. You can also configure custom log groups using the [CreateFunction](#) and [UpdateFunctionConfiguration](#) Lambda API commands and the AWS Serverless Application Model (AWS SAM) [AWS::Serverless::Function](#) resource.

You can configure multiple Lambda functions to send logs to the same CloudWatch log group. For example, you could use a single log group to store logs for all of the Lambda functions that make up a particular application. When you use a custom log group for a Lambda function, the log streams Lambda creates include the function name and function version. This ensures that the mapping between log messages and functions is preserved, even if you use the same log group for multiple functions.

The log stream naming format for custom log groups follows this convention:

```
YYYY/MM/DD/<function_name>[<function_version>][<execution_environment_GUID>]
```

Note that when configuring a custom log group, the name you select for your log group must follow the [CloudWatch Logs naming rules](#). Additionally, custom log group names mustn't begin

with the string `aws/`. If you create a custom log group beginning with `aws/`, Lambda won't be able to create the log group. As a result of this, your function's logs won't be sent to CloudWatch.

To change a function's log group (console)

1. Open the [Functions page](#) of the Lambda console.
2. Choose a function.
3. On the function configuration page, choose **Monitoring and operations tools**.
4. In the **Logging configuration** pane, choose **Edit**.
5. In the **Logging group** pane, for **CloudWatch log group**, choose **Custom**.
6. Under **Custom log group**, enter the name of the CloudWatch log group you want your function to send logs to. If you enter the name of an existing log group, then your function will use that group. If no log group exists with the name that you enter, then Lambda will create a new log group for your function with that name.

To change a function's log group (AWS CLI)

- To change the log group of an existing function, use the [update-function-configuration](#) command.

```
aws lambda update-function-configuration \  
  --function-name myFunction \  
  --logging-config LogGroup=myLogGroup
```

To specify a custom log group when you create a function (AWS CLI)

- To specify a custom log group when you create a new Lambda function using the AWS CLI, use the `--logging-config` option. The following example command creates a Node.js Lambda function that sends logs to a log group named `myLogGroup`.

```
aws lambda create-function \  
  --function-name myFunction \  
  --runtime nodejs24.x \  
  --handler index.handler \  
  --zip-file fileb://function.zip \  
  --role arn:aws:iam::123456789012:role/LambdaRole \  
  --logging-config LogGroup=myLogGroup
```

Execution role permissions

For your function to send logs to CloudWatch Logs, it must have the [logs:PutLogEvents](#) permission. When you configure your function's log group using the Lambda console, Lambda will add this permission to the role under the following conditions:

- The service destination is set to CloudWatch Logs
- Your function's execution role doesn't have permissions to upload logs to CloudWatch Logs (the default destination)

Note

Lambda does not add any Put permission for Amazon S3 or Firehose log destinations.

When Lambda adds this permission, it gives the function permission to send logs to any CloudWatch Logs log group.

To prevent Lambda from automatically updating the function's execution role and edit it manually instead, expand **Permissions** and uncheck **Add required permissions**.

When you configure your function's log group using the AWS CLI, Lambda won't automatically add the `logs:PutLogEvents` permission. Add the permission to your function's execution role if it doesn't already have it. This permission is included in the [AWSLambdaBasicExecutionRole](#) managed policy.

CloudWatch logging for Lambda Managed Instances

When using [Lambda Managed Instances](#), there are additional considerations for sending logs to CloudWatch Logs:

VPC networking requirements

Lambda Managed Instances run on customer-owned EC2 instances within your VPC. To send logs to CloudWatch Logs and traces to X-Ray, you must ensure that these AWS APIs are routable from your VPC. You have several options:

- **AWS PrivateLink (recommended):** Use [AWS PrivateLink](#) to create VPC endpoints for CloudWatch Logs and X-Ray services. This allows your instances to access these services privately without

requiring an internet gateway or NAT gateway. For more information, see [Using CloudWatch Logs with interface VPC endpoints](#).

- **NAT Gateway:** Configure a NAT gateway to allow outbound internet access from your private subnets.
- **Internet Gateway:** For public subnets, ensure your VPC has an internet gateway configured.

If CloudWatch Logs or X-Ray APIs are not routable from your VPC, your function logs and traces will not be delivered.

Concurrent invocations and log attribution

Lambda Managed Instances execution environments can process multiple invocations concurrently. When multiple invocations run simultaneously, their log entries are interleaved in the same log stream. To effectively filter and analyze logs from concurrent invocations, you should ensure each log entry includes the AWS request ID.

We recommend one of the following approaches:

- **Use default Lambda runtime loggers (recommended):** The default logging libraries provided by Lambda managed runtimes automatically include the request ID in each log entry.
- **Implement structured JSON logging:** If you're building a [custom runtime](#) or need custom logging, implement JSON-formatted logs that include the request ID in each entry. Lambda Managed Instances only support the JSON log format. Include the `requestId` field in your JSON logs to enable filtering by invocation:

```
{
  "timestamp": "2025-01-15T10:30:00.000Z",
  "level": "INFO",
  "requestId": "a1b2c3d4-e5f6-7890-abcd-ef1234567890",
  "message": "Processing request"
}
```

With request ID attribution, you can filter CloudWatch Logs log entries for a specific invocation using CloudWatch Logs Insights queries. For example:

```
fields @timestamp, @message
| filter requestId = "a1b2c3d4-e5f6-7890-abcd-ef1234567890"
| sort @timestamp asc
```

For more information about Lambda Managed Instances logging requirements, see [Understanding the Lambda Managed Instances execution environment](#).

Viewing CloudWatch logs for Lambda functions

You can view Amazon CloudWatch logs for your Lambda function using the Lambda console, the CloudWatch console, or the AWS Command Line Interface (AWS CLI). Follow the instructions in the following sections to access your function's logs.

Stream function logs with CloudWatch Logs Live Tail

Amazon CloudWatch Logs Live Tail helps you quickly troubleshoot your functions by displaying a streaming list of new log events directly in the Lambda console. You can view and filter ingested logs from your Lambda functions in real time, helping you to detect and resolve issues quickly.

Note

Live Tail sessions incur costs by session usage time, per minute. For more information about pricing, see [Amazon CloudWatch Pricing](#).

Comparing Live Tail and `--log-type Tail`

There are several differences between CloudWatch Logs Live Tail and the [LogType: Tail](#) option in the Lambda API (`--log-type Tail` in the AWS CLI):

- `--log-type Tail` returns only the first 4 KB of the invocation logs. Live Tail does not share this limit, and can receive up to 500 log events per second.
- `--log-type Tail` captures and sends the logs with the response, which can impact the function's response latency. Live Tail does not affect function response latency.
- `--log-type Tail` supports synchronous invocations only. Live Tail works for both synchronous and asynchronous invocations.

Note

[Lambda Managed Instances](#) does not support the `--log-type Tail` option. Use CloudWatch Logs Live Tail or query CloudWatch Logs directly to view logs for Managed Instances functions.

Permissions

The following permissions are required to start and stop CloudWatch Logs Live Tail sessions:

- `logs:DescribeLogGroups`
- `logs:StartLiveTail`
- `logs:StopLiveTail`

Start a Live Tail session in the Lambda console

1. Open the [Functions page](#) of the Lambda console.
2. Choose the name of the function.
3. Choose the **Test** tab.
4. In the **Test event** pane, choose **CloudWatch Logs Live Tail**.
5. For **Select log groups**, the function's log group is selected by default. You can select up to five log groups at a time.
6. (Optional) To display only log events that contain certain words or other strings, enter the word or string in the **Add filter pattern** box. The filters field is case-sensitive. You can include multiple terms and pattern operators in this field, including regular expressions (regex). For more information about pattern syntax, see [Filter pattern syntax](#) in the *Amazon CloudWatch Logs User Guide*.
7. Choose **Start**. Matching log events begin appearing in the window.
8. To stop the Live Tail session, choose **Stop**.

Note

The Live Tail session automatically stops after 15 minutes of inactivity or when the Lambda console session times out.

Access function logs using the console

1. Open the [Functions page](#) of the Lambda console.
2. Select a function.
3. Choose the **Monitor** tab.

4. Choose **View CloudWatch logs** to open the CloudWatch console.
5. Scroll down and choose the **Log stream** for the function invocations you want to look at.

Log streams (14)			Delete	Create log stream	Search all log streams
<input type="text" value="Filter log streams or try prefix search"/>		<input type="checkbox"/> Exact match	<input type="checkbox"/> Show expired	Info	< 1 >
<input type="checkbox"/>	Log stream	Last event time			
<input type="checkbox"/>	2024/04/30/[\$LATEST]e0fa	2024-04-30 17:24:16 (UTC)			
<input type="checkbox"/>	2024/04/19/[\$LATEST]e9a	2024-04-19 20:59:06 (UTC)			
<input type="checkbox"/>	2024/02/22/[\$LATEST]cf0	2024-02-22 18:38:41 (UTC)			
<input type="checkbox"/>	2024/02/21/[1]d132c4d	2024-02-21 21:37:01 (UTC)			
<input type="checkbox"/>	2024/02/21/[1]5ad	2024-02-21 21:37:01 (UTC)			

Each instance of a Lambda function has a dedicated log stream. If a function scales up, each concurrent instance has its own log stream. Each time a new execution environment is created in response to an invocation, this generates a new log stream. The naming convention for log streams is:

```
YYYY/MM/DD[Function version][Execution environment GUID]
```

A single execution environment writes to the same log stream during its lifetime. The log stream contains messages from that execution environment and also any output from your Lambda function's code. Every message is timestamped, including your custom logs. Even if your function does not log any output from your code, there are three minimal log statements generated per invocation (START, END and REPORT):

▼	2020-10-08T15:52:11.447-04:00	START RequestId: 345a1711-d325-4af6-b01f-b0648975743f Version: \$LATEST	START RequestId: 345a1711-d325-4af6-b01f-b0648975743f Version: \$LATEST	Copy
▼	2020-10-08T15:52:12.452-04:00	END RequestId: 345a1711-d325-4af6-b01f-b0648975743f	END RequestId: 345a1711-d325-4af6-b01f-b0648975743f	Copy
▼	2020-10-08T15:52:12.452-04:00	REPORT RequestId: 345a1711-d325-4af6-b01f-b0648975743f Duration: 1004.58 ms Billed Duration: 1100 ms Memory Size: 1...	REPORT RequestId: 345a1711-d325-4af6-b01f-b0648975743f Duration: 1004.58 ms Billed Duration: 1100 ms Memory Size: 128 MB Max Memory Used: 64 MB Init Duration: 295.85 ms	Copy

These logs show:

- **RequestId** – this is a unique ID generated per request. If the Lambda function retries a request, this ID does not change and appears in the logs for each subsequent retry.
- **Start/End** – these bookmark a single invocation, so every log line between these belongs to the same invocation.
- **Duration** – the total invocation time for the handler function, excluding INIT code.
- **Billed Duration** – applies rounding logic for billing purposes.
- **Memory Size** – the amount of memory allocated to the function.
- **Max Memory Used** – the maximum amount of memory used during the invocation.
- **Init Duration** – the time taken to run the INIT section of code, outside of the main handler.

Access logs with the AWS CLI

The AWS CLI is an open-source tool that enables you to interact with AWS services using commands in your command line shell. To complete the steps in this section, you must have the [AWS CLI version 2](#).

You can use the [AWS CLI](#) to retrieve logs for an invocation using the `--log-type` command option. The response contains a `LogResult` field that contains up to 4 KB of base64-encoded logs from the invocation.

Example retrieve a log ID

The following example shows how to retrieve a *log ID* from the `LogResult` field for a function named `my-function`.

```
aws lambda invoke --function-name my-function out --log-type Tail
```

You should see the following output:

```
{
  "StatusCode": 200,
  "LogResult":
    "U1RBu1QgUmVxdWVzdElk0iA4N2QwNDRI0C1mMTU0LTExZTgt0GNkYS0yOTc0YzVlNGZiMjEgVmVyc2lvb...",
  "ExecutedVersion": "$LATEST"
}
```

Example decode the logs

In the same command prompt, use the `base64` utility to decode the logs. The following example shows how to retrieve base64-encoded logs for `my-function`.

```
aws lambda invoke --function-name my-function out --log-type Tail \
--query 'LogResult' --output text --cli-binary-format raw-in-base64-out | base64 --
decode
```

The **cli-binary-format** option is required if you're using AWS CLI version 2. To make this the default setting, run `aws configure set cli-binary-format raw-in-base64-out`. For more information, see [AWS CLI supported global command line options](#) in the *AWS Command Line Interface User Guide for Version 2*.

You should see the following output:

```
START RequestId: 57f231fb-1730-4395-85cb-4f71bd2b87b8 Version: $LATEST
"AWS_SESSION_TOKEN": "AgoJb3JpZ2luX2VjELj...", "_X_AMZN_TRACE_ID": "Root=1-5d02e5ca-
f5792818b6fe8368e5b51d50;Parent=191db58857df8395;Sampled=0\"",ask/lib:/opt/lib",
END RequestId: 57f231fb-1730-4395-85cb-4f71bd2b87b8
REPORT RequestId: 57f231fb-1730-4395-85cb-4f71bd2b87b8  Duration: 79.67 ms      Billed
Duration: 80 ms      Memory Size: 128 MB      Max Memory Used: 73 MB
```

The `base64` utility is available on Linux, macOS, and [Ubuntu on Windows](#). macOS users may need to use `base64 -D`.

Example get-logs.sh script

In the same command prompt, use the following script to download the last five log events. The script uses `sed` to remove quotes from the output file, and sleeps for 15 seconds to allow time for the logs to become available. The output includes the response from Lambda and the output from the `get-log-events` command.

Copy the contents of the following code sample and save in your Lambda project directory as `get-logs.sh`.

The **cli-binary-format** option is required if you're using AWS CLI version 2. To make this the default setting, run `aws configure set cli-binary-format raw-in-base64-out`. For more

information, see [AWS CLI supported global command line options](#) in the *AWS Command Line Interface User Guide for Version 2*.

```
#!/bin/bash
aws lambda invoke --function-name my-function --cli-binary-format raw-in-base64-out --
payload '{"key": "value"}' out
sed -i'' -e 's/"//g' out
sleep 15
aws logs get-log-events --log-group-name /aws/lambda/my-function --log-stream-
name stream1 --limit 5
```

Example macOS and Linux (only)

In the same command prompt, macOS and Linux users may need to run the following command to ensure the script is executable.

```
chmod -R 755 get-logs.sh
```

Example retrieve the last five log events

In the same command prompt, run the following script to get the last five log events.

```
./get-logs.sh
```

You should see the following output:

```
{
  "StatusCode": 200,
  "ExecutedVersion": "$LATEST"
}
{
  "events": [
    {

}

```

Parsing logs and structured logging

With CloudWatch Logs Insights, you can search and analyze log data using a specialized [query syntax](#). It performs queries over multiple log groups and provides powerful filtering using [glob](#) and [regular expressions](#) pattern matching.

You can take advantage of these capabilities by implementing structured logging in your Lambda functions. Structured logging organizes your logs into a pre-defined format, making it easier to query for. Using log levels is an important first step in generating filter-friendly logs that separate informational messages from warnings or errors. For example, consider the following Node.js code:

```

exports.handler = async (event) => {
  console.log("console.log - Application is fine")
  console.info("console.info - This is the same as console.log")
  console.warn("console.warn - Application provides a warning")
}

```

```
console.error("console.error - An error occurred")
}
```

The resulting CloudWatch log file contains a separate field specifying the log level:

```
START RequestId: 99d91f9b-2dff-40ad-b9c8-664020094109 Version: $LATEST
2020-10-22T12:21:28.268Z      99d91f9b-2dff-40ad-b9c8-664020094109  INFO  console.log - Application is fine
2020-10-22T12:21:28.268Z      99d91f9b-2dff-40ad-b9c8-664020094109  INFO  console.info - This is the same as console.log
2020-10-22T12:21:28.268Z      99d91f9b-2dff-40ad-b9c8-664020094109  WARN  console.warn - Application provides a warning
2020-10-22T12:21:28.268Z      99d91f9b-2dff-40ad-b9c8-664020094109  ERROR  console.error - An error occurred
END RequestId: 99d91f9b-2dff-40ad-b9c8-664020094109
REPORT RequestId: 99d91f9b-2dff-40ad-b9c8-664020094109  Duration: 3.13 ms      Billed Duration: 100 ms Memory Size: 128 MB
Max Memory Used: 64 MB  Init Duration: 142.18 ms
```

A CloudWatch Logs Insights query can then filter on log level. For example, to query for errors only, you can use the following query:

```
fields @timestamp, @message
| filter @message like /ERROR/
| sort @timestamp desc
```

JSON structured logging

JSON is commonly used to provide structure for application logs. In the following example, the logs have been converted to JSON to output three distinct values:

```
START RequestId: 22fda338-7b46-4c49-9531-efd6e8568480 Version: $LATEST
2020-10-22T11:35:59.216Z      22fda338-7b46-4c49-9531-efd6e8568480  INFO  { uploadedBytes: 5453396,
invocation: 5, uploadTimeMS: 4519 }
END RequestId: 22fda338-7b46-4c49-9531-efd6e8568480
REPORT RequestId: 22fda338-7b46-4c49-9531-efd6e8568480  Duration: 1.25 ms      Billed Duration: 100 ms Memory
Size: 128 MB  Max Memory Used: 65 MB
```

The CloudWatch Logs Insights feature automatically discovers values in JSON output and parses the messages as fields, without the need for custom glob or regular expression. By using the JSON-structured logs, the following query finds invocations where the uploaded file was larger than 1 MB, the upload time was more than 1 second, and the invocation was not a cold start:

```
fields @message
| filter @message like /INFO/
| filter uploadedBytes > 1000000
| filter uploadTimeMS > 1000
| filter invocation != 1
```

This query might produce the following result:

The screenshot shows the AWS CloudWatch Logs Insights console. On the left is a navigation menu with options like CloudWatch, Dashboards, Alarms, and Insights. The main area displays a query editor with the following query:

```
fields @message
| filter @message like /INFO/
| filter uploadedBytes > 1000000
| filter uploadTimeMS > 1000
| filter invocation != 1
```

Below the query editor, the 'Logs' tab shows a list of log records. The 'Discovered fields' panel on the right lists fields found in the logs, including @timestamp, @logStream, @message, @requestId, @type, @duration, @billedDuration, @maxMemoryUsed, @memorySize, @initDuration, @xrayTraceId, and @xraySegmentId. The fields @timestamp, @logStream, @message, @requestId, @type, @duration, @billedDuration, @maxMemoryUsed, @memorySize, @initDuration, @xrayTraceId, and @xraySegmentId are highlighted with a red box.

The discovered fields in JSON are automatically populated in the *Discovered fields* menu on the right side. Standard fields emitted by the Lambda service are prefixed with '@', and you can query on these fields in the same way. Lambda logs always include the fields @timestamp, @logStream, @message, @requestId, @duration, @billedDuration, @type, @maxMemoryUsed, @memorySize. If X-Ray is enabled for a function, logs also include @xrayTraceId and @xraySegmentId.

When an AWS event source such as Amazon S3, Amazon SQS, or Amazon EventBridge invokes your function, the entire event is provided to the function as a JSON object input. By logging this event in the first line of the function, you can then query on any of the nested fields using CloudWatch Logs Insights.

Useful Insights queries

The following table shows example Insights queries that can be useful for monitoring Lambda functions.

Description	Example query syntax
The last 100 errors	<pre>fields Timestamp, LogLevel, Message filter LogLevel == "ERR" sort @timestamp desc limit 100</pre>
The top 100 highest billed invocations	<pre>filter @type = "REPORT"</pre>

Description	Example query syntax
	<pre> fields @requestId, @billedDuration sort by @billedDuration desc limit 100</pre>
Percentage of cold starts in total invocations	<pre>filter @type = "REPORT" stats sum(strcontains(@message, "Init Duration"))/count(*) * 100 as coldStartPct, avg(@duration) by bin(5m)</pre>
Percentile report of Lambda duration	<pre>filter @type = "REPORT" stats avg(@billedDuration) as Average, percentile(@billedDuration, 99) as NinetyNinth, percentile(@billedDuration, 95) as NinetyFifth, percentile(@billedDuration, 90) as Ninetieth by bin(30m)</pre>
Percentile report of Lambda memory usage	<pre>filter @type="REPORT" stats avg(@maxMemoryUsed/1024/1024) as mean_MemoryUsed, min(@maxMemoryUsed/1024/1024) as min_MemoryUsed, max(@maxMemoryUsed/1024/1024) as max_MemoryUsed, percentile(@maxMemoryUsed/1024/1024, 95) as Percentile95</pre>
Invocations using 100% of assigned memory	<pre>filter @type = "REPORT" and @maxMemoryUsed=@memorySize stats count_distinct(@requestId) by bin(30m)</pre>

Description	Example query syntax
Average memory used across invocations	<pre>avgMemoryUsedPERC, avg(@billedDuration) as avgDurationMS by bin(5m)</pre>
Visualization of memory statistics	<pre>filter @type = "REPORT" stats max(@maxMemoryUsed / 1024 / 1024) as maxMemMB, avg(@maxMemoryUsed / 1024 / 1024) as avgMemMB, min(@maxMemoryUsed / 1024 / 1024) as minMemMB, (avg(@maxMemoryUsed / 1024 / 1024) / max(@memorySize / 1024 / 1024)) * 100 as avgMemUsedPct, avg(@billedDuration) as avgDurationMS by bin(30m)</pre>
Invocations where Lambda exited	<pre>filter @message like /Process exited/ stats count() by bin(30m)</pre>
Invocations that timed out	<pre>filter @message like /Task timed out/ stats count() by bin(30m)</pre>
Latency report	<pre>filter @type = "REPORT" stats avg(@duration), max(@duration), min(@duration) by bin(5m)</pre>

Description	Example query syntax
Over-provisioned memory	<pre>filter @type = "REPORT" stats max(@memorySize / 1024 / 1024) as provisionedMemMB, min(@maxMemoryUsed / 1024 / 1024) as smallestMemReqMB, avg(@maxMemoryUsed / 1024 / 1024) as avgMemUsedMB, max(@maxMemoryUsed / 1024 / 1024) as maxMemUsedMB, provisionedMemMB - maxMemUsedMB as overProvisionedMB</pre>

Log visualization and dashboards

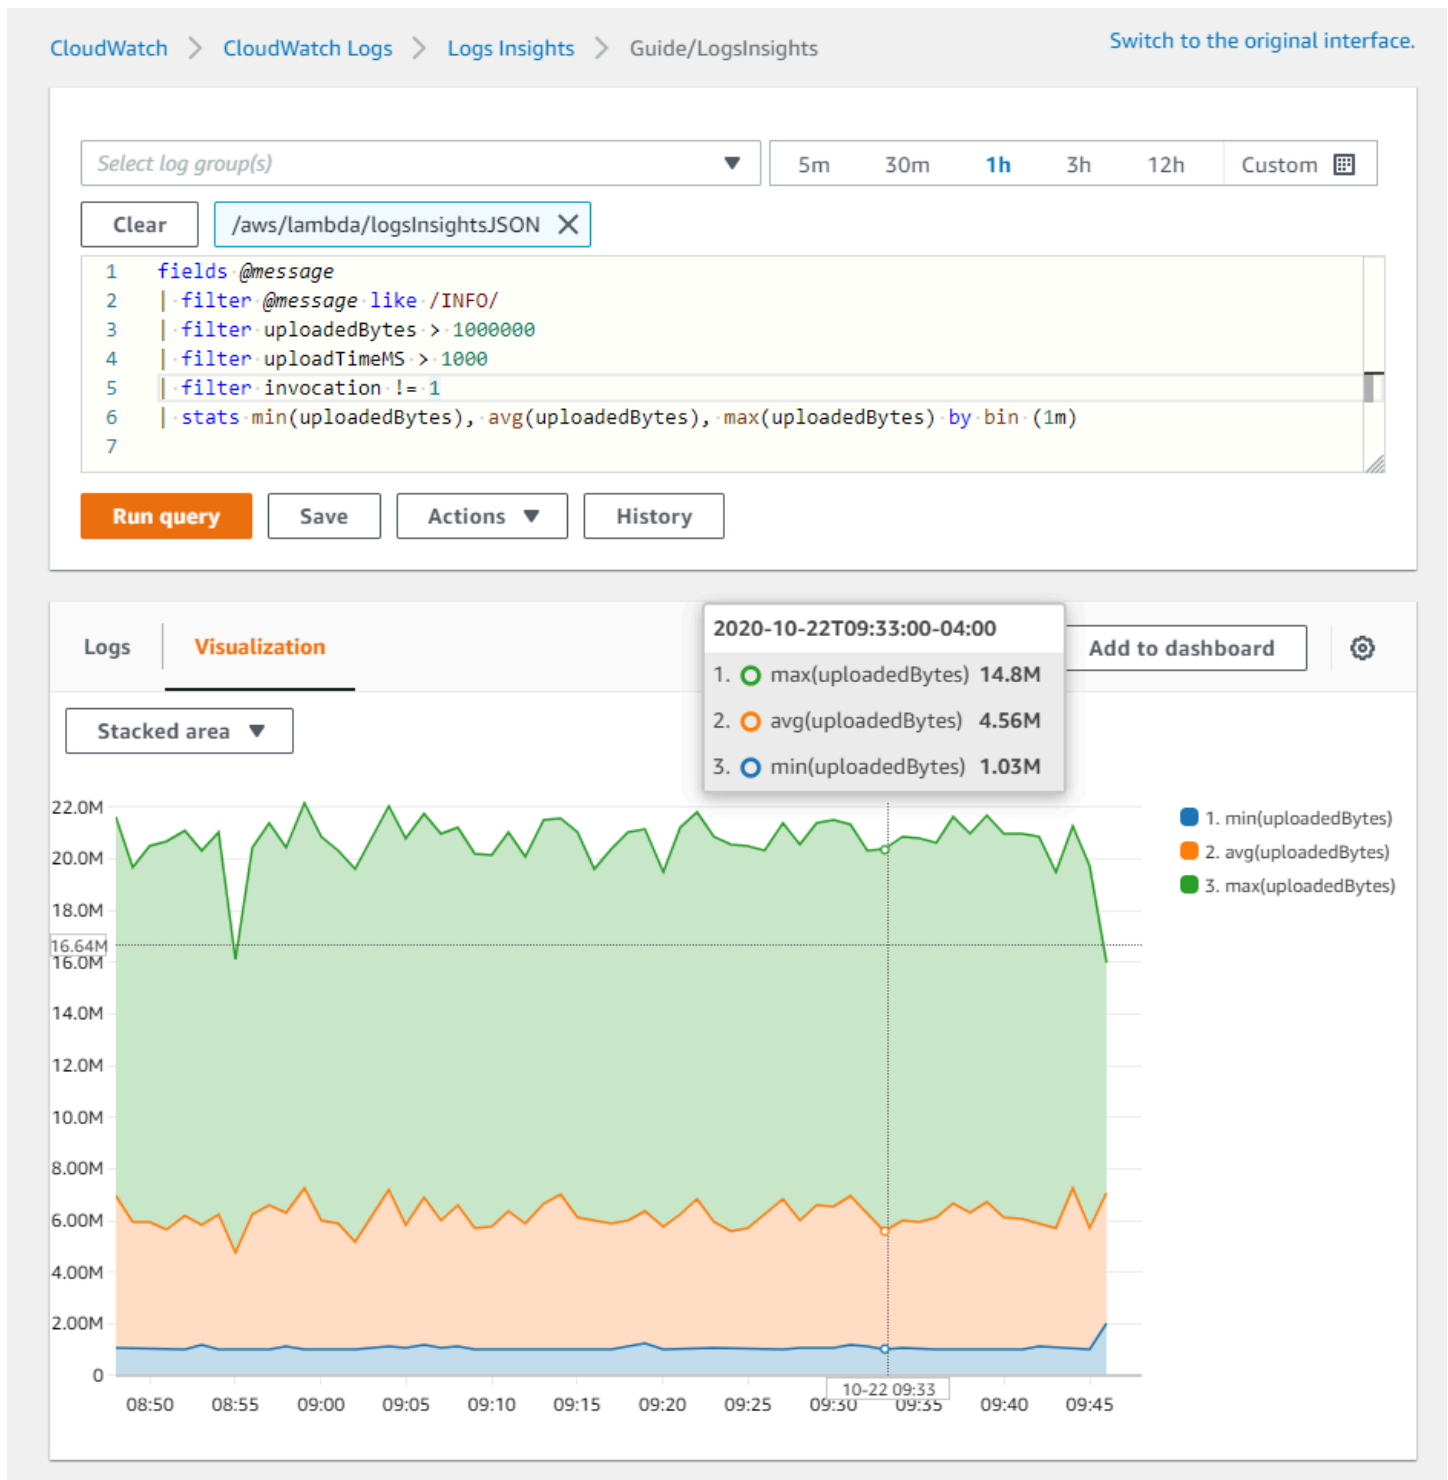

For any CloudWatch Logs Insights query, you can export the results to markdown or CSV format. In some cases, it might be more useful to create [visualizations from queries](#), providing there is at least one aggregation function. The `stats` function allows you to define aggregations and grouping.

The previous *logInsightsJSON* example filtered on upload size and upload time and excluded first invocations. This resulted in a table of data. For monitoring a production system, it may be more useful to visualize minimum, maximum, and average file sizes to find outliers. To do this, apply the `stats` function with the required aggregates, and group on a time value such as every minute:

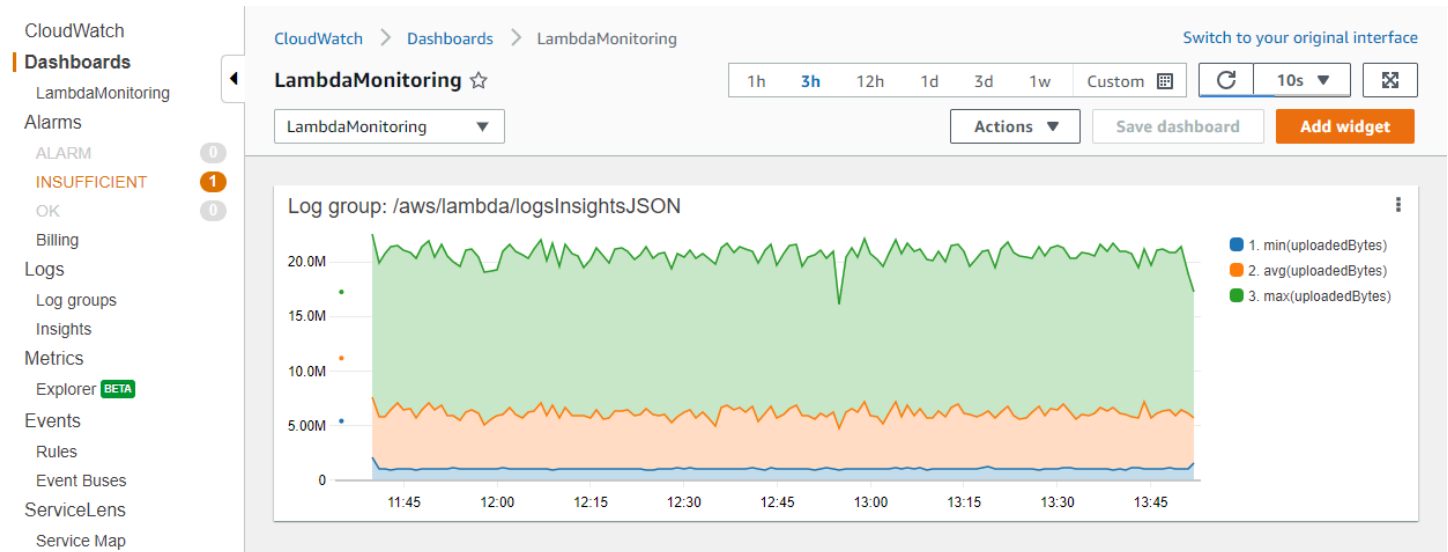

For example, consider the following query. This is the same example query from the [the section called “JSON structured logging”](#) section, but with additional aggregation functions:

```
fields @message
| filter @message like /INFO/
| filter uploadedBytes > 1000000
| filter uploadTimeMS > 1000
| filter invocation != 1
| stats min(uploadedBytes), avg(uploadedBytes), max(uploadedBytes) by bin (1m)
```

We included these aggregates because it may be more useful to visualize minimum, maximum, and average file sizes to find outliers. You can view the results in the **Visualization** tab:

After you have finished building the visualization, you can optionally add the graph to a CloudWatch dashboard. To do this, choose **Add to dashboard** above the visualization. This adds the query as a widget and enables you to select automatic refresh intervals, making it easier to continuously monitor the results:

Sending Lambda function logs to Firehose

The Lambda console now offers the option to send function logs to Firehose. This enables real-time streaming of your logs to various destinations supported by Firehose, including third-party analytics tools and custom endpoints.

Note

You can configure Lambda function logs to be sent to Firehose using the Lambda console, AWS CLI, AWS CloudFormation, and all AWS SDKs.

Pricing

For details on pricing, see [Amazon CloudWatch pricing](#).

Required permissions for Firehose log destination

When using the Lambda console to configure Firehose as your function's log destination, you need:

1. The [required IAM permissions](#) to use CloudWatch Logs with Lambda.
2. To [set up subscription filters with Firehose](#). This filter defines which log events are delivered to your Firehose stream.

Sending Lambda function logs to Firehose

In the Lambda console, you can send function logs directly to Firehose after creating a new function. To do this, complete these steps:

1. Sign in to the AWS Management Console and open the Lambda console.
2. Choose your function's name.
3. Choose the **Configuration** tab.
4. Choose the **Monitoring and operations tools** tab.
5. In the "Logging configuration" section, choose **Edit**.
6. In the "Log content" section, select a log format.
7. In the "Log destination" section, complete the following steps:
 - a. Select a destination service.
 - b. Choose to **Create a new log group** or use an **Existing log group**.

Note

If choosing an existing log group for a Firehose destination, ensure the log group you choose is a `Delivery` log group type.

- c. Choose a Firehose stream.
 - d. The CloudWatch `Delivery` log group will appear.
8. Choose **Save**.

Note

If the IAM role provided in the console doesn't have the required permission, then the destination setup will fail. To fix this, refer to [Required permissions for Firehose log destination](#) to provide the required permissions.

Cross-Account Logging

You can configure Lambda to send logs to Firehose delivery stream in a different AWS account. This requires setting up a destination and configuring appropriate permissions in both accounts.

For detailed instructions on setting up cross-account logging, including required IAM roles and policies, see [Setting up a new cross-account subscription](#) in the CloudWatch Logs documentation.

Sending Lambda function logs to Amazon S3

You can configure your Lambda function to send logs directly to Amazon S3 using the Lambda console. This feature provides a cost-effective solution for long-term log storage and enables powerful analysis options using services like Athena.

Note

You can configure Lambda function logs to be sent to Amazon S3 using the Lambda console, AWS CLI, AWS CloudFormation, and all AWS SDKs.

Pricing

For details on pricing, see [Amazon CloudWatch pricing](#).

Required permissions for Amazon S3 log destination

When using the Lambda console to configure Amazon S3 as your function's log destination, you need:

1. The [required IAM permissions](#) to use CloudWatch Logs with Lambda.
2. To [Set up a CloudWatch Logs subscriptions filter to send Lambda function logs to Amazon S3](#).
This filter defines which log events are delivered to your Amazon S3 bucket.

Set up a CloudWatch Logs subscriptions filter to send Lambda function logs to Amazon S3

To send logs from CloudWatch Logs to Amazon S3, you need to create a subscription filter. This filter defines which log events are delivered to your Amazon S3 bucket. Your Amazon S3 bucket must be in the same Region as your log group.

To create a subscription filter for Amazon S3

1. Create an Amazon Simple Storage Service (Amazon S3) bucket. We recommend that you use a bucket that was created specifically for CloudWatch Logs. However, if you want to use an existing bucket, skip to step 2.

Run the following command, replacing the placeholder Region with the Region you want to use:

```
aws s3api create-bucket --bucket amzn-s3-demo-bucket2 --create-bucket-configuration
LocationConstraint=region
```

Note

amzn-s3-demo-bucket2 is an example Amazon S3 bucket name. It is *reserved*. For this procedure to work, you must to replace it with your unique Amazon S3 bucket name.

The following is example output:

```
{
  "Location": "/amzn-s3-demo-bucket2"
}
```

2. Create the IAM role that grants CloudWatch Logs permission to put data into your Amazon S3 bucket. This policy includes a `aws:SourceArn` global condition context key to help prevent the confused deputy security issue. For more information, see [Confused deputy prevention](#).
 - a. Use a text editor to create a trust policy in a file `~/TrustPolicyForCWL.json` as follows:

```
{
  "Statement": {
    "Effect": "Allow",
    "Principal": { "Service": "logs.amazonaws.com" },
    "Condition": {
      "StringLike": {
        "aws:SourceArn": "arn:aws:logs:region:123456789012:*"
      }
    },
    "Action": "sts:AssumeRole"
  }
}
```

```
}
```

- b. Use the `create-role` command to create the IAM role, specifying the trust policy file. Note of the returned `Role.Arn` value, as you will need it in a later step:

```
aws iam create-role \
  --role-name CWLtoS3Role \
  --assume-role-policy-document file://~/TrustPolicyForCWL.json
{
  "Role": {
    "AssumeRolePolicyDocument": {
      "Statement": {
        "Action": "sts:AssumeRole",
        "Effect": "Allow",
        "Principal": {
          "Service": "logs.amazonaws.com"
        },
        "Condition": {
          "StringLike": {
            "aws:SourceArn": "arn:aws:logs:region:123456789012:*"
          }
        }
      }
    },
    "RoleId": "AA0IIAH450GAB4HC5F431",
    "CreateDate": "2015-05-29T13:46:29.431Z",
    "RoleName": "CWLtoS3Role",
    "Path": "/",
    "Arn": "arn:aws:iam::123456789012:role/CWLtoS3Role"
  }
}
```

3. Create a permissions policy to define what actions CloudWatch Logs can do on your account. First, use a text editor to create a permissions policy in a file `~/PermissionsForCWL.json`:

```
{
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["s3:PutObject"],
      "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket2/*"]
    }
  ]
}
```

```
}
```

Associate the permissions policy with the role using the following `put-role-policy` command:

```
aws iam put-role-policy --role-name CWLtoS3Role --policy-name Permissions-Policy-For-S3 --policy-document file://~/PermissionsForCWL.json
```

4. Create a Delivery log group or use a existing Delivery log group.

```
aws logs create-log-group --log-group-name my-logs --log-group-class DELIVERY --region REGION_NAME
```

5. PutSubscriptionFilter to set up destination

```
aws logs put-subscription-filter
--log-group-name my-logs
--filter-name my-lambda-delivery
--filter-pattern ""
--destination-arn arn:aws:s3:::amzn-s3-demo-bucket2
--role-arn arn:aws:iam::123456789012:role/CWLtoS3Role
--region REGION_NAME
```

Sending Lambda function logs to Amazon S3

In the Lambda console, you can send function logs directly to Amazon S3 after creating a new function. To do this, complete these steps:

1. Sign in to the AWS Management Console and open the Lambda console.
2. Choose your function's name.
3. Choose the **Configuration** tab.
4. Choose the **Monitoring and operations tools** tab.
5. In the "Logging configuration" section, choose **Edit**.
6. In the "Log content" section, select a log format.
7. In the "Log destination" section, complete the following steps:
 - a. Select a destination service.
 - b. Choose to **Create a new log group** or use an **Existing log group**.

Note

If choosing an existing log group for an Amazon S3 destination, ensure the log group you choose is a Delivery log group type.

- c. Choose an Amazon S3 bucket to be the destination for your function logs.
 - d. The CloudWatch Delivery log group will appear.
8. Choose **Save**.

Note

If the IAM role provided in the console doesn't have the required permissions, then the destination setup will fail. To fix this, refer to [Required permissions for Amazon S3 log destination](#).

Cross-Account Logging

You can configure Lambda to send logs to an Amazon S3 bucket in a different AWS account. This requires setting up a destination and configuring appropriate permissions in both accounts.

For detailed instructions on setting up cross-account logging, including required IAM roles and policies, see [Setting up a new cross-account subscription](#) in the CloudWatch Logs documentation.

Logging AWS Lambda API calls using AWS CloudTrail

AWS Lambda is integrated with [AWS CloudTrail](#), a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures API calls for Lambda as events. The calls captured include calls from the Lambda console and code calls to the Lambda API operations. Using the information collected by CloudTrail, you can determine the request that was made to Lambda, the IP address from which the request was made, when it was made, and additional details.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root user or user credentials.
- Whether the request was made on behalf of an IAM Identity Center user.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

CloudTrail is active in your AWS account when you create the account and you automatically have access to the CloudTrail **Event history**. The CloudTrail **Event history** provides a viewable, searchable, downloadable, and immutable record of the past 90 days of recorded management events in an AWS Region. For more information, see [Working with CloudTrail Event history](#) in the *AWS CloudTrail User Guide*. There are no CloudTrail charges for viewing the **Event history**.

For an ongoing record of events in your AWS account past 90 days, create a trail or a [CloudTrail Lake](#) event data store.

CloudTrail trails

A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. All trails created using the AWS Management Console are multi-Region. You can create a single-Region or a multi-Region trail by using the AWS CLI. Creating a multi-Region trail is recommended because you capture activity in all AWS Regions in your account. If you create a single-Region trail, you can view only the events logged in the trail's AWS Region. For more information about trails, see [Creating a trail for your AWS account](#) and [Creating a trail for an organization](#) in the *AWS CloudTrail User Guide*.

You can deliver one copy of your ongoing management events to your Amazon S3 bucket at no charge from CloudTrail by creating a trail, however, there are Amazon S3 storage charges. For

more information about CloudTrail pricing, see [AWS CloudTrail Pricing](#). For information about Amazon S3 pricing, see [Amazon S3 Pricing](#).

CloudTrail Lake event data stores

CloudTrail Lake lets you run SQL-based queries on your events. CloudTrail Lake converts existing events in row-based JSON format to [Apache ORC](#) format. ORC is a columnar storage format that is optimized for fast retrieval of data. Events are aggregated into *event data stores*, which are immutable collections of events based on criteria that you select by applying [advanced event selectors](#). The selectors that you apply to an event data store control which events persist and are available for you to query. For more information about CloudTrail Lake, see [Working with AWS CloudTrail Lake](#) in the *AWS CloudTrail User Guide*.

CloudTrail Lake event data stores and queries incur costs. When you create an event data store, you choose the [pricing option](#) you want to use for the event data store. The pricing option determines the cost for ingesting and storing events, and the default and maximum retention period for the event data store. For more information about CloudTrail pricing, see [AWS CloudTrail Pricing](#).

Lambda data events in CloudTrail

[Data events](#) provide information about the resource operations performed on or in a resource (for example, reading or writing to an Amazon S3 object). These are also known as data plane operations. Data events are often high-volume activities. By default, CloudTrail doesn't log most data events, and the CloudTrail **Event history** doesn't record them.

One CloudTrail data event that is logged by default for supported services is `LambdaESMDisabled`. To learn more about using this event to help troubleshoot issues with Lambda event source mappings, see [the section called "Using CloudTrail to troubleshoot disabled Lambda event sources"](#).

Additional charges apply for data events. For more information about CloudTrail pricing, see [AWS CloudTrail Pricing](#).

You can log data events for the `AWS::Lambda::Function` resource type by using the CloudTrail console, AWS CLI, or CloudTrail API operations. For more information about how to log data events, see [Logging data events with the AWS Management Console](#) and [Logging data events with the AWS Command Line Interface](#) in the *AWS CloudTrail User Guide*.

The following table lists the Lambda resource type for which you can log data events. The **Data event type (console)** column shows the value to choose from the **Data event type** list on the CloudTrail console. The **resources.type value** column shows the `resources.type` value, which you would specify when configuring advanced event selectors using the AWS CLI or CloudTrail APIs. The **Data APIs logged to CloudTrail** column shows the API calls logged to CloudTrail for the resource type.

Data event type (console)	resources.type value	Data APIs logged to CloudTrail
Lambda	<code>AWS::Lambda::Function</code>	Invoke

You can configure advanced event selectors to filter on the `eventName`, `readOnly`, and `resources.ARN` fields to log only those events that are important to you. The following example is the JSON view of a data event configuration that logs events for a specific function only. For more information about these fields, see [AdvancedFieldSelector](#) in the *AWS CloudTrail API Reference*.

```
[
  {
    "name": "function-invokes",
    "fieldSelectors": [
      {
        "field": "eventCategory",
        "equals": [
          "Data"
        ]
      },
      {
        "field": "resources.type",
        "equals": [
          "AWS::Lambda::Function"
        ]
      },
      {
        "field": "resources.ARN",
        "equals": [
          "arn:aws:lambda:us-east-1:111122223333:function:hello-world"
        ]
      }
    ]
  }
]
```

```
]
  }
]
}
]
```

Lambda management events in CloudTrail

[Management events](#) provide information about management operations that are performed on resources in your AWS account. These are also known as control plane operations. By default, CloudTrail logs management events.

Lambda supports logging the following actions as management events in CloudTrail log files.

Note

In the CloudTrail log file, the eventName might include date and version information, but it is still referring to the same public API action. For example the, GetFunction action appears as GetFunction20150331v2. The following list specifies when the event name differs from the API action name.

- [AddLayerVersionPermission](#)
- [AddPermission](#) (event name: AddPermission20150331v2)
- [CreateAlias](#) (event name: CreateAlias20150331)
- [CreateEventSourceMapping](#) (event name: CreateEventSourceMapping20150331)
- [CreateFunction](#) (event name: CreateFunction20150331)

(The Environment and ZipFile parameters are omitted from the CloudTrail logs for CreateFunction.)

- [CreateFunctionUrlConfig](#)
- [DeleteAlias](#) (event name: DeleteAlias20150331)
- [DeleteCodeSigningConfig](#)
- [DeleteEventSourceMapping](#) (event name: DeleteEventSourceMapping20150331)
- [DeleteFunction](#) (event name: DeleteFunction20150331)
- [DeleteFunctionConcurrency](#) (event name: DeleteFunctionConcurrency20171031)

- [DeleteFunctionUrlConfig](#)
- [DeleteProvisionedConcurrencyConfig](#)
- [GetAlias](#) (event name: GetAlias20150331)
- [GetEventSourceMapping](#)
- [GetFunction](#)
- [GetFunctionUrlConfig](#)
- [GetFunctionConfiguration](#)
- [GetLayerVersionPolicy](#)
- [GetPolicy](#)
- [ListEventSourceMappings](#)
- [ListFunctions](#)
- [ListFunctionUrlConfigs](#)
- [PublishLayerVersion](#) (event name: PublishLayerVersion20181031)

(The ZipFile parameter is omitted from the CloudTrail logs for PublishLayerVersion.)

- [PublishVersion](#) (event name: PublishVersion20150331)
- [PutFunctionConcurrency](#) (event name: PutFunctionConcurrency20171031)
- [PutFunctionCodeSigningConfig](#)
- [PutFunctionEventInvokeConfig](#)
- [PutProvisionedConcurrencyConfig](#)
- [PutRuntimeManagementConfig](#)
- [RemovePermission](#) (event name: RemovePermission20150331v2)
- [TagResource](#) (event name: TagResource20170331v2)
- [UntagResource](#) (event name: UntagResource20170331v2)
- [UpdateAlias](#) (event name: UpdateAlias20150331)
- [UpdateCodeSigningConfig](#)
- [UpdateEventSourceMapping](#) (event name: UpdateEventSourceMapping20150331)
- [UpdateFunctionCode](#) (event name: UpdateFunctionCode20150331v2)

(The ZipFile parameter is omitted from the CloudTrail logs for UpdateFunctionCode.)

- [UpdateFunctionConfiguration](#) (event name: UpdateFunctionConfiguration20150331v2)

(The `Environment` parameter is omitted from the CloudTrail logs for `UpdateFunctionConfiguration`.)

- [UpdateFunctionEventInvokeConfig](#)
- [UpdateFunctionUrlConfig](#)

Using CloudTrail to troubleshoot disabled Lambda event sources

When you change the state of an event source mapping using the [UpdateEventSourceMapping](#) API action, the API call is logged as a management event in CloudTrail. Event source mappings can also transition directly to the `Disabled` state due to errors.

For the following services, Lambda publishes the `LambdaESMDisabled` data event to CloudTrail when your event source transitions to the `Disabled` state:

- Amazon Simple Queue Service (Amazon SQS)
- Amazon DynamoDB
- Amazon Kinesis

Lambda doesn't support this event for any other event source mapping types.

To receive alerts when event source mappings for supported services transition to the `Disabled` state, set up an alarm in Amazon CloudWatch using the `LambdaESMDisabled` CloudTrail event. To learn more about setting up a CloudWatch alarm, see [Creating CloudWatch alarms for CloudTrail events: examples](#).

The `serviceEventDetails` entity in the `LambdaESMDisabled` event message contains one of the following error codes.

RESOURCE_NOT_FOUND

The resource specified in the request does not exist.

FUNCTION_NOT_FOUND

The function attached to the event source does not exist.

REGION_NAME_NOT_VALID

A Region name provided to the event source or function is invalid.

AUTHORIZATION_ERROR

Permissions have not been set, or are misconfigured.

FUNCTION_IN_FAILED_STATE

The function code does not compile, has encountered an unrecoverable exception, or a bad deployment has occurred.

Lambda event examples

An event represents a single request from any source and includes information about the requested API operation, the date and time of the operation, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so events don't appear in any specific order.

The following example shows CloudTrail log entries for the `GetFunction` and `DeleteFunction` actions.

Note

The `eventName` might include date and version information, such as `"GetFunction20150331"`, but it is still referring to the same public API.

```

```

For information about CloudTrail record contents, see [CloudTrail record contents](#) in the *AWS CloudTrail User Guide*.

Visualize Lambda function invocations using AWS X-Ray

You can use AWS X-Ray to visualize the components of your application, identify performance bottlenecks, and troubleshoot requests that resulted in an error. Your Lambda functions send trace data to X-Ray, and X-Ray processes the data to generate a service map and searchable trace summaries.

Lambda supports two tracing modes for X-Ray: `Active` and `PassThrough`. With `Active` tracing, Lambda automatically creates trace segments for function invocations and sends them to X-Ray. `PassThrough` mode, on the other hand, simply propagates the tracing context to downstream services. If you've enabled `Active` tracing for your function, Lambda automatically sends traces to X-Ray for sampled requests. Typically, an upstream service, such as Amazon API Gateway or an application hosted on Amazon EC2 that is instrumented with the X-Ray SDK, decides whether incoming requests should be traced, then adds that sampling decision as a tracing header. Lambda uses that header to decide to send traces or not. Traces from upstream message producers, such as Amazon SQS, are automatically linked to traces from downstream Lambda functions, creating an end-to-end view of the entire application. For more information, see [Tracing event-driven applications](#) in the *AWS X-Ray Developer Guide*.

Note

X-Ray tracing is currently not supported for Lambda functions with Amazon Managed Streaming for Apache Kafka (Amazon MSK), self-managed Apache Kafka, Amazon MQ with ActiveMQ and RabbitMQ, or Amazon DocumentDB event source mappings.

To toggle active tracing on your Lambda function with the console, follow these steps:

To turn on active tracing

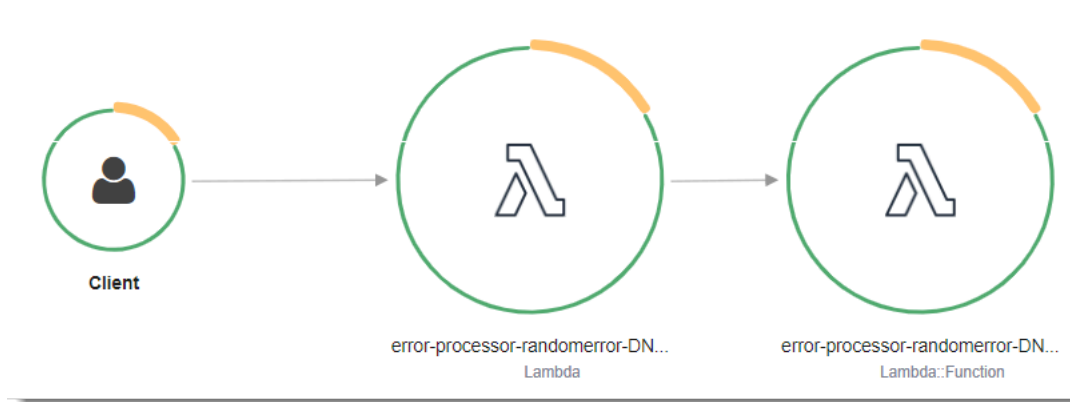

1. Open the [Functions page](#) of the Lambda console.
2. Choose a function.
3. Choose **Configuration** and then choose **Monitoring and operations tools**.
4. Under **Additional monitoring tools**, choose **Edit**.
5. Under **CloudWatch Application Signals and AWS X-Ray**, choose **Enable** for **Lambda service traces**.
6. Choose **Save**.

Your function needs permission to upload trace data to X-Ray. When you activate tracing in the Lambda console, Lambda adds the required permissions to your function's [execution role](#). Otherwise, add the [AWSXRayDaemonWriteAccess](#) policy to the execution role.

X-Ray doesn't trace all requests to your application. X-Ray applies a sampling algorithm to ensure that tracing is efficient, while still providing a representative sample of all requests. The sampling rate is 1 request per second and 5 percent of additional requests. You can't configure the X-Ray sampling rate for your functions.

Understanding X-Ray traces

In X-Ray, a *trace* records information about a request that is processed by one or more *services*. Lambda records 2 segments per trace, which creates two nodes on the service graph. The following image highlights these two nodes:

The first node on the left represents the Lambda service, which receives the invocation request. The second node represents your specific Lambda function.

The segment recorded for the Lambda service, `AWS::Lambda`, covers all the steps required to prepare the Lambda execution environment. This includes scheduling the MicroVM, creating or unfreezing an execution environment with the resources you have configured, as well as downloading your function code and all layers.

The `AWS::Lambda::Function` segment is for the work done by the function.

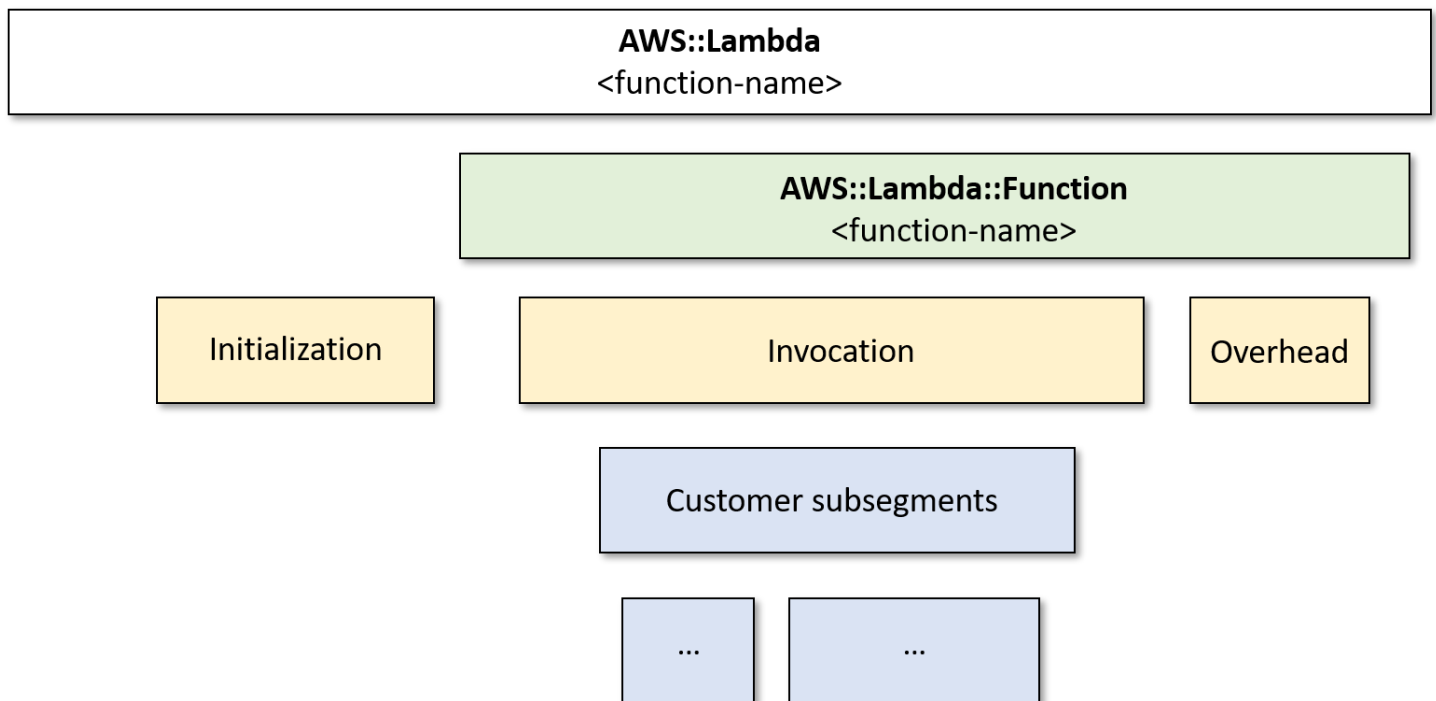

Note

AWS is currently implementing changes to the Lambda service. Due to these changes, you may see minor differences between the structure and content of system log messages and trace segments emitted by different Lambda functions in your AWS account.

This change affects the subsegments of the function segment. The following paragraphs describe both the old and new formats for these subsegments. These changes will be implemented during the coming weeks, and all functions in all AWS Regions except the China and GovCloud regions will transition to use the new-format log messages and trace segments.

Old-style AWS X-Ray Lambda segment structure

The old-style X-Ray structure for the AWS::Lambda segment looks like the following:

In this format, the function segment has subsegments for **Initialization**, **Invocation**, and **Overhead**. For [Lambda SnapStart](#) only, there is also a **Restore** subsegment (not shown on this diagram).

The **Initialization** subsegment represents the init phase of the Lambda execution environment lifecycle. During this phase, Lambda initializes extensions, initializes the runtime, and runs the function's initialization code.

The **Invocation** subsegment represents the invoke phase where Lambda invokes the function handler. This begins with runtime and extension registration and it ends when the runtime is ready to send the response.

(Lambda SnapStart only) The Restore subsegment shows the time it takes for Lambda to restore a snapshot, load the runtime, and run any after-restore [runtime hooks](#). The process of restoring snapshots can include time spent on activities outside the MicroVM. This time is reported in the Restore subsegment. You aren't charged for the time spent outside the microVM to restore a snapshot.

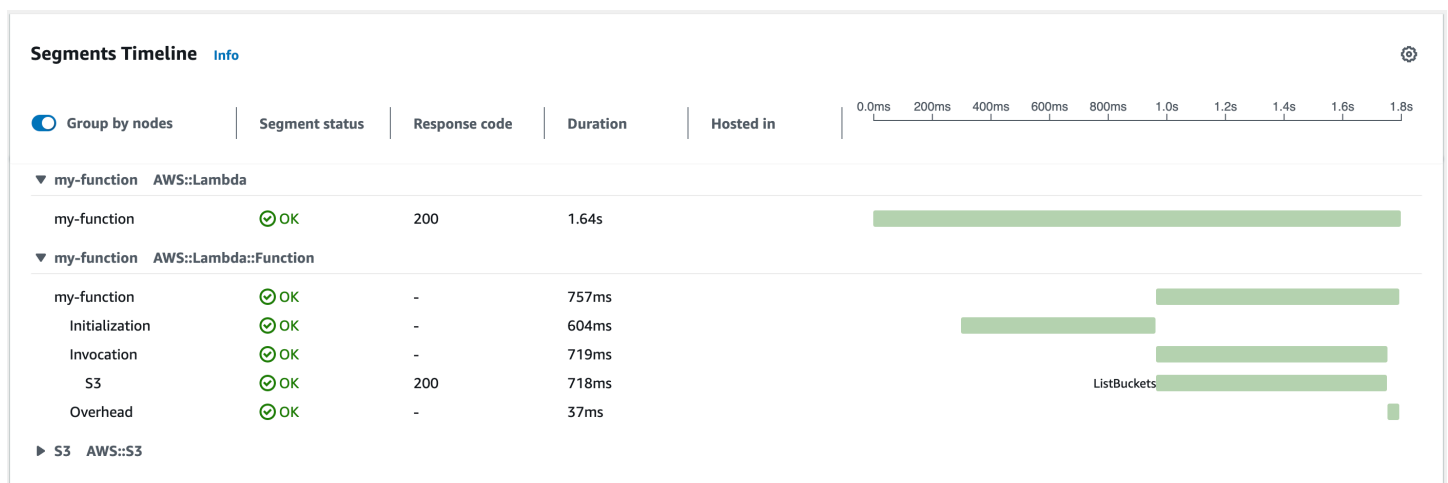

The Overhead subsegment represents the phase that occurs between the time when the runtime sends the response and the signal for the next invoke. During this time, the runtime finishes all tasks related to an invoke and prepares to freeze the sandbox.

Important

You can use the X-Ray SDK to extend the Invocation subsegment with additional subsegments for downstream calls, annotations, and metadata. You can't access the function segment directly or record work done outside of the handler invocation scope.

For more information about Lambda execution environment phases, see [the section called "Execution environment"](#).

An example trace using the old-style X-Ray structure is shown in the following diagram.

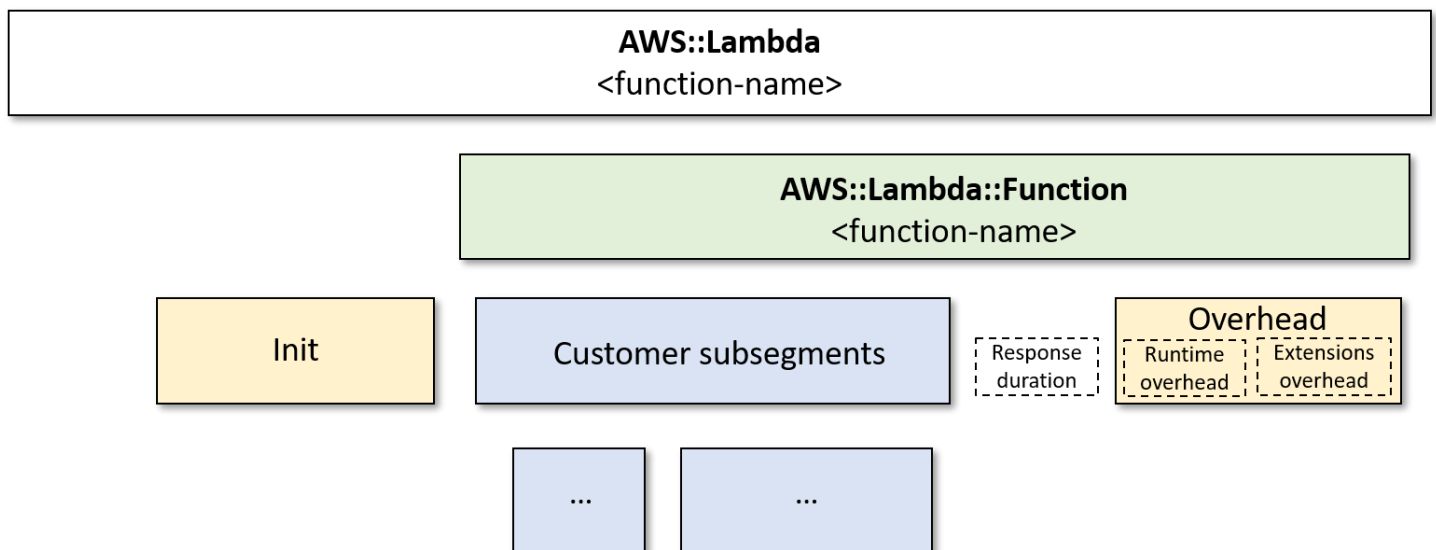

Note the two segments in the example. Both are named **my-function**, but one has an origin of `AWS::Lambda` and the other has an origin of `AWS::Lambda::Function`. If the `AWS::Lambda` segment shows an error, the Lambda service had an issue. If the `AWS::Lambda::Function` segment shows an error, your function had an issue.

Note

Occasionally, you may notice a large gap between the function initialization and invocation phases in your X-Ray traces. For functions using [provisioned concurrency](#), this is because Lambda initializes your function instances well in advance of invocation. For functions using [unreserved \(on-demand\) concurrency](#), Lambda may proactively initialize a function instance, even if there's no invocation. Visually, both of these cases show up as a time gap between the initialization and invocation phases.

New-style AWS X-Ray Lambda segment structure

The new-style X-Ray structure for the `AWS::Lambda` segment looks like the following:

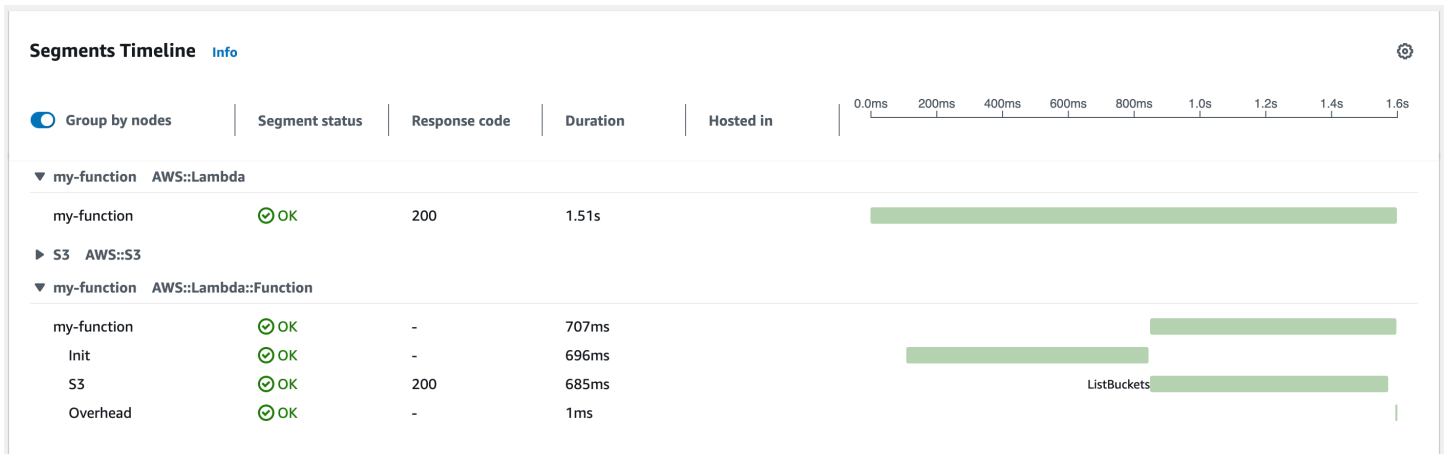

In this new format, The `Init` subsegment represents the init phase of the Lambda execution environment lifecycle as before.

There is no invocation segment in the new format. Instead, customer subsegments are attached directly to the `AWS::Lambda::Function` segment. This segment contains the following metrics as annotations:

- `aws.responseLatency` - the time taken for the function to run
- `aws.responseDuration` - the time taken to transfer the response to the customer
- `aws.runtimeOverhead` - the amount of additional time the runtime needed to finish
- `aws.extensionOverhead` - the amount of additional time the extensions needed to finish

An example trace using the new-style X-Ray structure is shown in the following diagram.

Note the two segments in the example. Both are named **my-function**, but one has an origin of `AWS::Lambda` and the other has an origin of `AWS::Lambda::Function`. If the `AWS::Lambda` segment shows an error, the Lambda service had an issue. If the `AWS::Lambda::Function` segment shows an error, your function had an issue.

See the following topics for a language-specific introduction to tracing in Lambda:

- [Instrumenting Node.js code in AWS Lambda](#)
- [Instrumenting Python code in AWS Lambda](#)
- [Instrumenting Ruby code in AWS Lambda](#)
- [Instrumenting Java code in AWS Lambda](#)
- [Instrumenting Go code in AWS Lambda](#)
- [Instrumenting C# code in AWS Lambda](#)

For a full list of services that support active instrumentation, see [Supported AWS services](#) in the AWS X-Ray Developer Guide.

Default tracing behavior in Lambda

If you do not have Active tracing turned on, Lambda defaults to PassThrough tracing mode.

In PassThrough mode, Lambda forwards the X-Ray tracing header to downstream services, but does not send traces automatically. This is true even if the tracing header contains a decision to sample the request. If the upstream service does not provide an X-Ray tracing header, Lambda

generates a header and makes the decision not to sample. However, you can send your own traces by calling tracing libraries from your function code.

Note

Previously, Lambda would send traces automatically when upstream services, such as Amazon API Gateway, added a tracing header. By not sending traces automatically, Lambda gives you the control to trace the functions that are important to you. If your solution depends on this passive tracing behavior, switch to Active tracing.

Execution role permissions

Lambda needs the following permissions to send trace data to X-Ray. Add them to your function's [execution role](#).

- [xray:PutTraceSegments](#)
- [xray:PutTelemetryRecords](#)

These permissions are included in the [AWSXRayDaemonWriteAccess](#) managed policy.

Enabling Active tracing with the Lambda API

To manage tracing configuration with the AWS CLI or AWS SDK, use the following API operations:

- [UpdateFunctionConfiguration](#)
- [GetFunctionConfiguration](#)
- [CreateFunction](#)

The following example AWS CLI command enables active tracing on a function named **my-function**.

```
aws lambda update-function-configuration --function-name my-function \  
--tracing-config Mode=Active
```

Tracing mode is part of the version-specific configuration when you publish a version of your function. You can't change the tracing mode on a published version.

Enabling Active tracing with CloudFormation

To activate tracing on an `AWS::Lambda::Function` resource in an CloudFormation template, use the `TracingConfig` property.

Example [function-inline.yml](#) – Tracing configuration

```
Resources:
  function:
    Type: AWS::Lambda::Function
    Properties:
      TracingConfig:
        Mode: Active
      ...
```

For an AWS Serverless Application Model (AWS SAM) `AWS::Serverless::Function` resource, use the `Tracing` property.

Example [template.yml](#) – Tracing configuration

```
Resources:
  function:
    Type: AWS::Serverless::Function
    Properties:
      Tracing: Active
      ...
```

Monitor function performance with Amazon CloudWatch Lambda Insights

Amazon CloudWatch Lambda Insights collects and aggregates Lambda function runtime performance metrics and logs for your serverless applications. This page describes how to enable and use Lambda Insights to diagnose issues with your Lambda functions.

Sections

- [How Lambda Insights monitors serverless applications](#)
- [Pricing](#)
- [Supported runtimes](#)
- [Enabling Lambda Insights in the Lambda console](#)
- [Enabling Lambda Insights programmatically](#)
- [Using the Lambda Insights dashboard](#)
- [Example workflow to detect function anomalies](#)
- [Example workflow using queries to troubleshoot a function](#)
- [What's next?](#)

How Lambda Insights monitors serverless applications

CloudWatch Lambda Insights is a monitoring and troubleshooting solution for serverless applications running on AWS Lambda. The solution collects, aggregates, and summarizes system-level metrics including CPU time, memory, disk and network usage. It also collects, aggregates, and summarizes diagnostic information such as cold starts and Lambda worker shutdowns to help you isolate issues with your Lambda functions and resolve them quickly.

Lambda Insights uses a new CloudWatch Lambda Insights [extension](#), which is provided as a [Lambda layer](#). When you enable this extension on a Lambda function for a supported runtime, it collects system-level metrics and emits a single performance log event for every invocation of that Lambda function. CloudWatch uses embedded metric formatting to extract metrics from the log events. For more information, see [Using AWS Lambda extensions](#).

The Lambda Insights layer extends the `CreateLogStream` and `PutLogEvents` for the `/aws/lambda-insights/` log group.

Pricing

When you enable Lambda Insights for your Lambda function, Lambda Insights reports 8 metrics per function and every function invocation sends about 1KB of log data to CloudWatch. You only pay for the metrics and logs reported for your function by Lambda Insights. There are no minimum fees or mandatory service usage policies. You do not pay for Lambda Insights if the function is not invoked. For a pricing example, see [Amazon CloudWatch pricing](#).

Supported runtimes

You can use Lambda Insights with any of the runtimes that support [Lambda extensions](#).

Enabling Lambda Insights in the Lambda console

You can enable Lambda Insights enhanced monitoring on new and existing Lambda functions. When you enable Lambda Insights on a function in the Lambda console for a supported runtime, Lambda adds the Lambda Insights [extension](#) as a layer to your function, and verifies or attempts to attach the [CloudWatchLambdaInsightsExecutionRolePolicy](#) policy to your function's [execution role](#).

To enable Lambda Insights in the Lambda console

1. Open the [Functions page](#) of the Lambda console.
2. Choose your function.
3. Choose the **Configuration** tab.
4. On the left menu, choose **Monitoring and operations tools**.
5. On the **Additional monitoring tools** pane, choose **Edit**.
6. Under **CloudWatch Lambda Insights**, turn on **Enhanced monitoring**.
7. Choose **Save**.

Enabling Lambda Insights programmatically

You can also enable Lambda Insights using the AWS Command Line Interface (AWS CLI), AWS Serverless Application Model (SAM) CLI, CloudFormation, or the AWS Cloud Development Kit (AWS CDK). When you enable Lambda Insights programmatically on a function for a supported runtime, CloudWatch attaches the [CloudWatchLambdaInsightsExecutionRolePolicy](#) policy to your function's [execution role](#).

For more information, see [Getting started with Lambda Insights](#) in the *Amazon CloudWatch User Guide*.

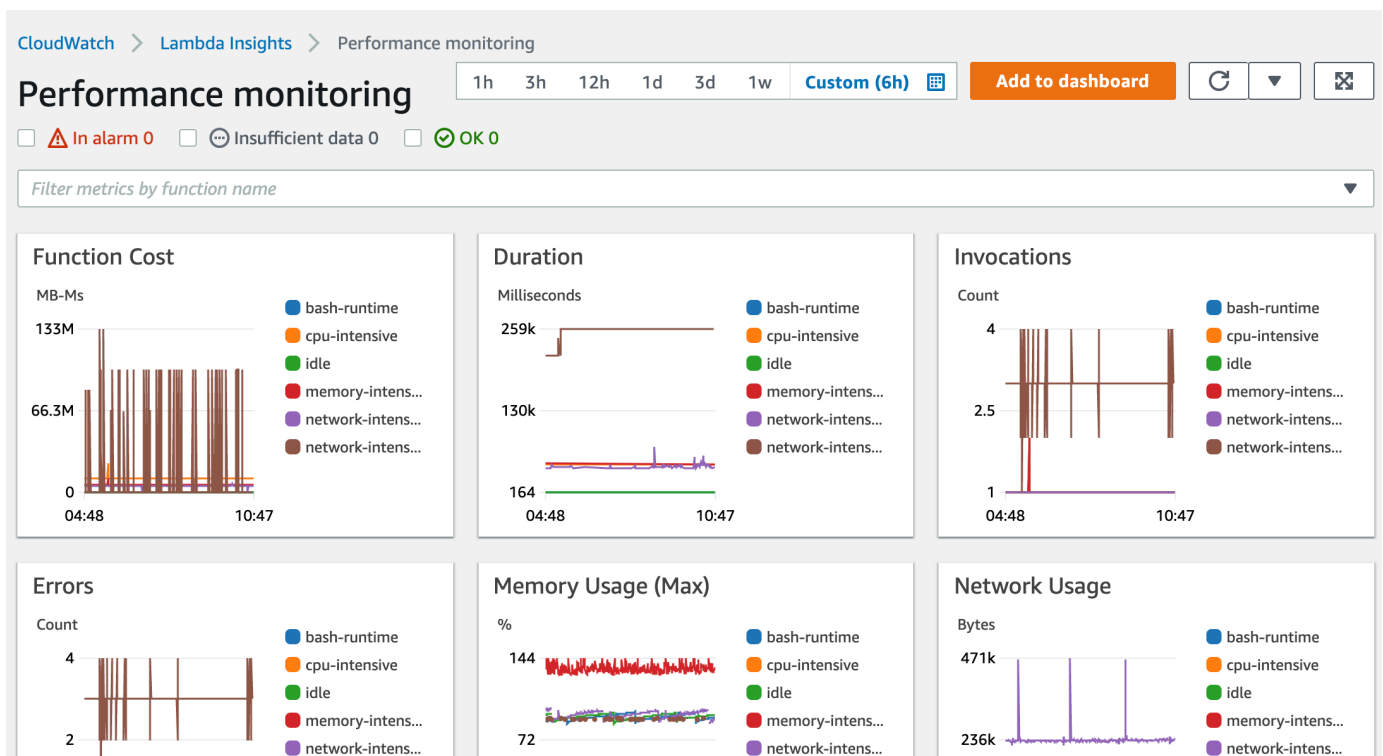

Using the Lambda Insights dashboard

The Lambda Insights dashboard has two views in the CloudWatch console: the multi-function overview and the single-function view. The multi-function overview aggregates the runtime metrics for the Lambda functions in the current AWS account and Region. The single-function view shows the available runtime metrics for a single Lambda function.

You can use the Lambda Insights dashboard multi-function overview in the CloudWatch console to identify over- and under-utilized Lambda functions. You can use the Lambda Insights dashboard single-function view in the CloudWatch console to troubleshoot individual requests.

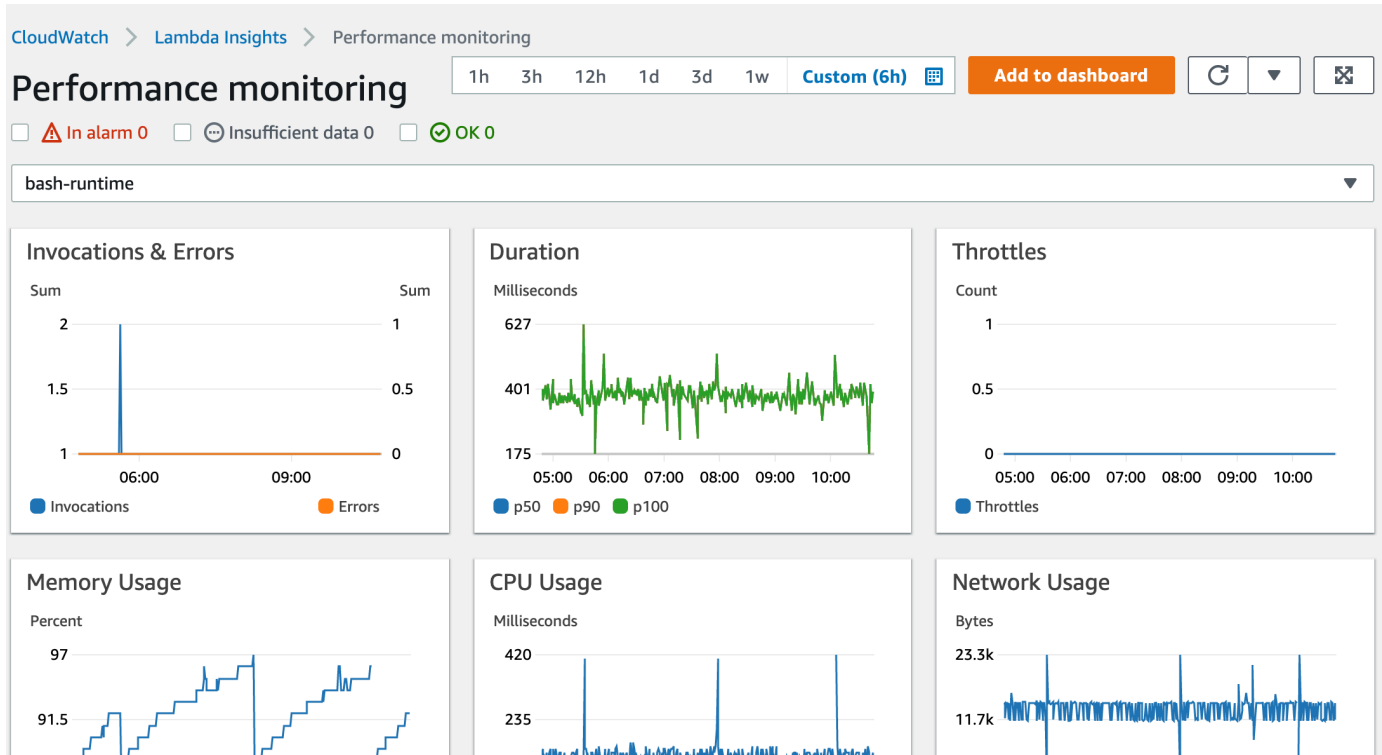

To view the runtime metrics for all functions

1. Open the [Multi-function](#) page in the CloudWatch console.
2. Choose from the predefined time ranges, or choose a custom time range.
3. (Optional) Choose **Add to dashboard** to add the widgets to your CloudWatch dashboard.

To view the runtime metrics of a single function

1. Open the [Single-function](#) page in the CloudWatch console.
2. Choose from the predefined time ranges, or choose a custom time range.
3. (Optional) Choose **Add to dashboard** to add the widgets to your CloudWatch dashboard.

For more information, see [Creating and working with widgets on CloudWatch dashboards](#).

Example workflow to detect function anomalies

You can use the multi-function overview on the Lambda Insights dashboard to identify and detect compute memory anomalies with your function. For example, if the multi-function overview indicates that a function is using a large amount of memory, you can view detailed memory utilization metrics in the **Memory Usage** pane. You can then go to the Metrics dashboard to enable anomaly detection or create an alarm.

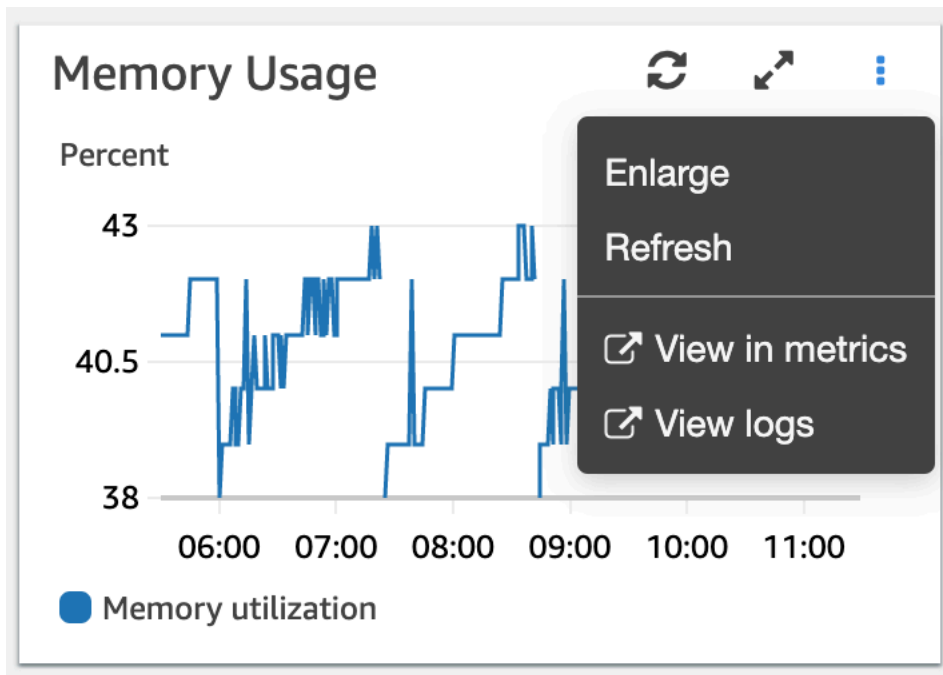

To enable anomaly detection for a function

1. Open the [Multi-function](#) page in the CloudWatch console.
2. Under **Function summary**, choose your function's name.

The single-function view opens with the function runtime metrics.

Function summary (6)								Actions 
								< 1 > 
<input type="checkbox"/>	Function name ▲	Invocations ▼	CPU time ▼	Network IO ▼	Max. memory ▼	Cold starts ▼		
<input type="checkbox"/>	bash-runtime	360	132.9167ms	4770 kB	<div><div></div></div> 97%	3		
<input type="checkbox"/>	cpu-intensive	359	6714.2897ms	4780 kB	<div><div></div></div> 43%	4		
<input type="checkbox"/>	idle	359	120.2507ms	4746 kB	<div><div></div></div> 96%	3		
<input type="checkbox"/>	memory-intensive	358	2385.9497ms	4794 kB	<div><div></div></div> 44%	4		
<input type="checkbox"/>	network-intensive	359	781.0585ms	82008 kB	<div><div></div></div> 99%	3		
<input type="checkbox"/>	network-intensive-vpc	43	2730.6977ms	95 kB	<div><div></div></div> 91%	43		

- On the **Memory Usage** pane, choose the three vertical dots, and then choose **View in metrics** to open the **Metrics** dashboard.

- On the **Graphed metrics** tab, in the **Actions** column, choose the first icon to enable anomaly detection for the function.

All metrics		Graphed metrics (6)		Graph options		Source	
<div>Math expression ? Dynamic labels ? Statistic: Maximum ? Period: 1 Minute ? Remove all</div>							
<input checked="" type="checkbox"/>		Label	Details	Statistic	Period	Y Axis	Actions
<input checked="" type="checkbox"/>		bash-runtime	LambdaInsights * memory_utilization * functio...	Maximum	1 Minute	<div><div><</div><div>></div></div>	<div></div>
<input checked="" type="checkbox"/>		cpu-intensive	LambdaInsights * memory_utilization * functio...	Maximum	1 Minute	<div><div><</div><div>></div></div>	<div></div>
<input checked="" type="checkbox"/>		idle	LambdaInsights * memory_utilization * functio...	Maximum	1 Minute	<div><div><</div><div>></div></div>	<div></div>
<input checked="" type="checkbox"/>		memory-intensive	LambdaInsights * memory_utilization * functio...	Maximum	1 Minute	<div><div><</div><div>></div></div>	<div></div>

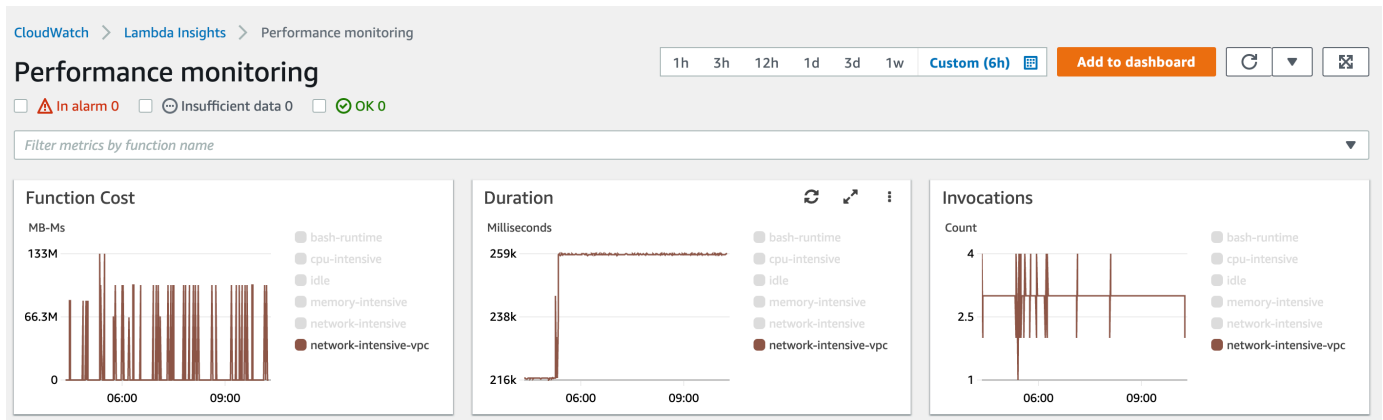

For more information, see [Using CloudWatch Anomaly Detection](#).

Example workflow using queries to troubleshoot a function

You can use the single-function view on the Lambda Insights dashboard to identify the root cause of a spike in function duration. For example, if the multi-function overview indicates a large increase in function duration, you can pause on or choose each function in the **Duration** pane to determine which function is causing the increase. You can then go to the single-function view and review the **Application logs** to determine the root cause.

To run queries on a function

1. Open the [Multi-function](#) page in the CloudWatch console.
2. In the **Duration** pane, choose your function to filter the duration metrics.

3. Open the [Single-function](#) page.
4. Choose the **Filter metrics by function name** dropdown list, and then choose your function.
5. To view the **Most recent 1000 application logs**, choose the **Application logs** tab.

- Review the **Timestamp** and **Message** to identify the invocation request that you want to troubleshoot.

Most recent 1000 application logs (1000)			View logs 
		< 1 2 3 4 5 6 7 ... 15 > 	
Timestamp	Message		
2020-09-30T16:24:36.121-06	0 0 0 0 0 0 0 --:--:-- 0:03:06 --:--:-- 0		
2020-09-30T16:24:34.917-06	0 0 0 0 0 0 0 --:--:-- 0:04:15 --:--:-- 0		
2020-09-30T16:24:34.120-06	0 0 0 0 0 0 0 --:--:-- 0:03:04 --:--:-- 0		
2020-09-30T16:24:33.033-06	0 0 0 0 0 0 0 --:--:-- 0:01:26 --:--:-- 0		

- To show the **Most recent 1000 invocations**, choose the **Invocations** tab.
- Select the **Timestamp** or **Message** for the invocation request that you want to troubleshoot.

Most recent 1000 invocations (1/45)								View logs 
								< 1 > 
	Timestamp	Request ID	Trace	Memory %	Network IO	CPU time	Cold start	
<input checked="" type="checkbox"/>	2020-09-30 16:22:34 (UTC-06:00)	247e6369-3a2b-...	-	<div><div></div></div> 91%	2 kB	2550ms	Yes	
<input type="checkbox"/>	2020-09-30 16:13:39 (UTC-06:00)	311fb438-fa9d-4...	-	<div><div></div></div> 90%	2 kB	2340ms	Yes	

- Choose the **View logs** dropdown list, and then choose **View performance logs**.

An autogenerated query for your function opens in the **Logs Insights** dashboard.

- Choose **Run query** to generate a **Logs** message for the invocation request.

The screenshot shows the AWS Lambda Insights console interface. At the top, there's a search bar with the text "Select log group(s)" and a dropdown arrow. To the right of the search bar are two date range selectors: "2020-09-30 (10:35:41)" and "2020-09-30 (16:35:41)". Below the search bar is a text input field containing "/aws/lambda-insights" with a clear button. To the right of the input field is a "Clear" button. Below the input field is a code editor with the following query:

```
1 fields @timestamp, @message
2 | .filter function_name = "network-intensive-vpc"
3 | .filter request_id = "247e6369-3a2b-4ccf-9e95-fb80c6ba711f"
4 | sort @timestamp desc
```

Below the code editor are three buttons: "Run query" (orange), "Save", and "History".

Below the buttons is a section with two tabs: "Logs" (selected) and "Visualization". To the right of the tabs are two buttons: "Export results" (with a dropdown arrow) and "Add to dashboard". To the far right is a settings gear icon. Below the tabs, the text "Showing 1 of 1 records matched ⓘ" is displayed. Below this text is a histogram showing a single bar at 04 PM. The histogram is labeled "1,856 records (2.0 MB) scanned in 4.0s @ 467 records/s (521.7 kB/s)". Below the histogram is a table with the following columns: "#", "@timestamp", and "@message". The table contains one row with the following data:

#	@timestamp	@message
1	2020-09-30T16:22:34....	{"cpu_system_time":1520,"shutdown":1,"cpu_user_time":1030,"agent_memory_avg":7487349,"used_memory..."}

What's next?

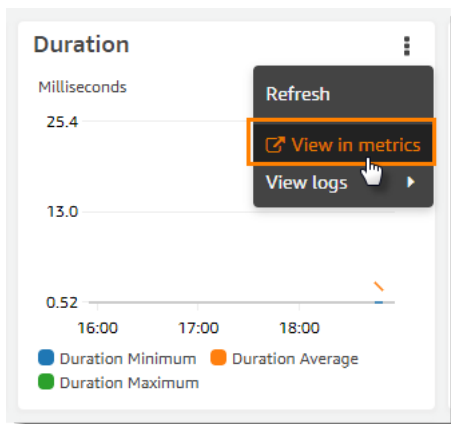

- Learn how to create a CloudWatch Logs dashboard in [Create a Dashboard](#) in the *Amazon CloudWatch User Guide*.
- Learn how to add queries to a CloudWatch Logs dashboard in [Add Query to Dashboard or Export Query Results](#) in the *Amazon CloudWatch User Guide*.

Monitoring Lambda applications

The **Applications** section of the Lambda console includes a **Monitoring** tab where you can review an Amazon CloudWatch dashboard with aggregate metrics for the resources in your application.

To monitor a Lambda application

1. Open the Lambda console [Applications page](#).
2. Choose **Monitoring**.
3. To see more details about the metrics in any graph, choose **View in metrics** from the drop-down menu.

The graph appears in a new tab, with the relevant metrics listed below the graph. You can customize your view of this graph, changing the metrics and resources shown, the statistic, the period, and other factors to get a better understanding of the current situation.

By default, the Lambda console shows a basic dashboard. You can customize this page by adding one or more Amazon CloudWatch dashboards to your application template with the [AWS::CloudWatch::Dashboard](#) resource type. When your template includes one or more dashboards, the page shows your dashboards instead of the default dashboard. You can switch between dashboards with the drop-down menu on the top right of the page. The following example creates a dashboard with a single widget that graphs the number of invocations of a function named `my-function`.

Example function dashboard template

```
Resources:
  MyDashboard:
```

```
Type: AWS::CloudWatch::Dashboard
Properties:
  DashboardName: my-dashboard
  DashboardBody: |
    {
      "widgets": [
        {
          "type": "metric",
          "width": 12,
          "height": 6,
          "properties": {
            "metrics": [
              [
                "AWS/Lambda",
                "Invocations",
                "FunctionName",
                "my-function",
                {
                  "stat": "Sum",
                  "label": "MyFunction"
                }
              ],
              [
                {
                  "expression": "SUM(METRICS())",
                  "label": "Total Invocations"
                }
              ]
            ],
            "region": "us-east-1",
            "title": "Invocations",
            "view": "timeSeries",
            "stacked": false
          }
        }
      ]
    }
  }
```

For more information about authoring CloudWatch dashboards and widgets, see [Dashboard body structure and syntax](#) in the *Amazon CloudWatch API Reference*.

Monitor application performance with Amazon CloudWatch Application Signals

Amazon CloudWatch Application Signals is an application performance monitoring (APM) solution that enables developers and operators to monitor the health and performance of their serverless applications built using Lambda. You can enable Application Signals in one-click from the Lambda console, and you don't need to add any instrumentation code or external dependencies to your Lambda function. After you enable Application Signals, you can view all collected metrics and traces in the CloudWatch console. This page describes how to enable and view Application Signals telemetry data for your applications.

Topics

- [How Application Signals integrates with Lambda](#)
- [Pricing](#)
- [Supported runtimes](#)
- [Enabling Application Signals in the Lambda console](#)
- [Using the Application Signals dashboard](#)

How Application Signals integrates with Lambda

Application Signals automatically instruments your Lambda functions using enhanced [AWS Distro for OpenTelemetry \(ADOT\)](#) libraries, provided via a [Lambda layer](#). Application Signals reads data collected by the layer and generates dashboards with key performance metrics for your applications.

You can attach this layer in one-click by [enabling Application Signals](#) in the Lambda console. When you enable Application Signals from the console, Lambda does the following on your behalf:

- Updates your function's execution role to include the `CloudWatchLambdaApplicationSignalsExecutionRolePolicy`. [This policy](#) provides write access to AWS X-Ray and CloudWatch log groups used for Application Signals.
- Adds a layer to your function which automatically instruments the function to capture telemetry data such as requests, availability, latency, errors, and faults. To ensure that Application Signals works properly, remove any existing X-Ray SDK instrumentation code from your function. Custom X-Ray SDK instrumentation code can interfere with the layer-provided instrumentation.

- Adds the `AWS_LAMBDA_EXEC_WRAPPER` environment variable to your function, and sets its value to `/opt/otel-instrument`. This environment variable modifies your function's startup behavior to utilize the Application Signals layer, and is required for proper instrumentation. If this environment variable already exists, ensure that it's set to the required value.

Pricing

Using Application Signals for your Lambda functions incurs costs. For pricing information, see [Amazon CloudWatch pricing](#).

Supported runtimes

The Application Signals integration with Lambda works with the following runtimes:

- .NET 8
- Java 11
- Java 17
- Java 21
- Python 3.10
- Python 3.11
- Python 3.12
- Python 3.13
- Node.js 18.x
- Node.js 20.x
- Node.js 22.x

Enabling Application Signals in the Lambda console

You can enable Application Signals on any existing Lambda function using a [supported runtime](#). The following steps describe how to enable Application Signals in one-click in the Lambda console.

To enable Application Signals in the Lambda console

1. Open the [Functions page](#) of the Lambda console.

2. Choose your function.
3. Choose the **Configuration** tab.
4. On the left menu, choose **Monitoring and operations tools**.
5. On the **Additional monitoring tools** pane, choose **Edit**.
6. Under **CloudWatch Application Signals and AWS X-Ray**, and under **Application Signals**, choose **Enable**.
7. Choose **Save**.

If this is your first time enabling Application Signals for your function, you must also do a one-time service discovery setup for Application Signals in the CloudWatch console. After you complete this one-time service discovery setup, Application Signals automatically discovers any additional Lambda functions that you enable Application Signals for, across all Regions.

Note

After you invoke your updated function, it can take up to 10 minutes for service data to start appearing in the Application Signals dashboard in the CloudWatch console.

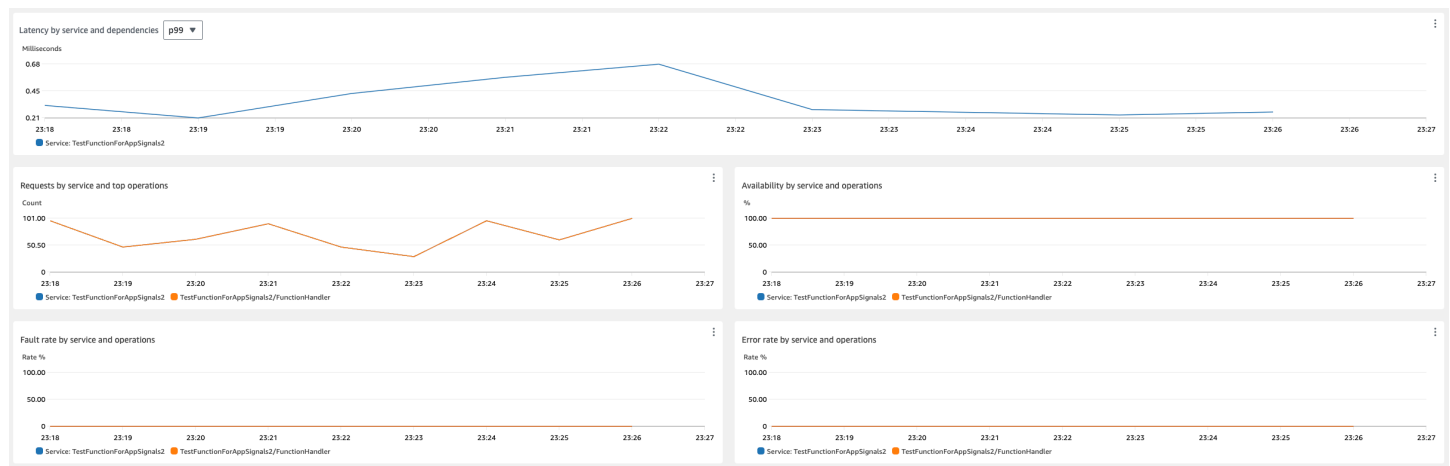

Using the Application Signals dashboard

After you enable Application Signals for your function, you can visualize your application metrics in the CloudWatch console. You can quickly view the associated Application Signals dashboard from the Lambda console with the following steps:

To view the Application Signals dashboard for your function

1. Open the [Functions page](#) of the Lambda console.
2. Choose your function.
3. Choose the **Monitor** tab.
4. Choose the **View Application Signals** button. This takes you directly to the Application Signals overview for your service in the CloudWatch console.

For example, the following screenshot shows metrics for latency, number of requests, availability, fault rate, and error rate for a function across a 10 minute time window.

To make the most out of your integration with Application Signals, you can create service-level objectives (SLOs) for your application. For example, you can create latency SLOs to ensure your application responds quickly to user requests, and availability SLOs to track uptime. SLOs can help you detect performance degradation or outages before they impact your users. For more information, see [Service level objectives \(SLOs\)](#) in the Amazon CloudWatch User Guide.

Remotely debug Lambda functions with Visual Studio Code

With the remote debugging feature in the [AWS Toolkit for Visual Studio Code](#), you can debug your Lambda functions running directly in the AWS cloud. This is useful when investigating issues that are difficult to replicate locally or diagnose only with logs.

With remote debugging, you can:

- Set breakpoints in your Lambda function code.
- Step through code execution in real-time.
- Inspect variables and state during runtime.
- Debug Lambda functions deployed to AWS, including those in VPCs or with specific IAM permissions.

Supported runtimes

Remote debugging is supported for the following runtimes:

- Python (AL2023)
- Java
- JavaScript/Node.js (AL2023)

Note

Remote debugging is supported for both x86_64 and arm64 architectures.

Security and remote debugging

Remote debugging operates within existing Lambda security boundaries. Users can attach layers to a function using the `UpdateFunctionConfiguration` permission, which already has the ability to access function environment variables and configuration. Remote debugging doesn't extend beyond these existing permissions. Instead, it adds extra security controls through secure tunneling and automatic session management. Additionally, remote debugging is entirely a customer-controlled feature that requires explicit permissions and actions:

- **IoT Secure Tunnel Creation:** The AWS Toolkit must create an IoT secure tunnel, which only occurs with the user's explicit permission using `iot:OpenTunnel`.
- **Debug Layer Attachment and Token Management:** The debugging process maintains security through these controls:
 - The debugging layer must be attached to the Lambda function and this process requires the following permissions: `lambda:UpdateFunctionConfiguration` and `lambda:GetLayerVersion`.
 - A security token (generated via `iot:OpenTunnel`) must be updated in the function environment variable before each debug session, which also requires `lambda:UpdateFunctionConfiguration`.
 - For security, this token is automatically rotated and the debug layer is automatically removed at the end of each debug session and cannot be reused.

Note

Remote debugging is supported for both x86_64 and arm64 architectures.

Prerequisites

Before you begin remote debugging, ensure you have the following:

1. A Lambda function deployed to your AWS account.
2. AWS Toolkit for Visual Studio Code. See [Setting up the AWS Toolkit for Visual Studio Code](#) for installation instructions.
3. The version of the AWS Toolkit you have installed is **3.69.0** or later.
4. AWS credentials configured in AWS Toolkit for Visual Studio Code. For more information, see [Authentication and access control](#).

Remotely debug Lambda functions

Follow these steps to start a remote debugging session:

1. Open the AWS Explorer in VS Code by selecting the AWS icon in the left sidebar.
2. Expand the Lambda section to see your functions.

3. Right-click on the function you want to debug.
4. From the context menu, select **Remotely invoke**.
5. In the invoke window that opens, check the box for **Enable debugging**.
6. Click **Invoke** to start the remote debugging session.

Note

Lambda functions have a 250MB combined limit for function code and all attached layers. The remote debugging layer adds approximately 40MB to your function's size.

A remote debugging session ends when you:

- Choose **Remove Debug Setup** from the Remote invoke configuration screen.
- Select the disconnect icon in the VS Code debugging controls.
- Select the handler file in the VS Code editor.

Note

The debug layer is automatically removed after 60 seconds of inactivity following your last invoke.

Disable remote debugging

There are three ways to disable this feature:

- **Deny Function Updates:** Set `lambda:UpdateFunctionConfiguration` to deny.
- **Restrict IoT Permissions:** Deny IoT-related permissions
- **Block Debug Layers:** Deny `lambda:GetLayerVersion` for the following ARNs:
 - `arn:aws:lambda:*:*:layer:LDKLayerX86:*`
 - `arn:aws:lambda:*:*:layer:LDKLayerArm64:*`

Note

Disabling this feature prevents the debugging layer from being added during function configuration updates.

Additional information

For more information on using Lambda in VS Code, refer to [Developing Lambda functions locally with VS Code](#).

For detailed instructions on troubleshooting, advanced use cases, and region availability, see [Remote debugging Lambda functions](#) in the AWS Toolkit for Visual Studio Code User Guide.

Managing Lambda dependencies with layers

A Lambda layer is a .zip file archive that contains supplementary code or data. Layers usually contain library dependencies, a [custom runtime](#), or configuration files.

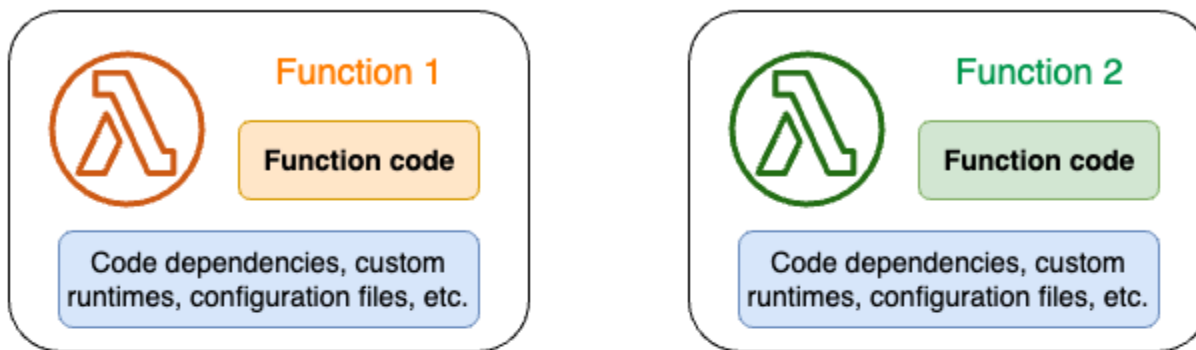

There are multiple reasons why you might consider using layers:

- **To reduce the size of your deployment packages.** Instead of including all of your function dependencies along with your function code in your deployment package, put them in a layer. This keeps deployment packages small and organized.
- **To separate core function logic from dependencies.** With layers, you can update your function dependencies independent of your function code, and vice versa. This promotes separation of concerns and helps you focus on your function logic.
- **To share dependencies across multiple functions.** After you create a layer, you can apply it to any number of functions in your account. Without layers, you need to include the same dependencies in each individual deployment package.
- **To use the Lambda console code editor.** The code editor is a useful tool for testing minor function code updates quickly. However, you can't use the editor if your deployment package size is too large. Using layers reduces your package size and can unlock usage of the code editor.
- **To lock an embedded SDK version.** The embedded SDKs may change without notice as AWS releases new services and features. You can lock a version of the SDK by [creating a Lambda layer](#) with the specific version needed. The function then always uses the version in the layer, even if the version embedded in the service changes.

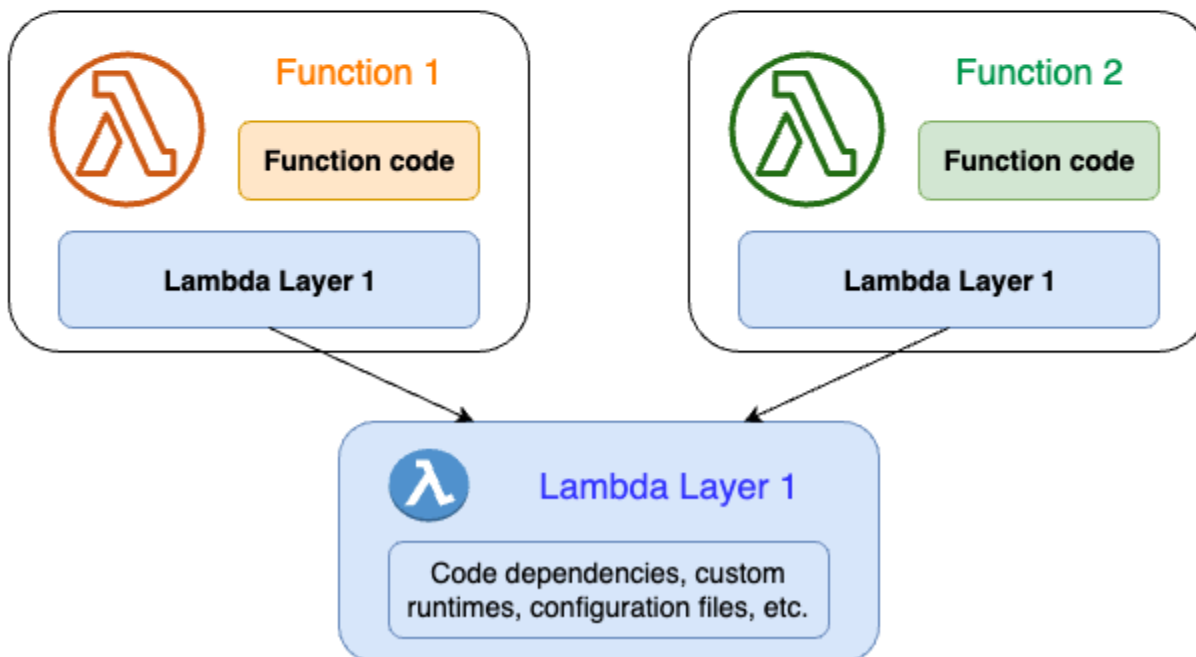

If you're working with Lambda functions in Go or Rust, we recommend against using layers. For Go and Rust functions, you provide your function code as an executable, which includes your compiled function code along with all of its dependencies. Putting your dependencies in a layer forces your function to manually load additional assemblies during the initialization phase, which can increase cold start times. For optimal performance for Go and Rust functions, include your dependencies along with your deployment package.

The following diagram illustrates the high-level architectural differences between two functions that share dependencies. One uses Lambda layers, and the other does not.

Lambda function components: Without layers

Lambda function components: With layers

When you add a layer to a function, Lambda extracts the layer contents into the `/opt` directory in your function's [execution environment](#). All natively supported Lambda runtimes include paths to specific directories within the `/opt` directory. This gives your function access to your layer content. For more information about these specific paths and how to properly package your layers, see [the section called "Packaging layers"](#).

You can include up to five layers per function. Also, you can use layers only with Lambda functions [deployed as a .zip file archive](#). For functions [defined as a container image](#), package your preferred

runtime and all code dependencies when you create the container image. For more information, see [Working with Lambda layers and extensions in container images](#) on the AWS Compute Blog.

Topics

- [How to use layers](#)
- [Layers and layer versions](#)
- [Packaging your layer content](#)
- [Creating and deleting layers in Lambda](#)
- [Adding layers to functions](#)
- [Using AWS CloudFormation with layers](#)
- [Using AWS SAM with layers](#)

How to use layers

To create a layer, package your dependencies into a .zip file, similar to how you [create a normal deployment package](#). More specifically, the general process of creating and using layers involves these three steps:

- **First, package your layer content.** This means creating a .zip file archive. For more information, see [the section called “Packaging layers”](#).
- **Next, create the layer in Lambda.** For more information, see [the section called “Creating and deleting layers”](#).
- **Add the layer to your function(s).** For more information, see [the section called “Adding layers”](#).

Layers and layer versions

A layer version is an immutable snapshot of a specific version of a layer. When you create a new layer, Lambda creates a new layer version with a version number of 1. Each time you publish an update to the layer, Lambda increments the version number and creates a new layer version.

Every layer version is identified by a unique Amazon Resource Name (ARN). When adding a layer to the function, you must specify the exact layer version you want to use (for example, `arn:aws:lambda:us-east-1:123456789012:layer:my-layer:1`).

Packaging your layer content

A Lambda layer is a .zip file archive that contains supplementary code or data. Layers usually contain library dependencies, a [custom runtime](#), or configuration files.

This section explains how to properly package your layer content. For more conceptual information about layers and why you might consider using them, see [Lambda layers](#).

The first step to creating a layer is to bundle all of your layer content into a .zip file archive. Because Lambda functions run on [Amazon Linux](#), your layer content must be able to compile and build in a Linux environment.

To ensure that your layer content works properly in a Linux environment, we recommend creating your layer content using a tool like [Docker](#).

Topics

- [Layer paths for each Lambda runtime](#)

Layer paths for each Lambda runtime

When you add a layer to a function, Lambda loads the layer content into the /opt directory of that execution environment. For each Lambda runtime, the PATH variable already includes specific folder paths within the /opt directory. To ensure that Lambda picks up your layer content, your layer .zip file should have its dependencies in one of the following folder paths:

Runtime	Path
Node.js	nodejs/node_modules
	nodejs/node18/node_modules (NODE_PATH)
	nodejs/node20/node_modules (NODE_PATH)
	nodejs/node22/node_modules (NODE_PATH)
Python	python
	python/lib/ <i>python3.x</i> /site-packages (site directories)

Runtime	Path
Java	java/lib (CLASSPATH)
Ruby	ruby/gems/3.4.0 (GEM_PATH)
	ruby/lib (RUBYLIB)
All runtimes	bin (PATH)
	lib (LD_LIBRARY_PATH)

The following examples show how you can structure the folders in your layer .zip archive.

Node.js

Example file structure for the AWS X-Ray SDK for Node.js

```
xray-sdk.zip
# nodejs/node_modules/aws-xray-sdk
```

Python

Example

```
python/                # Required top-level directory
### requests/
### boto3/
### numpy/
### (dependencies of the other packages)
```

Ruby

Example file structure for the JSON gem

```
json.zip
# ruby/gems/3.4.0/
| build_info
| cache
| doc
```

```
| extensions
| gems
| # json-2.1.0
# specifications
# json-2.1.0.gemspec
```

Java

Example file structure for the Jackson JAR file

```
layer_content.zip
# java
# lib
# jackson-core-2.17.0.jar
# <other potential dependencies>
# ...
```

All

Example file structure for the jq library

```
jq.zip
# bin/jq
```

For language-specific instructions on packaging, creating, and adding a layer, refer to the following pages:

- **Node.js** – [the section called “Layers”](#)
- **Python** – [the section called “Layers”](#)
- **Ruby** – [the section called “Layers”](#)
- **Java** – [the section called “Layers”](#)

We recommend **against** using layers to manage dependencies for Lambda functions written in Go and Rust. This is because Lambda functions written in these languages compile into a single executable, which you provide to Lambda when you deploy your function. This executable contains your compiled function code, along with all of its dependencies. Using layers not only complicates this process, but also leads to increased cold start times because your functions need to manually load extra assemblies into memory during the init phase.

To use external dependencies with Go and Rust Lambda functions, include them directly in your deployment package.

Creating and deleting layers in Lambda

A Lambda layer is a .zip file archive that contains supplementary code or data. Layers usually contain library dependencies, a [custom runtime](#), or configuration files.

This section explains how to create and delete layers in Lambda. For more conceptual information about layers and why you might consider using them, see [Lambda layers](#).

After you've [packaged your layer content](#), the next step is to create the layer in Lambda. This section demonstrates how to create and delete layers using the Lambda console or the Lambda API only. To create a layer using AWS CloudFormation, see [the section called "Layers with CloudFormation"](#). To create a layer using the AWS Serverless Application Model (AWS SAM), see [the section called "Layers with AWS SAM"](#).

Topics

- [Creating a layer](#)
- [Deleting a layer version](#)

Creating a layer

To create a layer, you can either upload the .zip file archive from your local machine or from Amazon Simple Storage Service (Amazon S3). Lambda extracts the layer contents into the /opt directory when setting up the execution environment for the function.

Layers can have one or more [layer versions](#). When you create a layer, Lambda sets the layer version to version 1. You can change the permissions on an existing layer version at any time. However, to update the code or make other configuration changes, you must create a new version of the layer.

To create a layer (console)

1. Open the [Layers page](#) of the Lambda console.
2. Choose **Create layer**.
3. Under **Layer configuration**, for **Name**, enter a name for your layer.
4. (Optional) For **Description**, enter a description for your layer.
5. To upload your layer code, do one of the following:
 - To upload a .zip file from your computer, choose **Upload a .zip file**. Then, choose **Upload** to select your local .zip file.

- To upload a file from Amazon S3, choose **Upload a file from Amazon S3**. Then, for **Amazon S3 link URL**, enter a link to the file.
6. (Optional) For **Compatible architectures**, choose one value or both values. For more information, see [the section called “Instruction sets \(ARM/x86\)”](#).
 7. (Optional) For **Compatible runtimes**, choose the runtimes that your layer is compatible with.
 8. (Optional) For **License**, enter any necessary license information.
 9. Choose **Create**.

Alternatively, you can run the [publish-layer-version](#) AWS Command Line Interface (CLI) command. Example:

```
aws lambda publish-layer-version --layer-name my-layer --zip-file fileb://layer.zip --  
compatible-runtimes python3.14
```

Each time that you run `publish-layer-version`, Lambda creates a new [version of the layer](#).

Deleting a layer version

To delete a layer version, use the [DeleteLayerVersion](#) API operation. For example, run the [delete-layer-version](#) AWS CLI command with the layer name and layer version specified.

```
aws lambda delete-layer-version --layer-name my-layer --version-number 1
```

When you delete a layer version, you can no longer configure a Lambda function to use it. However, any function that already uses the version continues to have access to it. Also, Lambda never reuses version numbers for a layer name.

When calculating [quotas](#), deleting a layer version means it's no longer counted as part of the default 75 GB quota for storage of functions and layers. However, for functions that consume a deleted layer version, the layer content still counts towards the function's deployment package size quota (i.e. 250MB for .zip file archives).

Adding layers to functions

A Lambda layer is a .zip file archive that contains supplementary code or data. Layers usually contain library dependencies, a [custom runtime](#), or configuration files.

This section explains how to add a layer to a Lambda function. For more conceptual information about layers and why you might consider using them, see [Lambda layers](#).

Before you can configure a Lambda function to use a layer, you must:

- [Package your layer content](#)
- [Create a layer in Lambda](#)
- Make sure that you have permission to call the [GetLayerVersion](#) API on the layer version. For functions in your AWS account, you must have this permission in your [user policy](#). To use a layer in another account, the owner of that account must grant your account permission in a [resource-based policy](#). For examples, see [the section called "Layer access for other accounts"](#).

You can add up to five layers to a Lambda function. The total unzipped size of the function and all layers cannot exceed the unzipped deployment package size quota of 250 MB. For more information, see [Lambda quotas](#).

Your functions can continue to use any layer version that you've already added, even after that layer version has been deleted, or after your permission to access the layer is revoked. However, you cannot create a new function that uses a deleted layer version.

To add a layer to a function

1. Open the [Functions page](#) of the Lambda console.
2. Choose the function.
3. Scroll down to the **Layers** section, and then choose **Add a layer**.
4. Under **Choose a layer**, choose a layer source:
 - a. **AWS layers:** Choose from the list of [AWS-managed extensions](#).
 - b. **Custom layers:** Choose a layer created in your AWS account.
 - c. **Specify an ARN:** To use a layer [from a different AWS account](#), such as a [third-party extension](#), enter the Amazon Resource Name (ARN).
5. Choose **Add**.

The order in which you add the layers is the order in which Lambda merges the layer content into the execution environment. You can change the layer merge order using the console.

To update layer merge order for your function (console)

1. Open the [Functions page](#) of the Lambda console.
2. Choose the function to configure.
3. Under **Layers**, choose **Edit**
4. Choose one of the layers.
5. Choose **Merge earlier** or **Merge later** to adjust the order of the layers.
6. Choose **Save**.

Layers are versioned. The content of each layer version is immutable. The owner of a layer can release new layer versions to provide updated content. You can use the console to update the layer version attached to your functions.

To update layer versions for your function (console)

1. Open the [Layers page](#) of the Lambda console.
2. Choose the layer you want to update the version for.
3. Choose the **Functions using this version** tab.
4. Choose the functions you want to modify, then choose **Edit**.
5. For **Layer version**, choose the layer version to change to.
6. Choose **Update functions**.

You cannot update function layer versions across AWS accounts.

Finding layer information

To find layers in your account that are compatible with your function's runtime, use the [ListLayers](#) API. For example, you can use the following [list-layers](#) AWS Command Line Interface (CLI) command:

```
aws lambda list-layers --compatible-runtime python3.14
```

You should see output similar to the following:

```
{
  "Layers": [
    {
      "LayerName": "my-layer",
      "LayerArn": "arn:aws:lambda:us-east-2:123456789012:layer:my-layer",
      "LatestMatchingVersion": {
        "LayerVersionArn": "arn:aws:lambda:us-east-2:123456789012:layer:my-layer:2",
        "Version": 2,
        "Description": "My layer",
        "CreateDate": "2025-04-15T00:37:46.592+0000",
        "CompatibleRuntimes": [
          "python3.14"
        ]
      }
    }
  ]
}
```

To list all layers in your account, omit the `--compatible-runtime` option. The response details show the latest version of each layer.

You can also get the latest version of a layer using the [ListLayerVersions](#) API. For example, you can use the following `list-layer-versions` CLI command:

```
aws lambda list-layer-versions --layer-name my-layer
```

You should see output similar to the following:

```
{
  "LayerVersions": [
    {
      "LayerVersionArn": "arn:aws:lambda:us-east-2:123456789012:layer:my-layer:2",
      "Version": 2,
      "Description": "My layer",
      "CreateDate": "2023-11-15T00:37:46.592+0000",
      "CompatibleRuntimes": [
        "java11"
      ]
    },
    {
```

```
    "LayerVersionArn": "arn:aws:lambda:us-east-2:123456789012:layer:my-  
layer:1",  
    "Version": 1,  
    "Description": "My layer",  
    "CreatedDate": "2023-11-15T00:27:46.592+0000",  
    "CompatibleRuntimes": [  
        "java11"  
    ]  
  }  
]  
}
```

Using AWS CloudFormation with layers

You can use CloudFormation to create a layer and associate the layer with your Lambda function. The following example template creates a layer named `my-lambda-layer` and attaches the layer to the Lambda function using the **Layers** property.

In this example, the template specifies the Amazon Resource Name (ARN) of an existing IAM [execution role](#). You can also create a new execution role in the template using the CloudFormation [AWS::IAM::Role](#) resource.

Your function doesn't need any special permissions to use layers.

```
---
Description: CloudFormation Template for Lambda Function with Lambda Layer
Resources:
  MyLambdaLayer:
    Type: AWS::Lambda::LayerVersion
    Properties:
      LayerName: my-lambda-layer
      Description: My Lambda Layer
      Content:
        S3Bucket: amzn-s3-demo-bucket
        S3Key: my-layer.zip
      CompatibleRuntimes:
        - python3.9
        - python3.10
        - python3.11

  MyLambdaFunction:
    Type: AWS::Lambda::Function
    Properties:
      FunctionName: my-lambda-function
      Runtime: python3.9
      Handler: index.handler
      Timeout: 10
      Role: arn:aws:iam::<111122223333>:role/my_lambda_role
      Layers:
        - !Ref MyLambdaLayer
```

Using AWS SAM with layers

You can use the AWS Serverless Application Model (AWS SAM) to automate the creation of layers in your application. The `AWS::Serverless::LayerVersion` resource type creates a layer version that you can reference from your Lambda function configuration.

```
AWSTemplateFormatVersion: '2010-09-09'
Transform: 'AWS::Serverless-2016-10-31'
Description: AWS SAM Template for Lambda Function with Lambda Layer

Resources:
  MyLambdaLayer:
    Type: AWS::Serverless::LayerVersion
    Properties:
      LayerName: my-lambda-layer
      Description: My Lambda Layer
      ContentUri: s3://amzn-s3-demo-bucket/my-layer.zip
      CompatibleRuntimes:
        - python3.9
        - python3.10
        - python3.11

  MyLambdaFunction:
    Type: AWS::Serverless::Function
    Properties:
      FunctionName: MyLambdaFunction
      Runtime: python3.9
      Handler: app.handler
      CodeUri: s3://amzn-s3-demo-bucket/my-function
      Layers:
        - !Ref MyLambdaLayer
```

Augment Lambda functions using Lambda extensions

You can use Lambda extensions to augment your Lambda functions. For example, use Lambda extensions to integrate functions with your preferred monitoring, observability, security, and governance tools. You can choose from a broad set of tools that [AWS Lambda Partners](#) provides, or you can [create your own Lambda extensions](#).

Lambda supports external and internal extensions. An external extension runs as an independent process in the execution environment and continues to run after the function invocation is fully processed. Because extensions run as separate processes, you can write them in a different language than the function. All [Lambda runtimes](#) support extensions.

An internal extension runs as part of the runtime process. Your function accesses internal extensions by using wrapper scripts or in-process mechanisms such as `JAVA_TOOL_OPTIONS`. For more information, see [Modifying the runtime environment](#).

You can add extensions to a function using the Lambda console, the AWS Command Line Interface (AWS CLI), or infrastructure as code (IaC) services and tools such as CloudFormation, AWS Serverless Application Model (AWS SAM), and Terraform.

You are charged for the execution time that the extension consumes (in 1 ms increments). There is no cost to install your own extensions. For more pricing information for extensions, see [AWS Lambda Pricing](#). For pricing information for partner extensions, see those partners' websites. See [the section called “Extensions partners”](#) for a list of official partner extensions.

For a tutorial on extensions and how to use them with your Lambda functions, see the [AWS Lambda Extensions Workshop](#).

Topics

- [Execution environment](#)
- [Impact on performance and resources](#)

Execution environment

Lambda invokes your function in an [execution environment](#), which provides a secure and isolated runtime environment. The execution environment manages the resources required to run your function and provides lifecycle support for the function's runtime and extensions.

The lifecycle of the execution environment includes the following phases:

- **Init:** In this phase, Lambda creates or unfreezes an execution environment with the configured resources, downloads the code for the function and all layers, initializes any extensions, initializes the runtime, and then runs the function's initialization code (the code outside the main handler). The Init phase happens either during the first invocation, or in advance of function invocations if you have enabled [provisioned concurrency](#).

The Init phase is split into three sub-phases: `Extension init`, `Runtime init`, and `Function init`. These sub-phases ensure that all extensions and the runtime complete their setup tasks before the function code runs.

When [Lambda SnapStart](#) is activated, the Init phase happens when you publish a function version. Lambda saves a snapshot of the memory and disk state of the initialized execution environment, persists the encrypted snapshot, and caches it for low-latency access. If you have a before-checkpoint [runtime hook](#), then the code runs at the end of Init phase.

- **Restore** (SnapStart only): When you first invoke a [SnapStart](#) function and as the function scales up, Lambda resumes new execution environments from the persisted snapshot instead of initializing the function from scratch. If you have an after-restore [runtime hook](#), the code runs at the end of the Restore phase. You are charged for the duration of after-restore runtime hooks. The runtime must load and after-restore runtime hooks must complete within the timeout limit (10 seconds). Otherwise, you'll get a `SnapStartTimeoutException`. When the Restore phase completes, Lambda invokes the function handler (the [Invoke phase](#)).
- **Invoke:** In this phase, Lambda invokes the function handler. After the function runs to completion, Lambda prepares to handle another function invocation.
- **Shutdown:** This phase is triggered if the Lambda function does not receive any invocations for a period of time. In the Shutdown phase, Lambda shuts down the runtime, alerts the extensions to let them stop cleanly, and then removes the environment. Lambda sends a Shutdown event to each extension, which tells the extension that the environment is about to be shut down.

During the `Init` phase, Lambda extracts layers containing extensions into the `/opt` directory in the execution environment. Lambda looks for extensions in the `/opt/extensions/` directory, interprets each file as an executable bootstrap for launching the extension, and starts all extensions in parallel.

Impact on performance and resources

The size of your function's extensions counts towards the deployment package size limit. For a .zip file archive, the total unzipped size of the function and all extensions cannot exceed the unzipped deployment package size limit of 250 MB.

Extensions can impact the performance of your function because they share function resources such as CPU, memory, and storage. For example, if an extension performs compute-intensive operations, you may see your function's execution duration increase.

Each extension must complete its initialization before Lambda invokes the function. Therefore, an extension that consumes significant initialization time can increase the latency of the function invocation.

To measure the extra time that the extension takes after the function execution, you can use the `PostRuntimeExtensionsDuration` [function metric](#). To measure the increase in memory used, you can use the `MaxMemoryUsed` metric. To understand the impact of a specific extension, you can run different versions of your functions side by side.

Note

`MaxMemoryUsed` metric is one of the [Metrics collected by Lambda Insights](#) and not a Lambda native metric.

Permissions

Extensions have access to the same resources as functions. Because extensions are executed within the same environment as the function, permissions are shared between the function and the extension.

For a .zip file archive, you can create an CloudFormation template to simplify the task of attaching the same extension configuration—including AWS Identity and Access Management (IAM) permissions—to multiple functions.

Configuring Lambda extensions

Configuring extensions (.zip file archive)

You can add an extension to your function as a [Lambda layer](#). Using layers enables you to share extensions across your organization or to the entire community of Lambda developers. You can add one or more extensions to a layer. You can register up to 10 extensions for a function.

You add the extension to your function using the same method as you would for any layer. For more information, see [Lambda layers](#).

Add an extension to your function (console)

1. Open the [Functions page](#) of the Lambda console.
2. Choose a function.
3. Choose the **Code** tab if it is not already selected.
4. Under **Layers**, choose **Edit**.
5. For **Choose a layer**, choose **Specify an ARN**.
6. For **Specify an ARN**, enter the Amazon Resource Name (ARN) of an extension layer.
7. Choose **Add**.

Using extensions in container images

You can add extensions to your [container image](#). The ENTRYPOINT container image setting specifies the main process for the function. Configure the ENTRYPOINT setting in the Dockerfile, or as an override in the function configuration.

You can run multiple processes within a container. Lambda manages the lifecycle of the main process and any additional processes. Lambda uses the [Extensions API](#) to manage the extension lifecycle.

Example: Adding an external extension

An external extension runs in a separate process from the Lambda function. Lambda starts a process for each extension in the `/opt/extensions/` directory. Lambda uses the Extensions API to manage the extension lifecycle. After the function has run to completion, Lambda sends a Shutdown event to each external extension.

Example of adding an external extension to a Python base image

```
FROM public.ecr.aws/lambda/python:3.11

# Copy and install the app
COPY /app /app
WORKDIR /app
RUN pip install -r requirements.txt

# Add an extension from the local directory into /opt/extensions
ADD my-extension.zip /opt/extensions
CMD python ./my-function.py
```

Next steps

To learn more about extensions, we recommend the following resources:

- For a basic working example, see [Building Extensions for AWS Lambda](#) on the AWS Compute Blog.
- For information about extensions that AWS Lambda Partners provides, see [Introducing AWS Lambda Extensions](#) on the AWS Compute Blog.
- To view available example extensions and wrapper scripts, see [AWS Lambda Extensions](#) on the AWS Samples GitHub repository.

AWS Lambda extensions partners

AWS Lambda has partnered with several third party entities to provide extensions to integrate with your Lambda functions. The following list details third party extensions that are ready for you to use at any time.

- [AppDynamics](#) – Provides automatic instrumentation of Node.js or Python Lambda functions, providing visibility and alerting on function performance.
- [Axiom](#) – Provides dashboards for monitoring Lambda function performance and aggregate system-level metrics.
- [Datadog](#) – Provides comprehensive, real-time visibility to your serverless applications through the use of metrics, traces, and logs.
- [Dynatrace](#) – Provides visibility into traces and metrics, and leverages AI for automated error detection and root cause analysis across the entire application stack.
- [Elastic](#) – Provides Application Performance Monitoring (APM) to identify and resolve root cause issues using correlated traces, metrics, and logs.
- [Epsagon](#) – Listens to invocation events, stores traces, and sends them in parallel to Lambda function executions.
- [Fastly](#) – Protects your Lambda functions from suspicious activity, such as injection-style attacks, account takeover via credential stuffing, malicious bots, and API abuse.
- [HashiCorp Vault](#) – Manages secrets and makes them available for developers to use within function code, without making functions Vault aware.
- [Honeycomb](#) – Observability tool for debugging your app stack.
- [Lumigo](#) – Profiles Lambda function invocations and collects metrics for troubleshooting issues in serverless and microservice environments.
- [New Relic](#) – Runs alongside Lambda functions, automatically collecting, enhancing, and transporting telemetry to New Relic's unified observability platform.
- [Sedai](#) – An autonomous cloud management platform, powered by AI/ML, that delivers continuous optimization for cloud operations teams to maximize cloud cost savings, performance, and availability at scale.
- [Sentry](#) – Diagnose, fix, and optimize performance of Lambda functions.
- [Site24x7](#) – Achieve real-time observability into your Lambda environments
- [Splunk](#) – Collects high-resolution, low-latency metrics for efficient and effective monitoring of Lambda functions.

- [Sumo Logic](#) – Provides visibility into the health and performance of serverless applications.
- [Salt Security](#) – Simplifies API posture governance and API security for Lambda functions through automated setup and support for diverse runtimes.

AWS managed extensions

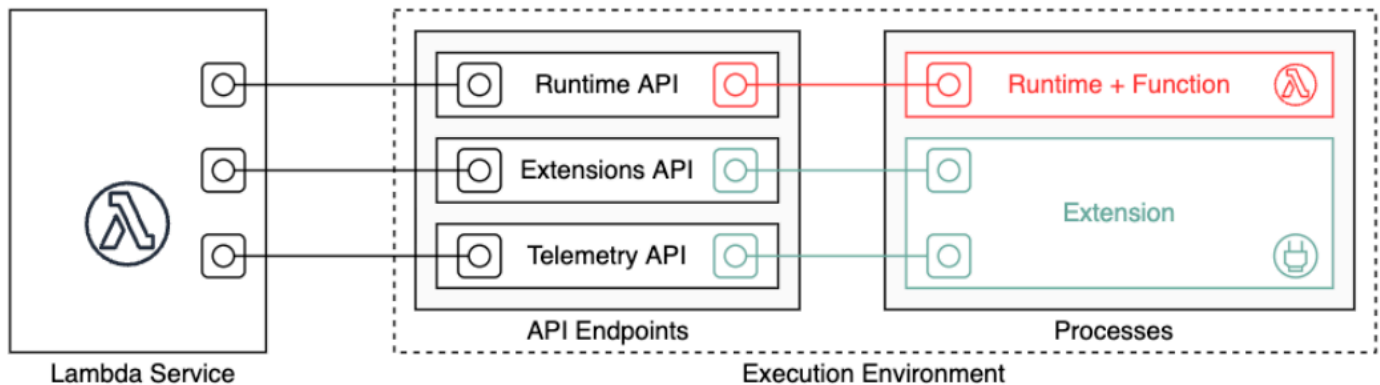

AWS provides its own managed extensions, including:

- [AWS AppConfig](#) – Use feature flags and dynamic data to update your Lambda functions. You can also use this extension to update other dynamic configuration, such as ops throttling and tuning.
- [Amazon CodeGuru Profiler](#) – Improves application performance and reduces cost by pinpointing an application's most expensive line of code and providing recommendations for improving code.
- [CloudWatch Lambda Insights](#) – Monitor, troubleshoot, and optimize the performance of your Lambda functions through automated dashboards.
- [AWS Distro for OpenTelemetry \(ADOT\)](#) – Enables functions to send trace data to AWS monitoring services such as AWS X-Ray, and to destinations that support OpenTelemetry such as Honeycomb and Lightstep.
- [AWS Parameters and Secrets](#) – Securely retrieve parameters from AWS Systems Manager Parameter Store and secrets from AWS Secrets Manager in Lambda functions.

For additional extensions samples and demo projects, see [AWS Lambda Extensions](#).

Using the Lambda Extensions API to create extensions

Lambda function authors use extensions to integrate Lambda with their preferred tools for monitoring, observability, security, and governance. Function authors can use extensions from AWS, [AWS Partners](#), and open-source projects. For more information on using extensions, see [Introducing AWS Lambda Extensions](#) on the AWS Compute Blog. This section describes how to use the Lambda Extensions API, the Lambda execution environment lifecycle, and the Lambda Extensions API reference.

As an extension author, you can use the Lambda Extensions API to integrate deeply into the Lambda [execution environment](#). Your extension can register for function and execution environment lifecycle events. In response to these events, you can start new processes, run logic, and control and participate in all phases of the Lambda lifecycle: initialization, invocation, and shutdown. In addition, you can use the [Runtime Logs API](#) to receive a stream of logs.

An extension runs as an independent process in the execution environment and can continue to run after the function invocation is fully processed. Because extensions run as processes, you can write them in a different language than the function. We recommend that you implement extensions using a compiled language. In this case, the extension is a self-contained binary that is compatible with supported runtimes. All [Lambda runtimes](#) support extensions. If you use a non-compiled language, ensure that you include a compatible runtime in the extension.

Lambda also supports *internal extensions*. An internal extension runs as a separate thread in the runtime process. The runtime starts and stops the internal extension. An alternative way to integrate with the Lambda environment is to use language-specific [environment variables and wrapper scripts](#). You can use these to configure the runtime environment and modify the startup behavior of the runtime process.

You can add extensions to a function in two ways. For a function deployed as a [.zip file archive](#), you deploy your extension as a [layer](#). For a function defined as a container image, you add [the extensions](#) to your container image.

 **Note**

For example extensions and wrapper scripts, see [AWS Lambda Extensions](#) on the AWS Samples GitHub repository.

Topics

- [Lambda execution environment lifecycle](#)
- [Extensions API reference](#)

Lambda execution environment lifecycle

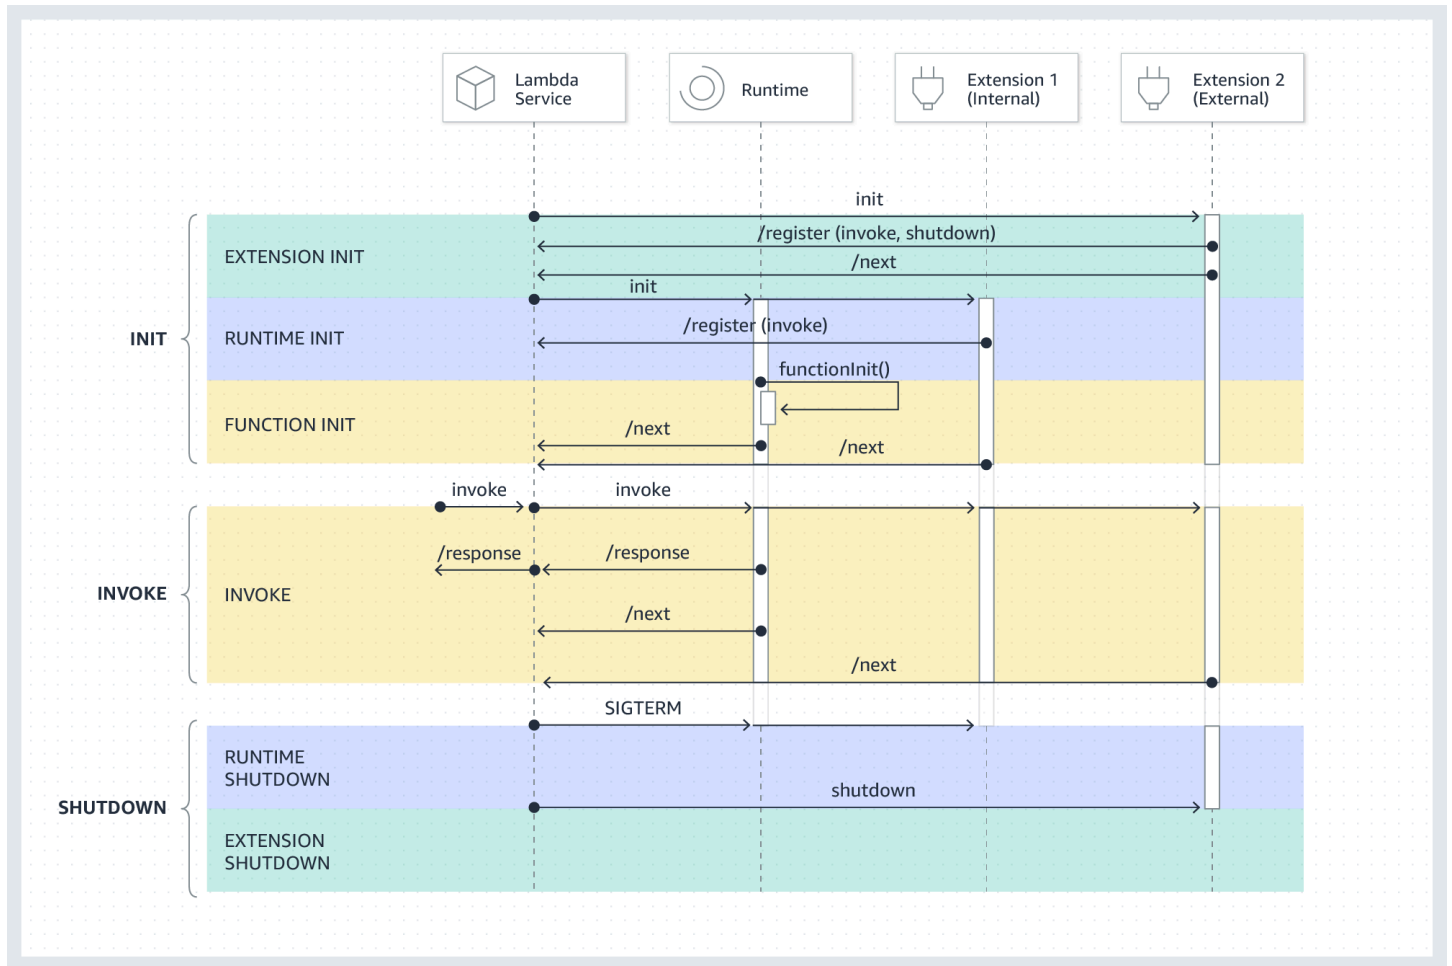

The lifecycle of the execution environment includes the following phases:

- **Init:** In this phase, Lambda creates or unfreezes an execution environment with the configured resources, downloads the code for the function and all layers, initializes any extensions, initializes the runtime, and then runs the function's initialization code (the code outside the main handler). The Init phase happens either during the first invocation, or in advance of function invocations if you have enabled [provisioned concurrency](#).

The Init phase is split into three sub-phases: `Extension init`, `Runtime init`, and `Function init`. These sub-phases ensure that all extensions and the runtime complete their setup tasks before the function code runs.

- **Invoke:** In this phase, Lambda invokes the function handler. After the function runs to completion, Lambda prepares to handle another function invocation.
- **Shutdown:** This phase is triggered if the Lambda function does not receive any invocations for a period of time. In the Shutdown phase, Lambda shuts down the runtime, alerts the extensions to let them stop cleanly, and then removes the environment. Lambda sends a Shutdown event to each extension, which tells the extension that the environment is about to be shut down.

Each phase starts with an event from Lambda to the runtime and to all registered extensions. The runtime and each extension signal completion by sending a Next API request. Lambda freezes the execution environment when each process has completed and there are no pending events.

Topics

- [Init phase](#)
- [Invoke phase](#)
- [Shutdown phase](#)
- [Permissions and configuration](#)
- [Failure handling](#)
- [Troubleshooting extensions](#)

Init phase

During the `Extension init` phase, each extension needs to register with Lambda to receive events. Lambda uses the full file name of the extension to validate that the extension has completed the bootstrap sequence. Therefore, each `Register` API call must include the `Lambda-Extension-Name` header with the full file name of the extension.

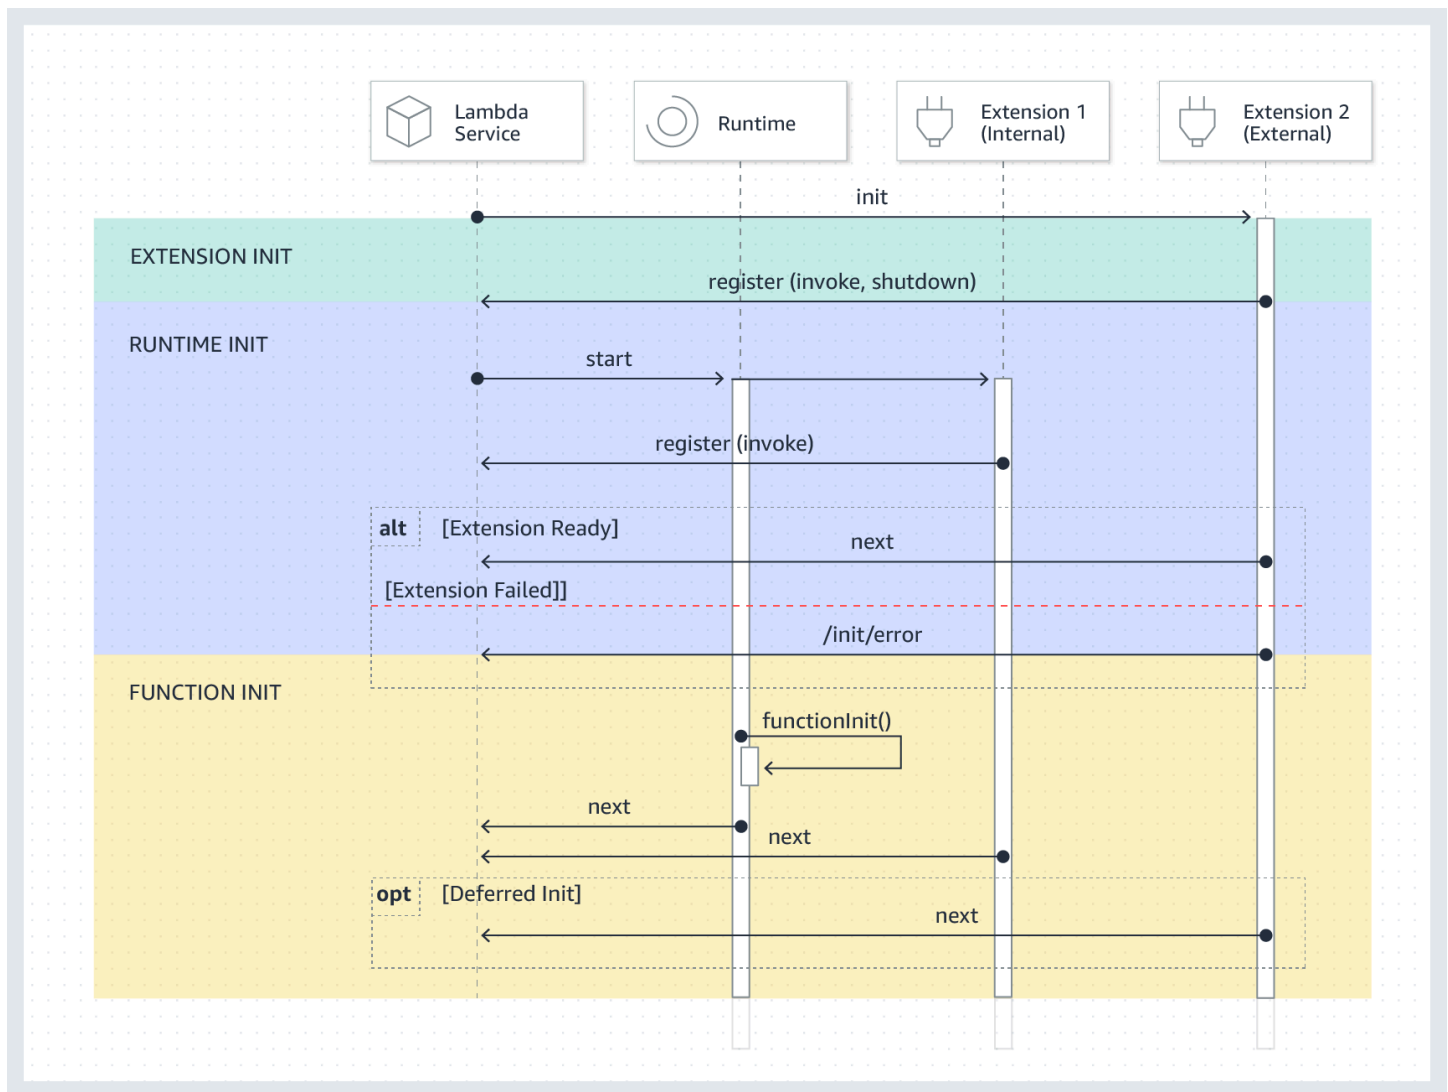

You can register up to 10 extensions for a function. This limit is enforced through the `Register` API call.

After each extension registers, Lambda starts the `Runtime init` phase. The runtime process calls `functionInit` to start the `Function init` phase.

The `Init` phase completes after the runtime and each registered extension indicate completion by sending a `Next` API request.

Note

Extensions can complete their initialization at any point in the `Init` phase.

Invoke phase

When a Lambda function is invoked in response to a Next API request, Lambda sends an Invoke event to the runtime and to each extension that is registered for the Invoke event.

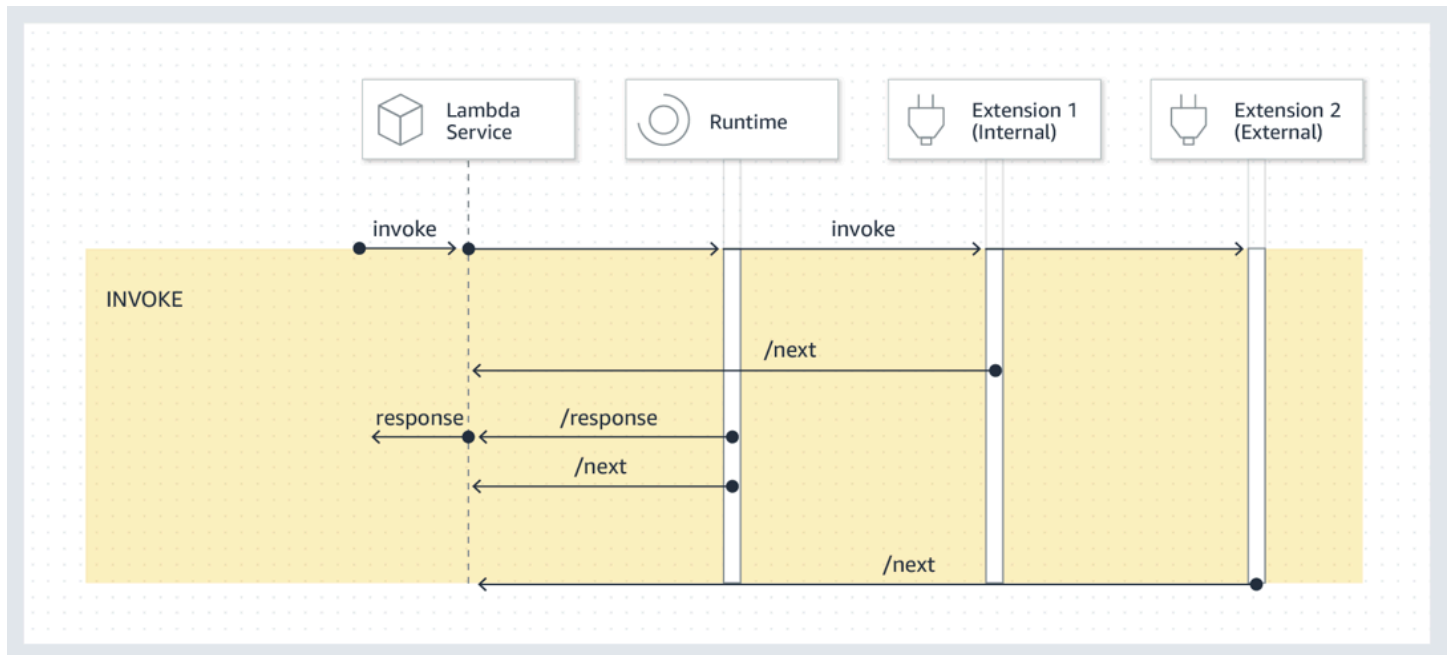

Note

Lambda Managed Instances: Extensions for Lambda Managed Instances functions cannot register for the Invoke event. Because Lambda Managed Instances supports concurrent invocations within a single execution environment, the Invoke event is not supported. Extensions can only register for the Shutdown event. If you need to track when invocations start and finish, use the `platform.report` platform event through the [Telemetry API](#).

During the invocation, external extensions run in parallel with the function. They also continue running after the function has completed. This enables you to capture diagnostic information or to send logs, metrics, and traces to a location of your choice.

After receiving the function response from the runtime, Lambda returns the response to the client, even if extensions are still running.

The Invoke phase ends after the runtime and all extensions signal that they are done by sending a Next API request.

Event payload: The event sent to the runtime (and the Lambda function) carries the entire request, headers (such as RequestId), and payload. The event sent to each extension contains metadata that describes the event content. This lifecycle event includes the type of the event, the time that the function times out (`deadlineMs`), the `requestId`, the invoked function's Amazon Resource Name (ARN), and tracing headers.

Extensions that want to access the function event body can use an in-runtime SDK that communicates with the extension. Function developers use the in-runtime SDK to send the payload to the extension when the function is invoked.

Here is an example payload:

```
{
  "eventType": "INVOKE",
```

```
{
  "deadlineMs": 676051,
  "requestId": "3da1f2dc-3222-475e-9205-e2e6c6318895",
  "invokedFunctionArn": "arn:aws:lambda:us-east-1:123456789012:function:ExtensionTest",
  "tracing": {
    "type": "X-Amzn-Trace-Id",
    "value": "Root=1-5f35ae12-0c0fec141ab77a00bc047aa2;Parent=2be948a625588e32;Sampled=1"
  }
}
```

Duration limit: The function's timeout setting limits the duration of the entire Invoke phase. For example, if you set the function timeout as 360 seconds, the function and all extensions need to complete within 360 seconds. Note that there is no independent post-invoke phase. The duration is the total time it takes for your runtime and all your extensions' invocations to complete and is not calculated until the function and all extensions have finished running.

Performance impact and extension overhead: Extensions can impact function performance. As an extension author, you have control over the performance impact of your extension. For example, if your extension performs compute-intensive operations, the function's duration increases because the extension and the function code share the same CPU resources. In addition, if your extension performs extensive operations after the function invocation completes, the function duration increases because the Invoke phase continues until all extensions signal that they are completed.

 **Note**

Lambda allocates CPU power in proportion to the function's memory setting. You might see increased execution and initialization duration at lower memory settings because the function and extension processes are competing for the same CPU resources. To reduce the execution and initialization duration, try increasing the memory setting.

To help identify the performance impact introduced by extensions on the Invoke phase, Lambda outputs the `PostRuntimeExtensionsDuration` metric. This metric measures the cumulative time spent between the runtime Next API request and the last extension Next API request. To measure the increase in memory used, use the `MaxMemoryUsed` metric. For more information about function metrics, see [Using CloudWatch metrics with Lambda](#).

Function developers can run different versions of their functions side by side to understand the impact of a specific extension. We recommend that extension authors publish expected resource consumption to make it easier for function developers to choose a suitable extension.

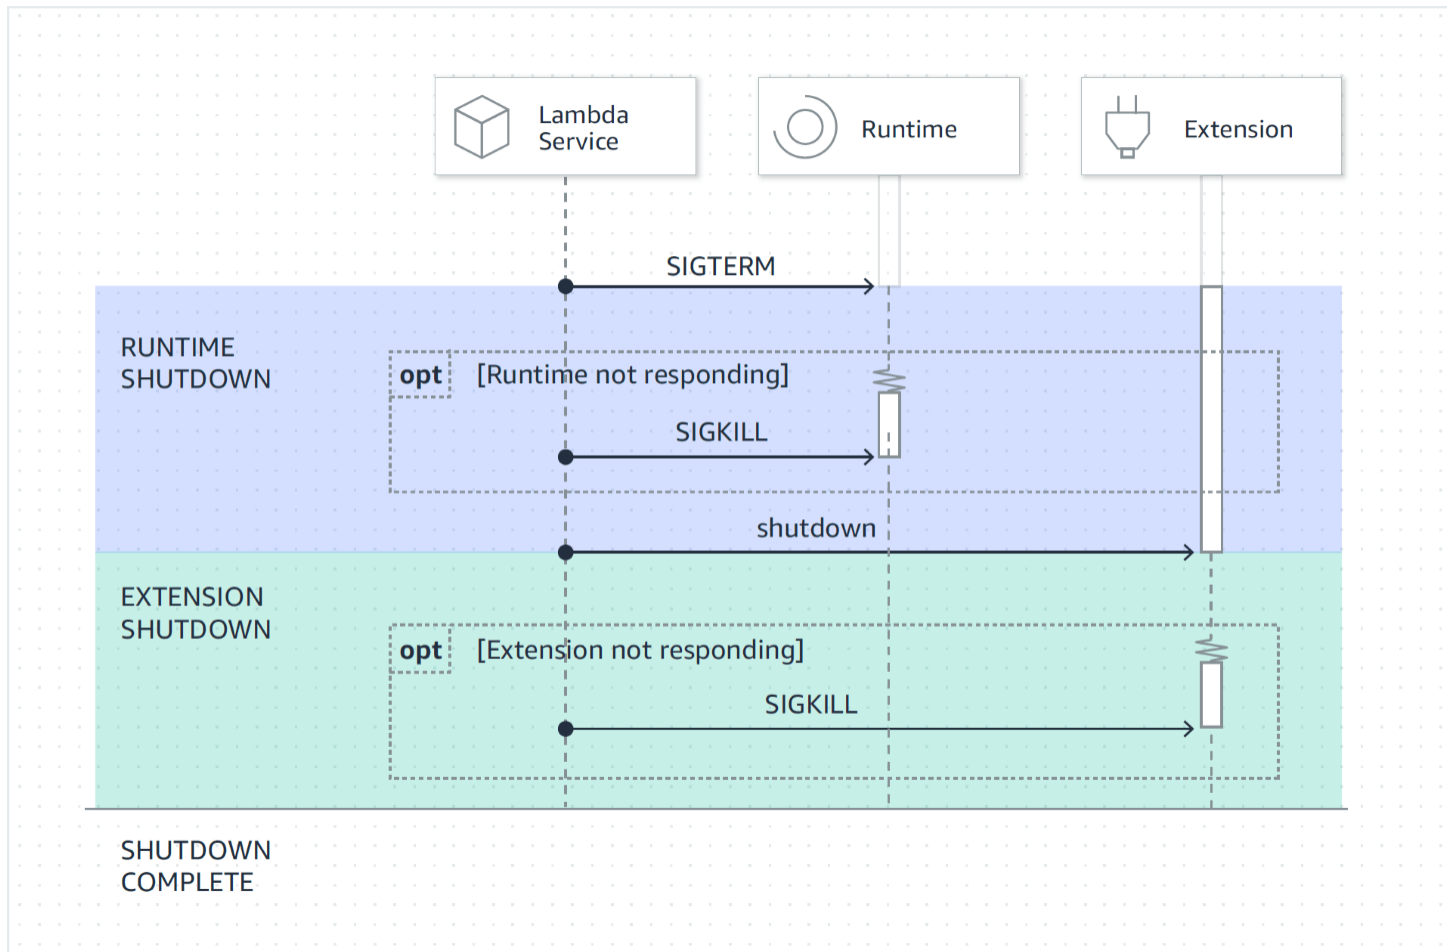

Shutdown phase

When Lambda is about to shut down the runtime, it sends a Shutdown to each registered external extension. Extensions can use this time for final cleanup tasks. The Shutdown event is sent in response to a Next API request.

Duration limit: The maximum duration of the Shutdown phase depends on the configuration of registered extensions:

- 0 ms – A function with no registered extensions
- 500 ms – A function with a registered internal extension
- 2,000 ms – A function with one or more registered external extensions

If the runtime or an extension does not respond to the Shutdown event within the limit, Lambda ends the process using a SIGKILL signal.

Event payload: The Shutdown event contains the reason for the shutdown and the time remaining in milliseconds.

The shutdownReason includes the following values:

- SPINDOWN – Normal shutdown
- TIMEOUT – Duration limit timed out
- FAILURE – Error condition, such as an out-of-memory event

```
{
  "eventType": "SHUTDOWN",
  "shutdownReason": "reason for shutdown",
  "deadlineMs": "the time and date that the function times out in Unix time milliseconds"
}
```

Permissions and configuration

Extensions run in the same execution environment as the Lambda function. Extensions also share resources with the function, such as CPU, memory, and /tmp disk storage. In addition, extensions use the same AWS Identity and Access Management (IAM) role and security context as the function.

File system and network access permissions: Extensions run in the same file system and network namespace as the function runtime. This means that extensions need to be compatible with the associated operating system. If an extension requires any additional outbound network traffic rules, you must apply these rules to the function configuration.

Note

Because the function code directory is read-only, extensions cannot modify the function code.

Environment variables: Extensions can access the function's [environment variables](#), except for the following variables that are specific to the runtime process:

- `AWS_EXECUTION_ENV`
- `AWS_LAMBDA_LOG_GROUP_NAME`
- `AWS_LAMBDA_LOG_STREAM_NAME`
- `AWS_XRAY_CONTEXT_MISSING`
- `AWS_XRAY_DAEMON_ADDRESS`
- `LAMBDA_RUNTIME_DIR`
- `LAMBDA_TASK_ROOT`
- `_AWS_XRAY_DAEMON_ADDRESS`
- `_AWS_XRAY_DAEMON_PORT`
- `_HANDLER`

Note

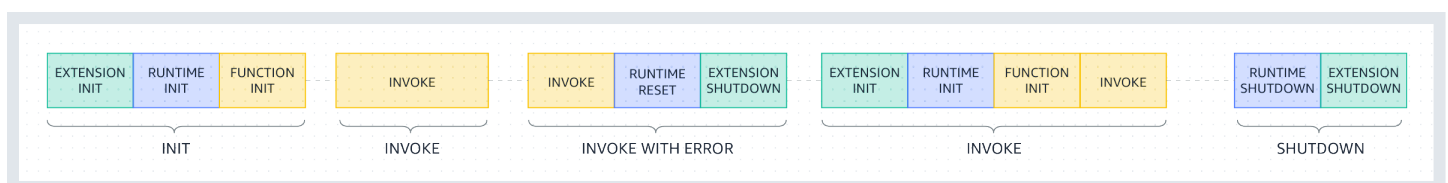

Detecting Lambda Managed Instances: Extensions can check the `AWS_LAMBDA_INITIALIZATION_TYPE` environment variable to determine if they are running on Lambda Managed Instances versus Lambda (default) functions. This is the recommended method for extensions to adapt their behavior based on the execution environment type.

Failure handling

Initialization failures: If an extension fails, Lambda restarts the execution environment to enforce consistent behavior and to encourage fail fast for extensions. Also, for some customers, the extensions must meet mission-critical needs such as logging, security, governance, and telemetry collection.

Invoke failures (such as out of memory, function timeout): Because extensions share resources with the runtime, memory exhaustion affects them. When the runtime fails, all extensions and the runtime itself participate in the Shutdown phase. In addition, the runtime is restarted—either automatically as part of the current invocation, or via a deferred re-initialization mechanism.

If there is a failure (such as a function timeout or runtime error) during Invoke, the Lambda service performs a reset. The reset behaves like a Shutdown event. First, Lambda shuts down the runtime, then it sends a Shutdown event to each registered external extension. The event includes the reason for the shutdown. If this environment is used for a new invocation, the extension and runtime are re-initialized as part of the next invocation.

For a more detailed explanation of the previous diagram, see [Failures during the invoke phase](#).

Extension logs: Lambda sends the log output of extensions to CloudWatch Logs. Lambda also generates an additional log event for each extension during `Init`. The log event records the name and registration preference (event, config) on success, or the failure reason on failure.

Troubleshooting extensions

- If a Register request fails, make sure that the Lambda-Extension-Name header in the Register API call contains the full file name of the extension.
- If the Register request fails for an internal extension, make sure that the request does not register for the Shutdown event.

Extensions API reference

The OpenAPI specification for the extensions API version **2020-01-01** is available here: [extensions-api.zip](#)

You can retrieve the value of the API endpoint from the `AWS_LAMBDA_RUNTIME_API` environment variable. To send a Register request, use the prefix `2020-01-01/` before each API path. For example:

```
http://${AWS_LAMBDA_RUNTIME_API}/2020-01-01/extension/register
```

API methods

- [Register](#)
- [Next](#)
- [Init error](#)
- [Exit error](#)

Register

During Extension `init`, all extensions need to register with Lambda to receive events. Lambda uses the full file name of the extension to validate that the extension has completed the bootstrap sequence. Therefore, each Register API call must include the Lambda-Extension-Name header with the full file name of the extension.

Internal extensions are started and stopped by the runtime process, so they are not permitted to register for the Shutdown event.

Path – `/extension/register`

Method – `POST`

Request headers

- `Lambda-Extension-Name` – The full file name of the extension. Required: yes. Type: string.
- `Lambda-Extension-Accept-Feature` – Use this to specify optional Extensions features during registration. Required: no. Type: comma separated string. Features available to specify using this setting:
 - `accountId` – If specified, the Extension registration response will contain the account ID associated with the Lambda function that you're registering the Extension for.

Request body parameters

- `events` – Array of the events to register for. Required: no. Type: array of strings. Valid strings: `INVOKE`, `SHUTDOWN`.

Note

Lambda Managed Instances: Extensions for Lambda Managed Instances functions can only register for the `SHUTDOWN` event. Attempting to register for the `INVOKE` event will result in an error. This is because Lambda Managed Instances supports concurrent invocations within a single execution environment.

Response headers

- `Lambda-Extension-Identifier` – Generated unique agent identifier (UUID string) that is required for all subsequent requests.

Response codes

- 200 – Response body contains the function name, function version, and handler name.
- 400 – Bad Request
- 403 – Forbidden
- 500 – Container error. Non-recoverable state. Extension should exit promptly.

Example request body

```
{
  'events': [ 'INVOKE', 'SHUTDOWN' ]
}
```

Example response body

```
{
  "functionName": "helloWorld",
  "functionVersion": "$LATEST",
  "handler": "lambda_function.lambda_handler"
}
```

Example response body with optional accountId feature

```
{
  "functionName": "helloWorld",
  "functionVersion": "$LATEST",
  "handler": "lambda_function.lambda_handler",
  "accountId": "123456789012"
}
```

Next

Extensions send a Next API request to receive the next event, which can be an Invoke event or a Shutdown event. The response body contains the payload, which is a JSON document that contains event data.

The extension sends a Next API request to signal that it is ready to receive new events. This is a blocking call.

Do not set a timeout on the GET call, as the extension can be suspended for a period of time until there is an event to return.

Path – /extension/event/next

Method – GET

Request headers

- `Lambda-Extension-Identifier` – Unique identifier for extension (UUID string). Required: yes. Type: UUID string.

Response headers

- `Lambda-Extension-Event-Identifier` – Unique identifier for the event (UUID string).

Response codes

- 200 – Response contains information about the next event (`EventInvoke` or `EventShutdown`).
- 403 – Forbidden
- 500 – Container error. Non-recoverable state. Extension should exit promptly.

Init error

The extension uses this method to report an initialization error to Lambda. Call it when the extension fails to initialize after it has registered. After Lambda receives the error, no further API calls succeed. The extension should exit after it receives the response from Lambda.

Path – `/extension/init/error`

Method – POST

Request headers

- `Lambda-Extension-Identifier` – Unique identifier for extension. Required: yes. Type: UUID string.
- `Lambda-Extension-Function-Error-Type` – Error type that the extension encountered. Required: yes. This header consists of a string value. Lambda accepts any string, but we recommend a format of `<category.reason>`. For example:
 - `Extension.NoSuchHandler`
 - `Extension.APIKeyNotFound`
 - `Extension.ConfigInvalid`
 - `Extension.UnknownReason`

Request body parameters

- `ErrorRequest` – Information about the error. Required: no.

This field is a JSON object with the following structure:

```
{
  errorMessage: string (text description of the error),
  errorType: string,
  stackTrace: array of strings
}
```

Note that Lambda accepts any value for `errorType`.

The following example shows a Lambda function error message in which the function could not parse the event data provided in the invocation.

Example Function error

```
{
  "errorMessage" : "Error parsing event data.",
  "errorType" : "InvalidEventDataException",
  "stackTrace": [ ]
}
```

Response codes

- 202 – Accepted
- 400 – Bad Request
- 403 – Forbidden
- 500 – Container error. Non-recoverable state. Extension should exit promptly.

Exit error

The extension uses this method to report an error to Lambda before exiting. Call it when you encounter an unexpected failure. After Lambda receives the error, no further API calls succeed. The extension should exit after it receives the response from Lambda.

Path – `/extension/exit/error`

Method – POST

Request headers

- `Lambda-Extension-Identifier` – Unique identifier for extension. Required: yes. Type: UUID string.
- `Lambda-Extension-Function-Error-Type` – Error type that the extension encountered. Required: yes. This header consists of a string value. Lambda accepts any string, but we recommend a format of `<category.reason>`. For example:
 - `Extension.NoSuchHandler`
 - `Extension.APIKeyNotFound`
 - `Extension.ConfigInvalid`
 - `Extension.UnknownReason`

Request body parameters

- `ErrorRequest` – Information about the error. Required: no.

This field is a JSON object with the following structure:

```
{
  errorMessage: string (text description of the error),
  errorType: string,
  stackTrace: array of strings
}
```

Note that Lambda accepts any value for `errorType`.

The following example shows a Lambda function error message in which the function could not parse the event data provided in the invocation.

Example Function error

```
{
  "errorMessage" : "Error parsing event data.",
  "errorType" : "InvalidEventDataException",
  "stackTrace": [ ]
}
```

Response codes

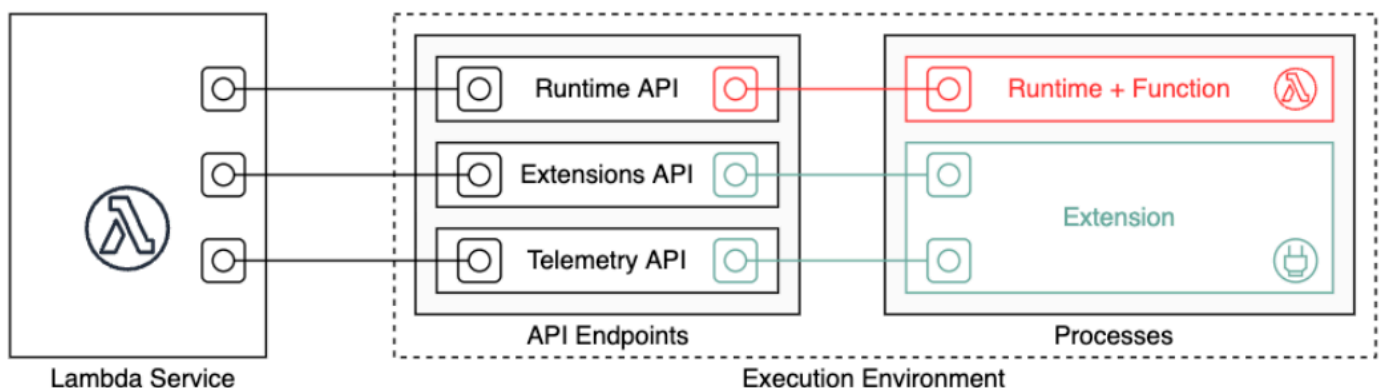

- 202 – Accepted
- 400 – Bad Request
- 403 – Forbidden
- 500 – Container error. Non-recoverable state. Extension should exit promptly.

Accessing real-time telemetry data for extensions using the Telemetry API

The Telemetry API enables your extensions to receive telemetry data directly from Lambda. During function initialization and invocation, Lambda automatically captures telemetry, including logs, platform metrics, and platform traces. The Telemetry API enables extensions to access this telemetry data directly from Lambda in near real time.

Within the Lambda execution environment, you can subscribe your Lambda extensions to telemetry streams. After subscribing, Lambda automatically sends all telemetry data to your extensions. You then have the flexibility to process, filter, and dispatch the data to your preferred destination, such as an Amazon Simple Storage Service (Amazon S3) bucket or a third-party observability tools provider.

The following diagram shows how the Extensions API and Telemetry API link extensions to Lambda from within the execution environment. Additionally, the Runtime API connects your runtime and function to Lambda.

⚠ Important

The Lambda Telemetry API supersedes the Lambda Logs API. **While the Logs API remains fully functional, we recommend using only the Telemetry API going forward.** You can subscribe your extension to a telemetry stream using either the Telemetry API or the Logs API. After subscribing using one of these APIs, any attempt to subscribe using the other API returns an error.

Lambda Managed Instances schema version requirement

Lambda Managed Instances support only the 2025-01-29 schema version of the Telemetry API. When subscribing to telemetry streams for Managed Instance functions, you **must** use "schemaVersion": "2025-01-29" in your subscription request. Using previous schema versions will result in events being rejected by Lambda.

The 2025-01-29 schema version is backward compatible and can be used with both Lambda Managed Instances and Lambda (default) functions. We recommend using this version for all new extensions to ensure compatibility across both deployment models.

Extensions can use the Telemetry API to subscribe to three different telemetry streams:

- **Platform telemetry** – Logs, metrics, and traces, which describe events and errors related to the execution environment runtime lifecycle, extension lifecycle, and function invocations.
- **Function logs** – Custom logs that the Lambda function code generates.
- **Extension logs** – Custom logs that the Lambda extension code generates.

Note

Lambda sends logs and metrics to CloudWatch, and traces to X-Ray (if you've activated tracing), even if an extension subscribes to telemetry streams.

Creating extensions using the Telemetry API

Lambda extensions run as independent processes in the execution environment. Extensions can continue to run after function invocation completes. Because extensions are separate processes, you can write them in a language different from the function code. We recommend writing extensions using a compiled language such as Golang or Rust. This way, the extension is a self-contained binary that can be compatible with any supported runtime.

The following diagram illustrates a four-step process to create an extension that receives and processes telemetry data using the Telemetry API.

Here is each step in more detail:

1. Register your extension using the [the section called "Extensions API"](#). This provides you with a `Lambda-Extension-Identifier`, which you'll need in the following steps. For more information about how to register your extension, see [the section called "Registering your extension"](#).

2. Create a telemetry listener. This can be a basic HTTP or TCP server. Lambda uses the URI of the telemetry listener to send telemetry data to your extension. For more information, see [the section called “Creating a telemetry listener”](#).
3. Using the Subscribe API in the Telemetry API, subscribe your extension to the desired telemetry streams. You'll need the URI of your telemetry listener for this step. For more information, see [the section called “Sending a subscription request to the Telemetry API”](#).
4. Get telemetry data from Lambda via the telemetry listener. You can do any custom processing of this data, such as dispatching the data to Amazon S3 or to an external observability service.

Note

A Lambda function's execution environment can start and stop multiple times as part of its [lifecycle](#). In general, your extension code runs during function invocations, and also up to 2 seconds during the shutdown phase. We recommend batching the telemetry as it arrives to your listener. Then, use the Invoke and Shutdown lifecycle events to send each batch to their desired destinations.

Registering your extension

Before you can subscribe to telemetry data, you must register your Lambda extension. Registration occurs during the [extension initialization phase](#). The following example shows an HTTP request to register an extension.

```
POST http://${AWS_LAMBDA_RUNTIME_API}/2020-01-01/extension/register
Lambda-Extension-Name: lambda_extension_name
{
  'events': [ 'INVOKE', 'SHUTDOWN' ]
}
```

If the request succeeds, the subscriber receives an HTTP 200 success response. The response header contains the `Lambda-Extension-Identifier`. The response body contains other properties of the function.

```
HTTP/1.1 200 OK
Lambda-Extension-Identifier: a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
{
```

```

    "functionName": "lambda_function",
    "functionVersion": "$LATEST",
    "handler": "lambda_handler",
    "accountId": "123456789012"
}

```

For more information, see the [the section called “Extensions API reference”](#).

Creating a telemetry listener

Your Lambda extension must have a listener that handles incoming requests from the Telemetry API. The following code shows an example telemetry listener implementation in Golang:

```

// Starts the server in a goroutine where the log events will be sent
func (s *TelemetryApiListener) Start() (string, error) {
    address := listenOnAddress()
    l.Info("[listener:Start] Starting on address", address)
    s.httpServer = &http.Server{Addr: address}
    http.HandleFunc("/", s.http_handler)
    go func() {
        err := s.httpServer.ListenAndServe()
        if err != http.ErrServerClosed {
            l.Error("[listener:goroutine] Unexpected stop on Http Server:", err)
            s.Shutdown()
        } else {
            l.Info("[listener:goroutine] Http Server closed:", err)
        }
    }()
    return fmt.Sprintf("http://%s/", address), nil
}

// http_handler handles the requests coming from the Telemetry API.
// Everytime Telemetry API sends log events, this function will read them from the
// response body
// and put into a synchronous queue to be dispatched later.
// Logging or printing besides the error cases below is not recommended if you have
// subscribed to
// receive extension logs. Otherwise, logging here will cause Telemetry API to send new
// logs for
// the printed lines which may create an infinite loop.
func (s *TelemetryApiListener) http_handler(w http.ResponseWriter, r *http.Request) {
    body, err := ioutil.ReadAll(r.Body)
    if err != nil {

```

```
l.Error("[listener:http_handler] Error reading body:", err)
return
}

// Parse and put the log messages into the queue
var slice []interface{}
_ = json.Unmarshal(body, &slice)

for _, el := range slice {
    s.LogEventsQueue.Put(el)
}

l.Info("[listener:http_handler] logEvents received:", len(slice), " LogEventsQueue
length:", s.LogEventsQueue.Len())
slice = nil
}
```

Specifying a destination protocol

When you subscribe to receive telemetry using the Telemetry API, you can specify a destination protocol in addition to the destination URI:

```
{
  "destination": {
    "protocol": "HTTP",
    "URI": "http://sandbox.localdomain:8080"
  }
}
```

Lambda accepts two protocols for receiving telemetry:

- **HTTP (recommended)** – Lambda delivers telemetry to a local HTTP endpoint (`http://sandbox.localdomain:${PORT}/${PATH}`) as an array of records in JSON format. The `$PATH` parameter is optional. Lambda supports only HTTP, not HTTPS. Lambda delivers telemetry through POST requests.
- **TCP** – Lambda delivers telemetry to a TCP port in [Newline delimited JSON \(NDJSON\) format](#).

Note

We strongly recommend using HTTP rather than TCP. With TCP, the Lambda platform cannot acknowledge when it delivers telemetry to the application layer. Therefore, if your extension crashes, you might lose telemetry. HTTP does not have this limitation.

Before subscribing to receive telemetry, establish the local HTTP listener or TCP port. During setup, note the following:

- Lambda sends telemetry only to destinations that are inside the execution environment.
- Lambda retries to send telemetry (with backoff) in the absence of a listener, or if the POST request encounters an error. If the telemetry listener crashes, it resumes receiving telemetry after Lambda restarts the execution environment.
- Lambda reserves port 9001. There are no other port number restrictions or recommendations.

Configuring memory usage and buffering

Memory usage in an execution environment grows linearly with the number of subscribers. Subscriptions consume memory resources because each one opens a new memory buffer to store telemetry data. Buffer memory usage contributes to the overall memory consumption in the execution environment.

When subscribing to receive telemetry through the Telemetry API, you have the option to buffer telemetry data and deliver it to subscribers in batches. To optimize memory usage, you can specify a buffering configuration:

```
{
  "buffering": {
    "maxBytes": 256*1024,
    "maxItems": 1000,
    "timeoutMs": 100
  }
}
```

Parameter	Description	Defaults and limits
maxBytes	The maximum volume of telemetry (in bytes) to buffer in memory.	Default: 262,144 Minimum: 262,144 Maximum: 1,048,576
maxItems	The maximum number of events to buffer in memory.	Default: 10,000 Minimum: 1,000 Maximum: 10,000
timeoutMs	The maximum time (in milliseconds) to buffer a batch.	Default: 1,000 Minimum: 25 Maximum: 30,000

When setting up buffering, keep these points in mind:

- If any of the input streams are closed, Lambda flushes the logs. For example, this can occur if the runtime crashes.
- Each subscriber can customize their buffering configuration in their subscription request.
- When determining the buffer size for reading the data, anticipate receiving payloads as large as $2 * \text{maxBytes} + \text{metadataBytes}$, where `maxBytes` is a component of your buffering setup. To gauge the amount of `metadataBytes` to consider, review the following metadata. Lambda appends metadata similar to this to each record:

```
{
  "time": "2022-08-20T12:31:32.123Z",
  "type": "function",
  "record": "Hello World"
}
```

- If the subscriber cannot process incoming telemetry fast enough, or if your function code generates very high log volume, Lambda might drop records to keep memory utilization bounded. When this occurs, Lambda sends a `platform.logsDropped` event.

Sending a subscription request to the Telemetry API

Lambda extensions can subscribe to receive telemetry data by sending a subscription request to the Telemetry API. The subscription request should contain information about the types of events that you want the extension to subscribe to. In addition, the request can contain [delivery destination information](#) and a [buffering configuration](#).

Before sending a subscription request, you must have an extension ID (Lambda-Extension-Identifier). When you [register your extension with the Extensions API](#), you obtain an extension ID from the API response.

Subscription occurs during the [extension initialization phase](#). The following example shows an HTTP request to subscribe to all three telemetry streams: platform telemetry, function logs, and extension logs.

```
PUT http://${AWS_LAMBDA_RUNTIME_API}/2022-07-01/telemetry HTTP/1.1
{
  "schemaVersion": "2025-01-29",
  "types": [
    "platform",
    "function",
    "extension"
  ],
  "buffering": {
    "maxItems": 1000,
    "maxBytes": 256*1024,
    "timeoutMs": 100
  },
  "destination": {
    "protocol": "HTTP",
    "URI": "http://sandbox.localdomain:8080"
  }
}
```

If the request succeeds, then the subscriber receives an HTTP 200 success response.

```
HTTP/1.1 200 OK
"OK"
```

Inbound Telemetry API messages

After subscribing using the Telemetry API, an extension automatically starts to receive telemetry from Lambda via POST requests. Each POST request body contains an array of Event objects. Each Event has the following schema:

```
{
  time: String,
  type: String,
  record: Object
}
```

- The `time` property defines when the Lambda platform generated the event. This is different from when the event actually occurred. The string value of `time` is a timestamp in ISO 8601 format.
- The `type` property defines the event type. The following table describes all possible values.
- The `record` property defines a JSON object that contains the telemetry data. The schema of this JSON object depends on the type.

Event ordering with concurrent invocations

For [Lambda Managed Instances](#), multiple function invocations can execute concurrently within the same execution environment. In this case, the order of `platform.start` and `platform.report` events is not guaranteed between different concurrent invocations. Extensions must handle events from multiple invocations running in parallel and should not assume sequential ordering.

To properly attribute events to specific invocations, extensions should use the `requestId` field present in these platform events. Each invocation has a unique request ID that remains consistent across all events for that invocation, allowing extensions to correlate events correctly even when they arrive out of order.

The following table summarizes all types of Event objects, and links to the [Telemetry API Event schema reference](#) for each event type.

Category	Event type	Description	Event record schema
Platform event	platform. initStart	Function initialization started.	the section called "platform.initStart " schema
Platform event	platform. initRuntimeDone	Function initialization completed.	the section called "platform.initRuntimeDone " schema
Platform event	platform. initReport	A report of function initialization.	the section called "platform.initReport " schema
Platform event	platform.start	Function invocation started.	the section called "platform.start " schema
Platform event	platform. runtimeDone	The runtime finished processing an event with either success or failure.	the section called "platform.runtimeDone " schema
Platform event	platform.report	A report of function invocation.	the section called "platform.report " schema
Platform event	platform. restoreStart	Runtime restore started.	the section called "platform.restoreStart " schema
Platform event	platform. restoreRuntimeDone	Runtime restore completed.	the section called "platform.restoreRu

Category	Event type	Description	Event record schema
			runtimeDone schema
Platform event	platform.restoreReport	Report of runtime restore.	the section called "platform.restoreReport" schema
Platform event	platform.telemetrySubscription	The extension subscribed to the Telemetry API.	the section called "platform.telemetrySubscription" schema
Platform event	platform.logsDropped	Lambda dropped log entries.	the section called "platform.logsDropped" schema
Function logs	function	A log line from function code.	the section called "function" schema
Extension logs	extension	A log line from extension code.	the section called "extension" schema

Lambda Telemetry API reference

Use the Lambda Telemetry API endpoint to subscribe extensions to telemetry streams. You can retrieve the Telemetry API endpoint from the `AWS_LAMBDA_RUNTIME_API` environment variable. To send an API request, append the API version (`2022-07-01/`) and `telemetry/`. For example:

```
http://${AWS_LAMBDA_RUNTIME_API}/2022-07-01/telemetry/
```

For the OpenAPI Specification (OAS) definition of the subscription responses version `2025-01-29`, see the following:

- **HTTP** – [telemetry-api-http-schema.zip](#)
- **TCP** – [telemetry-api-tcp-schema.zip](#)

API operations

- [Subscribe](#)

Subscribe

To subscribe to a telemetry stream, a Lambda extension can send a Subscribe API request.

- **Path** – `/telemetry`
- **Method** – `PUT`
- **Headers**
 - `Content-Type: application/json`
- **Request body parameters**
 - **schemaVersion**
 - Required: Yes
 - Type: String
 - Valid values: `"2025-01-29"`, `"2022-12-13"`, or `"2022-07-01"`
 - **Note:** Lambda Managed Instances require `"2025-01-29"`. This version is backward compatible with Lambda (default) functions.
 - **destination** – The configuration settings that define the telemetry event destination and the protocol for event delivery.

- Required: Yes
- Type: Object

```
{  
  "protocol": "HTTP",  
  "URI": "http://sandbox.localdomain:8080"  
}
```

- **protocol** – The protocol that Lambda uses to send telemetry data.
 - Required: Yes
 - Type: String
 - Valid values: "HTTP"|"TCP"
- **URI** – The URI to send telemetry data to.
 - Required: Yes
 - Type: String
- For more information, see [the section called “Specifying a destination protocol”](#).
- **types** – The types of telemetry that you want the extension to subscribe to.
 - Required: Yes
 - Type: Array of strings
 - Valid values: "platform"|"function"|"extension"
- **buffering** – The configuration settings for event buffering.
 - Required: No
 - Type: Object

```
{  
  "buffering": {  
    "maxItems": 1000,  
    "maxBytes": 256*1024,  
    "timeoutMs": 100  
  }  
}
```

- **maxItems** – The maximum number of events to buffer in memory.
 - Required: No

- Default: 1,000
- Minimum: 1,000
- Maximum: 10,000
- **maxBytes** – The maximum volume of telemetry (in bytes) to buffer in memory.
 - Required: No
 - Type: Integer
 - Default: 262,144
 - Minimum: 262,144
 - Maximum: 1,048,576
- **timeoutMs** – The maximum time (in milliseconds) to buffer a batch.
 - Required: No
 - Type: Integer
 - Default: 1,000
 - Minimum: 25
 - Maximum: 30,000
- For more information, see [the section called “Configuring memory usage and buffering”](#).

Example Subscribe API request

```
PUT http://${AWS_LAMBDA_RUNTIME_API}/2022-07-01/telemetry HTTP/1.1
{
  "schemaVersion": "2025-01-29",
  "types": [
    "platform",
    "function",
    "extension"
  ],
  "buffering": {
    "maxItems": 1000,
    "maxBytes": 256*1024,
    "timeoutMs": 100
  },
  "destination": {
    "protocol": "HTTP",
    "URI": "http://sandbox.localdomain:8080"
```

```
}
```

If the Subscribe request succeeds, the extension receives an HTTP 200 success response:

```
HTTP/1.1 200 OK
"OK"
```

If the Subscribe request fails, the extension receives an error response. For example:

```
HTTP/1.1 400 OK
{
  "errorType": "ValidationError",
  "errorMessage": "URI port is not provided; types should not be empty"
}
```

Here are some additional response codes that the extension can receive:

- 200 – Request completed successfully
- 202 – Request accepted. Subscription request response in local testing environment
- 400 – Bad request
- 500 – Service error

Lambda Telemetry API Event schema reference

Use the Lambda Telemetry API endpoint to subscribe extensions to telemetry streams. You can retrieve the Telemetry API endpoint from the `AWS_LAMBDA_RUNTIME_API` environment variable. To send an API request, append the API version (`2022-07-01/`) and `telemetry/`. For example:

```
http://${AWS_LAMBDA_RUNTIME_API}/2022-07-01/telemetry/
```

For the OpenAPI Specification (OAS) definition of the subscription responses version 2025-01-29, see the following:

- **HTTP** – [telemetry-api-http-schema.zip](#)
- **TCP** – [telemetry-api-tcp-schema.zip](#)

The following table is a summary of all the types of Event objects that the Telemetry API supports.

Category	Event type	Description	Event record schema
Platform event	<code>platform.initStart</code>	Function initialization started.	the section called "platform.initStart " schema
Platform event	<code>platform.initRuntimeDone</code>	Function initialization completed.	the section called "platform.initRuntimeDone " schema
Platform event	<code>platform.initReport</code>	A report of function initialization.	the section called "platform.initReport " schema
Platform event	<code>platform.start</code>	Function invocation started.	the section called "platform.start " schema

Category	Event type	Description	Event record schema
Platform event	platform.runtimeDone	The runtime finished processing an event with either success or failure.	the section called "platform.runtimeDone " schema
Platform event	platform.report	A report of function invocation.	the section called "platform.report " schema
Platform event	platform.restoreStart	Runtime restore started.	the section called "platform.restoreStart " schema
Platform event	platform.restoreRuntimeDone	Runtime restore completed.	the section called "platform.restoreRuntimeDone " schema
Platform event	platform.restoreReport	Report of runtime restore.	the section called "platform.restoreReport " schema
Platform event	platform.telemetrySubscription	The extension subscribed to the Telemetry API.	the section called "platform.telemetrySubscription " schema
Platform event	platform.logsDropped	Lambda dropped log entries.	the section called "platform.logsDropped " schema

Category	Event type	Description	Event record schema
Function logs	function	A log line from function code.	the section called "function" schema
Extension logs	extension	A log line from extension code.	the section called "extension " schema

Telemetry API Event object types

This section details the types of Event objects that the Lambda Telemetry API supports. In the event descriptions, a question mark (?) indicates that the attribute may not be present in the object.

platform.initStart

A `platform.initStart` event indicates that the function initialization phase has started. A `platform.initStart` Event object has the following shape:

```
Event: Object
- time: String
- type: String = platform.initStart
- record: PlatformInitStart
```

The `PlatformInitStart` object has the following attributes:

- **functionName** – String
- **functionVersion** – String
- **initializationType** – [the section called “InitType”](#) object
- **instanceId?** – String
- **instanceMaxMemory?** – Integer
- **phase** – [the section called “InitPhase”](#) object
- **runtimeVersion?** – String
- **runtimeVersionArn?** – String

The following is an example Event of type `platform.initStart`:

```
{
  "time": "2022-10-12T00:00:15.064Z",
```

```
{
  "type": "platform.initStart",
  "record": {
    "initializationType": "on-demand",
    "phase": "init",
    "runtimeVersion": "nodejs-14.v3",
    "runtimeVersionArn": "arn",
    "functionName": "myFunction",
    "functionVersion": "$LATEST",
    "instanceId": "82561ce0-53dd-47d1-90e0-c8f5e063e62e",
    "instanceMaxMemory": 256
  }
}
```

platform.initRuntimeDone

A `platform.initRuntimeDone` event indicates that the function initialization phase has completed. A `platform.initRuntimeDone` Event object has the following shape:

```
Event: Object
- time: String
- type: String = platform.initRuntimeDone
- record: PlatformInitRuntimeDone
```

The `PlatformInitRuntimeDone` object has the following attributes:

- **initializationType** – [the section called “InitType”](#) object
- **phase** – [the section called “InitPhase”](#) object
- **status** – [the section called “Status”](#) object
- **spans?** – List of [the section called “Span”](#) objects

The following is an example Event of type `platform.initRuntimeDone`:

```
{
  "time": "2022-10-12T00:01:15.000Z",
  "type": "platform.initRuntimeDone",
  "record": {
    "initializationType": "on-demand",
    "status": "success",
    "spans": [
      {
        "name": "someTimeSpan",
```

```

        "start": "2022-06-02T12:02:33.913Z",
        "durationMs": 70.5
      }
    ]
  }
}

```

platform.initReport

A `platform.initReport` event contains an overall report of the function initialization phase. A `platform.initReport` Event object has the following shape:

```

Event: Object
- time: String
- type: String = platform.initReport
- record: PlatformInitReport

```

The `PlatformInitReport` object has the following attributes:

- **errorType?** – string
- **initializationType** – [the section called “InitType”](#) object
- **phase** – [the section called “InitPhase”](#) object
- **metrics** – [the section called “InitReportMetrics”](#) object
- **spans?** – List of [the section called “Span”](#) objects
- **status** – [the section called “Status”](#) object

The following is an example Event of type `platform.initReport`:

```

{
  "time": "2022-10-12T00:01:15.000Z",
  "type": "platform.initReport",
  "record": {
    "initializationType": "on-demand",
    "status": "success",
    "phase": "init",
    "metrics": {
      "durationMs": 125.33
    },
    "spans": [
      {

```

```

        "name": "someTimeSpan",
        "start": "2022-06-02T12:02:33.913Z",
        "durationMs": 90.1
      }
    ]
  }
}

```

platform.start

A `platform.start` event indicates that the function invocation phase has started. A `platform.start` Event object has the following shape:

```

Event: Object
- time: String
- type: String = platform.start
- record: PlatformStart

```

The `PlatformStart` object has the following attributes:

- **requestId** – String
- **version?** – String
- **tracing?** – [the section called “TraceContext”](#)

The following is an example Event of type `platform.start`:

```

{
  "time": "2022-10-12T00:00:15.064Z",
  "type": "platform.start",
  "record": {
    "requestId": "6d68ca91-49c9-448d-89b8-7ca3e6dc66aa",
    "version": "$LATEST",
    "tracing": {
      "spanId": "54565fb41ac79632",
      "type": "X-Amzn-Trace-Id",
      "value":
"Root=1-62e900b2-710d76f009d6e7785905449a;Parent=0efbd19962d95b05;Sampled=1"
    }
  }
}

```

platform.runtimeDone

A `platform.runtimeDone` event indicates that the function invocation phase has completed. A `platform.runtimeDone` Event object has the following shape:

Lambda Managed Instances

The `platform.runtimeDone` event is not supported for Lambda Managed Instances. Extensions running on Managed Instances will not receive this event because extensions cannot subscribe to the `INVOKED` event on Managed Instances. Due to the concurrent execution model where multiple invocations can be processed simultaneously, extensions cannot perform post-invoke processing for individual invocations as they traditionally do on Lambda (default) functions.

For Managed Instances, the `responseLatency` and `responseDuration` spans that are normally included in `platform.runtimeDone` are instead available in the `platform.report` event. See [the section called “platform.report”](#) for details.

```
Event: Object
- time: String
- type: String = platform.runtimeDone
- record: PlatformRuntimeDone
```

The `PlatformRuntimeDone` object has the following attributes:

- **errorType?** – String
- **metrics?** – [the section called “RuntimeDoneMetrics”](#) object
- **requestId** – String
- **status** – [the section called “Status”](#) object
- **spans?** – List of [the section called “Span”](#) objects
- **tracing?** – [the section called “TraceContext”](#) object

The following is an example Event of type `platform.runtimeDone`:

```
{
  "time": "2022-10-12T00:01:15.000Z",
  "type": "platform.runtimeDone",
```

```

    "record": {
      "requestId": "6d68ca91-49c9-448d-89b8-7ca3e6dc66aa",
      "status": "success",
      "tracing": {
        "spanId": "54565fb41ac79632",
        "type": "X-Amzn-Trace-Id",
        "value":
"Root=1-62e900b2-710d76f009d6e7785905449a;Parent=0efbd19962d95b05;Sampled=1"
      },
      "spans": [
        {
          "name": "someTimeSpan",
          "start": "2022-08-02T12:01:23:521Z",
          "durationMs": 80.0
        }
      ],
      "metrics": {
        "durationMs": 140.0,
        "producedBytes": 16
      }
    }
  }
}

```

platform.report

A `platform.report` event contains an overall report of the function invoke phase. A `platform.report` Event object has the following shape:

Lambda Managed Instances

The `platform.report` event for Lambda Managed Instances has different metrics and spans compared to Lambda (default) functions. For Managed Instances:

- **Spans:** Contains `responseLatency` and `responseDuration` instead of `extensionOverhead`. The `extensionOverhead` span is not available because extensions cannot subscribe to the `INVOKE` event on Managed Instances due to the concurrent execution model.
- **Metrics:** Only includes `durationMs`. The following metrics are not included: `billedDurationMs`, `initDurationMs`, `maxMemoryUsedMB`, and `memorySizeMB`. These per-invoke metrics are not applicable in the concurrent execution environment.

For resource utilization metrics, use [Monitoring Lambda Managed Instances](#) or [Lambda Insights](#).

```
Event: Object
- time: String
- type: String = platform.report
- record: PlatformReport
```

The PlatformReport object has the following attributes:

- **metrics** – [the section called “ReportMetrics”](#) object
- **requestId** – String
- **spans?** – List of [the section called “Span”](#) objects
- **status** – [the section called “Status”](#) object
- **tracing?** – [the section called “TraceContext”](#) object

The following is an example Event of type `platform.report`:

```
{
  "time": "2022-10-12T00:01:15.000Z",
  "type": "platform.report",
  "record": {
    "metrics": {
      "billedDurationMs": 694,
      "durationMs": 693.92,
      "initDurationMs": 397.68,
      "maxMemoryUsedMB": 84,
      "memorySizeMB": 128
    },
    "requestId": "6d68ca91-49c9-448d-89b8-7ca3e6dc66aa",
  }
}
```

platform.restoreStart

A `platform.restoreStart` event indicates that a function environment restoration event started. In an environment restoration event, Lambda creates the environment from a cached

snapshot rather than initializing it from scratch. For more information, see [Lambda SnapStart](#). A `platform.restoreStart` Event object has the following shape:

```
Event: Object
- time: String
- type: String = platform.restoreStart
- record: PlatformRestoreStart
```

The `PlatformRestoreStart` object has the following attributes:

- **functionName** – String
- **functionVersion** – String
- **instanceId?** – String
- **instanceMaxMemory?** – String
- **runtimeVersion?** – String
- **runtimeVersionArn?** – String

The following is an example Event of type `platform.restoreStart`:

```
{
  "time": "2022-10-12T00:00:15.064Z",
  "type": "platform.restoreStart",
  "record": {
    "runtimeVersion": "nodejs-14.v3",
    "runtimeVersionArn": "arn",
    "functionName": "myFunction",
    "functionVersion": "$LATEST",
    "instanceId": "82561ce0-53dd-47d1-90e0-c8f5e063e62e",
    "instanceMaxMemory": 256
  }
}
```

platform.restoreRuntimeDone

A `platform.restoreRuntimeDone` event indicates that a function environment restoration event completed. In an environment restoration event, Lambda creates the environment from a cached snapshot rather than initializing it from scratch. For more information, see [Lambda SnapStart](#). A `platform.restoreRuntimeDone` Event object has the following shape:

```
Event: Object
- time: String
- type: String = platform.restoreRuntimeDone
- record: PlatformRestoreRuntimeDone
```

The PlatformRestoreRuntimeDone object has the following attributes:

- **errorType?** – String
- **spans?** – List of [the section called “Span”](#) objects
- **status** – [the section called “Status”](#) object

The following is an example Event of type `platform.restoreRuntimeDone`:

```
{
  "time": "2022-10-12T00:00:15.064Z",
  "type": "platform.restoreRuntimeDone",
  "record": {
    "status": "success",
    "spans": [
      {
        "name": "someTimeSpan",
        "start": "2022-08-02T12:01:23:521Z",
        "durationMs": 80.0
      }
    ]
  }
}
```

platform.restoreReport

A `platform.restoreReport` event contains an overall report of a function restoration event. A `platform.restoreReport` Event object has the following shape:

```
Event: Object
- time: String
- type: String = platform.restoreReport
- record: PlatformRestoreReport
```

The PlatformRestoreReport object has the following attributes:

- **errorType?** – string
- **metrics?** – [the section called “RestoreReportMetrics”](#) object
- **spans?** – List of [the section called “Span”](#) objects
- **status** – [the section called “Status”](#) object

The following is an example Event of type `platform.restoreReport`:

```
{
  "time": "2022-10-12T00:00:15.064Z",
  "type": "platform.restoreReport",
  "record": {
    "status": "success",
    "metrics": {
      "durationMs": 15.19
    },
    "spans": [
      {
        "name": "someTimeSpan",
        "start": "2022-08-02T12:01:23:521Z",
        "durationMs": 30.0
      }
    ]
  }
}
```

platform.extension

An extension event contains logs from the extension code. An extension Event object has the following shape:

```
Event: Object
- time: String
- type: String = extension
- record: {}
```

The PlatformExtension object has the following attributes:

- **events** – List of String
- **name** – String
- **state** – String

The following is an example Event of type `platform.extension`:

```
{
  "time": "2022-10-12T00:02:15.000Z",
  "type": "platform.extension",
  "record": {
    "events": [ "INVOKE", "SHUTDOWN" ],
    "name": "my-telemetry-extension",
    "state": "Ready"
  }
}
```

platform.telemetrySubscription

A `platform.telemetrySubscription` event contains information about an extension subscription. A `platform.telemetrySubscription` Event object has the following shape:

```
Event: Object
- time: String
- type: String = platform.telemetrySubscription
- record: PlatformTelemetrySubscription
```

The `PlatformTelemetrySubscription` object has the following attributes:

- **name** – String
- **state** – String
- **types** – List of String

The following is an example Event of type `platform.telemetrySubscription`:

```
{
  "time": "2022-10-12T00:02:35.000Z",
  "type": "platform.telemetrySubscription",
  "record": {
    "name": "my-telemetry-extension",
    "state": "Subscribed",
    "types": [ "platform", "function" ]
  }
}
```

platform.logsDropped

A `platform.logsDropped` event contains information about dropped events. Lambda emits the `platform.logsDropped` event when a function outputs logs at too high a rate for Lambda to process them. When Lambda can't send logs to CloudWatch or to the extension subscribed to Telemetry API at the rate the function produces them, it drops logs to prevent the function's execution from slowing down. A `platform.logsDropped` Event object has the following shape:

```
Event: Object
- time: String
- type: String = platform.logsDropped
- record: PlatformLogsDropped
```

The `PlatformLogsDropped` object has the following attributes:

- **droppedBytes** – Integer
- **droppedRecords** – Integer
- **reason** – String

The following is an example Event of type `platform.logsDropped`:

```
{
  "time": "2022-10-12T00:02:35.000Z",
  "type": "platform.logsDropped",
  "record": {
    "droppedBytes": 12345,
    "droppedRecords": 123,
    "reason": "Some logs were dropped because the downstream consumer is slower than the logs production rate"
  }
}
```

function

A function event contains logs from the function code. A function Event object has the following shape:

```
Event: Object
- time: String
- type: String = function
```

```
- record: {}
```

The format of the `record` field depends on whether your function's logs are formatted in plain text or JSON format. To learn more about log format configuration options, see [the section called “Log formats”](#)

The following is an example Event of type `function` where the log format is plain text:

```
{
  "time": "2022-10-12T00:03:50.000Z",
  "type": "function",
  "record": "[INFO] Hello world, I am a function!"
}
```

The following is an example Event of type `function` where the log format is JSON:

```
{
  "time": "2022-10-12T00:03:50.000Z",
  "type": "function",
  "record": {
    "timestamp": "2022-10-12T00:03:50.000Z",
    "level": "INFO",
    "requestId": "79b4f56e-95b1-4643-9700-2807f4e68189",
    "message": "Hello world, I am a function!"
  }
}
```

Note

If the schema version you're using is older than the 2022-12-13 version, then the `"record"` is always rendered as a string even when your function's logging format is configured as JSON. For Lambda Managed Instances, you must use schema version 2025-01-29.

extension

A `extension` event contains logs from the extension code. A `extension` Event object has the following shape:

```
Event: Object
```

```
- time: String
- type: String = extension
- record: {}
```

The format of the `record` field depends on whether your function's logs are formatted in plain text or JSON format. To learn more about log format configuration options, see [the section called "Log formats"](#)

The following is an example Event of type `extension` where the log format is plain text:

```
{
  "time": "2022-10-12T00:03:50.000Z",
  "type": "extension",
  "record": "[INFO] Hello world, I am an extension!"
}
```

The following is an example Event of type `extension` where the log format is JSON:

```
{
  "time": "2022-10-12T00:03:50.000Z",
  "type": "extension",
  "record": {
    "timestamp": "2022-10-12T00:03:50.000Z",
    "level": "INFO",
    "requestId": "79b4f56e-95b1-4643-9700-2807f4e68189",
    "message": "Hello world, I am an extension!"
  }
}
```

Note

If the schema version you're using is older than the 2022-12-13 version, then the `"record"` is always rendered as a string even when your function's logging format is configured as JSON. For Lambda Managed Instances, you must use schema version 2025-01-29.

Shared object types

This section details the types of shared objects that the Lambda Telemetry API supports.

InitPhase

A string enum that describes the phase when the initialization step occurs. In most cases, Lambda runs the function initialization code during the `init` phase. However, in some error cases, Lambda may re-run the function initialization code during the `invoke` phase. (This is called a *suppressed init*.)

- **Type** – String
- **Valid values** – `init|invoke|snap-start`

InitReportMetrics

An object that contains metrics about an initialization phase.

- **Type** – Object

An `InitReportMetrics` object has the following shape:

```
InitReportMetrics: Object
- durationMs: Double
```

The following is an example `InitReportMetrics` object:

```
{
  "durationMs": 247.88
}
```

InitType

A string enum that describes how Lambda initialized the environment.

- **Type** – String
- **Valid values** – `on-demand|provisioned-concurrency`

ReportMetrics

An object that contains metrics about a completed phase.

- **Type** – Object

A `ReportMetrics` object has the following shape:

```
ReportMetrics: Object
- billedDurationMs: Integer
- durationMs: Double
- initDurationMs?: Double
- maxMemoryUsedMB: Integer
- memorySizeMB: Integer
- restoreDurationMs?: Double
```

The following is an example `ReportMetrics` object:

```
{
  "billedDurationMs": 694,
  "durationMs": 693.92,
  "initDurationMs": 397.68,
  "maxMemoryUsedMB": 84,
  "memorySizeMB": 128
}
```

RestoreReportMetrics

An object that contains metrics about a completed restoration phase.

- **Type** – Object

A `RestoreReportMetrics` object has the following shape:

```
RestoreReportMetrics: Object
- durationMs: Double
```

The following is an example `RestoreReportMetrics` object:

```
{
  "durationMs": 15.19
}
```

RuntimeDoneMetrics

An object that contains metrics about an invocation phase.

- **Type** – Object

A `RuntimeDoneMetrics` object has the following shape:

```
RuntimeDoneMetrics: Object
- durationMs: Double
- producedBytes?: Integer
```

The following is an example `RuntimeDoneMetrics` object:

```
{
  "durationMs": 200.0,
  "producedBytes": 15
}
```

Span

An object that contains details about a span. A span represents a unit of work or operation in a trace. For more information about spans, see [Span](#) on the **Tracing API** page of the OpenTelemetry Docs website.

Lambda supports the following spans for the `platform.RuntimeDone` event:

- The `responseLatency` span describes how long it took your Lambda function to start sending the response.
- The `responseDuration` span describes how long it took your Lambda function to finish sending the entire response.
- The `runtimeOverhead` span describes how long it took the Lambda runtime to signal that it is ready to process the next function invoke. This is how long the runtime took to call the [next invocation](#) API to get the next event after returning your function response.

The following is an example `responseLatency` span object:

```
{
  "name": "responseLatency",
  "start": "2022-08-02T12:01:23.521Z",
  "durationMs": 23.02
}
```

Status

An object that describes the status of an initialization or invocation phase. If the status is either `failure` or `error`, then the `Status` object also contains an `errorType` field describing the error.

- **Type** – `Object`
- **Valid status values** – `success|failure|error|timeout`

TraceContext

An object that describes the properties of a trace.

- **Type** – `Object`

A `TraceContext` object has the following shape:

```
TraceContext: Object
- spanId?: String
- type: TracingType enum
- value: String
```

The following is an example `TraceContext` object:

```
{
  "spanId": "073a49012f3c312e",
  "type": "X-Amzn-Trace-Id",
  "value":
    "Root=1-62e900b2-710d76f009d6e7785905449a;Parent=0efbd19962d95b05;Sampled=1"
}
```

TracingType

A string enum that describes the type of tracing in a [the section called “TraceContext”](#) object.

- **Type** – `String`
- **Valid values** – `X-Amzn-Trace-Id`

Converting Lambda Telemetry API Event objects to OpenTelemetry Spans

The AWS Lambda Telemetry API schema is semantically compatible with OpenTelemetry (OTel). This means that you can convert your AWS Lambda Telemetry API Event objects to OpenTelemetry (OTel) Spans. When converting, you shouldn't map a single Event object to a single OTel Span. Instead, you should present all three events related to a lifecycle phase in a single OTel Span. For example, the `start`, `runtimeDone`, and `runtimeReport` events represent a single function invocation. Present all three of these events as a single OTel Span.

You can convert your events using Span Events or Child (nested) Spans. The tables on this page describe the mappings between Telemetry API schema properties and OTel Span properties for both approaches. For more information about OTel Spans, see [Span](#) on the **Tracing API** page of the OpenTelemetry Docs website.

Sections

- [Map to OTel Spans with Span Events](#)
- [Map to OTel Spans with Child Spans](#)

Map to OTel Spans with Span Events

In the following tables, `e` represents the event coming from the telemetry source.

Mapping the *Start events

OpenTelemetry	Lambda Telemetry API schema
<code>Span.Name</code>	Your extension generates this value based on the <code>type</code> field.
<code>Span.StartTime</code>	Use <code>e.time</code> .
<code>Span.EndTime</code>	N/A, because the event hasn't completed yet.
<code>Span.Kind</code>	Set to <code>Server</code> .
<code>Span.Status</code>	Set to <code>Unset</code> .

OpenTelemetry	Lambda Telemetry API schema
<code>Span.TraceId</code>	Parse the AWS X-Ray header found in <code>e.tracing.value</code> , then use the <code>TraceId</code> value.
<code>Span.ParentId</code>	Parse the X-Ray header found in <code>e.tracing.value</code> , then use the <code>Parent</code> value.
<code>Span.SpanId</code>	Use <code>e.tracing.spanId</code> if available. Otherwise, generate a new <code>SpanId</code> .
<code>Span.SpanContext.TraceState</code>	N/A for an X-Ray trace context.
<code>Span.SpanContext.TraceFlags</code>	Parse the X-Ray header found in <code>e.tracing.value</code> , then use the <code>Sampled</code> value.
<code>Span.Attributes</code>	Your extension can add any custom values here.

Mapping the *RuntimeDone events

OpenTelemetry	Lambda Telemetry API schema
<code>Span.Name</code>	Your extension generates the value based on the <code>type</code> field.
<code>Span.StartTime</code>	Use <code>e.time</code> from the matching <code>*Start</code> event. Alternatively, use <code>e.time - e.metrics.durationMs</code> .
<code>Span.EndTime</code>	N/A, because the event hasn't completed yet.
<code>Span.Kind</code>	Set to <code>Server</code> .
<code>Span.Status</code>	If <code>e.status</code> doesn't equal <code>success</code> , then set to <code>Error</code> .

OpenTelemetry	Lambda Telemetry API schema
	Otherwise, set to 0k.
<code>Span.Events[]</code>	Use <code>e.spans[]</code> .
<code>Span.Events[i].Name</code>	Use <code>e.spans[i].name</code> .
<code>Span.Events[i].Time</code>	Use <code>e.spans[i].start</code> .
<code>Span.TraceId</code>	Parse the AWS X-Ray header found in <code>e.tracing.value</code> , then use the <code>TraceId</code> value.
<code>Span.ParentId</code>	Parse the X-Ray header found in <code>e.tracing.value</code> , then use the <code>Parent</code> value.
<code>Span.SpanId</code>	Use the same <code>SpanId</code> from the <code>*Start</code> event. If unavailable, then use <code>e.tracing.spanId</code> , or generate a new <code>SpanId</code> .
<code>Span.SpanContext.TraceState</code>	N/A for an X-Ray trace context.
<code>Span.SpanContext.TraceFlags</code>	Parse the X-Ray header found in <code>e.tracing.value</code> , then use the <code>Sampled</code> value.
<code>Span.Attributes</code>	Your extension can add any custom values here.

Mapping the `*Report` events

OpenTelemetry	Lambda Telemetry API schema
<code>Span.Name</code>	Your extension generates the value based on the <code>type</code> field.
<code>Span.StartTime</code>	Use <code>e.time</code> from the matching <code>*Start</code> event.

OpenTelemetry	Lambda Telemetry API schema
	Alternatively, use <code>e.time - e.metrics.durationMs</code> .
<code>Span.EndTime</code>	Use <code>e.time</code> .
<code>Span.Kind</code>	Set to <code>Server</code> .
<code>Span.Status</code>	Use the same value as the <code>*RuntimeDone</code> event.
<code>Span.TraceId</code>	Parse the AWS X-Ray header found in <code>e.tracing.value</code> , then use the <code>TraceId</code> value.
<code>Span.ParentId</code>	Parse the X-Ray header found in <code>e.tracing.value</code> , then use the <code>Parent</code> value.
<code>Span.SpanId</code>	Use the same <code>SpanId</code> from the <code>*Start</code> event. If unavailable, then use <code>e.tracing.spanId</code> , or generate a new <code>SpanId</code> .
<code>Span.SpanContext.TraceState</code>	N/A for an X-Ray trace context.
<code>Span.SpanContext.TraceFlags</code>	Parse the X-Ray header found in <code>e.tracing.value</code> , then use the <code>Sampled</code> value.
<code>Span.Attributes</code>	Your extension can add any custom values here.

Map to OTel Spans with Child Spans

The following table describes how to convert Lambda Telemetry API events into OTel Spans with Child (nested) Spans for `*RuntimeDone` Spans. For `*Start` and `*Report` mappings, refer to the tables in [the section called “Map to OTel Spans with Span Events”](#), as they're the same for Child Spans. In this table, `e` represents the event coming from the telemetry source.

Mapping the `*RuntimeDone` events

OpenTelemetry	Lambda Telemetry API schema
<code>Span.Name</code>	Your extension generates the value based on the <code>type</code> field.
<code>Span.StartTime</code>	Use <code>e.time</code> from the matching <code>*Start</code> event. Alternatively, use <code>e.time - e.metrics.durationMs</code> .
<code>Span.EndTime</code>	N/A, because the event hasn't completed yet.
<code>Span.Kind</code>	Set to <code>Server</code> .
<code>Span.Status</code>	If <code>e.status</code> doesn't equal <code>success</code> , then set to <code>Error</code> . Otherwise, set to <code>Ok</code> .
<code>Span.TraceId</code>	Parse the AWS X-Ray header found in <code>e.tracing.value</code> , then use the <code>TraceId</code> value.
<code>Span.ParentId</code>	Parse the X-Ray header found in <code>e.tracing.value</code> , then use the <code>Parent</code> value.
<code>Span.SpanId</code>	Use the same <code>SpanId</code> from the <code>*Start</code> event. If unavailable, then use <code>e.tracing.spanId</code> , or generate a new <code>SpanId</code> .
<code>Span.SpanContext.TraceState</code>	N/A for an X-Ray trace context.
<code>Span.SpanContext.TraceFlags</code>	Parse the X-Ray header found in <code>e.tracing.value</code> , then use the <code>Sampled</code> value.
<code>Span.Attributes</code>	Your extension can add any custom values here.
<code>ChildSpan[i].Name</code>	Use <code>e.spans[i].name</code> .

OpenTelemetry	Lambda Telemetry API schema
<code>ChildSpan[i].StartTime</code>	Use <code>e.spans[i].start</code> .
<code>ChildSpan[i].EndTime</code>	Use <code>e.spans[i].start + e.spans[i].durations</code> .
<code>ChildSpan[i].Kind</code>	Same as parent <code>Span.Kind</code> .
<code>ChildSpan[i].Status</code>	Same as parent <code>Span.Status</code> .
<code>ChildSpan[i].TraceId</code>	Same as parent <code>Span.TraceId</code> .
<code>ChildSpan[i].ParentId</code>	Use parent <code>Span.SpanId</code> .
<code>ChildSpan[i].SpanId</code>	Generate a new <code>SpanId</code> .
<code>ChildSpan[i].SpanContext.TraceState</code>	N/A for an X-Ray trace context.
<code>ChildSpan[i].SpanContext.TraceFlags</code>	Same as parent <code>Span.SpanContext.TraceFlags</code> .

Using the Lambda Logs API

⚠ Important

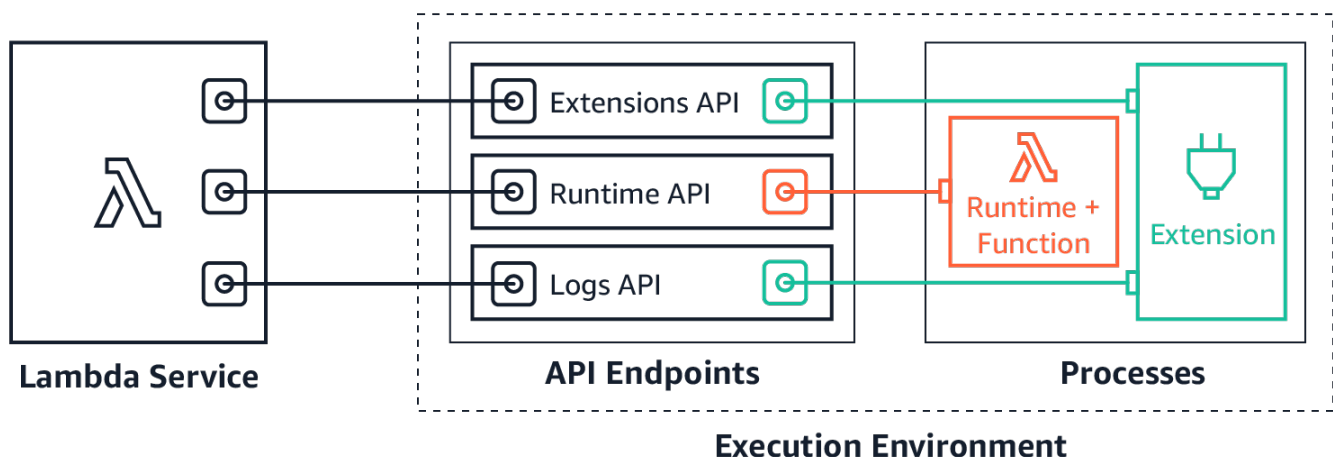

The Lambda Telemetry API supersedes the Lambda Logs API. **While the Logs API remains fully functional, we recommend using only the Telemetry API going forward.** You can subscribe your extension to a telemetry stream using either the Telemetry API or the Logs API. After subscribing using one of these APIs, any attempt to subscribe using the other API returns an error.

⚠ Lambda Managed Instances do not support Logs API

Lambda Managed Instances do not support the Logs API. If you are using Managed Instance functions, use the [Telemetry API](#) instead. The Telemetry API provides enhanced capabilities for collecting and processing telemetry data from your Lambda functions.

Lambda automatically captures runtime logs and streams them to Amazon CloudWatch. This log stream contains the logs that your function code and extensions generate, and also the logs that Lambda generates as part of the function invocation.

[Lambda extensions](#) can use the Lambda Runtime Logs API to subscribe to log streams directly from within the Lambda [execution environment](#). Lambda streams the logs to the extension, and the extension can then process, filter, and send the logs to any preferred destination.

The Logs API allows extensions to subscribe to three different logs streams:

- Function logs that the Lambda function generates and writes to `stdout` or `stderr`.
- Extension logs that extension code generates.
- Lambda platform logs, which record events and errors related to invocations and extensions.

 **Note**

Lambda sends all logs to CloudWatch, even when an extension subscribes to one or more of the log streams.

Topics

- [Subscribing to receive logs](#)
- [Memory usage](#)
- [Destination protocols](#)
- [Buffering configuration](#)
- [Example subscription](#)
- [Sample code for Logs API](#)
- [Logs API reference](#)
- [Log messages](#)

Subscribing to receive logs

A Lambda extension can subscribe to receive logs by sending a subscription request to the Logs API.

To subscribe to receive logs, you need the extension identifier (`Lambda-Extension-Identifier`). First [register the extension](#) to receive the extension identifier. Then subscribe to the Logs API during [initialization](#). After the initialization phase completes, Lambda does not process subscription requests.

Note

Logs API subscription is idempotent. Duplicate subscribe requests do not result in duplicate subscriptions.

Memory usage

Memory usage increases linearly as the number of subscribers increases. Subscriptions consume memory resources because each subscription opens a new memory buffer to store the logs. To help optimize memory usage, you can adjust the [buffering configuration](#). Buffer memory usage counts towards overall memory consumption in the execution environment.

Destination protocols

You can choose one of the following protocols to receive the logs:

1. **HTTP** (recommended) – Lambda delivers logs to a local HTTP endpoint (`http://sandbox.localdomain:${PORT}/${PATH}`) as an array of records in JSON format. The `$PATH` parameter is optional. Note that only HTTP is supported, not HTTPS. You can choose to receive logs through PUT or POST.
2. **TCP** – Lambda delivers logs to a TCP port in [Newline delimited JSON \(NDJSON\) format](#).

We recommend using HTTP rather than TCP. With TCP, the Lambda platform cannot acknowledge when it delivers logs to the application layer. Therefore, you might lose logs if your extension crashes. HTTP does not share this limitation.

We also recommend setting up the local HTTP listener or the TCP port before subscribing to receive logs. During setup, note the following:

- Lambda sends logs only to destinations that are inside the execution environment.
- Lambda retries the attempt to send the logs (with backoff) if there is no listener, or if the POST or PUT request results in an error. If the log subscriber crashes, it continues to receive logs after Lambda restarts the execution environment.
- Lambda reserves port 9001. There are no other port number restrictions or recommendations.

Buffering configuration

Lambda can buffer logs and deliver them to the subscriber. You can configure this behavior in the subscription request by specifying the following optional fields. Note that Lambda uses the default value for any field that you do not specify.

- **timeoutMs** – The maximum time (in milliseconds) to buffer a batch. Default: 1,000. Minimum: 25. Maximum: 30,000.
- **maxBytes** – The maximum size (in bytes) of the logs to buffer in memory. Default: 262,144. Minimum: 262,144. Maximum: 1,048,576.
- **maxItems** – The maximum number of events to buffer in memory. Default: 10,000. Minimum: 1,000. Maximum: 10,000.

During buffering configuration, note the following points:

- Lambda flushes the logs if any of the input streams are closed, for example, if the runtime crashes.
- Each subscriber can specify a different buffering configuration in their subscription request.
- Consider the buffer size that you need for reading the data. Expect to receive payloads as large as $2 * \text{maxBytes} + \text{metadata}$, where `maxBytes` is configured in the subscribe request. For example, Lambda adds the following metadata bytes to each record:

```
{
  "time": "2020-08-20T12:31:32.123Z",
  "type": "function",
  "record": "Hello World"
}
```

- If the subscriber cannot process incoming logs quickly enough, Lambda might drop logs to keep memory utilization bounded. To indicate the number of dropped records, Lambda sends a `platform.logsDropped` log. For more information, see [the section called “Lambda: Not all of my function's logs appear”](#).

Example subscription

The following example shows a request to subscribe to the platform and function logs.

```
PUT http://${AWS_LAMBDA_RUNTIME_API}/2020-08-15/logs HTTP/1.1
```

```
{ "schemaVersion": "2020-08-15",
  "types": [
    "platform",
    "function"
  ],
  "buffering": {
    "maxItems": 1000,
    "maxBytes": 262144,
    "timeoutMs": 100
  },
  "destination": {
    "protocol": "HTTP",
    "URI": "http://sandbox.localdomain:8080/lambda_logs"
  }
}
```

If the request succeeds, the subscriber receives an HTTP 200 success response.

```
HTTP/1.1 200 OK
"OK"
```

Sample code for Logs API

For sample code showing how to send logs to a custom destination, see [Using AWS Lambda extensions to send logs to custom destinations](#) on the AWS Compute Blog.

For Python and Go code examples showing how to develop a basic Lambda extension and subscribe to the Logs API, see [AWS Lambda Extensions](#) on the AWS Samples GitHub repository. For more information about building a Lambda extension, see [the section called “Extensions API”](#).

Logs API reference

You can retrieve the Logs API endpoint from the `AWS_LAMBDA_RUNTIME_API` environment variable. To send an API request, use the prefix `2020-08-15/` before the API path. For example:

```
http://${AWS_LAMBDA_RUNTIME_API}/2020-08-15/logs
```

The OpenAPI specification for the Logs API version **2020-08-15** is available here: [logs-api-request.zip](#)

Subscribe

To subscribe to one or more of the log streams available in the Lambda execution environment, extensions send a Subscribe API request.

Path – /logs

Method – PUT

Body parameters

destination – See [the section called “Destination protocols”](#). Required: yes. Type: strings.

buffering – See [the section called “Buffering configuration”](#). Required: no. Type: strings.

types – An array of the types of logs to receive. Required: yes. Type: array of strings. Valid values: "platform", "function", "extension".

schemaVersion – Required: no. Default value: "2020-08-15". Set to "2021-03-18" for the extension to receive [platform.runtimeDone](#) messages.

Response parameters

The OpenAPI specifications for the subscription responses version **2020-08-15** are available for the HTTP and TCP protocols:

- HTTP: [logs-api-http-response.zip](#)
- TCP: [logs-api-tcp-response.zip](#)

Response codes

- 200 – Request completed successfully
- 202 – Request accepted. Response to a subscription request during local testing.
- 4XX – Bad Request
- 500 – Service error

If the request succeeds, the subscriber receives an HTTP 200 success response.

```
HTTP/1.1 200 OK
"OK"
```

If the request fails, the subscriber receives an error response. For example:

```
HTTP/1.1 400 OK
{
  "errorType": "Logs.ValidationError",
  "errorMessage": "URI port is not provided; types should not be empty"
}
```

Log messages

The Logs API allows extensions to subscribe to three different logs streams:

- Function – Logs that the Lambda function generates and writes to `stdout` or `stderr`.
- Extension – Logs that extension code generates.
- Platform – Logs that the runtime platform generates, which record events and errors related to invocations and extensions.

Topics

- [Function logs](#)
- [Extension logs](#)
- [Platform logs](#)

Function logs

The Lambda function and internal extensions generate function logs and write them to `stdout` or `stderr`.

The following example shows the format of a function log message. { "time": "2020-08-20T12:31:32.123Z", "type": "function", "record": "ERROR encountered. Stack trace:\n\nmy-function (line 10)\n" }

Extension logs

Extensions can generate extension logs. The log format is the same as for a function log.

Platform logs

Lambda generates log messages for platform events such as `platform.start`, `platform.end`, and `platform.fault`.

Optionally, you can subscribe to the **2021-03-18** version of the Logs API schema, which includes the `platform.runtimeDone` log message.

Example platform log messages

The following example shows the platform start and platform end logs. These logs indicate the invocation start time and invocation end time for the invocation that the `requestId` specifies.

```
{
  "time": "2020-08-20T12:31:32.123Z",
  "type": "platform.start",
  "record": {"requestId": "6f7f0961f83442118a7af6fe80b88d56"}
}
{
  "time": "2020-08-20T12:31:32.123Z",
  "type": "platform.end",
  "record": {"requestId": "6f7f0961f83442118a7af6fe80b88d56"}
}
```

The **platform.initRuntimeDone** log message shows the status of the `Runtime init` sub-phase, which is part of the [Init lifecycle phase](#). When `Runtime init` is successful, the runtime sends a /next runtime API request (for the on-demand and provisioned-concurrency initialization types) or `restore/next` (for the snap-start initialization type). The following example shows a successful **platform.initRuntimeDone** log message for the snap-start initialization type.

```
{
  "time": "2022-07-17T18:41:57.083Z",
  "type": "platform.initRuntimeDone",
  "record": {
    "initializationType": "snap-start",
    "status": "success"
  }
}
```

The **platform.initReport** log message shows how long the `Init` phase lasted and how many milliseconds you were billed for during this phase. When the initialization type is provisioned-concurrency, Lambda sends this message during invocation. When the initialization type is snap-start, Lambda sends this message after restoring the snapshot. The following example shows a **platform.initReport** log message for the snap-start initialization type.

```
{
```

```
"time": "2022-07-17T18:41:57.083Z",
"type": "platform.initReport",
"record": {
  "initializationType": "snap-start",
  "metrics": {
    "durationMs": 731.79,
    "billedDurationMs": 732
  }
}
```

The platform report log includes metrics about the invocation that the `requestId` specifies. The `initDurationMs` field is included in the log only if the invocation included a cold start. If AWS X-Ray tracing is active, the log includes X-Ray metadata. The following example shows a platform report log for an invocation that included a cold start.

```
{
  "time": "2020-08-20T12:31:32.123Z",
  "type": "platform.report",
  "record": { "requestId": "6f7f0961f83442118a7af6fe80b88d56",
    "metrics": { "durationMs": 101.51,
      "billedDurationMs": 300,
      "memorySizeMB": 512,
      "maxMemoryUsedMB": 33,
      "initDurationMs": 116.67
    }
  }
}
```

The platform fault log captures runtime or execution environment errors. The following example shows a platform fault log message.

```
{
  "time": "2020-08-20T12:31:32.123Z",
  "type": "platform.fault",
  "record": "RequestId: d783b35e-a91d-4251-af17-035953428a2c Process exited before completing request"
}
```

Note

AWS is currently implementing changes to the Lambda service. Due to these changes, you may see minor differences between the structure and content of system log messages and trace segments emitted by different Lambda functions in your AWS account.

One of the log outputs affected by this change is the platform fault log "record" field. The following examples show illustrative "record" fields in the old and new formats. The new style of fault log contains a more concise message

These changes will be implemented during the coming weeks, and all functions in all AWS Regions except the China and GovCloud regions will transition to use the new-format log messages and trace segments.

Example platform fault log record (old style)

```
"record": "RequestId: ... \tError: Runtime exited with error: exit status
255\nRuntime.ExitError"
```

Example platform fault log record (new style)

```
"record": "RequestId: ... Status: error \tErrorType: Runtime.ExitError"
```

Lambda generates a platform extension log when an extension registers with the extensions API. The following example shows a platform extension message.

```
{
  "time": "2020-08-20T12:31:32.123Z",
  "type": "platform.extension",
  "record": { "name": "Foo.bar",
    "state": "Ready",
    "events": ["INVOKE", "SHUTDOWN"]
  }
}
```

Lambda generates a platform logs subscription log when an extension subscribes to the logs API. The following example shows a logs subscription message.

```
{
```

```
{
  "time": "2020-08-20T12:31:32.123Z",
  "type": "platform.logsSubscription",
  "record": {"name": "Foo.bar",
    "state": "Subscribed",
    "types": ["function", "platform"]},
}
```

Lambda generates a platform logs dropped log when an extension is not able to process the number of logs that it is receiving. The following example shows a `platform.logsDropped` log message.

```
{
  "time": "2020-08-20T12:31:32.123Z",
  "type": "platform.logsDropped",
  "record": {"reason": "Consumer seems to have fallen behind as it has not
acknowledged receipt of logs.",
    "droppedRecords": 123,
    "droppedBytes": 12345},
}
```

The **platform.restoreStart** log message shows the time that the Restore phase started (snap-start initialization type only). Example:

```
{
  "time": "2022-07-17T18:43:44.782Z",
  "type": "platform.restoreStart",
  "record": {}
}
```

The **platform.restoreReport** log message shows how long the Restore phase lasted and how many milliseconds you were billed for during this phase (snap-start initialization type only). Example:

```
{
  "time": "2022-07-17T18:43:45.936Z",
  "type": "platform.restoreReport",
  "record": {
    "metrics": {
      "durationMs": 70.87,

```

```
        "billedDurationMs":13
    }
}
```

Platform runtimeDone messages

If you set the schema version to "2021-03-18" in the subscribe request, Lambda sends a `platform.runtimeDone` message after the function invocation completes either successfully or with an error. The extension can use this message to stop all the telemetry collection for this function invocation.

The OpenAPI specification for the Log event type in schema version **2021-03-18** is available here: [schema-2021-03-18.zip](#)

Lambda generates the `platform.runtimeDone` log message when the runtime sends a Next or Error runtime API request. The `platform.runtimeDone` log informs consumers of the Logs API that the function invocation completes. Extensions can use this information to decide when to send all the telemetry collected during that invocation.

Examples

Lambda sends the `platform.runtimeDone` message after the runtime sends the NEXT request when the function invocation completes. The following examples show messages for each of the status values: success, failure, and timeout.

Example success message

```
{
  "time": "2021-02-04T20:00:05.123Z",
  "type": "platform.runtimeDone",
  "record": {
    "requestId": "6f7f0961f83442118a7af6fe80b88",
    "status": "success"
  }
}
```

Example failure message

```
{
  "time": "2021-02-04T20:00:05.123Z",
```

```
"type": "platform.runtimeDone",
"record": {
  "requestId": "6f7f0961f83442118a7af6fe80b88",
  "status": "failure"
}
}
```

Example timeout message

```
{
  "time": "2021-02-04T20:00:05.123Z",
  "type": "platform.runtimeDone",
  "record": {
    "requestId": "6f7f0961f83442118a7af6fe80b88",
    "status": "timeout"
  }
}
```

Example platform.restoreRuntimeDone message (snap-start initialization type only)

The **platform.restoreRuntimeDone** log message shows whether or not the Restore phase was successful. Lambda sends this message when the runtime sends a `restore/next` runtime API request. There are three possible statuses: success, failure, and timeout. The following example shows a successful **platform.restoreRuntimeDone** log message.

```
{
  "time": "2022-07-17T18:43:45.936Z",
  "type": "platform.restoreRuntimeDone",
  "record": {
    "status": "success"
  }
}
```

Troubleshooting issues in Lambda

The following topics provide troubleshooting advice for errors and issues that you might encounter when using the Lambda API, console, or tools. If you find an issue that is not listed here, you can use the **Feedback** button on this page to report it.

For more troubleshooting advice and answers to common support questions, visit the [AWS Knowledge Center](#).

For more information about debugging and troubleshooting Lambda applications, see [Debugging](#) in Serverless Land.

Topics

- [Troubleshoot configuration issues in Lambda](#)
- [Troubleshoot deployment issues in Lambda](#)
- [Troubleshoot invocation issues in Lambda](#)

Troubleshoot configuration issues in Lambda

Your function configuration settings can have an impact on the overall performance and behavior of your Lambda function. These may not cause actual function errors, but can cause unexpected timeouts and results.

The following topics provide troubleshooting advice for common issues that you might encounter related to Lambda function configuration settings.

Topics

- [Memory configurations](#)
- [CPU-bound configurations](#)
- [Timeouts](#)
- [Memory leakage between invocations](#)
- [Asynchronous results returned to a later invocation](#)

Memory configurations

You can configure a Lambda function to use between 128 MB and 10,240 MB of memory. By default, any function created in the console is assigned the smallest amount of memory. Many Lambda functions are performant at this lowest setting. However, if you are importing large code libraries or completing memory intensive tasks, 128 MB is not sufficient.

If your functions are running much slower than expected, the first step is to increase the memory setting. For memory-bound functions, this will resolve the bottleneck and may improve the performance of your function.

CPU-bound configurations

For compute-intensive operations, if your function experiences slower-than-expected performance, this may be due to your function being CPU-bound. In this case, the computational capacity of the function cannot keep pace with the work.

While Lambda doesn't allow you to modify CPU configuration directly, CPU is indirectly controlled via the memory settings. The Lambda service proportionally allocates more virtual CPU as you allocate more memory. At 1.8 GB memory, a Lambda function has an entire vCPU allocated, and above this level it has access to more than one vCPU core. At 10,240MB, it has 6 vCPUs available. In other words, you can improve performance by increasing the memory allocation, even if the function doesn't use all of the memory.

Timeouts

[Timeouts](#) for Lambda functions can be set between 1 and 900 seconds (15 minutes). By default, the Lambda console sets this to 3 seconds. The timeout value is a safety valve that ensures functions do not run indefinitely. After the timeout value is reached, Lambda stops the function invocation.

If a timeout value is set close to the average duration of a function, this increases the risk that the function will time out unexpectedly. The duration of a function can vary based on the amount of data transfer and processing, and the latency of any services the function interacts with. Common causes of timeout include:

- When downloading data from S3 buckets or other data stores, the download is larger or takes longer than average.

- A function makes a request to another service, which takes longer to respond.
- The parameters provided to a function require more computational complexity in the function, which causes the invocation to take longer.

When testing your application, ensure that your tests accurately reflect the size and quantity of data, and realistic parameter values. Importantly, use datasets at the upper bounds of what is reasonably expected for your workload.

Additionally, implement upper-bound limits in your workload wherever practical. In this example, the application could use a maximum size limit for each file type. You can then test the performance of your application for a range of expected file sizes, up to and including the maximum limits.

Memory leakage between invocations

Global variables and objects stored in the INIT phase of a Lambda invocation retain their state between warm invocations. They are completely reset only when the execution environment is run for the first time (also known as a “cold start”). Any variables stored in the handler are destroyed when the handler exits. It’s best practice to use the INIT phase to set up database connections, load libraries, create caches, and load immutable assets.

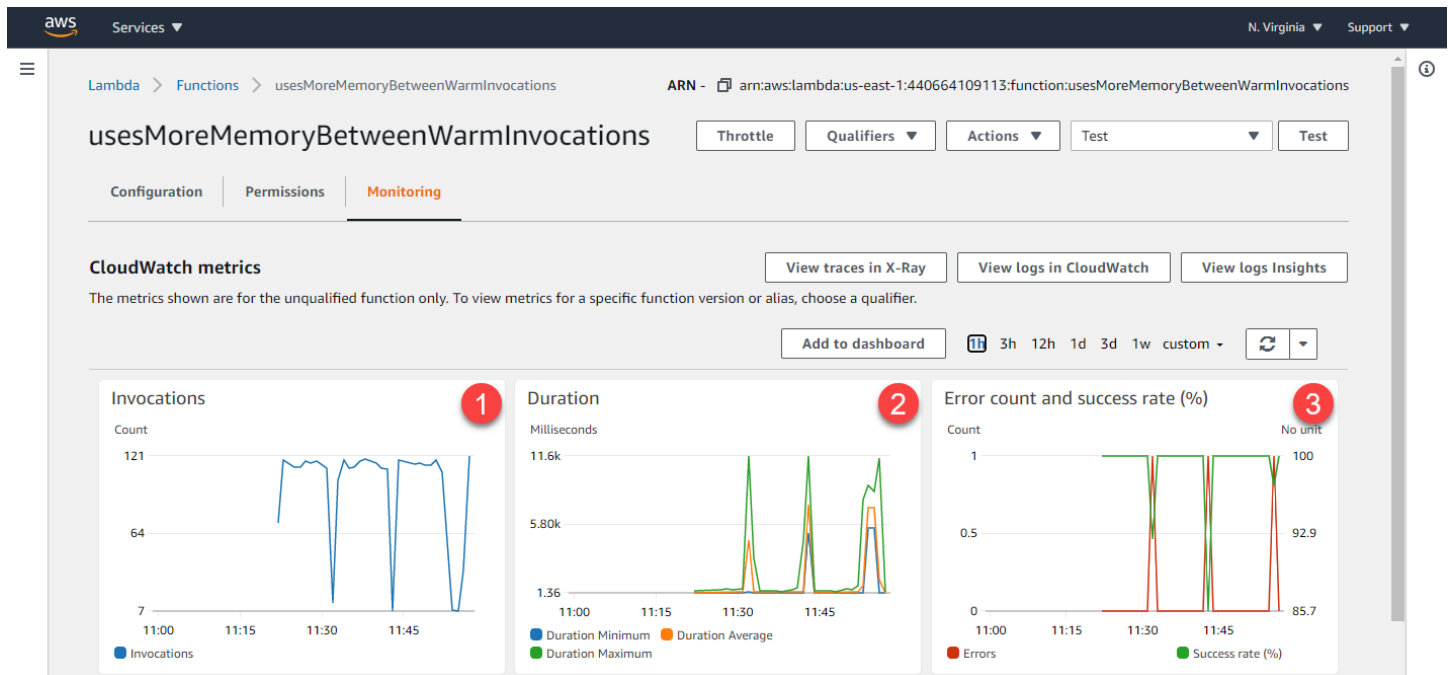

When you use third-party libraries across multiple invocations in the same execution environment, check their documentation for usage in a serverless compute environment. Some database connection and logging libraries may save intermediate invocation results and other data. This causes the memory usage of these libraries to grow with subsequent warm invocations. If this is the case, you may find the Lambda function runs out of memory, even if your custom code is disposing of variables correctly.

This issue affects invocations occurring in warm execution environments. For example, the following code creates a memory leak between invocations. The Lambda function consumes additional memory with each invocation by increasing the size of a global array:

```
let a = []

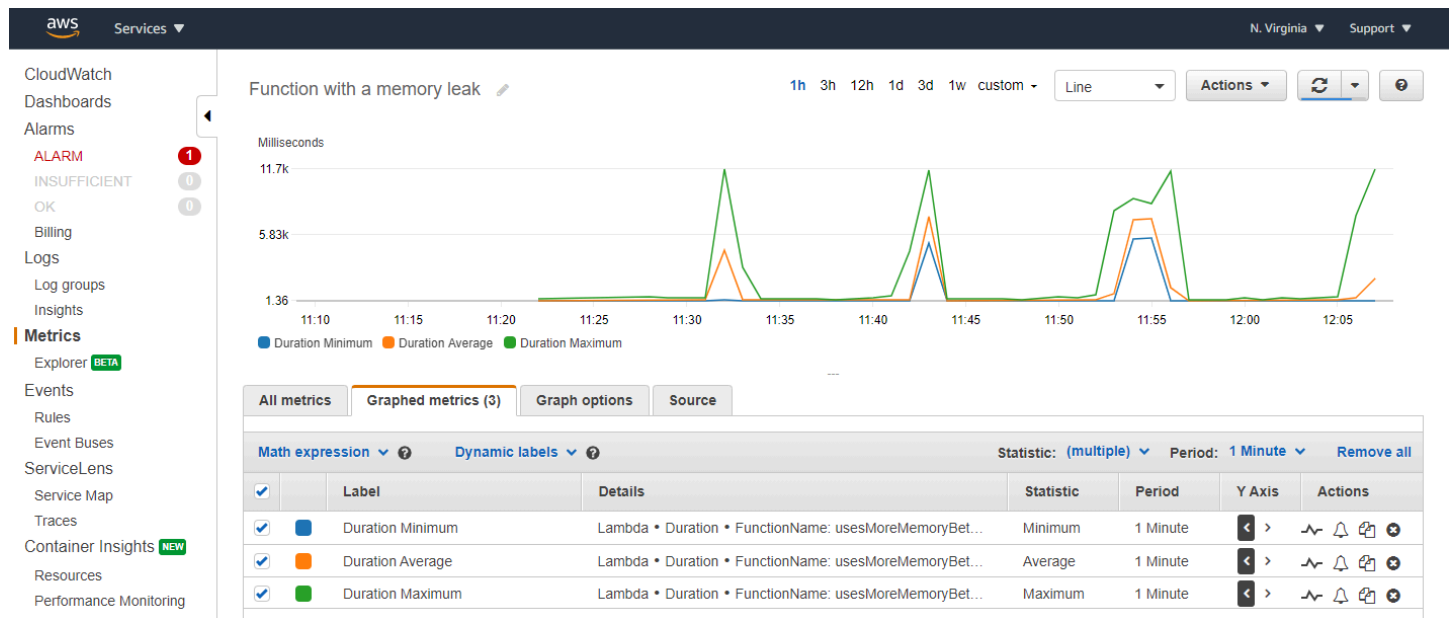

exports.handler = async (event) => {
  a.push(Array(100000).fill(1))
}
```

Configured with 128 MB of memory, after invoking this function 1000 times, the **Monitoring** tab of the Lambda function shows the typical changes in invocations, duration, and error counts when a memory leak occurs:

- 1. Invocations** – A steady transaction rate is interrupted periodically as the invocations take longer to complete. During the steady state, the memory leak is not consuming all of the function's allocated memory. As performance degrades, the operating system is paging local storage to accommodate the growing memory required by the function, which results in fewer transactions being completed.
- 2. Duration** – Before the function runs out of memory, it finishes invocations at a steady double-digit millisecond rate. As paging occurs, the duration takes an order of magnitude longer.
- 3. Error count** – As the memory leak exceeds allocated memory, eventually the function errors due to the computation exceeding the timeout, or the execution environment stops the function.

After the error, Lambda restarts the execution environment, which explains why all three graphs show a return to the original state. Expanding the CloudWatch metrics for duration provides more detail for the minimum, maximum and average duration statistics:

To find the errors generated across the 1000 invocations, you can use the CloudWatch Insights query language. The following query excludes informational logs to report only the errors:

```
fields @timestamp, @message
| sort @timestamp desc
| filter @message not like 'EXTENSION'
| filter @message not like 'Lambda Insights'
| filter @message not like 'INFO'
| filter @message not like 'REPORT'
| filter @message not like 'END'
| filter @message not like 'START'
```

When run against the log group for this function, this shows that timeouts were responsible for the periodic errors:

The screenshot shows the AWS CloudWatch Logs Insights interface. The left sidebar contains navigation options like CloudWatch, Dashboards, Alarms, and Insights. The main panel displays a query for the log group `/aws/lambda/usesMoreMemoryBetweenWarmInvocations`. The query is as follows:

```
1 fields @timestamp, @message
2 | sort @timestamp desc
3 | filter @message not like 'EXTENSION'
4 | filter @message not like 'Lambda Insights'
5 | filter @message not like 'INFO'
6 | filter @message not like 'REPORT'
7 | filter @message not like 'END'
8 | filter @message not like 'START'
9 | limit 20
```

The results section shows a histogram and a table of logs. The table has columns for record number, timestamp, and message. The first four records are highlighted with a red box, showing task timeouts:

#	@timestamp	@message
1	2020-10-14T08:07:46.36...	2020-10-14T12:07:46.361Z 1917d63d-ccf5-4547-987a-1fecb469447f Task timed out after 11.65 seconds
2	2020-10-14T07:56:39.57...	2020-10-14T11:56:39.579Z 1a00b31d-86cb-42e6-b916-eb57c3d3b69a Task timed out after 11.45 seconds
3	2020-10-14T07:44:00.65...	2020-10-14T11:44:00.652Z 43644f33-8dec-4cea-87c5-a92a8c2da8cf Task timed out after 11.56 seconds
4	2020-10-14T07:33:05.92...	2020-10-14T11:33:05.929Z abab510c-92a3-4b69-8be7-a62b23876418 Task timed out after 11.61 seconds

Asynchronous results returned to a later invocation

For function code that uses asynchronous patterns, it's possible for the callback results from one invocation to be returned in a future invocation. This example uses Node.js, but the same logic can apply to other runtimes using asynchronous patterns. The function uses the traditional callback syntax in JavaScript. It calls an asynchronous function with an incremental counter that tracks the number of invocations:

```
let seqId = 0

exports.handler = async (event, context) => {
  console.log(`Starting: sequence Id=${++seqId}`)
  doWork(seqId, function(id) {
    console.log(`Work done: sequence Id=${id}`)
  })
}

function doWork(id, callback) {
  setTimeout(() => callback(id), 3000)
```

}

When invoked several times in succession, the results of the callbacks occur in subsequent invocations:

The screenshot displays the AWS Lambda console interface for a function named 'delayedAsyncReturn'. The function code in `index.js` is as follows:

```

1 let seqId = 0
2
3 exports.handler = async (event) => {
4   console.log(`Starting: sequence Id=${++seqId}`)
5   doWork(seqId, function(id) {
6     console.log(`Work done: sequence Id=${id}`)
7   })
8 }
9
10 function doWork(id, callback) {
11   setTimeout(() => callback(id), 3000)
12 }

```

The execution results show a 'Succeeded' status with a response of 'null'. The logs indicate three sequential invocations, with the third invocation's logs appearing first, demonstrating the event loop behavior:

```

Function logs:
START RequestId: 6afdf887-424a-4ec6-b622-3ffc07eebb64 Version: $LATEST
2020-10-13T19:22:38.586Z 6afdf887-424a-4ec6-b622-3ffc07eebb64 INFO Starting: sequence Id=5
2020-10-13T19:22:38.587Z 6afdf887-424a-4ec6-b622-3ffc07eebb64 INFO Work done: sequence Id=2
2020-10-13T19:22:38.587Z 6afdf887-424a-4ec6-b622-3ffc07eebb64 INFO Work done: sequence Id=3
END RequestId: 6afdf887-424a-4ec6-b622-3ffc07eebb64
REPORT RequestId: 6afdf887-424a-4ec6-b622-3ffc07eebb64 Duration: 1.54 ms Billed Duration: 100 ms Memory Size: 128 MB Max Memory Used: 64 MB

```

1. The code calls the `doWork` function, providing a callback function as the last parameter.
2. The `doWork` function takes some period of time to complete before invoking the callback.
3. The function's logging indicates that the invocation is ending before the `doWork` function finishes execution. Additionally, after starting an iteration, callbacks from previous iterations are being processed, as shown in the logs.

In JavaScript, asynchronous callbacks are handled with an [event loop](#). Other runtimes use different mechanisms to handle concurrency. When the function's execution environment ends, Lambda freezes the environment until the next invocation. After it resumes, JavaScript continues processing the event loop, which in this case includes an asynchronous callback from a previous invocation. Without this context, it can appear that the function is running code for no reason, and returning arbitrary data. In fact, it is really an artifact of how runtime concurrency and the execution environments interact.

This creates the potential for private data from a previous invocation to appear in a subsequent invocation. There are two ways to prevent or detect this behavior. First, JavaScript provides the

[async and await keywords](#) to simplify asynchronous development and also force code execution to wait for an asynchronous call to complete. The function above can be rewritten using this approach as follows:

```
let seqId = 0
exports.handler = async (event) => {
    console.log(`Starting: sequence Id=${++seqId}`)
    const result = await doWork(seqId)
    console.log(`Work done: sequence Id=${result}`)
}

function doWork(id) {
    return new Promise(resolve => {
        setTimeout(() => resolve(id), 4000)
    })
}
```

Using this syntax prevents the handler from exiting before the asynchronous function is finished. In this case, if the callback takes longer than the Lambda function's timeout, the function will throw an error, instead of returning the callback result in a later invocation:

The screenshot displays the AWS Lambda console interface. The top section shows the function code for `es6-js.js` and `index.js`. The code is as follows:

```
1 let seqId = 0
2
3 exports.handler = async (event) => {
4     console.log(`Starting: sequence Id=${++seqId}`)
5     const result = await doWork(seqId)
6     console.log(`Work done: sequence Id=${result}`)
7 }
8
9 function doWork(id) {
10     return new Promise(resolve => {
11         setTimeout(() => resolve(id), 4000)
12     })
13 }
```

Red circles 1 and 2 highlight the `await doWork(seqId)` line in the handler and the `setTimeout` call in the `doWork` function, respectively.

The bottom section shows the execution results. The status is **Failed**. The error message is: "Task timed out after 3.00 seconds". The request ID is "0d4a1340-e9ce-47c2-8034-e35ec9cb1c9b". The function logs show the execution details, including the start and end times, the sequence ID, and the timeout error.

Red circle 3 highlights the error message in the execution results.

1. The code calls the asynchronous `doWork` function using the `await` keyword in the handler.

2. The `doWork` function takes some period of time to complete before resolving the promise.
3. The function times out because `doWork` takes longer than the timeout limit allows and the callback result is not returned in a later invocation.

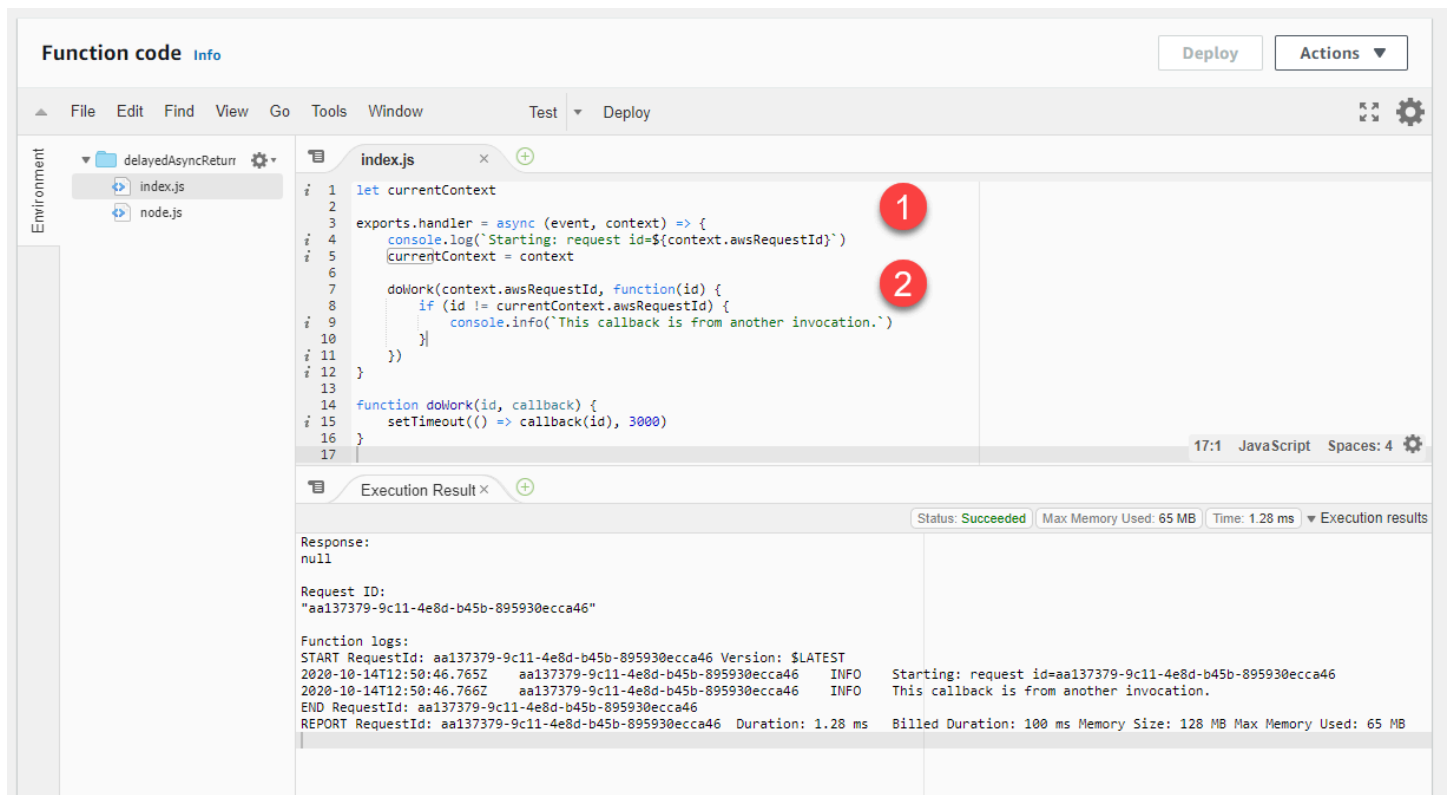

Generally, you should make sure any background processes or callbacks in the code are complete before the code exits. If this is not possible in your use case, you can use an identifier to ensure that the callback belongs to the current invocation. To do this, you can use the *`awsRequestId`* provided by the context object. By passing this value to the asynchronous callback, you can compare the passed value with the current value to detect if the callback originated from another invocation:

```
let currentContext

exports.handler = async (event, context) => {
  console.log(`Starting: request id=${context.awsRequestId}`)
  currentContext = context

  doWork(context.awsRequestId, function(id) {
    if (id !== currentContext.awsRequestId) {
      console.info(`This callback is from another invocation.`)
    }
  })
}

function doWork(id, callback) {
  setTimeout(() => callback(id), 3000)
}
```

1. The Lambda function handler takes the context parameter, which provides access to a unique invocation request ID.
2. The `awsRequestId` is passed to the `doWork` function. In the callback, the ID is compared with the `awsRequestId` of the current invocation. If these values are different, the code can take action accordingly.

Troubleshoot deployment issues in Lambda

When you update your function, Lambda deploys the change by launching new instances of the function with the updated code or settings. Deployment errors prevent the new version from being used and can arise from issues with your deployment package, code, permissions, or tools.

When you deploy updates to your function directly with the Lambda API or with a client such as the AWS CLI, you can see errors from Lambda directly in the output. If you use services like AWS CloudFormation, AWS CodeDeploy, or AWS CodePipeline, look for the response from Lambda in the logs or event stream for that service.

The following topics provide troubleshooting advice for errors and issues that you might encounter when using the Lambda API, console, or tools. If you find an issue that is not listed here, you can use the **Feedback** button on this page to report it.

For more troubleshooting advice and answers to common support questions, visit the [AWS Knowledge Center](#).

For more information about debugging and troubleshooting Lambda applications, see [Debugging](#) in Serverless Land.

Topics

- [General: Permission is denied / Cannot load such file](#)

General: Permission is denied / Cannot load such file

Error: *EACCES: permission denied, open '/var/task/index.js'*

Error: *cannot load such file -- function*

Error: *[Errno 13] Permission denied: '/var/task/function.py'*

The Lambda runtime needs permission to read the files in your deployment package. In Linux permissions octal notation, Lambda needs 644 permissions for non-executable files (rw-r--r--) and 755 permissions (rwxr-xr-x) for directories and executable files.

In Linux and MacOS, use the `chmod` command to change file permissions on files and directories in your deployment package. For example, to give a non-executable file the correct permissions, run the following command.

```
chmod 644 <filepath>
```

To change file permissions in Windows, see [Set, View, Change, or Remove Permissions on an Object](#) in the Microsoft Windows documentation.

Note

If you don't grant Lambda the permissions it needs to access directories in your deployment package, Lambda sets the permissions for those directories to 755 (rwxr-xr-x).

General: Error occurs when calling the UpdateFunctionCode

Error: *An error occurred (RequestEntityTooLargeException) when calling the UpdateFunctionCode operation*

When you upload a deployment package or layer archive directly to Lambda, the size of the ZIP file is limited to 50 MB. To upload a larger file, store it in Amazon S3 and use the `S3Bucket` and `S3Key` parameters.

Note

When you upload a file directly with the AWS CLI, AWS SDK, or otherwise, the binary ZIP file is converted to base64, which increases its size by about 30%. To allow for this, and the size of other parameters in the request, the actual request size limit that Lambda applies is larger. Due to this, the 50 MB limit is approximate.

Amazon S3: Error Code PermanentRedirect.

Error: *Error occurred while GetObject. S3 Error Code: PermanentRedirect. S3 Error Message: The bucket is in this region: us-east-2. Please use this region to retry the request*

When you upload a function's deployment package from an Amazon S3 bucket, the bucket must be in the same Region as the function. This issue can occur when you specify an Amazon S3 object in a

call to [UpdateFunctionCode](#), or use the package and deploy commands in the AWS CLI or AWS SAM CLI. Create a deployment artifact bucket for each Region where you develop applications.

General: Cannot find, cannot load, unable to import, class not found, no such file or directory

Error: *Cannot find module 'function'*

Error: *cannot load such file -- function*

Error: *Unable to import module 'function'*

Error: *Class not found: function.Handler*

Error: *fork/exec /var/task/function: no such file or directory*

Error: *Unable to load type 'Function.Handler' from assembly 'Function'.*

The name of the file or class in your function's handler configuration doesn't match your code. See the following section for more information.

General: Undefined method handler

Error: *index.handler is undefined or not exported*

Error: *Handler 'handler' missing on module 'function'*

Error: *undefined method `handler' for #<LambdaHandler:0x000055b76cceb9f8>*

Error: *No public method named handleRequest with appropriate method signature found on class function.Handler*

Error: *Unable to find method 'handleRequest' in type 'Function.Handler' from assembly 'Function'*

The name of the handler method in your function's handler configuration doesn't match your code. Each runtime defines a naming convention for handlers, such as *filename.methodname*. The handler is the method in your function's code that the runtime runs when your function is invoked.

For some languages, Lambda provides a library with an interface that expects a handler method to have a specific name. For details about handler naming for each language, see the following topics.

- [Building Lambda functions with Node.js](#)

- [Building Lambda functions with Python](#)
- [Building Lambda functions with Ruby](#)
- [Building Lambda functions with Java](#)
- [Building Lambda functions with Go](#)
- [Building Lambda functions with C#](#)
- [Building Lambda functions with PowerShell](#)

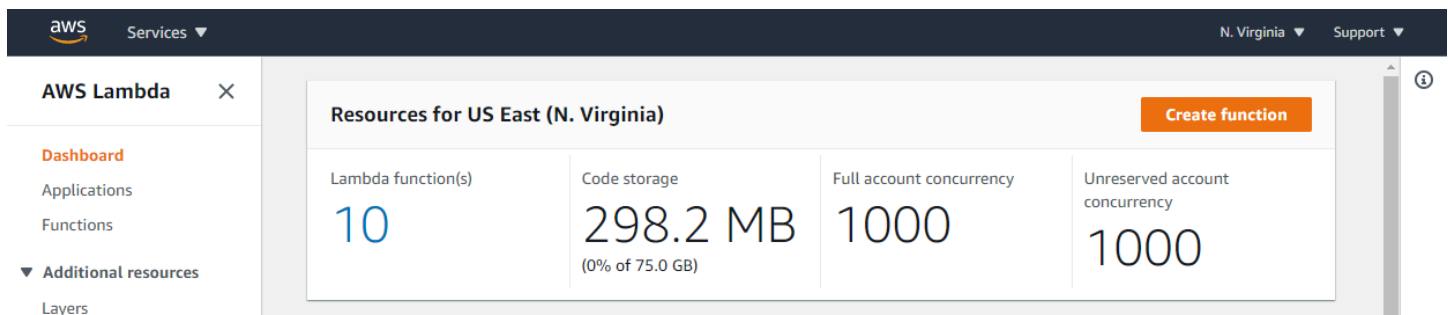

General: Lambda code storage limit exceeded

Error: *Code storage limit exceeded.*

Lambda stores your function code in an internal S3 bucket that's private to your account. Each AWS account is allocated 75 GB of storage in each Region. Code storage includes the total storage used by both Lambda functions and layers. If you reach the quota, you receive a *CodeStorageExceededException* when you attempt to deploy new functions.

Manage the storage space available by cleaning up old versions of functions, removing unused code, or using Lambda layers. In addition, it's good practice to [use separate AWS accounts for separate workloads](#) to help manage storage quotas.

You can view your total storage usage in the Lambda console, under the **Dashboard** submenu:

Lambda: Layer conversion failed

Error: *Lambda layer conversion failed. For advice on resolving this issue, see the Troubleshoot deployment issues in Lambda page in the Lambda User Guide.*

When you configure a Lambda function with a layer, Lambda merges the layer with your function code. If this process fails to complete, Lambda returns this error. If you encounter this error, take the following steps:

- Delete any unused files from your layer
- Delete any symbolic links in your layer
- Rename any files that have the same name as a directory in any of your function's layers

Lambda: InvalidParameterValueException or RequestEntityTooLargeException

Error: *InvalidParameterValueException: Lambda was unable to configure your environment variables because the environment variables you have provided exceeded the 4KB limit. String measured: {"A1":"uSFeY5cyPiPn7AtnX5BsM...*

Error: *RequestEntityTooLargeException: Request must be smaller than 5120 bytes for the UpdateFunctionConfiguration operation*

The maximum size of the variables object that is stored in the function's configuration must not exceed 4096 bytes. This includes key names, values, quotes, commas, and brackets. The total size of the HTTP request body is also limited.

```
{
  "FunctionName": "my-function",
  "FunctionArn": "arn:aws:lambda:us-east-2:123456789012:function:my-function",
  "Runtime": "nodejs24.x",
  "Role": "arn:aws:iam::123456789012:role/lambda-role",
  "Environment": {
    "Variables": {
      "BUCKET": "amzn-s3-demo-bucket",
      "KEY": "file.txt"
    }
  },
  ...
}
```

In this example, the object is 39 characters and takes up 39 bytes when it's stored (without white space) as the string `{"BUCKET": "amzn-s3-demo-bucket", "KEY": "file.txt"}`. Standard ASCII characters in environment variable values use one byte each. Extended ASCII and Unicode characters can use between 2 bytes and 4 bytes per character.

Lambda: InvalidParameterValueException

Error: *InvalidParameterValueException: Lambda was unable to configure your environment variables because the environment variables you have provided contains reserved keys that are currently not supported for modification.*

Lambda reserves some environment variable keys for internal use. For example, `AWS_REGION` is used by the runtime to determine the current Region and cannot be overridden. Other variables, like `PATH`, are used by the runtime but can be extended in your function configuration. For a full list, see [Defined runtime environment variables](#).

Lambda: Concurrency and memory quotas

Error: *Specified ConcurrentExecutions for function decreases account's UnreservedConcurrentExecution below its minimum value*

Error: *'MemorySize' value failed to satisfy constraint: Member must have value less than or equal to 3008*

These errors occur when you exceed the concurrency or memory [quotas](#) for your account. New AWS accounts have reduced concurrency and memory quotas. To resolve errors related to concurrency, you can [request a quota increase](#). You cannot request memory quota increases.

- **Concurrency:** You might get an error if you try to create a function using reserved or provisioned concurrency, or if your per-function concurrency request ([PutFunctionConcurrency](#)) exceeds your account's concurrency quota.
- **Memory:** Errors occur if the amount of memory allocated to the function exceeds your account's memory quota.

Lambda: Invalid alias configuration for provisioned concurrency

Error: *Invalid alias configuration for provisioned concurrency*

This error occurs when you try to update a Lambda function's code or configuration while an alias with provisioned concurrency is pointing to a version that has issues. Lambda pre-initializes execution environments for provisioned concurrency, and if these environments can't be properly initialized due to code errors, resource constraints, or affected stack and alias, the deployment fails. If you encounter this issue, take the following steps:

1. **Roll back the alias:** Temporarily update the alias to point to the previously working version.

```
aws lambda update-alias \  
  --function-name <function-name> \  
  --name <alias-name> \  
  --function-version <known-good-version>
```

2. **Fix Lambda initialization code:** Ensure the initialization code that runs outside the handler doesn't have any uncaught exceptions and initialize the clients and connections.
3. **Redeploy safety:** Deploy fixed code and publish a new version. Then, update alias to point to the fixed version. Optionally, re-enable [provisioned concurrency](#), if necessary.

If using AWS CloudFormation, update stack definition `FunctionVersion: !GetAtt version.Version` so that the alias points to the working version:

```
alias:  
  Type: AWS::Lambda::Alias  
  Properties:  
    FunctionName: !Ref function  
    FunctionVersion: !GetAtt version.Version  
    Name: BLUE  
    ProvisionedConcurrencyConfig:  
      ProvisionedConcurrentExecutions: 1
```

Troubleshoot invocation issues in Lambda

When you invoke a Lambda function, Lambda validates the request and checks for scaling capacity before sending the event to your function or, for asynchronous invocation, to the event queue. Invocation errors can be caused by issues with request parameters, event structure, function settings, user permissions, resource permissions, or limits.

If you invoke your function directly, you see any invocation errors in the response from Lambda. If you invoke your function asynchronously with an event source mapping or through another service, you might find errors in logs, a dead-letter queue, or a failed-event destination. Error handling options and retry behavior vary depending on how you invoke your function and on the type of error.

For a list of error types that the `Invoke` operation can return, see [Invoke](#).

Lambda: Function times out during Init phase (Sandbox.Timeout)

Error: *Task timed out after 3.00 seconds*

When the [Init](#) phase times out, Lambda initializes the execution environment again by re-running the Init phase when the next invoke request arrives. This is called a [suppressed init](#). However, if your function is configured with a short [timeout duration](#) (generally around 3 seconds), the suppressed init might not complete during the allocated timeout duration, causing the Init phase to time out again. Alternatively, the suppressed init completes but does not leave enough time for the [Invoke](#) phase to complete, causing the Invoke phase to time out.

To reduce timeout errors, use one or more of the following strategies:

- **Increase the function timeout duration:** Extend the [timeout](#) to give the Init and Invoke phases time to complete successfully.
- **Increase the function memory allocation:** More [memory](#) also means more proportional CPU allocation, which can speed up both the Init and Invoke phases.
- **Optimize the function initialization code:** Reduce the time needed for initialization to ensure that the the Init and Invoke phase can complete within the configured timeout.

IAM: lambda:InvokeFunction not authorized

Error: *User: arn:aws:iam::123456789012:user/developer is not authorized to perform: lambda:InvokeFunction on resource: my-function*

Your user, or the role that you assume, must have permission to invoke a function. This requirement also applies to Lambda functions and other compute resources that invoke functions. Add the AWS managed policy **AWSLambdaRole** to your user, or add a custom policy that allows the `lambda:InvokeFunction` action on the target function.

Note

The name of the IAM action (`lambda:InvokeFunction`) refers to the Invoke Lambda API operation.

For more information, see [Managing permissions in AWS Lambda](#).

Lambda: Couldn't find valid bootstrap (Runtime.InvalidEntrypoint)

Error: *Couldn't find valid bootstrap(s): [/var/task/bootstrap /opt/bootstrap]*

This error typically occurs when the root of your deployment package doesn't contain an executable file named `bootstrap`. For example, if you're deploying a provided.al2023 function with a .zip file, the `bootstrap` file must be at the root of the .zip file, not in a directory.

Lambda: Operation cannot be performed ResourceConflictException

Error: *ResourceConflictException: The operation cannot be performed at this time. The function is currently in the following state: Pending*

When you connect a function to a virtual private cloud (VPC) at the time of creation, the function enters a Pending state while Lambda creates elastic network interfaces. During this time, you can't invoke or modify your function. If you connect your function to a VPC after creation, you can invoke it while the update is pending, but you can't modify its code or configuration.

For more information, see [Lambda function states](#) .

Lambda: Function is stuck in Pending

Error: *A function is stuck in the Pending state for several minutes.*

If a function is stuck in the Pending state for more than six minutes, call one of the following API operations to unblock it:

- [UpdateFunctionCode](#)
- [UpdateFunctionConfiguration](#)
- [PublishVersion](#)

Lambda cancels the pending operation and puts the function into the Failed state. You can then attempt another update.

Lambda: One function is using all concurrency

Issue: *One function is using all of the available concurrency, causing other functions to be throttled.*

To divide your AWS account's available concurrency in an AWS Region into pools, use [reserved concurrency](#). Reserved concurrency ensures that a function can always scale to its assigned concurrency, and that it doesn't scale beyond its assigned concurrency.

General: Cannot invoke function with other accounts or services

Issue: *You can invoke your function directly, but it doesn't run when another service or account invokes it.*

You grant [other services](#) and accounts permission to invoke a function in the function's [resource-based policy](#). If the invoker is in another account, that user must also have [permission to invoke functions](#).

General: Function invocation is looping

Issue: *Function is invoked continuously in a loop.*

This typically occurs when your function manages resources in the same AWS service that triggers it. For example, it's possible to create a function that stores an object in an Amazon Simple Storage Service (Amazon S3) bucket that's configured with a [notification that invokes the function again](#). To stop the function from running, reduce the available [concurrency](#) to zero, which throttles all future invocations. Then, identify the code path or configuration error that caused the recursive invocation. Lambda automatically detects and stops recursive loops for some AWS services and SDKs. For more information, see [the section called "Recursive loop detection"](#).

Lambda: Alias routing with provisioned concurrency

Issue: *Provisioned concurrency spillover invocations during alias routing.*

Lambda uses a simple probabilistic model to distribute the traffic between the two function versions. At low traffic levels, you might see a high variance between the configured and actual percentage of traffic on each version. If your function uses provisioned concurrency, you can avoid [spillover invocations](#) by configuring a higher number of provisioned concurrency instances during the time that alias routing is active.

Lambda: Cold starts with provisioned concurrency

Issue: *You see cold starts after enabling provisioned concurrency.*

When the number of concurrent executions on a function is less than or equal to the [configured level of provisioned concurrency](#), there shouldn't be any cold starts. To help you confirm if provisioned concurrency is operating normally, do the following:

- [Check that provisioned concurrency is enabled](#) on the function version or alias.

Note

Provisioned concurrency is not configurable on the unpublished [version of the function](#) (\$LATEST).

- Ensure that your triggers invoke the correct function version or alias. For example, if you're using Amazon API Gateway, check that API Gateway invokes the function version or alias with provisioned concurrency, not \$LATEST. To confirm that provisioned concurrency is being used,

you can check the [ProvisionedConcurrencyInvocations Amazon CloudWatch metric](#). A non-zero value indicates that the function is processing invocations on initialized execution environments.

- Determine whether your function concurrency exceeds the configured level of provisioned concurrency by checking the [ProvisionedConcurrencySpilloverInvocations CloudWatch metric](#). A non-zero value indicates that all provisioned concurrency is in use and some invocation occurred with a cold start.
- Check your [invocation frequency](#) (requests per second). Functions with provisioned concurrency have a maximum rate of 10 requests per second per provisioned concurrency. For example, a function configured with 100 provisioned concurrency can handle 1,000 requests per second. If the invocation rate exceeds 1,000 requests per second, some cold starts can occur.

Lambda: Cold starts with new versions

Issue: *You see cold starts while deploying new versions of your function.*

When you update a function alias, Lambda automatically shifts provisioned concurrency to the new version based on the weights configured on the alias.

Error: *KMSDisabledException: Lambda was unable to decrypt the environment variables because the KMS key used is disabled. Please check the function's KMS key settings.*

This error can occur if your AWS Key Management Service (AWS KMS) key is disabled, or if the grant that allows Lambda to use the key is revoked. If the grant is missing, configure the function to use a different key. Then, reassign the custom key to recreate the grant.

Lambda: Unexpected Node.js exit in runtime (Runtime.NodejsExit)

Issue: *Lambda runtime client detected an unexpected Node.js exit code.*

This error occurs when your function exits before all Promises are settled, for example due to a code bug. It can also occur when Node.js detects a deadlock that prevents Promises from being settled. This error affects only async style handlers, not callback-style handlers.

Affected runtimes: Node.js 18 and later.

To resolve this issue:

1. Check your function code for unsettled promises in async handlers.
2. Ensure all promises are properly settled (resolved or rejected) before the function completes.

3. Review your code for potential race conditions in asynchronous operations.

For more information about Node.js exit codes and process termination, see the [Node.js documentation](#).

EFS: Function could not mount the EFS file system

Error: *EFSMountFailureException: The function could not mount the EFS file system with access point arn:aws:elasticfilesystem:us-east-2:123456789012:access-point/fsap-015cxmplb72b405fd.*

The mount request to the function's [file system](#) was rejected. Check the function's permissions, and confirm that its file system and access point exist and are ready for use.

EFS: Function could not connect to the EFS file system

Error: *EFSMountConnectivityException: The function couldn't connect to the Amazon EFS file system with access point arn:aws:elasticfilesystem:us-east-2:123456789012:access-point/fsap-015cxmplb72b405fd. Check your network configuration and try again.*

The function couldn't establish a connection to the function's [file system](#) with the NFS protocol (TCP port 2049). Check the [security group and routing configuration](#) for the VPC's subnets.

If you get these errors after updating your function's VPC configuration settings, try unmounting and remounting the file system.

EFS: Function could not mount the EFS file system due to timeout

Error: *EFSMountTimeoutException: The function could not mount the EFS file system with access point {arn:aws:elasticfilesystem:us-east-2:123456789012:access-point/fsap-015cxmplb72b405fd} due to mount time out.*

The function could connect to the function's [file system](#), but the mount operation timed out. Try again after a short time and consider limiting the function's [concurrency](#) to reduce load on the file system.

Lambda: Lambda detected an IO process that was taking too long

EFSIOException: This function instance was stopped because Lambda detected an IO process that was taking too long.

A previous invocation timed out and Lambda couldn't terminate the function handler. This issue can occur when an attached file system runs out of burst credits and the baseline throughput is insufficient. To increase throughput, you can increase the size of the file system or use provisioned throughput.

Container: CodeArtifactUserException errors

Error: *CodeArtifactUserPendingException error message*

The CodeArtifact is pending optimization. The function transitions to the [Active state](#) when Lambda completes the optimization. HTTP response code 409.

Error: *CodeArtifactUserDeletedException error message*

The CodeArtifact is scheduled to be deleted. HTTP response code 409.

Error: *CodeArtifactUserFailedException error message*

Lambda failed to optimize the code. You need to correct the code and upload it again. HTTP response code 409.

Container: InvalidEntrypoint errors

Error: *Runtime.ExitError or "errorType": "Runtime.InvalidEntrypoint"*

Verify that the ENTRYPOINT to your container image includes the absolute path as the location. Also verify that the image does not contain a symlink as the ENTRYPOINT.

Error: *You are using an CloudFormation template, and your container ENTRYPOINT is being overridden with a null or empty value.*

Review the [ImageConfig](#) resource in the CloudFormation template. If you declare an ImageConfig resource in your template, you must provide non-empty values for all three of the properties.

Troubleshoot execution issues in Lambda

When the Lambda runtime runs your function code, the event might be processed on an instance of the function that's been processing events for some time, or it might require a new instance to be initialized. Errors can occur during function initialization, when your handler code processes the event, or when your function returns (or fails to return) a response.

Function execution errors can be caused by issues with your code, function configuration, downstream resources, or permissions. If you invoke your function directly, you see function errors in the response from Lambda. If you invoke your function asynchronously, with an event source mapping, or through another service, you might find errors in logs, a dead-letter queue, or an on-failure destination. Error handling options and retry behavior vary depending on how you invoke your function and on the type of error.

When your function code or the Lambda runtime return an error, the status code in the response from Lambda is 200 OK. The presence of an error in the response is indicated by a header named `X-Amz-Function-Error`. 400 and 500-series status codes are reserved for [invocation errors](#).

Lambda: Remote debugging with Visual Studio Code

Issue: *Difficulty troubleshooting complex Lambda function behavior in the actual AWS environment*

Lambda provides a remote debugging feature through the AWS Toolkit for Visual Studio Code. For set up and general instructions, see [Remotely debug Lambda functions with Visual Studio Code](#).

For detailed instructions on troubleshooting, advanced use cases, and region availability, see [Remote debugging Lambda functions](#) in the AWS Toolkit for Visual Studio Code User Guide.

Lambda: Execution takes too long

Issue: *Function execution takes too long.*

If your code takes much longer to run in Lambda than on your local machine, it may be constrained by the memory or processing power available to the function. [Configure the function with additional memory](#) to increase both memory and CPU.

Lambda: Unexpected event payload

Issue: *Function errors related to malformed JSON or inadequate data validation.*

All Lambda functions receive an event payload in the first parameter of the handler. The event payload is a JSON structure that may contain arrays and nested elements.

Malformed JSON can occur when provided by upstream services that do not use a robust process for checking JSON structures. This occurs when services concatenate text strings or embed user input that has not been sanitized. JSON is also frequently serialized for passing between services. Always parse JSON structures both as the producer and consumer of JSON to ensure that the structure is valid.

Similarly, failing to check for ranges of values in the event payload can result in errors. This example shows a function that calculates a tax withholding:

```
exports.handler = async (event) => {  
  let pct = event.taxPct  
  let salary = event.salary  
  
  // Calculate % of paycheck for taxes  
  return (salary * pct)  
}
```

This function uses a salary and tax rate from the event payload to perform the calculation. However, the code fails to check if the attributes are present. It also fails to check data types, or ensure boundaries, such as ensuring that the tax percentage is between 0 and 1. As a result, values outside of these bounds produce nonsensical results. An incorrect type or missing attribute causes a runtime error.

Create tests to ensure that your function handles larger payload sizes. The maximum size for a Lambda event payload is 1 MB. Depending upon the content, larger payloads may mean more items passed to the function or more binary data embedded in a JSON attribute. In both cases, this can result in more processing for a Lambda function.

Larger payloads can also cause timeouts. For example, a Lambda function processes one record per 100 ms and has a timeout of 3 seconds. Processing is successful for 0-29 items in the payload. However, once the payload contains more than 30 items, the function times out and throws an error. To avoid this, ensure that timeouts are set to handle the additional processing time for the maximum number of items expected.

Lambda: Unexpectedly large payload sizes

Issue: *Functions are timing out or causing errors due to large payloads.*

Larger payloads can cause timeouts and errors. We recommend creating tests to ensure that your function handles your largest expected payloads, and ensuring the function timeout is properly set.

In addition, certain event payloads can contain pointers to other resources. For example, a Lambda function with 128 MB of memory may perform image processing on a JPG file stored as an object in S3. The function works as expected with smaller image files. However, when a larger JPG file is provided as input, the Lambda function throws an error due to running out of memory. To avoid this, the test cases should include examples from the upper bounds of expected data sizes. The code should also validate payload sizes.

Lambda: JSON encoding and decoding errors

Issue: *NoSuchKey exception when parsing JSON inputs.*

Check to ensure you are processing JSON attributes correctly. For example, for events generated by S3, the `s3.object.key` attribute contains a URL encoded object key name. Many functions process this attribute as text to load the referenced S3 object:

Example

```
const originalText = await s3.getObject({
  Bucket: event.Records[0].s3.bucket.name,
  Key: event.Records[0].s3.object.key
}).promise()
```

This code works with the key name `james.jpg` but throws a `NoSuchKey` error when the name is `james beswick.jpg`. Since URL encoding converts spaces and other characters in a key name, you must ensure that functions decode keys before using this data:

Example

```
const originalText = await s3.getObject({
  Bucket: event.Records[0].s3.bucket.name,
  Key: decodeURIComponent(event.Records[0].s3.object.key.replace(/\+/g, " "))
}).promise()
```

Lambda: Logs or traces don't appear

Issue: *Logs don't appear in CloudWatch Logs.*

Issue: *Traces don't appear in AWS X-Ray.*

Your function needs permission to call CloudWatch Logs and X-Ray. Update its [execution role](#) to grant it permission. Add the following managed policies to enable logs and tracing.

- **AWSLambdaBasicExecutionRole**
- **AWSXRayDaemonWriteAccess**

When you add permissions to your function, perform a trivial update to its code or configuration as well. This forces running instances of your function, which have outdated credentials, to stop and be replaced.

Note

It may take 5 to 10 minutes for logs to show up after a function invocation.

Lambda: Not all of my function's logs appear

Issue: *Function logs are missing in CloudWatch Logs, even though my permissions are correct*

If your AWS account reaches its [CloudWatch Logs quota limits](#), CloudWatch throttles function logging. When this happens, some of the logs output by your functions may not appear in CloudWatch Logs.

If your function outputs logs at too high a rate for Lambda to process them, this can also cause log outputs not to appear in CloudWatch Logs. When Lambda can't send logs to CloudWatch at the rate your function produces them, it drops logs to prevent the execution of your function from slowing down. Expect to consistently observe dropped logs when your log throughput exceeds 2 MB/s for a single log stream.

If your function is configured to use [JSON formatted logs](#), Lambda tries to send a [logsDropped](#) event to CloudWatch Logs when it drops logs. However, when CloudWatch throttles your function's logging, this event might not reach CloudWatch Logs, so you won't always see a record when Lambda drops logs.

To check if your AWS account has reached its CloudWatch Logs quota limits, do the following:

1. Open the [Service Quotas console](#).
2. In the navigation pane, choose **AWS services**.
3. From the **AWS services** list, search for Amazon CloudWatch Logs.
4. In the **Service quotas** list, choose the `CreateLogGroup` throttle limit in transactions per second, `CreateLogStream` throttle limit in transactions per second and `PutLogEvents` throttle limit in transactions per second quotas to view your utilization.

You can also set CloudWatch alarms to alert you when your account utilization exceeds a limit you specify for these quotas. See [Create a CloudWatch alarm based on a static threshold](#) to learn more.

If the default quota limits for CloudWatch Logs aren't enough for your use case, you can [request a quota increase](#).

Lambda: The function returns before execution finishes

Issue: (Node.js) *Function returns before code finishes executing*

Many libraries, including the AWS SDK, operate asynchronously. When you make a network call or perform another operation that requires waiting for a response, libraries return an object called a promise that tracks the progress of the operation in the background.

To wait for the promise to resolve into a response, use the `await` keyword. This blocks your handler code from executing until the promise is resolved into an object that contains the

response. If you don't need to use the data from the response in your code, you can return the promise directly to the runtime.

Some libraries don't return promises but can be wrapped in code that does. For more information, see [Define Lambda function handler in Node.js](#).

Lambda: Running an unintended function version or alias

Issue: Function version or alias not invoked

When you publish new Lambda functions in the console or using AWS SAM, the latest code version is represented by `$LATEST`. By default, invocations that don't specify a version or alias automatically targets the `$LATEST` version of your function code.

If you use specific function versions or aliases, these are immutable published versions of a function in addition to `$LATEST`. When troubleshooting these functions, first determine that the caller has invoked the intended version or alias. You can do this by checking your function logs. The version of the function that was invoked is always shown in the `START` log line:

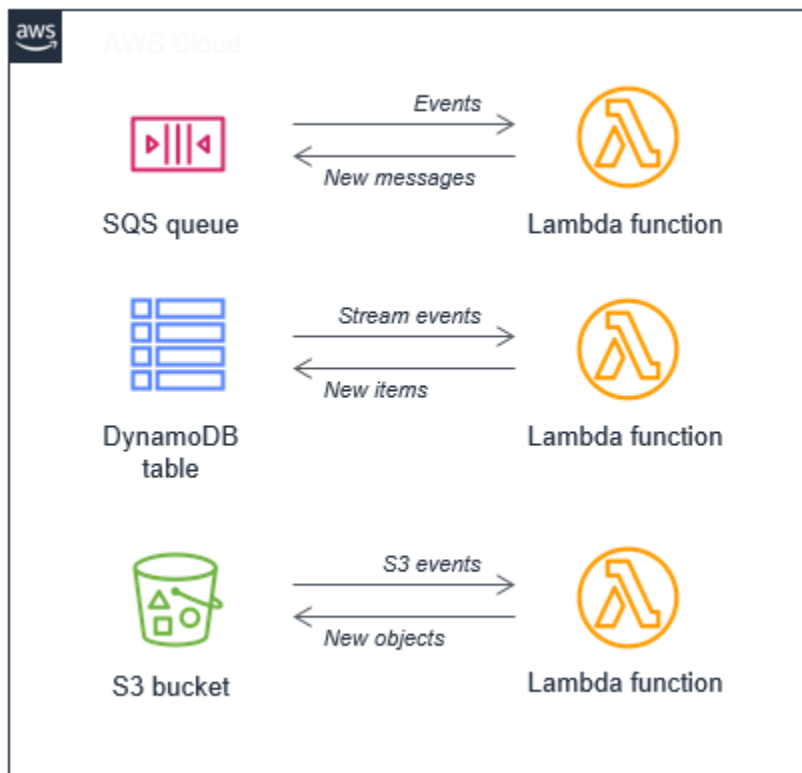

2020-11-13T09:53:21.179-05:00	START RequestId: a37400cb-f3bc-441b-8592-dcb9fa552995 Version: 1
2020-11-13T08:14:27.834-05:00	START RequestId: f4943cb9-58a1-472a-af81-5801b6f0eb8d Version: \$LATEST

Lambda: Detecting infinite loops

Issue: Infinite loop patterns related to Lambda functions

There are two types of infinite loops in Lambda functions. The first is within the function itself, caused by a loop that never exits. The invocation ends only when the function times out. You can identify these by monitoring timeouts, and then fixing the looping behavior.

The second type of loop is between Lambda functions and other AWS resources. These occur when an event from a resource like an S3 bucket invokes a Lambda function, which then interacts with the same source resource to trigger another event. This invokes the function again, which creates another interaction with the same S3 bucket, and so on. These types of loops can be caused by a number of different AWS event sources, including Amazon SQS queues and DynamoDB tables. You can use [recursive loop detection](#) to identify these patterns.

You can avoid these loops by ensuring that Lambda functions write to resources that are not the same as the consuming resource. If you must publish data back to the consuming resource, ensure that the new data doesn't trigger the same event. Alternatively, use [event filtering](#). For example, here are two proposed solutions to infinite loops with S3 and DynamoDB resources:

- If you write back to the same S3 bucket, use a different prefix or suffix from the event trigger.
- If you write items to the same DynamoDB table, include an attribute that a consuming Lambda function can filter on. If Lambda finds the attribute, it will not result in another invocation.

General: Downstream service unavailability

Issue: *Downstream services that your Lambda function relies on are unavailable*

For Lambda functions that call out to third-party endpoints or other downstream resources, ensure that they can handle service errors and timeouts. These downstream resources can have variable response times, or become unavailable due to service disruptions. Depending upon the implementation, these downstream errors may appear as Lambda timeouts or exceptions if the service's error response is not handled within the function code.

Anytime a function depends on a downstream service, such as an API call, implement appropriate error handling and retry logic. For critical services, the Lambda function should publish metrics or logs to CloudWatch. For example, if a third-party payment API becomes unavailable, your Lambda function can log this information. You can then set up CloudWatch alarms to send notifications related to these errors.

Since Lambda can scale quickly, non-serverless downstream services may struggle to handle spikes in traffic. There are three common approaches to handling this:

- **Caching** – Consider caching the result of values returned by third-party services if they don't change frequently. You can store these values in global variable in your function, or another service. For example, the results for a product list query from an Amazon RDS instance could be saved for a period of time within the function to prevent redundant queries.
- **Queuing** – When saving or updating data, add an Amazon SQS queue between the Lambda function and the resource. The queue durably persists data while the downstream service processes messages.
- **Proxies** – Where long-lived connections are typically used, such as for Amazon RDS instances, use a proxy layer to pool and reuse those connections. For relational databases, [Amazon RDS Proxy](#) is a service designed to help improve scalability and resiliency in Lambda-based applications.

AWS SDK: Versions and updates

Issue: *The AWS SDK included on the runtime is not the latest version*

Issue: *The AWS SDK included on the runtime updates automatically*

Runtimes for interpreted languages include a version of the AWS SDK. Lambda periodically updates these runtimes to use the latest SDK version. To find the version of the SDK that's included in your runtime, see the following sections:

- [Runtime included SDK versions \(Node.js\)](#)
- [Runtime included SDK versions \(Python\)](#)
- [Runtime included SDK versions \(Ruby\)](#)

To use a newer version of the AWS SDK, or to lock your functions to a specific version, you can bundle the library with your function code, or [create a Lambda layer](#). For details on creating a deployment package with dependencies, see the following topics:

Node.js

[Deploy Node.js Lambda functions with .zip file archives](#)

Python

[Working with .zip file archives for Python Lambda functions](#)

Ruby

[Deploy Ruby Lambda functions with .zip file archives](#)

Java

[Deploy Java Lambda functions with .zip or JAR file archives](#)

Go

[Deploy Go Lambda functions with .zip file archives](#)

C#

[Build and deploy C# Lambda functions with .zip file archives](#)

PowerShell

[Deploy PowerShell Lambda functions with .zip file archives](#)

Python: Libraries load incorrectly

Issue: (Python) *Some libraries don't load correctly from the deployment package*

Libraries with extension modules written in C or C++ must be compiled in an environment with the same processor architecture as Lambda (Amazon Linux). For more information, see [Working with .zip file archives for Python Lambda functions](#).

Java: Your function takes longer to process events after updating to Java 17 from Java 11

Issue: (Java) *Your function takes longer to process events after updating to Java 17 from Java 11*

Tune your compiler using the `JAVA_TOOL_OPTIONS` parameter. Lambda runtimes for Java 17 and later Java versions change the default compiler options. The change improves cold start times

for short-lived functions, but the previous behavior is better suited to computationally intensive, longer-running functions. Set `JAVA_TOOL_OPTIONS` to `-XX:-TieredCompilation` to revert to the Java 11 behavior. For more information about the `JAVA_TOOL_OPTIONS` parameter, see [the section called “Understanding the `JAVA_TOOL_OPTIONS` environment variable”](#).

Kafka: Error handling and retry configuration issues

Issue: *Kafka event source mapping fails to configure retry settings or on-failure destinations*

Kafka retry configurations and on-failure destinations are only available for event source mappings with provisioned mode enabled. Ensure that you have configured `MinimumPollers` in your `ProvisionedPollerConfig` before attempting to set retry configurations.

Common configuration errors:

- **Infinite retries with bisect batch** – You cannot enable `BisectBatchOnFunctionError` when `MaximumRetryAttempts` is set to -1 (infinite). Set a finite retry limit or disable bisect batch.
- **Same topic recursion** – The Kafka on-failure destination topic cannot be the same as any of your source topics. Choose a different topic name for your dead letter topic.
- **Invalid Kafka destination format** – Use the `kafka://<topic-name>` format when specifying a Kafka topic as an on-failure destination.
- **kafka:WriteData permission issues** – Ensure your execution role has `kafka-cluster:WriteData` permissions for the destination topic. Topic doesn't exist timeout exceptions or write API throttling issues may require increasing the account limits.

Troubleshoot event source mapping issues in Lambda

Issues in Lambda that relate to an [event source mapping](#) can be more complex because they involve debugging across multiple services. Moreover, event source behavior can differ based on the exact event source used. This section lists common issues that involve event source mappings, and provides guidance on how to identify and troubleshoot them.

Note

This section uses an Amazon SQS event source for illustration, but the principles apply to other event source mappings that queue messages for Lambda functions.

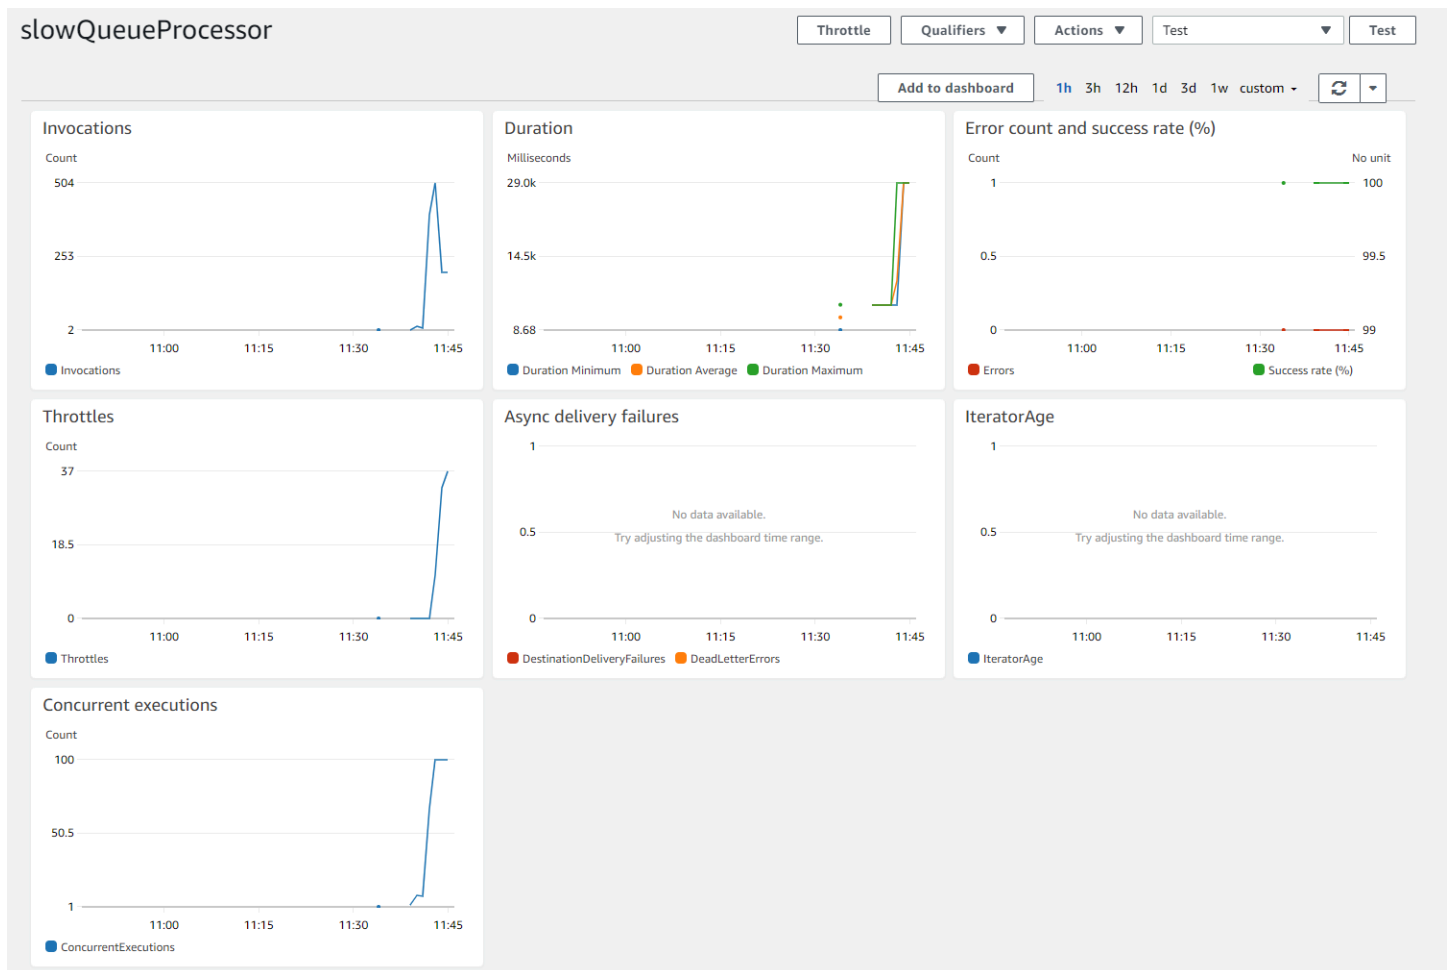

Identifying and managing throttling

In Lambda, throttling occurs when you reach your function's or account's concurrency limit. Consider the following example, where there is a Lambda function that reads messages from an Amazon SQS queue. This Lambda function simulates 30 second invocations, and has a batch size of 1. This means that the function processes only 1 message every 30 seconds:

```
const doWork = (ms) => new Promise(resolve => setTimeout(resolve, ms))

exports.handler = async (event) => {
  await doWork(30000)
}
```

With such a long invocation time, messages begin arriving in the queue more rapidly than they are processed. If your account's unreserved concurrency is 100, Lambda scales up to 100 concurrent executions, and then throttling occurs. You can see this pattern in the CloudWatch metrics for the function:

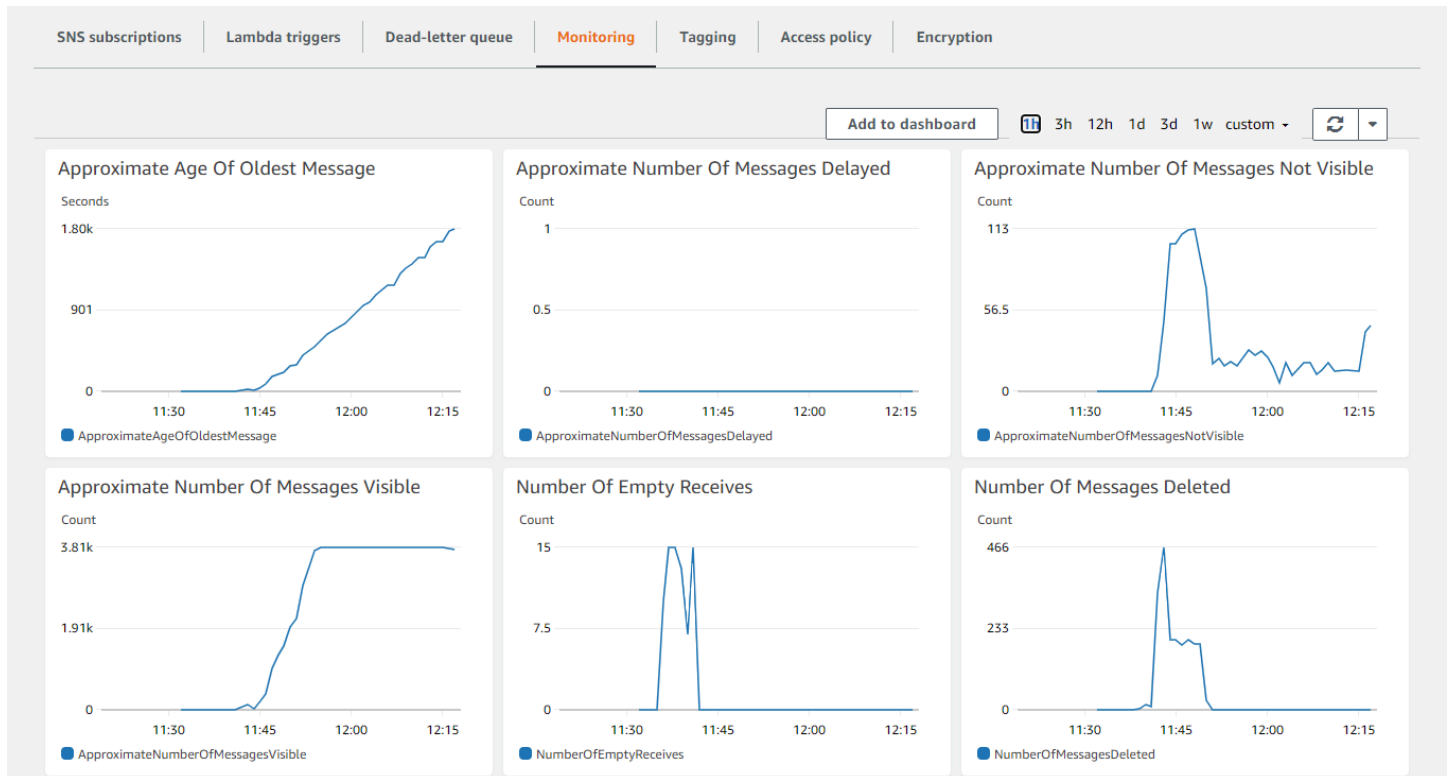

CloudWatch metrics for the function show no errors, but the **Concurrent executions** chart shows that the maximum concurrency of 100 is reached. As a result, the **Throttles** chart shows the throttling in place.

You can detect throttling with CloudWatch alarms, and setting an alarm anytime the throttling metric for a function is greater than 0. After you've identified the throttling issue, you have a few options for resolution:

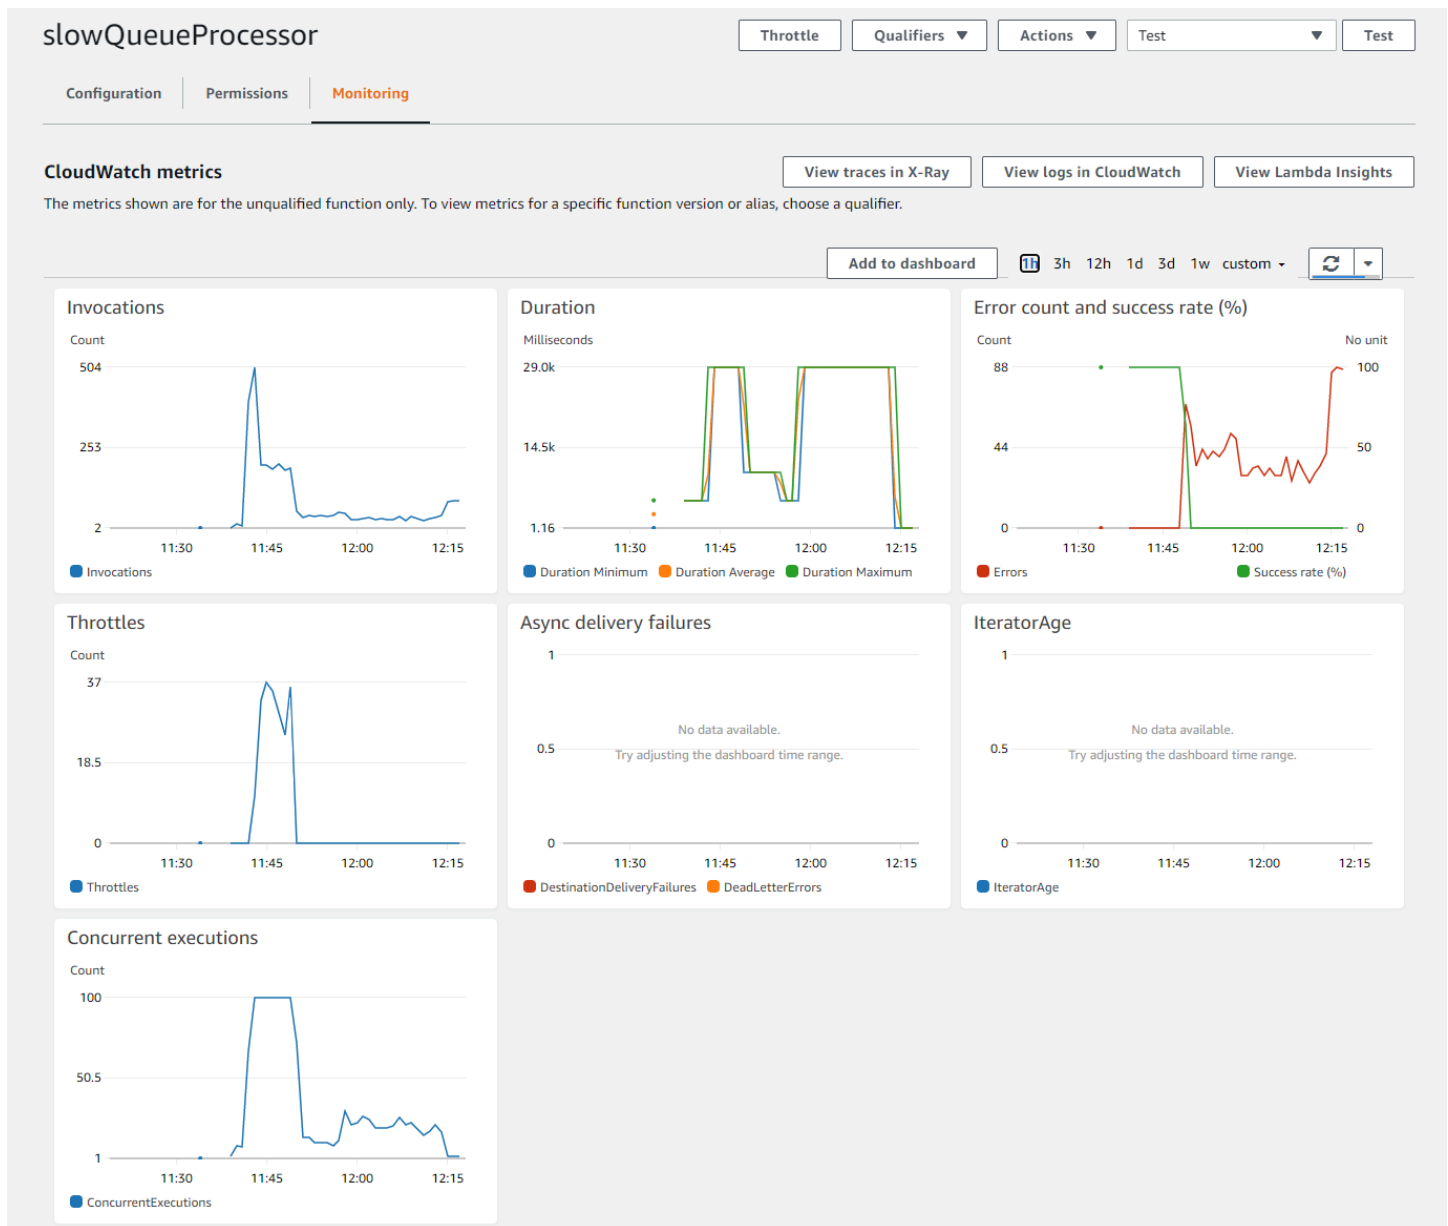

- Request a concurrency increase from AWS Support in this Region.
- Identify performance issues in the function to improve the speed of processing and therefore improve throughput.
- Increase the batch size of the function, so more messages are processed by each invocation.

Errors in the processing function

If the processing function throws errors, Lambda returns the messages to the SQS queue. Lambda prevents your function from scaling to prevent errors at scale. The following SQS metrics in CloudWatch indicate an issue with queue processing:

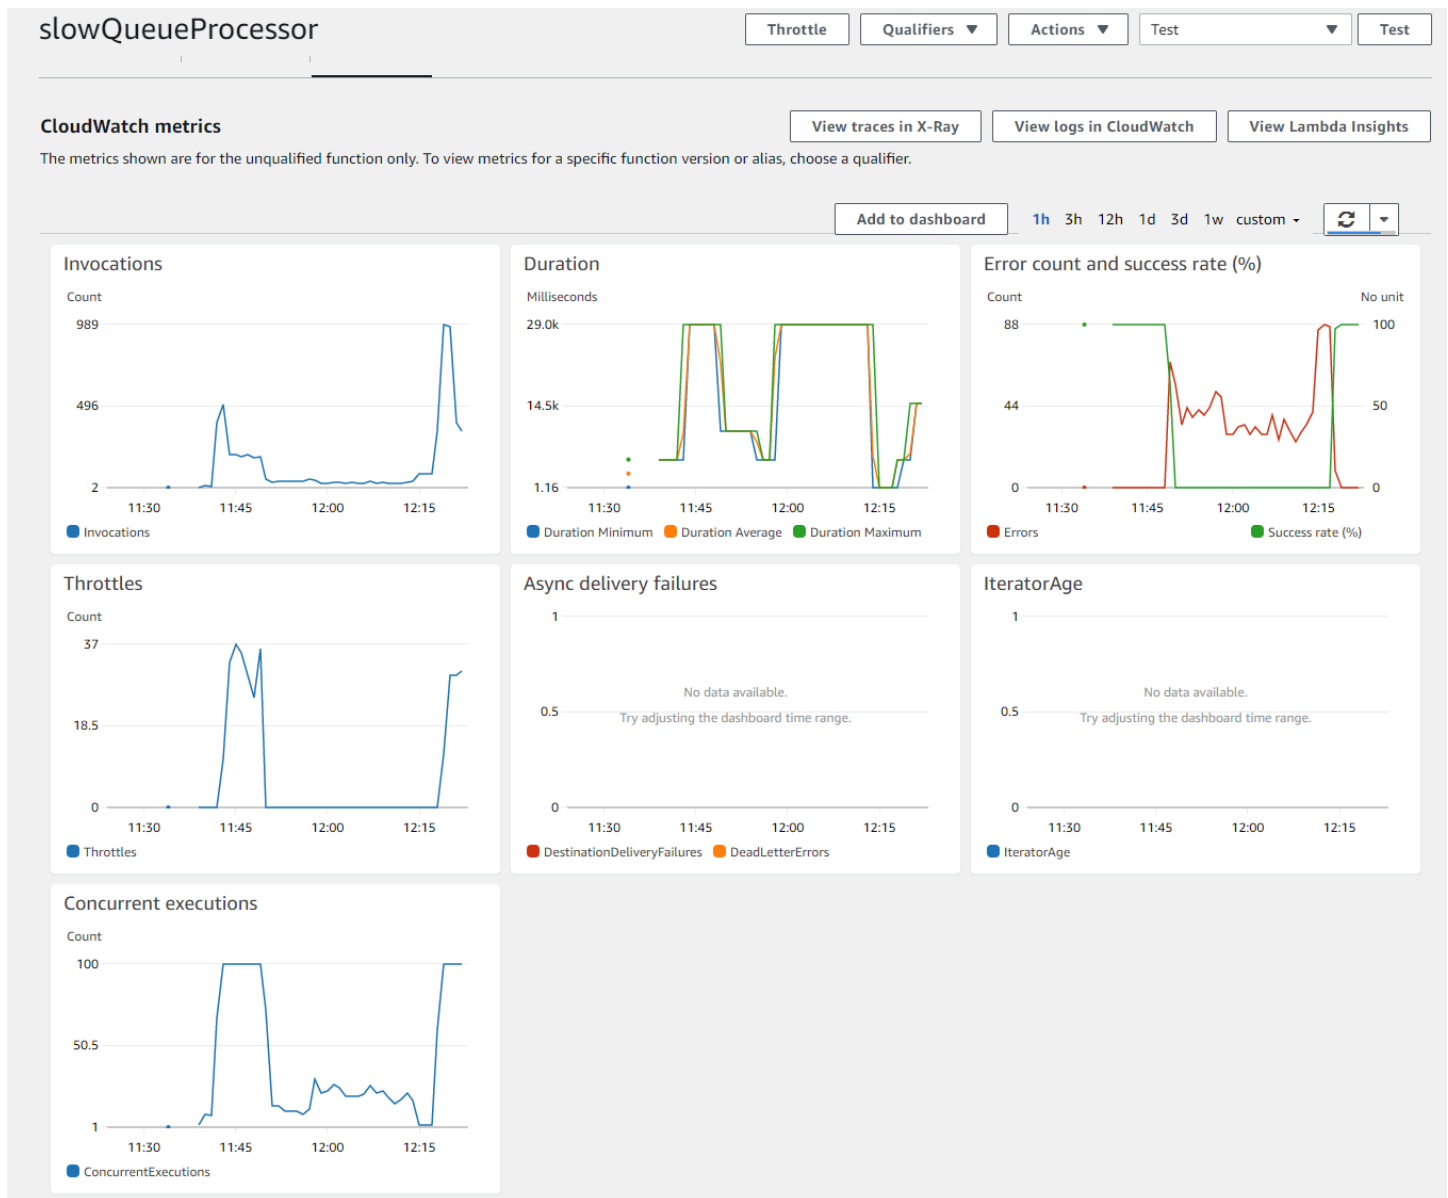

In particular, both the age of the oldest message and the number of messages visible are increasing, while no messages are deleted. The queue continues to grow but messages are not being processed. The CloudWatch metrics for the processing Lambda function also indicate that there is a problem:

The **Error count** metric is non-zero and growing, while **Concurrent executions** have reduced and throttling has stopped. This shows that Lambda has stopped scaling up your function due to errors. The CloudWatch logs for the function provide details of the type of error.

You can resolve this issue by identifying the function causing the error, then finding and resolving the error. After you fix the error and deploy the new function code, the CloudWatch metrics should show the processing recover:

Here, the **Error count** metric drops to zero and the **Success rate** metric returns to 100%. Lambda starts scaling up the function again, as shown in the **Concurrent executions** graph.

Identifying and handling backpressure

If an event producer consistently generates messages for an SQS queue faster than a Lambda function can process them, backpressure occurs. In this case, SQS monitoring should show the age of the oldest message growing linearly, along with the approximate number of messages visible. You can detect backpressure in queues using CloudWatch alarms.

The steps to resolve backpressure depend on your workload. If the primary goal is to increase processing capability and throughput by the Lambda function, you have a few options:

- Request a concurrency increase in the specific Region from AWS Support.
- Increase the batch size of the function, so more messages are processed by each invocation.

Troubleshoot networking issues in Lambda

By default, Lambda runs your functions in an internal virtual private cloud (VPC) with connectivity to AWS services and the internet. To access local network resources, you can [configure your function to connect to a VPC in your account](#). When you use this feature, you manage the function's internet access and network connectivity with Amazon Virtual Private Cloud (Amazon VPC) resources.

Network connectivity errors can result from issues with your VPC's routing configuration, security group rules, AWS Identity and Access Management (IAM) role permissions, or network address translation (NAT), or from the availability of resources such as IP addresses or network interfaces. Depending on the issue, you might see a specific error or timeout if a request can't reach its destination.

Topics

- [VPC: Function loses internet access or times out](#)
- [VPC: TCP or UDP connection intermittently fails](#)
- [VPC: Function needs access to AWS services without using the internet](#)
- [VPC: Elastic network interface limit reached](#)
- [EC2: Elastic network interface with type of "lambda"](#)
- [DNS: Fail to connect to hosts with UNKNOWNHOSTEXCEPTION](#)

VPC: Function loses internet access or times out

Issue: *Your Lambda function loses internet access after connecting to a VPC.*

Error: *Error: connect ETIMEDOUT 176.32.98.189:443*

Error: *Error: Task timed out after 10.00 seconds*

Error: *ReadTimeoutError: Read timed out. (read timeout=15)*

When you connect a function to a VPC, all outbound requests go through the VPC. To connect to the internet, configure your VPC to send outbound traffic from the function's subnet to a NAT

gateway in a public subnet. For more information and sample VPC configurations, see [the section called “Internet access for VPC functions”](#).

If some of your TCP connections are timing out, see [the section called “VPC: TCP or UDP connection intermittently fails”](#) if your subnet is using a network access control list (NACL). Otherwise, this is likely due to packet fragmentation. Lambda functions cannot handle incoming fragmented TCP requests, since Lambda does not support IP fragmentation for TCP or ICMP.

VPC: TCP or UDP connection intermittently fails

Note

This issue applies only if your subnet uses a [network access control list \(ACL\)](#). Network ACLs aren't required for Lambda to connect to your subnets.

Issue: *Lambda intermittently loses connection to your VPC subnets, which you have configured a network access control list (ACL) for.*

For VPC-enabled Lambda functions, AWS creates [hyperplane ENIs](#) in the customer's account, and uses ephemeral ports 1024 to 65535 to connect Lambda to the customer's VPC. If you use network ACLs in the target subnet, you must allow the port range 1024 to 65535 for both TCP and UDP. Not allowing this full port range can cause intermittent connection failures.

VPC: Function needs access to AWS services without using the internet

Issue: *Your Lambda function needs access to AWS services without using the internet.*

To connect a function to AWS services from a private subnet with no internet access, use VPC endpoints.

VPC: Elastic network interface limit reached

Error: *ENILimitReachedException: The elastic network interface limit was reached for the function's VPC.*

When you connect a Lambda function to a VPC, Lambda creates an elastic network interface for each combination of subnet and security group attached to the function. The default service quota is 250 network interfaces per VPC. To request a quota increase, use the [Service Quotas console](#).

EC2: Elastic network interface with type of "lambda"

Error Code: *Client.OperationNotPermitted*

Error message: *The security group can not be modified for this type of interface*

You will receive this error if you attempt to modify an elastic network interface (ENI) that is managed by Lambda. The `ModifyNetworkInterfaceAttribute` is not included in the Lambda API for update operations on elastic network interfaces created by Lambda.

DNS: Fail to connect to hosts with UNKNOWNHOSTEXCEPTION

Error Message: *UNKNOWNHOSTEXCEPTION*

Lambda functions support a maximum of 20 concurrent TCP connections for DNS resolution. Your function may be exhausting that limit. Most common DNS requests are done over UDP. If your function is only making UDP DNS connections, this is unlikely to be your issue. This error is commonly thrown due to misconfiguration or degraded infrastructure, so before examining your DNS traffic in depth, confirm that your DNS infrastructure is properly configured and healthy and that your Lambda function is referring to a host specified in DNS.

If you diagnose your issue as related to the TCP connection maximum, note that you cannot request an increase to this limit. If your Lambda function is falling back to TCP DNS because of large DNS payloads, confirm that your solution is using libraries that support EDNS. For more information about EDNS, see [the RFC 6891 standard](#). If your DNS payloads consistently exceed EDNS max sizes, your solution may still exhaust the TCP DNS limit.

Lambda sample applications

The GitHub repository for this guide includes sample applications that demonstrate the use of various languages and AWS services. Each sample application includes scripts for easy deployment and cleanup and supporting resources.

Node.js

Sample Lambda applications in Node.js

- [blank-nodejs](#) – A Node.js function that shows the use of logging, environment variables, AWS X-Ray tracing, layers, unit tests and the AWS SDK.
- [nodejs-apig](#) – A function with a public API endpoint that processes an event from API Gateway and returns an HTTP response.

Python

Sample Lambda applications in Python

- [blank-python](#) – A Python function that shows the use of logging, environment variables, AWS X-Ray tracing, layers, unit tests and the AWS SDK.

Ruby

Sample Lambda applications in Ruby

- [blank-ruby](#) – A Ruby function that shows the use of logging, environment variables, AWS X-Ray tracing, layers, unit tests and the AWS SDK.
- [Ruby Code Samples for AWS Lambda](#) – Code samples written in Ruby that demonstrate how to interact with AWS Lambda.

Java

Sample Lambda applications in Java

- [example-java](#) – A Java function that demonstrates how you can use Lambda to process orders. This function illustrates how to define and deserialize a custom input event object, use the AWS SDK, and output logging.

- [java-basic](#) – A collection of minimal Java functions with unit tests and variable logging configuration.
- [java-events](#) – A collection of Java functions that contain skeleton code for how to handle events from various services such as Amazon API Gateway, Amazon SQS, and Amazon Kinesis. These functions use the latest version of the [aws-lambda-java-events](#) library (3.0.0 and newer). These examples do not require the AWS SDK as a dependency.
- [s3-java](#) – A Java function that processes notification events from Amazon S3 and uses the Java Class Library (JCL) to create thumbnails from uploaded image files.
- [layer-java](#) – A Java function that illustrates how to use a Lambda layer to package dependencies separate from your core function code.

Running popular Java frameworks on Lambda

- [spring-cloud-function-samples](#) – An example from Spring that shows how to use the [Spring Cloud Function](#) framework to create AWS Lambda functions.
- [Serverless Spring Boot Application Demo](#) – An example that shows how to set up a typical Spring Boot application in a managed Java runtime with and without SnapStart, or as a GraalVM native image with a custom runtime.
- [Serverless Micronaut Application Demo](#) – An example that shows how to use Micronaut in a managed Java runtime with and without SnapStart, or as a GraalVM native image with a custom runtime. Learn more in the [Micronaut/Lambda guides](#).
- [Serverless Quarkus Application Demo](#) – An example that shows how to use Quarkus in a managed Java runtime with and without SnapStart, or as a GraalVM native image with a custom runtime. Learn more in the [Quarkus/Lambda guide](#) and [Quarkus/SnapStart guide](#).

Go

Lambda provides the following sample applications for the Go runtime:

Sample Lambda applications in Go

- [go-al2](#) – A hello world function that returns the public IP address. This app uses the `provided.al2` custom runtime.
- [blank-go](#) – A Go function that shows the use of Lambda's Go libraries, logging, environment variables, and the AWS SDK. This app uses the `go1.x` runtime.

C#

Sample Lambda applications in C#

- [blank-csharp](#) – A C# function that shows the use of Lambda's .NET libraries, logging, environment variables, AWS X-Ray tracing, unit tests, and the AWS SDK.
- [blank-csharp-with-layer](#) – A C# function that uses the .NET CLI to create a layer that packages the function's dependencies.
- [ec2-spot](#) – A function that manages spot instance requests in Amazon EC2.

PowerShell

Lambda provides the following sample applications for PowerShell:

- [blank-powershell](#) – A PowerShell function that shows the use of logging, environment variables, and the AWS SDK.

To deploy a sample application, follow the instructions in its README file.

Using Lambda with an AWS SDK

AWS software development kits (SDKs) are available for many popular programming languages. Each SDK provides an API, code examples, and documentation that make it easier for developers to build applications in their preferred language.

SDK documentation	Code examples
AWS SDK for C++	AWS SDK for C++ code examples
AWS CLI	AWS CLI code examples
AWS SDK for Go	AWS SDK for Go code examples
AWS SDK for Java	AWS SDK for Java code examples
AWS SDK for JavaScript	AWS SDK for JavaScript code examples
AWS SDK for Kotlin	AWS SDK for Kotlin code examples
AWS SDK for .NET	AWS SDK for .NET code examples
AWS SDK for PHP	AWS SDK for PHP code examples
AWS Tools for PowerShell	AWS Tools for PowerShell code examples
AWS SDK for Python (Boto3)	AWS SDK for Python (Boto3) code examples
AWS SDK for Ruby	AWS SDK for Ruby code examples
AWS SDK for Rust	AWS SDK for Rust code examples
AWS SDK for SAP ABAP	AWS SDK for SAP ABAP code examples
AWS SDK for Swift	AWS SDK for Swift code examples

For examples specific to Lambda, see [Code examples for Lambda using AWS SDKs](#).

 **Example availability**

Can't find what you need? Request a code example by using the **Provide feedback** link at the bottom of this page.

Code examples for Lambda using AWS SDKs

The following code examples show how to use Lambda with an AWS software development kit (SDK).

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

AWS community contributions are examples that were created and are maintained by multiple teams across AWS. To provide feedback, use the mechanism provided in the linked repositories.

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Hello Lambda

The following code examples show how to get started using Lambda.

.NET

SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
namespace LambdaActions;

using Amazon.Lambda;

public class HelloLambda
{
    static async Task Main(string[] args)
    {
        var lambdaClient = new AmazonLambdaClient();

        Console.WriteLine("Hello AWS Lambda");
        Console.WriteLine("Let's get started with AWS Lambda by listing your existing Lambda functions:");

        var response = await lambdaClient.ListFunctionsAsync();
        response.Functions.ForEach(function =>
        {
            Console.WriteLine($"{function.FunctionName}\t{function.Description}");
        });
    }
}
```

- For API details, see [ListFunctions](#) in *AWS SDK for .NET API Reference*.

C++

SDK for C++

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Code for the CMakeLists.txt CMake file.

```
# Set the minimum required version of CMake for this project.
cmake_minimum_required(VERSION 3.13)

# Set the AWS service components used by this project.
set(SERVICE_COMPONENTS lambda)

# Set this project's name.
project("hello_lambda")

# Set the C++ standard to use to build this target.
# At least C++ 11 is required for the AWS SDK for C++.
set(CMAKE_CXX_STANDARD 11)

# Use the MSVC variable to determine if this is a Windows build.
set(WINDOWS_BUILD ${MSVC})

if (WINDOWS_BUILD) # Set the location where CMake can find the installed
  libraries for the AWS SDK.
    string(REPLACE ";" "/aws-cpp-sdk-all;" SYSTEM_MODULE_PATH
      "${CMAKE_SYSTEM_PREFIX_PATH}/aws-cpp-sdk-all")
    list(APPEND CMAKE_PREFIX_PATH ${SYSTEM_MODULE_PATH})
  endif ()

```

- For API details, see [ListFunctions](#) in *AWS SDK for Ruby API Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Learn the basics of Lambda with an AWS SDK

The following code examples show how to:

- Create an IAM role and Lambda function, then upload handler code.
- Invoke the function with a single parameter and get results.
- Update the function code and configure with an environment variable.
- Invoke the function with new parameters and get results. Display the returned execution log.
- List the functions for your account, then clean up resources.

For more information, see [Create a Lambda function with the console](#).

.NET

SDK for .NET

Java

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/*
 * Lambda function names appear as:
 *
```

```

*   arn:aws:lambda:us-west-2:335556666777:function:HelloFunction
*
*   To find this value, look at the function in the AWS Management Console.
*
*   Before running this Java code example, set up your development environment,
including your credentials.
*
*   For more information, see this documentation topic:
*
*   https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
*
*   This example performs the following tasks:
*
*   1. Creates an AWS Lambda function.
*   2. Gets a specific AWS Lambda function.
*   3. Lists all Lambda functions.
*   4. Invokes a Lambda function.
*   5. Updates the Lambda function code and invokes it again.
*   6. Updates a Lambda function's configuration value.
*   7. Deletes a Lambda function.

SDK for JavaScript (v3)

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Create an AWS Identity and Access Management (IAM) role that grants Lambda permission to write to logs.

```
logger.log(`Creating role (${NAME_ROLE_LAMBDA})...`);
const response = await createRole(NAME_ROLE_LAMBDA);

import { AttachRolePolicyCommand, IAMClient } from "@aws-sdk/client-iam";

const client = new IAMClient({});

/**
 *
 * @param {string} policyArn
 * @param {string} roleName
 */
export const attachRolePolicy = (policyArn, roleName) => {
  const command = new AttachRolePolicyCommand({
    PolicyArn: policyArn,
    RoleName: roleName,
  });

  return client.send(command);
};
```

Create a Lambda function and upload handler code.

```
const createFunction = async (funcName, roleArn) => {
  const client = new LambdaClient({});
  const code = await readFile(`${dirname}../functions/${funcName}.zip`);

  const command = new CreateFunctionCommand({
    Code: { ZipFile: code },
    FunctionName: funcName,
    Role: roleArn,
    Architectures: [Architecture.arm64],
    Handler: "index.handler", // Required when sending a .zip file
    PackageType: PackageType.Zip, // Required when sending a .zip file
    Runtime: Runtime.nodejs16x, // Required when sending a .zip file
  });

  return client.send(command);
};
```

Invoke the function with a single parameter and get results.

```
const invoke = async (funcName, payload) => {
  const client = new LambdaClient({});
  const command = new InvokeCommand({
    FunctionName: funcName,
    Payload: JSON.stringify(payload),
    LogType: LogType.Tail,
  });

  const { Payload, LogResult } = await client.send(command);
  const result = Buffer.from(Payload).toString();
  const logs = Buffer.from(LogResult, "base64").toString();
  return { logs, result };
};
```

Update the function code and configure its Lambda environment with an environment variable.

```
const updateFunctionCode = async (funcName, newFunc) => {
  const client = new LambdaClient({});
```

```

const code = await readFile(`${dirname}../functions/${newFunc}.zip`);
const command = new UpdateFunctionCodeCommand({
  ZipFile: code,
  FunctionName: funcName,
  Architectures: [Architecture.arm64],
  Handler: "index.handler", // Required when sending a .zip file
  PackageType: PackageType.Zip, // Required when sending a .zip file
  Runtime: Runtime.nodejs16x, // Required when sending a .zip file
});

return client.send(command);
};

const updateFunctionConfiguration = (funcName) => {
  const client = new LambdaClient({});
  const config = readFileSync(`${dirname}../functions/config.json`).toString();
  const command = new UpdateFunctionConfigurationCommand({
    ...JSON.parse(config),
    FunctionName: funcName,
  });
  const result = client.send(command);
  waitForFunctionUpdated({ FunctionName: funcName });
  return result;
};

```

List the functions for your account.

```

const listFunctions = () => {
  const client = new LambdaClient({});
  const command = new ListFunctionsCommand({});

  return client.send(command);
};

```

Delete the IAM role and the Lambda function.

```

import { DeleteRoleCommand, IAMClient } from "@aws-sdk/client-iam";

const client = new IAMClient({});

/**

```

```
*
* @param {string} roleName
*/
export const deleteRole = (roleName) => {
  const command = new DeleteRoleCommand({ RoleName: roleName });
  return client.send(command);
};

/**
* @param {string} funcName
*/
const deleteFunction = (funcName) => {
  const client = new LambdaClient({});
  const command = new DeleteFunctionCommand({ FunctionName: funcName });
  return client.send(command);
};
```

```
suspend fun main(args: Array<String>) {
```

```
val usage = ""
Usage:
    <functionName> <role> <handler> <bucketName> <updatedBucketName>
<key>

Where:
    functionName - The name of the AWS Lambda function.
    role - The AWS Identity and Access Management (IAM) service role that
has AWS Lambda permissions.
    handler - The fully qualified method name (for example,
example.Handler::handleRequest).
    bucketName - The Amazon Simple Storage Service (Amazon S3) bucket
name that contains the ZIP or JAR used for the Lambda function's code.
    updatedBucketName - The Amazon S3 bucket name that contains the .zip
or .jar used to update the Lambda function's code.
    key - The Amazon S3 key name that represents the .zip or .jar file
(for example, LambdaHello-1.0-SNAPSHOT.jar).

Define a Lambda handler that increments a number.

```
import logging

logger = logging.getLogger()
logger.setLevel(logging.INFO)
```

```
def lambda_handler(event, context):
    """
    Accepts an action and a single number, performs the specified action on the
    number,
    and returns the result. The only allowable action is 'increment'.

    :param event: The event dict that contains the parameters sent when the
    function
                  is invoked.
    :param context: The context in which the function is called.
    :return: The result of the action.
    """
    result = None
    action = event.get("action")
    if action == "increment":
        result = event.get("number", 0) + 1
        logger.info("Calculated result of %s", result)
    else:
        logger.error("%s is not a valid action.", action)

    response = {"result": result}
    return response
```

Define a second Lambda handler that performs arithmetic operations.

```
import logging
import os

logger = logging.getLogger()

# Define a list of Python lambda functions that are called by this AWS Lambda
function.
ACTIONS = {
    "plus": lambda x, y: x + y,
    "minus": lambda x, y: x - y,
    "times": lambda x, y: x * y,
    "divided-by": lambda x, y: x / y,
}
```

```
def lambda_handler(event, context):
    """
    Accepts an action and two numbers, performs the specified action on the
    numbers,
    and returns the result.

    :param event: The event dict that contains the parameters sent when the
    function
                  is invoked.
    :param context: The context in which the function is called.
    :return: The result of the specified action.
    """
    # Set the log level based on a variable configured in the Lambda environment.
    logger.setLevel(os.environ.get("LOG_LEVEL", logging.INFO))
    logger.debug("Event: %s", event)

    }
  })

  @lambda_client.wait_until(:function_active_v2, { function_name:
function_name }) do |w|

```

```

        w.max_attempts = 5
        w.delay = 5
    end
    response
rescue Aws::Lambda::Errors::ServiceException => e
    @logger.error("There was an error creating #{function_name}:\n #{e.message}")
rescue Aws::Waiters::Errors::WaiterFailed => e
    @logger.error("Failed waiting for #{function_name} to activate:\n
#{e.message}")
end

```

Invoke your Lambda function with optional runtime parameters.

```

# Invokes a Lambda function.
# @param function_name [String] The name of the function to invoke.
# @param payload [nil] Payload containing runtime parameters.
# @return [Object] The response from the function invocation.
def invoke_function(function_name, payload = nil)
    params = { function_name: function_name }
    params[:payload] = payload unless payload.nil?
    @lambda_client.invoke(params)
rescue Aws::Lambda::Errors::ServiceException => e
    @logger.error("There was an error executing #{function_name}:\n
#{e.message}")
end

```

Update your Lambda function's configuration to inject a new environment variable.

```

# Updates the environment variables for a Lambda function.
# @param function_name: The name of the function to update.
# @param log_level: The log level of the function.
# @return: Data about the update, including the status.
def update_function_configuration(function_name, log_level)
    @lambda_client.update_function_configuration({
        function_name: function_name,
        environment: {
            variables: {
                'LOG_LEVEL' => log_level
            }
        }
    })

```

```

    @lambda_client.wait_until(:function_updated_v2, { function_name:
function_name }) do |w|
      w.max_attempts = 5
      w.delay = 5
    end
  rescue Aws::Lambda::Errors::ServiceException => e
    @logger.error("There was an error updating configurations for
#{function_name}:\n #{e.message}")
  rescue Aws::Waiters::Errors::WaiterFailed => e
    @logger.error("Failed waiting for #{function_name} to activate:\n
#{e.message}")
  end
end

```

Update your Lambda function's code with a different deployment package containing different code.

```

# Updates the code for a Lambda function by submitting a .zip archive that
contains
# the code for the function.
#
# @param function_name: The name of the function to update.
# @param deployment_package: The function code to update, packaged as bytes in
#                               .zip format.
# @return: Data about the update, including the status.
def update_function_code(function_name, deployment_package)
  @lambda_client.update_function_code(
    function_name: function_name,
    zip_file: deployment_package
  )
  @lambda_client.wait_until(:function_updated_v2, { function_name:
function_name }) do |w|
    w.max_attempts = 5
    w.delay = 5
  end
  rescue Aws::Lambda::Errors::ServiceException => e
    @logger.error("There was an error updating function code for:
#{function_name}:\n #{e.message}")
    nil
  rescue Aws::Waiters::Errors::WaiterFailed => e
    @logger.error("Failed waiting for #{function_name} to update:\n
#{e.message}")
  end
end

```

List all existing Lambda functions using the built-in paginator.

```
# Lists the Lambda functions for the current account.
def list_functions
  functions = []
  @lambda_client.list_functions.each do |response|
    response['functions'].each do |function|
      functions.append(function['function_name'])
    end
  end
  functions
rescue Aws::Lambda::Errors::ServiceException => e
  @logger.error("There was an error listing functions:\n #{e.message}")
end
```

Delete a specific Lambda function.

```
# Deletes a Lambda function.
# @param function_name: The name of the function to delete.
def delete_function(function_name)
  print "Deleting function: #{function_name}..."
  @lambda_client.delete_function(
    function_name: function_name
  )
  print 'Done!'.green
rescue Aws::Lambda::Errors::ServiceException => e
  @logger.error("There was an error deleting #{function_name}:\n #{e.message}")
end
```

/*
## Service actions

Service actions wrap the SDK call, taking a client and any specific parameters
necessary for the call.

* CreateFunction
* GetFunction
* ListFunctions
* Invoke
* UpdateFunctionCode
* UpdateFunctionConfiguration
* DeleteFunction

## Scenario

```

A scenario runs at a command prompt and prints output to the user on the result of each service action. A scenario can run in one of two ways: straight through, printing out progress as it goes, or as an interactive question/answer script.

Getting started with functions

Use an SDK to manage AWS Lambda functions: create a function, invoke it, update its code, invoke it again, view its output and logs, and delete it.

This scenario uses two Lambda handlers:

Note: Handlers don't use AWS SDK API calls.

The increment handler is straightforward:

1. It accepts a number, increments it, and returns the new value.
2. It performs simple logging of the result.

The arithmetic handler is more complex:

1. It accepts a set of actions ['plus', 'minus', 'times', 'divided-by'] and two numbers, and returns the result of the calculation.
2. It uses an environment variable to control log level (such as DEBUG, INFO, WARNING, ERROR).

It logs a few things at different levels, such as:

- * DEBUG: Full event data.
- * INFO: The calculation result.
- * WARN~ING~: When a divide by zero error occurs.
- * This will be the typical `RUST_LOG` variable.

The steps of the scenario are:

1. Create an AWS Identity and Access Management (IAM) role that meets the following requirements:
 - * Has an assume_role policy that grants 'lambda.amazonaws.com' the 'sts:AssumeRole' action.
 - * Attaches the 'arn:aws:iam::aws:policy/service-role/AWSLambdaBasicExecutionRole' managed role.
 - * You must wait for ~10 seconds after the role is created before you can use it!
2. Create a function (CreateFunction) for the increment handler by packaging it as a zip and doing one of the following:
 - * Adding it with CreateFunction Code.ZipFile.
 - * --or--

- * Uploading it to Amazon Simple Storage Service (Amazon S3) and adding it with CreateFunction Code.S3Bucket/S3Key.
- * `_Note`: Zipping the file does not have to be done in code._
- * If you have a waiter, use it to wait until the function is active. Otherwise, call GetFunction until State is Active.
- 3. Invoke the function with a number and print the result.
- 4. Update the function (UpdateFunctionCode) to the arithmetic handler by packaging it as a zip and doing one of the following:
 - * Adding it with UpdateFunctionCode ZipFile.
 - * `--or--`
 - * Uploading it to Amazon S3 and adding it with UpdateFunctionCode S3Bucket/S3Key.
- 5. Call GetFunction until Configuration.LastUpdateStatus is 'Successful' (or 'Failed').
- 6. Update the environment variable by calling UpdateFunctionConfiguration and pass it a log level, such as:
 - * `Environment={'Variables': {'RUST_LOG': 'TRACE'}}`
- 7. Invoke the function with an action from the list and a couple of values. Include LogType='Tail' to get logs in the result. Print the result of the calculation and the log.
- 8. [Optional] Invoke the function to provoke a divide-by-zero error and show the log result.
- 9. List all functions for the account, using pagination (ListFunctions).
- 10. Delete the function (DeleteFunction).
- 11. Delete the role.

Each step should use the function created in Service Actions to abstract calling the SDK.

Swift

SDK for Swift

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Define the first Lambda function, which simply increments the specified value.

Actions for Lambda using AWS SDKs

The following code examples demonstrate how to perform individual Lambda actions with AWS SDKs. Each example includes a link to GitHub, where you can find instructions for setting up and running the code.

These excerpts call the Lambda API and are code excerpts from larger programs that must be run in context. You can see actions in context in [Scenarios for Lambda using AWS SDKs](#).

The following examples include only the most commonly used actions. For a complete list, see the [AWS Lambda API Reference](#).

Examples

- [Use CreateAlias with a CLI](#)
- [Use CreateFunction with an AWS SDK or CLI](#)
- [Use DeleteAlias with a CLI](#)
- [Use DeleteFunction with an AWS SDK or CLI](#)
- [Use DeleteFunctionConcurrency with a CLI](#)
- [Use DeleteProvisionedConcurrencyConfig with a CLI](#)
- [Use GetAccountSettings with a CLI](#)
- [Use GetAlias with a CLI](#)
- [Use GetFunction with an AWS SDK or CLI](#)

- [Use GetFunctionConcurrency with a CLI](#)
- [Use GetFunctionConfiguration with a CLI](#)
- [Use GetPolicy with a CLI](#)
- [Use GetProvisionedConcurrencyConfig with a CLI](#)
- [Use Invoke with an AWS SDK or CLI](#)
- [Use ListFunctions with an AWS SDK or CLI](#)
- [Use ListProvisionedConcurrencyConfigs with a CLI](#)
- [Use ListTags with a CLI](#)
- [Use ListVersionsByFunction with a CLI](#)
- [Use PublishVersion with a CLI](#)
- [Use PutFunctionConcurrency with a CLI](#)
- [Use PutProvisionedConcurrencyConfig with a CLI](#)
- [Use RemovePermission with a CLI](#)
- [Use TagResource with a CLI](#)
- [Use UntagResource with a CLI](#)
- [Use UpdateAlias with a CLI](#)
- [Use UpdateFunctionCode with an AWS SDK or CLI](#)
- [Use UpdateFunctionConfiguration with an AWS SDK or CLI](#)

Use CreateAlias with a CLI

The following code examples show how to use CreateAlias.

CLI

AWS CLI

To create an alias for a Lambda function

The following create-alias example creates an alias named LIVE that points to version 1 of the my-function Lambda function.

```
aws lambda create-alias \  
  --function-name my-function \  
  --description "alias for live version of function" \  
  --version 1
```

```
--function-version 1 \  
--name LIVE
```

Output:

```
{  
  "FunctionVersion": "1",  
  "Name": "LIVE",  
  "AliasArn": "arn:aws:lambda:us-west-2:123456789012:function:my-  
function:LIVE",  
  "RevisionId": "873282ed-4cd3-4dc8-a069-d0c647e470c6",  
  "Description": "alias for live version of function"  
}
```

For more information, see [Configuring AWS Lambda Function Aliases](#) in the *AWS Lambda Developer Guide*.

- For API details, see [CreateAlias](#) in *AWS CLI Command Reference*.

PowerShell

Tools for PowerShell V4

Example 1: This example creates a New Lambda Alias for specified version and routing configuration to specify the percentage of invocation requests that it receives.

```
New-LMAlias -FunctionName "MylambdaFunction123" -  
RoutingConfig_AdditionalVersionWeight @{Name="1";Value="0.6"} -Description "Alias  
for version 4" -FunctionVersion 4 -Name "PowershellAlias"
```

- For API details, see [CreateAlias](#) in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: This example creates a New Lambda Alias for specified version and routing configuration to specify the percentage of invocation requests that it receives.

```
New-LMAlias -FunctionName "MylambdaFunction123" -  
RoutingConfig_AdditionalVersionWeight @{Name="1";Value="0.6"} -Description "Alias  
for version 4" -FunctionVersion 4 -Name "PowershellAlias"
```

- For API details, see [CreateAlias](#) in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use CreateFunction with an AWS SDK or CLI

The following code examples show how to use CreateFunction.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

PowerShell

Tools for PowerShell V4

Example 1: This example creates a new C# (dotnetcore1.0 runtime) function named **MyFunction** in AWS Lambda, providing the compiled binaries for the function from a zip file on the local file system (relative or absolute paths may be used). C# Lambda functions specify the handler for the function using the designation **AssemblyName::Namespace.ClassName::MethodName**. You should replace the assembly name (without .dll suffix), namespace, class name and method name parts of the handler spec appropriately. The new function will have environment variables 'envvar1' and 'envvar2' set up from the provided values.

```
Publish-LMFunction -Description "My C# Lambda Function" `
    -FunctionName MyFunction `
    -ZipFilename .\MyFunctionBinaries.zip `
    -Handler "AssemblyName::Namespace.ClassName::MethodName" `
    -Role "arn:aws:iam::123456789012:role/LambdaFullExecRole" `
    -Runtime dotnetcore1.0 `
    -Environment_Variable @{ "envvar1"="value";"envvar2"="value" }
```

Output:

```
CodeSha256      : /NgBMd...gq71I=
CodeSize        : 214784
DeadLetterConfig :
Description      : My C# Lambda Function
Environment      : Amazon.Lambda.Model.EnvironmentResponse
FunctionArn      : arn:aws:lambda:us-west-2:123456789012:function:ToUpper
FunctionName     : MyFunction
Handler          : AssemblyName::Namespace.ClassName::MethodName
KMSKeyArn        :
LastModified     : 2016-12-29T23:50:14.207+0000
MemorySize      : 128
Role             : arn:aws:iam::123456789012:role/LambdaFullExecRole
Runtime          : dotnetcore1.0
```

```
Timeout      : 3
Version      : $LATEST
VpcConfig    :
```

Example 2: This example is similar to the previous one except the function binaries are first uploaded to an Amazon S3 bucket (which must be in the same region as the intended Lambda function) and the resulting S3 object is then referenced when creating the function.

```
Write-S3Object -BucketName amzn-s3-demo-bucket -Key MyFunctionBinaries.zip -
File .\MyFunctionBinaries.zip
Publish-LMFunction -Description "My C# Lambda Function" `
    -FunctionName MyFunction `
    -BucketName amzn-s3-demo-bucket `
    -Key MyFunctionBinaries.zip `
    -Handler "AssemblyName::Namespace.ClassName::MethodName" `
    -Role "arn:aws:iam::123456789012:role/LambdaFullExecRole" `
    -Runtime dotnetcore1.0 `
    -Environment_Variable @{ "envvar1"="value";"envvar2"="value" }
```

- For API details, see [CreateFunction](#) in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Use DeleteAlias with a CLI

The following code examples show how to use DeleteAlias.

CLI

AWS CLI

To delete an alias of a Lambda function

The following delete-alias example deletes the alias named LIVE from the my-function Lambda function.

```
aws lambda delete-alias \  
  --function-name my-function \  
  --name LIVE
```

This command produces no output.

For more information, see [Configuring AWS Lambda Function Aliases](#) in the *AWS Lambda Developer Guide*.

- For API details, see [DeleteAlias](#) in *AWS CLI Command Reference*.

PowerShell

Tools for PowerShell V4

Example 1: This example deletes the Lambda function Alias mentioned in the command.

```
Remove-LMAlias -FunctionName "MylambdaFunction123" -Name "NewAlias"
```

- For API details, see [DeleteAlias](#) in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: This example deletes the Lambda function Alias mentioned in the command.

```
Remove-LMAlias -FunctionName "MyLambdaFunction123" -Name "NewAlias"
```

- For API details, see [DeleteAlias](#) in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use DeleteFunction with an AWS SDK or CLI

The following code examples show how to use DeleteFunction.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Learn the basics](#)

.NET

SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/// <summary>
/// Delete an AWS Lambda function.
/// </summary>
/// <param name="functionName">The name of the Lambda function to
/// delete.</param>
/// <returns>A Boolean value that indicates the success of the action.</
returns>
public async Task<bool> DeleteFunctionAsync(string functionName)
```

```
{
    var request = new DeleteFunctionRequest
    {
        FunctionName = functionName,
    };

    var response = await _lambdaService.DeleteFunctionAsync(request);

    // A return value of NoContent means that the request was processed.
    // In this case, the function was deleted, and the return value
    // is intentionally blank.
    return response.HttpStatusCode == System.Net.HttpStatusCode.NoContent;
}
```

- For API details, see [DeleteFunction](#) in *AWS SDK for .NET API Reference*.

C++

SDK for C++

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
Aws::Client::ClientConfiguration clientConfig;
// Optional: Set to the AWS Region in which the bucket was created
(overrides config file).
// clientConfig.region = "us-east-1";

Aws::Lambda::LambdaClient client(clientConfig);

Aws::Lambda::Model::DeleteFunctionRequest request;
request.SetFunctionName(LAMBDA_NAME);

Aws::Lambda::Model::DeleteFunctionOutcome outcome = client.DeleteFunction(
    request);

if (outcome.IsSuccess()) {
```

```
        std::cout << "The lambda function was successfully deleted." <<
std::endl;
    }
    else {
        std::cerr << "Error with Lambda::DeleteFunction. "
        << outcome.GetError().GetMessage()
        << std::endl;
    }
}
```

- For API details, see [DeleteFunction](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

Example 1: To delete a Lambda function by function name

The following delete-function example deletes the Lambda function named my-function by specifying the function's name.

```
aws lambda delete-function \
    --function-name my-function
```

This command produces no output.

Example 2: To delete a Lambda function by function ARN

The following delete-function example deletes the Lambda function named my-function by specifying the function's ARN.

```
aws lambda delete-function \
    --function-name arn:aws:lambda:us-west-2:123456789012:function:my-function
```

This command produces no output.

Example 3: To delete a Lambda function by partial function ARN

The following delete-function example deletes the Lambda function named my-function by specifying the function's partial ARN.

```
aws lambda delete-function \  
  --function-name 123456789012:function:my-function
```

This command produces no output.

For more information, see [AWS Lambda Function Configuration](#) in the *AWS Lambda Developer Guide*.

- For API details, see [DeleteFunction](#) in *AWS CLI Command Reference*.

Go

Use DeleteFunctionConcurrency with a CLI

The following code examples show how to use DeleteFunctionConcurrency.

CLI

AWS CLI

To remove the reserved concurrent execution limit from a function

The following delete-function-concurrency example deletes the reserved concurrent execution limit from the my-function function.

```
aws lambda delete-function-concurrency \  
  --function-name my-function
```

This command produces no output.

For more information, see [Reserving Concurrency for a Lambda Function](#) in the *AWS Lambda Developer Guide*.

- For API details, see [DeleteFunctionConcurrency](#) in *AWS CLI Command Reference*.

PowerShell

Tools for PowerShell V4

Example 1: This examples removes the Function Concurrency of the Lambda Function.

```
Remove-LMFunctionConcurrency -FunctionName "MylambdaFunction123"
```

- For API details, see [DeleteFunctionConcurrency](#) in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: This examples removes the Function Concurrency of the Lambda Function.

```
Remove-LMFunctionConcurrency -FunctionName "MyLambdaFunction123"
```

- For API details, see [DeleteFunctionConcurrency](#) in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use DeleteProvisionedConcurrencyConfig with a CLI

The following code examples show how to use DeleteProvisionedConcurrencyConfig.

CLI

AWS CLI

To delete a provisioned concurrency configuration

The following delete-provisioned-concurrency-config example deletes the provisioned concurrency configuration for the GREEN alias of the specified function.

```
aws lambda delete-provisioned-concurrency-config \  
  --function-name my-function \  
  --qualifier GREEN
```

- For API details, see [DeleteProvisionedConcurrencyConfig](#) in *AWS CLI Command Reference*.

PowerShell

Tools for PowerShell V4

Example 1: This example removes the Provisioned Concurrency Configuration for a specific Alias.

```
Remove-LMProvisionedConcurrencyConfig -FunctionName "MyLambdaFunction123" -  
Qualifier "NewAlias1"
```

- For API details, see [DeleteProvisionedConcurrencyConfig](#) in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: This example removes the Provisioned Concurrency Configuration for a specific Alias.

```
Remove-LMProvisionedConcurrencyConfig -FunctionName "MyLambdaFunction123" -
Qualifier "NewAlias1"
```

- For API details, see [DeleteProvisionedConcurrencyConfig](#) in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use GetAccountSettings with a CLI

The following code examples show how to use GetAccountSettings.

CLI

AWS CLI

To retrieve details about your account in an AWS Region

The following get-account-settings example displays the Lambda limits and usage information for your account.

```
aws lambda get-account-settings
```

Output:

```
{
  "AccountLimit": {
    "CodeSizeUnzipped": 262144000,
    "UnreservedConcurrentExecutions": 1000,
    "ConcurrentExecutions": 1000,
    "CodeSizeZipped": 52428800,
    "TotalCodeSize": 80530636800
  },
}
```

```

    "AccountUsage": {
      "FunctionCount": 4,
      "TotalCodeSize": 9426
    }
  }
}

```

For more information, see [AWS Lambda Limits](#) in the *AWS Lambda Developer Guide*.

- For API details, see [GetAccountSettings](#) in *AWS CLI Command Reference*.

PowerShell

Tools for PowerShell V4

Example 1: This sample displays to compare the Account Limit and Account Usage

```

Get-LMAccountSetting | Select-Object
@{Name="TotalCodeSizeLimit";Expression={$_.AccountLimit.TotalCodeSize}},
@{Name="TotalCodeSizeUsed";Expression={$_.AccountUsage.TotalCodeSize}}

```

Output:

```

TotalCodeSizeLimit TotalCodeSizeUsed
-----
      80530636800      15078795

```

- For API details, see [GetAccountSettings](#) in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: This sample displays to compare the Account Limit and Account Usage

```

Get-LMAccountSetting | Select-Object
@{Name="TotalCodeSizeLimit";Expression={$_.AccountLimit.TotalCodeSize}},
@{Name="TotalCodeSizeUsed";Expression={$_.AccountUsage.TotalCodeSize}}

```

Output:

```

TotalCodeSizeLimit TotalCodeSizeUsed
-----

```

80530636800

15078795

- For API details, see [GetAccountSettings](#) in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use GetAlias with a CLI

The following code examples show how to use GetAlias.

CLI

AWS CLI

To retrieve details about a function alias

The following `get-alias` example displays details for the alias named `LIVE` on the `my-function` Lambda function.

```
aws lambda get-alias \  
  --function-name my-function \  
  --name LIVE
```

Output:

```
{  
  "FunctionVersion": "3",  
  "Name": "LIVE",  
  "AliasArn": "arn:aws:lambda:us-west-2:123456789012:function:my-  
function:LIVE",  
  "RevisionId": "594f41fb-b85f-4c20-95c7-6ca5f2a92c93",  
  "Description": "alias for live version of function"  
}
```

For more information, see [Configuring AWS Lambda Function Aliases](#) in the *AWS Lambda Developer Guide*.

- For API details, see [GetAlias](#) in *AWS CLI Command Reference*.

PowerShell

Tools for PowerShell V4

Example 1: This example retrieves the Routing Config weights for a specific Lambda Function Alias.

```
Get-LMAlias -FunctionName "MylambdaFunction123" -Name "newlabel1" -Select  
RoutingConfig
```

Output:

```
AdditionalVersionWeights  
-----  
{[1, 0.6]}
```

- For API details, see [GetAlias](#) in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: This example retrieves the Routing Config weights for a specific Lambda Function Alias.

```
Get-LMAlias -FunctionName "MylambdaFunction123" -Name "newlabel1" -Select  
RoutingConfig
```

Output:

```
AdditionalVersionWeights  
-----  
{[1, 0.6]}
```

- For API details, see [GetAlias](#) in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

Use GetFunctionConcurrency with a CLI

The following code examples show how to use GetFunctionConcurrency.

CLI

AWS CLI

To view the reserved concurrency setting for a function

The following `get-function-concurrency` example retrieves the reserved concurrency setting for the specified function.

```
aws lambda get-function-concurrency \  
  --function-name my-function
```

Output:

```
{  
  "ReservedConcurrentExecutions": 250  
}
```

- For API details, see [GetFunctionConcurrency](#) in *AWS CLI Command Reference*.

PowerShell

Tools for PowerShell V4

Example 1: This examples gets the Reserved concurrency for the Lambda Function

```
Get-LMFunctionConcurrency -FunctionName "MylambdaFunction123" -Select *
```

Output:

```
ReservedConcurrentExecutions  
-----  
100
```

- For API details, see [GetFunctionConcurrency](#) in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: This examples gets the Reserved concurrency for the Lambda Function

```
Get-LMFunctionConcurrency -FunctionName "MylambdaFunction123" -Select *
```

Output:

```
ReservedConcurrentExecutions  
-----
```

100

- For API details, see [GetFunctionConcurrency](#) in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use GetFunctionConfiguration with a CLI

The following code examples show how to use GetFunctionConfiguration.

CLI

AWS CLI

To retrieve the version-specific settings of a Lambda function

The following get-function-configuration example displays the settings for version 2 of the my-function function.

```
aws lambda get-function-configuration \  
  --function-name my-function:2
```

Output:

```
{  
  "FunctionName": "my-function",  
  "LastModified": "2019-09-26T20:28:40.438+0000",

Use GetPolicy with a CLI

The following code examples show how to use GetPolicy.

CLI

AWS CLI

To retrieve the resource-based IAM policy for a function, version, or alias

The following get-policy example displays policy information about the my-function Lambda function.

```

aws lambda get-policy \
  --function-name my-function

```

Output:

```

{
  "Policy": {
    "Version": "2012-10-17",
    "Id": "default",

```

```

    "Statement":
    [
        {
            "Sid": "iot-events",
            "Effect": "Allow",
            "Principal": {"Service": "iotevents.amazonaws.com"},
            "Action": "lambda:InvokeFunction",
            "Resource": "arn:aws:lambda:us-west-2:123456789012:function:my-
function"
        }
    ],
    "RevisionId": "93017fc9-59cb-41dc-901b-4845ce4bf668"
}

```

For more information, see [Using Resource-based Policies for AWS Lambda](#) in the *AWS Lambda Developer Guide*.

- For API details, see [GetPolicy](#) in *AWS CLI Command Reference*.

PowerShell

Tools for PowerShell V4

Example 1: This sample displays the Function policy of the Lambda function

```
Get-LMPolicy -FunctionName test -Select Policy
```

Output:

```

{"Version": "2012-10-17",      "Id": "default", "Statement":
[{"Sid": "xxxx", "Effect": "Allow", "Principal":
{"Service": "sns.amazonaws.com"}, "Action": "lambda:InvokeFunction", "Resource": "arn:aws:lambda:us-east-1:123456789102:function:test"]}]}

```

- For API details, see [GetPolicy](#) in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: This sample displays the Function policy of the Lambda function

```
Get-LMPolicy -FunctionName test -Select Policy
```

Output:

```
{
  "Version": "2012-10-17",
  "Id": "default",
  "Statement": [
    {
      "Sid": "xxxx",
      "Effect": "Allow",
      "Principal": {
        "Service": "sns.amazonaws.com"
      },
      "Action": "lambda:InvokeFunction",
      "Resource": "arn:aws:lambda:us-east-1:123456789102:function:test"
    }
  ]
}
```

- For API details, see [GetPolicy](#) in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use GetProvisionedConcurrencyConfig with a CLI

The following code examples show how to use GetProvisionedConcurrencyConfig.

CLI**AWS CLI****To view a provisioned concurrency configuration**

The following get-provisioned-concurrency-config example displays details for the provisioned concurrency configuration for the BLUE alias of the specified function.

```
aws lambda get-provisioned-concurrency-config \
  --function-name my-function \
  --qualifier BLUE
```

Output:

```
{
  "RequestedProvisionedConcurrentExecutions": 100,
  "AvailableProvisionedConcurrentExecutions": 100,
  "AllocatedProvisionedConcurrentExecutions": 100,
  "Status": "READY",
  "LastModified": "2019-12-31T20:28:49+0000"
}
```

- For API details, see [GetProvisionedConcurrencyConfig](#) in *AWS CLI Command Reference*.

PowerShell

Tools for PowerShell V4

Example 1: This example gets the provisioned Concurrency Configuration for the specified Alias of the Lambda Function.

```
C:\>Get-LMProvisionedConcurrencyConfig -FunctionName "MyLambdaFunction123" -
Qualifier "NewAlias1"
```

Output:

```
AllocatedProvisionedConcurrentExecutions : 0
AvailableProvisionedConcurrentExecutions : 0
LastModified                             : 2020-01-15T03:21:26+0000
RequestedProvisionedConcurrentExecutions : 70
Status                                    : IN_PROGRESS
StatusReason                             :
```

- For API details, see [GetProvisionedConcurrencyConfig](#) in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: This example gets the provisioned Concurrency Configuration for the specified Alias of the Lambda Function.

```
C:\>Get-LMProvisionedConcurrencyConfig -FunctionName "MyLambdaFunction123" -
Qualifier "NewAlias1"
```

Output:

```
AllocatedProvisionedConcurrentExecutions : 0
AvailableProvisionedConcurrentExecutions : 0
LastModified                             : 2020-01-15T03:21:26+0000
RequestedProvisionedConcurrentExecutions : 70
Status                                    : IN_PROGRESS
StatusReason                             :
```

- For API details, see [GetProvisionedConcurrencyConfig](#) in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use Invoke with an AWS SDK or CLI

The following code examples show how to use Invoke.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Learn the basics](#)

.NET

SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/// <summary>
/// Invoke a Lambda function.
/// </summary>
/// <param name="functionName">The name of the Lambda function to
/// invoke.</param>
/// <param name="parameters">The parameter values that will be passed to the
function.</param>
/// <returns>A System Threading Task.</returns>
public async Task<string> InvokeFunctionAsync(
    string functionName,
    string parameters)
{
    var payload = parameters;
    var request = new InvokeRequest
    {
        FunctionName = functionName,
        Payload = payload,
    };
};
```

```

        var response = await _lambdaService.InvokeAsync(request);
        MemoryStream stream = response.Payload;
        string returnValue =
System.Text.Encoding.UTF8.GetString(stream.ToArray());
        return returnValue;
    }

```

- For API details, see [Invoke](#) in *AWS SDK for .NET API Reference*.

C++

SDK for C++

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```

    Aws::Client::ClientConfiguration clientConfig;
    // Optional: Set to the AWS Region in which the bucket was created
    (overrides config file).
    // clientConfig.region = "us-east-1";

    Aws::Lambda::LambdaClient client(clientConfig);

    Aws::Lambda::Model::InvokeRequest request;
    request.SetFunctionName(LAMBDA_NAME);
    request.SetLogType(logType);
    std::shared_ptr<Aws::IOStream> payload =
    Aws::MakeShared<Aws::StringStream>(
        "FunctionTest");
    *payload << jsonPayload.View().WriteReadable();
    request.SetBody(payload);
    request.SetContentType("application/json");
    Aws::Lambda::Model::InvokeOutcome outcome = client.Invoke(request);

    if (outcome.IsSuccess()) {
        invokeResult = std::move(outcome.GetResult());
    }

```

```
        result = true;
        break;
    }

    else {
        std::cerr << "Error with Lambda::InvokeRequest. "
                   << outcome.GetError().GetMessage()
                   << std::endl;
        break;
    }
}
```

- For API details, see [Invoke](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

Example 1: To invoke a Lambda function synchronously

The following invoke example invokes the `my-function` function synchronously. The `cli-binary-format` option is required if you're using AWS CLI version 2. For more information, see [AWS CLI supported global command line options](#) in the *AWS Command Line Interface User Guide*.

```
aws lambda invoke \
    --function-name my-function \
    --cli-binary-format raw-in-base64-out \
    --payload '{ "name": "Bob" }' \
    response.json
```

Output:

```
{
  "ExecutedVersion": "$LATEST",
  "StatusCode": 200
}
```

For more information, see [Invoke a Lambda function synchronously](#) in the *AWS Lambda Developer Guide*.

Example 2: To invoke a Lambda function asynchronously

The following invoke example invokes the `my-function` function asynchronously. The `cli-binary-format` option is required if you're using AWS CLI version 2. For more information, see [AWS CLI supported global command line options](#) in the *AWS Command Line Interface User Guide*.

```
aws lambda invoke \  
    --function-name my-function \  
    --invocation-type Event \  
    --cli-binary-format raw-in-base64-out \  
    --payload '{ "name": "Bob" }' \  
    response.json
```

Output:

```
{  
    "StatusCode": 202  
}
```

For more information, see [Invoking a Lambda function asynchronously](#) in the *AWS Lambda Developer Guide*.

- For API details, see [Invoke](#) in *AWS CLI Command Reference*.

Use ListProvisionedConcurrencyConfigs with a CLI

The following code examples show how to use ListProvisionedConcurrencyConfigs.

CLI

AWS CLI

To get a list of provisioned concurrency configurations

The following list-provisioned-concurrency-configs example lists the provisioned concurrency configurations for the specified function.

```
aws lambda list-provisioned-concurrency-configs \
  --function-name my-function
```

Output:

```
{
  "ProvisionedConcurrencyConfigs": [
    {
      "FunctionArn": "arn:aws:lambda:us-east-2:123456789012:function:my-
function:GREEN",
      "RequestedProvisionedConcurrentExecutions": 100,
      "AvailableProvisionedConcurrentExecutions": 100,
      "AllocatedProvisionedConcurrentExecutions": 100,
      "Status": "READY",
      "LastModified": "2019-12-31T20:29:00+0000"
    },
    {
      "FunctionArn": "arn:aws:lambda:us-east-2:123456789012:function:my-
function:BLUE",
      "RequestedProvisionedConcurrentExecutions": 100,
      "AvailableProvisionedConcurrentExecutions": 100,
      "AllocatedProvisionedConcurrentExecutions": 100,
```

```
        "Status": "READY",  
        "LastModified": "2019-12-31T20:28:49+0000"  
      }  
    ]  
  }  
}
```

- For API details, see [ListProvisionedConcurrencyConfigs](#) in *AWS CLI Command Reference*.

PowerShell

Tools for PowerShell V4

Example 1: This example retrieves the list of provisioned concurrency configurations for a Lambda function.

```
Get-LMProvisionedConcurrencyConfigList -FunctionName "MylambdaFunction123"
```

- For API details, see [ListProvisionedConcurrencyConfigs](#) in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: This example retrieves the list of provisioned concurrency configurations for a Lambda function.

```
Get-LMProvisionedConcurrencyConfigList -FunctionName "MylambdaFunction123"
```

- For API details, see [ListProvisionedConcurrencyConfigs](#) in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use ListTags with a CLI

The following code examples show how to use ListTags.

CLI

AWS CLI

To retrieve the list of tags for a Lambda function

The following `list-tags` example displays the tags attached to the `my-function` Lambda function.

```
aws lambda list-tags \  
  --resource arn:aws:lambda:us-west-2:123456789012:function:my-function
```

Output:

```
{  
  "Tags": {  
    "Category": "Web Tools",  
    "Department": "Sales"  
  }  
}
```

For more information, see [Tagging Lambda Functions](#) in the *AWS Lambda Developer Guide*.

- For API details, see [ListTags](#) in *AWS CLI Command Reference*.

PowerShell

Tools for PowerShell V4

Example 1: Retrieves the tags and their values currently set on the specified function.

```
Get-LMResourceTag -Resource "arn:aws:lambda:us-  
west-2:123456789012:function:MyFunction"
```

Output:

Key	Value
---	-----
California	Sacramento
Oregon	Salem

Washington Olympia

- For API details, see [ListTags](#) in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: Retrieves the tags and their values currently set on the specified function.

```
Get-LMResourceTag -Resource "arn:aws:lambda:us-west-2:123456789012:function:MyFunction"
```

Output:

Key	Value
---	----
California	Sacramento
Oregon	Salem
Washington	Olympia

- For API details, see [ListTags](#) in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use ListVersionsByFunction with a CLI

The following code examples show how to use ListVersionsByFunction.

CLI

AWS CLI

To retrieve a list of versions of a function

The following list-versions-by-function example displays the list of versions for the my-function Lambda function.

```
aws lambda list-versions-by-function \  
  --function-name my-function
```

Output:

```
{
  "Versions": [
    {
      "TracingConfig": {
        "Mode": "PassThrough"
      },
      "Version": "$LATEST",

2019-12-25T09:52:59.872+0000 lambda

```

- For API details, see [ListVersionsByFunction](#) in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use PublishVersion with a CLI

The following code examples show how to use PublishVersion.

CLI

AWS CLI

To publish a new version of a function

The following publish-version example publishes a new version of the my-function Lambda function.

```

aws lambda publish-version \
  --function-name my-function

```

Output:

```

{
  "TracingConfig": {
    "Mode": "PassThrough"
  },
  "CodeSha256": "dBG9m8SGdm1Ejw/JYX1hhvCrAv5TxvXsbl/RM10fT/I=",
  "FunctionName": "my-function",
  "CodeSize": 294,
  "RevisionId": "f31d3d39-cc63-4520-97d4-43cd44c94c20",
  "MemorySize": 128,

```

```
{
  "FunctionArn": "arn:aws:lambda:us-west-2:123456789012:function:my-
function:3",
  "Version": "2",
  "Role": "arn:aws:iam::123456789012:role/service-role/MyTestFunction-role-
zgur6bf4",
  "Timeout": 3,
  "LastModified": "2019-09-23T18:32:33.857+0000",
  "Handler": "my-function.handler",
  "Runtime": "nodejs10.x",
  "Description": ""
}
```

For more information, see [Configuring AWS Lambda Function Aliases](#) in the *AWS Lambda Developer Guide*.

- For API details, see [PublishVersion](#) in *AWS CLI Command Reference*.

PowerShell

Tools for PowerShell V4

Example 1: This example creates a version for the existing snapshot of Lambda Function Code

```
Publish-LMVersion -FunctionName "MylambdaFunction123" -Description "Publishing
Existing Snapshot of function code as a new version through Powershell"
```

- For API details, see [PublishVersion](#) in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: This example creates a version for the existing snapshot of Lambda Function Code

```
Publish-LMVersion -FunctionName "MylambdaFunction123" -Description "Publishing
Existing Snapshot of function code as a new version through Powershell"
```

- For API details, see [PublishVersion](#) in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use PutFunctionConcurrency with a CLI

The following code examples show how to use PutFunctionConcurrency.

CLI

AWS CLI

To configure a reserved concurrency limit for a function

The following put-function-concurrency example configures 100 reserved concurrent executions for the my-function function.

```
aws lambda put-function-concurrency \
  --function-name my-function \
  --reserved-concurrent-executions 100
```

Output:

```
{
  "ReservedConcurrentExecutions": 100
}
```

For more information, see [Reserving Concurrency for a Lambda Function](#) in the *AWS Lambda Developer Guide*.

- For API details, see [PutFunctionConcurrency](#) in *AWS CLI Command Reference*.

PowerShell

Tools for PowerShell V4

Example 1: This example applies the concurrency settings for the Function as a whole.

```
Write-LMFunctionConcurrency -FunctionName "MylambdaFunction123" -
ReservedConcurrentExecution 100
```

- For API details, see [PutFunctionConcurrency](#) in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: This example applies the concurrency settings for the Function as a whole.

```
Write-LMFunctionConcurrency -FunctionName "MyLambdaFunction123" -
ReservedConcurrentExecution 100
```

- For API details, see [PutFunctionConcurrency](#) in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use PutProvisionedConcurrencyConfig with a CLI

The following code examples show how to use PutProvisionedConcurrencyConfig.

CLI

AWS CLI

To allocate provisioned concurrency

The following put-provisioned-concurrency-config example allocates 100 provisioned concurrency for the BLUE alias of the specified function.

```
aws lambda put-provisioned-concurrency-config \
  --function-name my-function \
  --qualifier BLUE \
  --provisioned-concurrent-executions 100
```

Output:

```
{
  "Requested ProvisionedConcurrentExecutions": 100,
  "Allocated ProvisionedConcurrentExecutions": 0,
  "Status": "IN_PROGRESS",
  "LastModified": "2019-11-21T19:32:12+0000"
}
```

- For API details, see [PutProvisionedConcurrencyConfig](#) in *AWS CLI Command Reference*.

PowerShell

Tools for PowerShell V4

Example 1: This example adds a provisioned concurrency configuration to a Function's Alias

```
Write-LMProvisionedConcurrencyConfig -FunctionName "MyLambdaFunction123" -  
ProvisionedConcurrentExecution 20 -Qualifier "NewAlias1"
```

- For API details, see [PutProvisionedConcurrencyConfig](#) in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: This example adds a provisioned concurrency configuration to a Function's Alias

```
Write-LMProvisionedConcurrencyConfig -FunctionName "MyLambdaFunction123" -  
ProvisionedConcurrentExecution 20 -Qualifier "NewAlias1"
```

- For API details, see [PutProvisionedConcurrencyConfig](#) in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use RemovePermission with a CLI

The following code examples show how to use RemovePermission.

CLI

AWS CLI

To remove permissions from an existing Lambda function

The following remove-permission example removes permission to invoke a function named my-function.

```
aws lambda remove-permission \  
  --function-name my-function \  
  --statement-id sns
```

This command produces no output.

For more information, see [Using Resource-based Policies for AWS Lambda](#) in the *AWS Lambda Developer Guide*.

- For API details, see [RemovePermission](#) in *AWS CLI Command Reference*.

PowerShell

Tools for PowerShell V4

Example 1: This example removes the function policy for the specified StatementId of a Lambda Function.

```
$policy = Get-LMPolicy -FunctionName "MylambdaFunction123" -Select Policy |  
  ConvertFrom-Json| Select-Object -ExpandProperty Statement  
Remove-LMPermission -FunctionName "MylambdaFunction123" -StatementId  
  $policy[0].Sid
```

- For API details, see [RemovePermission](#) in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: This example removes the function policy for the specified StatementId of a Lambda Function.

```
$policy = Get-LMPolicy -FunctionName "MylambdaFunction123" -Select Policy |  
  ConvertFrom-Json| Select-Object -ExpandProperty Statement  
Remove-LMPermission -FunctionName "MylambdaFunction123" -StatementId  
  $policy[0].Sid
```

- For API details, see [RemovePermission](#) in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use TagResource with a CLI

The following code examples show how to use TagResource.

CLI

AWS CLI

To add tags to an existing Lambda function

The following tag-resource example adds a tag with the key name DEPARTMENT and a value of Department A to the specified Lambda function.

```
aws lambda tag-resource \  
  --resource arn:aws:lambda:us-west-2:123456789012:function:my-function \  
  --tags "DEPARTMENT=Department A"
```

This command produces no output.

For more information, see [Tagging Lambda Functions](#) in the *AWS Lambda Developer Guide*.

- For API details, see [TagResource](#) in *AWS CLI Command Reference*.

PowerShell

Tools for PowerShell V4

Example 1: Adds the three tags (Washington, Oregon and California) and their associated values to the specified function identified by its ARN.

```
Add-LMResourceTag -Resource "arn:aws:lambda:us-  
west-2:123456789012:function:MyFunction" -Tag @{ "Washington" = "Olympia";  
  "Oregon" = "Salem"; "California" = "Sacramento" }
```

- For API details, see [TagResource](#) in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: Adds the three tags (Washington, Oregon and California) and their associated values to the specified function identified by its ARN.

```
Add-LMResourceTag -Resource "arn:aws:lambda:us-west-2:123456789012:function:MyFunction" -Tag @{ "Washington" = "Olympia";  
  "Oregon" = "Salem"; "California" = "Sacramento" }
```

- For API details, see [TagResource](#) in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use UntagResource with a CLI

The following code examples show how to use UntagResource.

CLI

AWS CLI

To remove tags from an existing Lambda function

The following `untag-resource` example removes the tag with the key name `DEPARTMENT` tag from the `my-function` Lambda function.

```
aws lambda untag-resource \  
  --resource arn:aws:lambda:us-west-2:123456789012:function:my-function \  
  --tag-keys DEPARTMENT
```

This command produces no output.

For more information, see [Tagging Lambda Functions](#) in the *AWS Lambda Developer Guide*.

- For API details, see [UntagResource](#) in *AWS CLI Command Reference*.

PowerShell

Tools for PowerShell V4

Example 1: Removes the supplied tags from a function. The cmdlet will prompt for confirmation before proceeding unless the `-Force` switch is specified. A single call is made to the service to remove the tags.

```
Remove-LMResourceTag -Resource "arn:aws:lambda:us-west-2:123456789012:function:MyFunction" -TagKey  
"Washington","Oregon","California"
```

Example 2: Removes the supplied tags from a function. The cmdlet will prompt for confirmation before proceeding unless the -Force switch is specified. Once call to the service is made per supplied tag.

```
"Washington","Oregon","California" | Remove-LMResourceTag -Resource  
"arn:aws:lambda:us-west-2:123456789012:function:MyFunction"
```

- For API details, see [UntagResource](#) in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: Removes the supplied tags from a function. The cmdlet will prompt for confirmation before proceeding unless the -Force switch is specified. A single call is made to the service to remove the tags.

```
Remove-LMResourceTag -Resource "arn:aws:lambda:us-west-2:123456789012:function:MyFunction" -TagKey  
"Washington","Oregon","California"
```

Example 2: Removes the supplied tags from a function. The cmdlet will prompt for confirmation before proceeding unless the -Force switch is specified. Once call to the service is made per supplied tag.

```
"Washington","Oregon","California" | Remove-LMResourceTag -Resource  
"arn:aws:lambda:us-west-2:123456789012:function:MyFunction"
```

- For API details, see [UntagResource](#) in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use UpdateAlias with a CLI

The following code examples show how to use UpdateAlias.

CLI

AWS CLI

To update a function alias

The following `update-alias` example updates the alias named `LIVE` to point to version 3 of the `my-function` Lambda function.

```
aws lambda update-alias \  
  --function-name my-function \  
  --function-version 3 \  
  --name LIVE
```

Output:

```
{  
  "FunctionVersion": "3",  
  "Name": "LIVE",  
  "AliasArn": "arn:aws:lambda:us-west-2:123456789012:function:my-  
function:LIVE",  
  "RevisionId": "594f41fb-b85f-4c20-95c7-6ca5f2a92c93",  
  "Description": "alias for live version of function"  
}
```

For more information, see [Configuring AWS Lambda Function Aliases](#) in the *AWS Lambda Developer Guide*.

- For API details, see [UpdateAlias](#) in *AWS CLI Command Reference*.

PowerShell

Tools for PowerShell V4

Example 1: This example updates the Configuration of an existing Lambda function Alias. It updates the `RoutingConfiguration` value to shift 60% (0.6) of traffic to version 1

```
Update-LMAlias -FunctionName "MyLambdaFunction123" -Description  
  " Alias for version 2" -FunctionVersion 2 -Name "newlabel1" -  
RoutingConfig_AdditionalVersionWeight @{Name="1";Value="0.6"}
```

- For API details, see [UpdateAlias](#) in *AWS Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: This example updates the Configuration of an existing Lambda function Alias. It updates the RoutingConfiguration value to shift 60% (0.6) of traffic to version 1

```
Update-LMAlias -FunctionName "MylambdaFunction123" -Description  
  " Alias for version 2" -FunctionVersion 2 -Name "newlabel1" -  
  RoutingConfig_AdditionalVersionWeight @{Name="1";Value="0.6"}
```

- For API details, see [UpdateAlias](#) in *AWS Tools for PowerShell Cmdlet Reference (V5)*.

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use UpdateFunctionCode with an AWS SDK or CLI

The following code examples show how to use UpdateFunctionCode.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

CLI

AWS CLI

To modify the configuration of a function

The following update-function-configuration example modifies the memory size to be 256 MB for the unpublished (\$LATEST) version of the my-function function.

```

aws lambda update-function-configuration \
    --function-name my-function \
    --memory-size 256

```

Output:

```

{
    "FunctionName": "my-function",
    "LastModified": "2019-09-26T20:28:40.438+0000",
    "RevisionId": "e52502d4-9320-4688-9cd6-152a6ab7490d",
    "MemorySize": 256,

```

```

    "Version": "$LATEST",

Scenarios for Lambda using AWS SDKs

The following code examples show you how to implement common scenarios in Lambda with AWS SDKs. These scenarios show you how to accomplish specific tasks by calling multiple functions

within Lambda or combined with other AWS services. Each scenario includes a link to the complete source code, where you can find instructions on how to set up and run the code.

Scenarios target an intermediate level of experience to help you understand service actions in context.

Examples

- [Automatically confirm known Amazon Cognito users with a Lambda function using an AWS SDK](#)
- [Automatically migrate known Amazon Cognito users with a Lambda function using an AWS SDK](#)
- [Create an API Gateway REST API to track COVID-19 data](#)
- [Create a lending library REST API](#)
- [Create a messenger application with Step Functions](#)
- [Create a photo asset management application that lets users manage photos using labels](#)
- [Create a websocket chat application with API Gateway](#)
- [Create an application that analyzes customer feedback and synthesizes audio](#)
- [Invoke a Lambda function from a browser](#)
- [Transform data for your application with S3 Object Lambda](#)
- [Use API Gateway to invoke a Lambda function](#)
- [Use Step Functions to invoke Lambda functions](#)
- [Use scheduled events to invoke a Lambda function](#)
- [Use the Amazon Neptune API to develop a Lambda function that queries graph data](#)
- [Write custom activity data with a Lambda function after Amazon Cognito user authentication using an AWS SDK](#)

Automatically confirm known Amazon Cognito users with a Lambda function using an AWS SDK

The following code examples show how to automatically confirm known Amazon Cognito users with a Lambda function.

- Configure a user pool to call a Lambda function for the PreSignUp trigger.
- Sign up a user with Amazon Cognito.
- The Lambda function scans a DynamoDB table and automatically confirms known users.

- Sign in as the new user, then clean up resources.

JavaScript

SDK for JavaScript (v3)

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Configure an interactive "Scenario" run. The JavaScript (v3) examples share a Scenario runner to streamline complex examples. The complete source code is on GitHub.

```
import { AutoConfirm } from "../scenario-auto-confirm.js";
```

```

/**
 * The context is passed to every scenario. Scenario steps
 * will modify the context.
 */
const context = {
  errors: [],
  users: [
    {
      UserName: "test_user_1",
      userEmail: "test_email_1@example.com",
    },
    {
      UserName: "test_user_2",
      userEmail: "test_email_2@example.com",
    },
    {
      UserName: "test_user_3",
      userEmail: "test_email_3@example.com",
    },
  ],
};

/**
 * Three Scenarios are created for the workflow. A Scenario is an orchestration
 * class
 * that simplifies running a series of steps.
 */
export const scenarios = {
  // Demonstrate automatically confirming known users in a database.
  "auto-confirm": AutoConfirm(context),
};

// Call function if run directly
import { fileURLToPath } from "node:url";
import { parseScenarioArgs } from "@aws-doc-sdk-examples/lib/scenario/index.js";

if (process.argv[1] === fileURLToPath(import.meta.url)) {
  parseScenarioArgs(scenarios, {
    name: "Cognito user pools and triggers",
    description:
      "Demonstrate how to use the AWS SDKs to customize Amazon Cognito
      authentication behavior.",
  });
}

```

This Scenario demonstrates auto-confirming a known user. It orchestrates the example steps.

Automatically migrate known Amazon Cognito users with a Lambda function using an AWS SDK

The following code example shows how to automatically migrate known Amazon Cognito users with a Lambda function.

- Configure a user pool to call a Lambda function for the `MigrateUser` trigger.
- Sign in to Amazon Cognito with a username and email that is not in the user pool.
- The Lambda function scans a DynamoDB table and automatically migrates known users to the user pool.
- Perform the forgot password flow to reset the password for the migrated user.
- Sign in as the new user, then clean up resources.

Go

SDK for Go V2

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Run an interactive scenario at a command prompt.

Create an API Gateway REST API to track COVID-19 data

The following code example shows how to create a REST API that simulates a system to track daily cases of COVID-19 in the United States, using fictional data.

Python

SDK for Python (Boto3)

Shows how to use AWS Chalice with the AWS SDK for Python (Boto3) to create a serverless REST API that uses Amazon API Gateway, AWS Lambda, and Amazon DynamoDB. The REST

API simulates a system that tracks daily cases of COVID-19 in the United States, using fictional data. Learn how to:

- Use AWS Chalice to define routes in Lambda functions that are called to handle REST requests that come through API Gateway.
- Use Lambda functions to retrieve and store data in a DynamoDB table to serve REST requests.
- Define table structure and security role resources in an AWS CloudFormation template.
- Use AWS Chalice and CloudFormation to package and deploy all necessary resources.
- Use CloudFormation to clean up all created resources.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- API Gateway
- CloudFormation
- DynamoDB
- Lambda

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Create a lending library REST API

The following code example shows how to create a lending library where patrons can borrow and return books by using a REST API backed by an Amazon Aurora database.

Python

SDK for Python (Boto3)

Shows how to use the AWS SDK for Python (Boto3) with the Amazon Relational Database Service (Amazon RDS) API and AWS Chalice to create a REST API backed by an Amazon Aurora database. The web service is fully serverless and represents a simple lending library where patrons can borrow and return books. Learn how to:

- Create and manage a serverless Aurora database cluster.

- Use AWS Secrets Manager to manage database credentials.
- Implement a data storage layer that uses Amazon RDS to move data into and out of the database.
- Use AWS Chalice to deploy a serverless REST API to Amazon API Gateway and AWS Lambda.
- Use the Requests package to send requests to the web service.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- API Gateway
- Aurora
- Lambda
- Secrets Manager

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Create a messenger application with Step Functions

The following code example shows how to create an AWS Step Functions messenger application that retrieves message records from a database table.

Python

SDK for Python (Boto3)

Shows how to use the AWS SDK for Python (Boto3) with AWS Step Functions to create a messenger application that retrieves message records from an Amazon DynamoDB table and sends them with Amazon Simple Queue Service (Amazon SQS). The state machine integrates with an AWS Lambda function to scan the database for unsent messages.

- Create a state machine that retrieves and updates message records from an Amazon DynamoDB table.
- Update the state machine definition to also send messages to Amazon Simple Queue Service (Amazon SQS).

- Start and stop state machine runs.
- Connect to Lambda, DynamoDB, and Amazon SQS from a state machine by using service integrations.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- Lambda
- Amazon SQS
- Step Functions

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Create a photo asset management application that lets users manage photos using labels

The following code examples show how to create a serverless application that lets users manage photos using labels.

.NET

SDK for .NET

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

For a deep dive into the origin of this example see the post on [AWS Community](#).

Services used in this example

- API Gateway

- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

C++

SDK for C++

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

For a deep dive into the origin of this example see the post on [AWS Community](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

Java

SDK for Java 2.x

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

For a deep dive into the origin of this example see the post on [AWS Community](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

JavaScript

SDK for JavaScript (v3)

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

For a deep dive into the origin of this example see the post on [AWS Community](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

Kotlin

SDK for Kotlin

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

For a deep dive into the origin of this example see the post on [AWS Community](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

PHP

SDK for PHP

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

For a deep dive into the origin of this example see the post on [AWS Community](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

Rust

SDK for Rust

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

For a deep dive into the origin of this example see the post on [AWS Community](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Create a websocket chat application with API Gateway

The following code example shows how to create a chat application that is served by a websocket API built on Amazon API Gateway.

Python

SDK for Python (Boto3)

Shows how to use the AWS SDK for Python (Boto3) with Amazon API Gateway V2 to create a websocket API that integrates with AWS Lambda and Amazon DynamoDB.

- Create a websocket API served by API Gateway.
- Define a Lambda handler that stores connections in DynamoDB and posts messages to other chat participants.
- Connect to the websocket chat application and send messages with the Websockets package.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Create an application that analyzes customer feedback and synthesizes audio

The following code examples show how to create an application that analyzes customer comment cards, translates them from their original language, determines their sentiment, and generates an audio file from the translated text.

.NET

SDK for .NET

This example application analyzes and stores customer feedback cards. Specifically, it fulfills the need of a fictitious hotel in New York City. The hotel receives feedback from guests in various languages in the form of physical comment cards. That feedback is uploaded into the app through a web client. After an image of a comment card is uploaded, the following steps occur:

- Text is extracted from the image using Amazon Textract.
- Amazon Comprehend determines the sentiment of the extracted text and its language.
- The extracted text is translated to English using Amazon Translate.
- Amazon Polly synthesizes an audio file from the extracted text.

The full app can be deployed with the AWS CDK. For source code and deployment instructions, see the project in [GitHub](#).

Services used in this example

- Amazon Comprehend
- Lambda

- Amazon Polly
- Amazon Textract
- Amazon Translate

Java

SDK for Java 2.x

This example application analyzes and stores customer feedback cards. Specifically, it fulfills the need of a fictitious hotel in New York City. The hotel receives feedback from guests in various languages in the form of physical comment cards. That feedback is uploaded into the app through a web client. After an image of a comment card is uploaded, the following steps occur:

- Text is extracted from the image using Amazon Textract.
- Amazon Comprehend determines the sentiment of the extracted text and its language.
- The extracted text is translated to English using Amazon Translate.
- Amazon Polly synthesizes an audio file from the extracted text.

The full app can be deployed with the AWS CDK. For source code and deployment instructions, see the project in [GitHub](#).

Services used in this example

- Amazon Comprehend
- Lambda
- Amazon Polly
- Amazon Textract
- Amazon Translate

JavaScript

SDK for JavaScript (v3)

This example application analyzes and stores customer feedback cards. Specifically, it fulfills the need of a fictitious hotel in New York City. The hotel receives feedback from guests in various languages in the form of physical comment cards. That feedback is uploaded into

the app through a web client. After an image of a comment card is uploaded, the following steps occur:

- Text is extracted from the image using Amazon Textract.
- Amazon Comprehend determines the sentiment of the extracted text and its language.
- The extracted text is translated to English using Amazon Translate.
- Amazon Polly synthesizes an audio file from the extracted text.

The full app can be deployed with the AWS CDK. For source code and deployment instructions, see the project in [GitHub](#). The following excerpts show how the AWS SDK for JavaScript is used inside of Lambda functions.

```
import {
  ComprehendClient,
  DetectDominantLanguageCommand,
  DetectSentimentCommand,
} from "@aws-sdk/client-comprehend";

/**
 * Determine the language and sentiment of the extracted text.
 *
 * @param {{ source_text: string }} extractTextOutput
 */
export const handler = async (extractTextOutput) => {
  const comprehendClient = new ComprehendClient({});

  const detectDominantLanguageCommand = new DetectDominantLanguageCommand({
    Text: extractTextOutput.source_text,
  });

  // The source language is required for sentiment analysis and
  // translation in the next step.
  const { Languages } = await comprehendClient.send(
    detectDominantLanguageCommand,
  );

  const languageCode = Languages[0].LanguageCode;

  const detectSentimentCommand = new DetectSentimentCommand({
    Text: extractTextOutput.source_text,
    LanguageCode: languageCode,
  });
```

```

const { Sentiment } = await comprehendClient.send(detectSentimentCommand);

return {
  sentiment: Sentiment,
  language_code: languageCode,
};
};

```

```

import {
  DetectDocumentTextCommand,
  TextractClient,

Services used in this example

- Amazon Comprehend
- Lambda
- Amazon Polly
- Amazon Textract
- Amazon Translate

Ruby

SDK for Ruby

This example application analyzes and stores customer feedback cards. Specifically, it fulfills the need of a fictitious hotel in New York City. The hotel receives feedback from guests in various languages in the form of physical comment cards. That feedback is uploaded into

the app through a web client. After an image of a comment card is uploaded, the following steps occur:

- Text is extracted from the image using Amazon Textract.
- Amazon Comprehend determines the sentiment of the extracted text and its language.
- The extracted text is translated to English using Amazon Translate.
- Amazon Polly synthesizes an audio file from the extracted text.

The full app can be deployed with the AWS CDK. For source code and deployment instructions, see the project in [GitHub](#).

Services used in this example

- Amazon Comprehend
- Lambda
- Amazon Polly
- Amazon Textract
- Amazon Translate

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Invoke a Lambda function from a browser

The following code example shows how to invoke an AWS Lambda function from a browser.

JavaScript

SDK for JavaScript (v2)

You can create a browser-based application that uses an AWS Lambda function to update an Amazon DynamoDB table with user selections.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB

- Lambda

SDK for JavaScript (v3)

You can create a browser-based application that uses an AWS Lambda function to update an Amazon DynamoDB table with user selections. This app uses AWS SDK for JavaScript v3.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- Lambda

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Transform data for your application with S3 Object Lambda

The following code example shows how to transform data for your application with S3 Object Lambda.

.NET

SDK for .NET

Shows how to add custom code to standard S3 GET requests to modify the requested object retrieved from S3 so that the object suit the needs of the requesting client or application.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- Lambda
- Amazon S3

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use API Gateway to invoke a Lambda function

The following code examples show how to create an AWS Lambda function invoked by Amazon API Gateway.

Java

SDK for Java 2.x

Shows how to create an AWS Lambda function by using the Lambda Java runtime API. This example invokes different AWS services to perform a specific use case. This example demonstrates how to create a Lambda function invoked by Amazon API Gateway that scans an Amazon DynamoDB table for work anniversaries and uses Amazon Simple Notification Service (Amazon SNS) to send a text message to your employees that congratulates them at their one year anniversary date.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon SNS

JavaScript

SDK for JavaScript (v3)

Shows how to create an AWS Lambda function by using the Lambda JavaScript runtime API. This example invokes different AWS services to perform a specific use case. This example demonstrates how to create a Lambda function invoked by Amazon API Gateway that scans an Amazon DynamoDB table for work anniversaries and uses Amazon Simple Notification Service (Amazon SNS) to send a text message to your employees that congratulates them at their one year anniversary date.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

This example is also available in the [AWS SDK for JavaScript v3 developer guide](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon SNS

Python

SDK for Python (Boto3)

This example shows how to create and use an Amazon API Gateway REST API that targets an AWS Lambda function. The Lambda handler demonstrates how to route based on HTTP methods; how to get data from the query string, header, and body; and how to return a JSON response.

- Deploy a Lambda function.
- Create an API Gateway REST API.
- Create a REST resource that targets the Lambda function.
- Grant permission to let API Gateway invoke the Lambda function.
- Use the Requests package to send requests to the REST API.
- Clean up all resources created during the demo.

This example is best viewed on GitHub. For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon SNS

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use Step Functions to invoke Lambda functions

The following code example shows how to create an AWS Step Functions state machine that invokes AWS Lambda functions in sequence.

Java

SDK for Java 2.x

Shows how to create an AWS serverless workflow by using AWS Step Functions and the AWS SDK for Java 2.x. Each workflow step is implemented using an AWS Lambda function.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- Lambda
- Amazon SES
- Step Functions

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use scheduled events to invoke a Lambda function

The following code examples show how to create an AWS Lambda function invoked by an Amazon EventBridge scheduled event.

Java

SDK for Java 2.x

Shows how to create an Amazon EventBridge scheduled event that invokes an AWS Lambda function. Configure EventBridge to use a cron expression to schedule when the Lambda function is invoked. In this example, you create a Lambda function by using the Lambda Java runtime API. This example invokes different AWS services to perform a specific use case.

This example demonstrates how to create an app that sends a mobile text message to your employees that congratulates them at the one year anniversary date.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- CloudWatch Logs
- DynamoDB
- EventBridge
- Lambda
- Amazon SNS

JavaScript

SDK for JavaScript (v3)

Shows how to create an Amazon EventBridge scheduled event that invokes an AWS Lambda function. Configure EventBridge to use a cron expression to schedule when the Lambda function is invoked. In this example, you create a Lambda function by using the Lambda JavaScript runtime API. This example invokes different AWS services to perform a specific use case. This example demonstrates how to create an app that sends a mobile text message to your employees that congratulates them at the one year anniversary date.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

This example is also available in the [AWS SDK for JavaScript v3 developer guide](#).

Services used in this example

- CloudWatch Logs
- DynamoDB
- EventBridge
- Lambda
- Amazon SNS

Python

SDK for Python (Boto3)

This example shows how to register an AWS Lambda function as the target of a scheduled Amazon EventBridge event. The Lambda handler writes a friendly message and the full event data to Amazon CloudWatch Logs for later retrieval.

- Deploys a Lambda function.
- Creates an EventBridge scheduled event and makes the Lambda function the target.
- Grants permission to let EventBridge invoke the Lambda function.
- Prints the latest data from CloudWatch Logs to show the result of the scheduled invocations.
- Cleans up all resources created during the demo.

This example is best viewed on GitHub. For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- CloudWatch Logs
- DynamoDB
- EventBridge
- Lambda
- Amazon SNS

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use the Amazon Neptune API to develop a Lambda function that queries graph data

The following code example shows how to use the Neptune API to query graph data.

Java

SDK for Java 2.x

Shows how to use Amazon Neptune Java API to create a Lambda function that queries graph data within the VPC.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- Lambda
- Neptune

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Write custom activity data with a Lambda function after Amazon Cognito user authentication using an AWS SDK

The following code example shows how to write custom activity data with a Lambda function after Amazon Cognito user authentication.

- Use administrator functions to add a user to a user pool.
- Configure a user pool to call a Lambda function for the PostAuthentication trigger.
- Sign the new user in to Amazon Cognito.
- The Lambda function writes custom information to CloudWatch Logs and to an DynamoDB table.
- Get and display custom data from the DynamoDB table, then clean up resources.

Go

SDK for Go V2

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Run an interactive scenario at a command prompt.

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Serverless examples for Lambda

The following code examples show how to use Lambda with AWS SDKs.

Examples

- [Connecting to an Amazon RDS database in a Lambda function](#)
- [Invoke a Lambda function from a Kinesis trigger](#)
- [Invoke a Lambda function from a DynamoDB trigger](#)
- [Invoke a Lambda function from an Amazon DocumentDB trigger](#)
- [Invoke a Lambda function from an Amazon MSK trigger](#)
- [Invoke a Lambda function from an Amazon S3 trigger](#)
- [Invoke a Lambda function from an Amazon SNS trigger](#)
- [Invoke a Lambda function from an Amazon SQS trigger](#)
- [Reporting batch item failures for Lambda functions with a Kinesis trigger](#)
- [Reporting batch item failures for Lambda functions with a DynamoDB trigger](#)
- [Reporting batch item failures for Lambda functions with an Amazon SQS trigger](#)

Connecting to an Amazon RDS database in a Lambda function

The following code examples show how to implement a Lambda function that connects to an RDS database. The function makes a simple database request and returns the result.

.NET

SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Serverless examples](#) repository.

Connecting to an Amazon RDS database in a Lambda function using .NET.

```
using System.Data;
using System.Text.Json;
using Amazon.Lambda.APIGatewayEvents;
using Amazon.Lambda.Core;
using MySql.Data.MySqlClient;

// Assembly attribute to enable the Lambda function's JSON input to be converted
// into a .NET class.
[assembly:
    LambdaSerializer(typeof(Amazon.Lambda.Serialization.SystemTextJson.DefaultLambdaJsonSerializer))]

namespace aws_rds;

public class InputModel
{
    public string key1 { get; set; }
    public string key2 { get; set; }
}

public class Function
{
    /// <summary>
    /// Handles the Lambda function execution for connecting to RDS using IAM
    /// authentication.
    /// </summary>
    /// <param name="input">The input event data passed to the Lambda function</
    param>
    /// <param name="context">The Lambda execution context that provides runtime
    information</param>
    /// <returns>A response object containing the execution result</returns>
```

```

public async Task<APIGatewayProxyResponse>
FunctionHandler(APIGatewayProxyRequest request, ILambdaContext context)
{
    // Sample Input: {"body": "{\"key1\":\"20\", \"key2\":\"25\"}"}
    var input = JsonSerializer.Deserialize<InputModel>(request.Body);

    /// Obtain authentication token
    var authToken = RDSAuthTokenGenerator.GenerateAuthToken(
        Environment.GetEnvironmentVariable("RDS_ENDPOINT"),

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Invoke a Lambda function from a Kinesis trigger

The following code examples show how to implement a Lambda function that receives an event triggered by receiving records from a Kinesis stream. The function retrieves the Kinesis payload, decodes from Base64, and logs the record contents.

.NET

SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Serverless examples](#) repository.

For a complete list of AWS SDK developer guides and code examples, see [Using Lambda with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Invoke a Lambda function from an Amazon SNS trigger

The following code examples show how to implement a Lambda function that receives an event triggered by receiving messages from an SNS topic. The function retrieves the messages from the event parameter and logs the content of each message.

.NET

Invoke a Lambda function from an Amazon SQS trigger

The following code examples show how to implement a Lambda function that receives an event triggered by receiving messages from an SQS queue. The function retrieves the messages from the event parameter and logs the content of each message.

Lambda quotas

Important

New AWS accounts have reduced concurrency and memory quotas. AWS raises these quotas automatically based on your usage.

AWS Lambda is designed to scale rapidly to meet demand, allowing your functions to scale up to serve traffic in your application. Lambda is designed for short-lived compute tasks that do not retain or rely upon state between invocations. Code can run for up to 15 minutes in a single invocation and a single function can use up to 10,240 MB of memory.

It's important to understand the guardrails that are put in place to protect your account and the workloads of other customers. Service quotas exist in all AWS services and consist of hard limits, which you cannot change, and soft limits, which you can request increases for. By default, all new accounts are assigned a quota profile that allows exploration of AWS services.

To see the quotas that apply to your account, navigate to the [Service Quotas dashboard](#). Here, you can view your service quotas, request a quota increase, and view current utilization. From here, you can drill down to a specific AWS service, such as Lambda:

 **AWS Lambda**

AWS Lambda is a compute service that runs your code in response to events and automatically manages the compute resources for you.

Request increase at account level

< 1 > 

The following sections list default quotas and limits in Lambda by category.

Topics

- [Compute and storage](#)
- [Function configuration, deployment, and execution](#)
- [Lambda API requests](#)
- [Other services](#)

Compute and storage

Lambda sets quotas for the amount of compute and storage resources that you can use to run and store functions. Quotas for concurrent executions and storage apply per AWS Region. Elastic

Compute and storage

2827

network interface (ENI) quotas apply per virtual private cloud (VPC), regardless of Region. The following quotas can be increased from their default values. For more information, see [Requesting a quota increase](#) in the *Service Quotas User Guide*.

Resource	Default quota	Can be increased up to
Concurrent executions	1,000	Tens of thousands
Storage for uploaded functions (.zip file archives) and layers. Each function version and layer version consumes storage. For best practices on managing your code storage, see Monitoring Lambda code storage in Serverless Land.	75 GB	Terabytes
Storage for functions defined as container images. These images are stored in Amazon ECR.	See Amazon ECR service quotas .	
Elastic network interfaces per virtual private cloud (VPC) <div>  Note This quota is shared with other services, such as Amazon Elastic File System (Amazon EFS). See Amazon VPC quotas. </div>	500	Thousands

For details on concurrency and how Lambda scales your function concurrency in response to traffic, see [Understanding Lambda function scaling](#).

Function configuration, deployment, and execution

The following quotas apply to function configuration, deployment, and execution. Except as noted, they can't be changed.

Note

The Lambda documentation, log messages, and console use the abbreviation MB (rather than MiB) to refer to 1,024 KB.

Resource	Quota
Function memory allocation	128 MB to 10,240 MB, in 1-MB increments. Note: Lambda allocates CPU power in proportion to the amount of memory configured. You can increase or decrease the memory and CPU power allocated to your function using the Memory (MB) setting. At 1,769 MB, a function has the equivalent of one vCPU.
Function timeout	900 seconds (15 minutes)
Function environment variables	4 KB, for all environment variables associated with the function, in aggregate
Function resource-based policy	20 KB
Function layers	5 layers
Function concurrency scaling limit	For each function, 1,000 execution environments every 10 seconds

Resource	Quota
Invocation payload (request and response)	<p>6 MB each for request and response (synchronous)</p> <p>200 MB for each streamed response (synchronous)</p> <p>1 MB (asynchronous)</p> <p>1 MB for the total combined size of request line and header values</p>
Bandwidth for streamed responses	<p>Uncapped for the first 6 MB of your function's response</p> <p>For responses larger than 6 MB, 2MBps for the remainder of the response</p>
Deployment package (.zip file archive) size	<p>50 MB (zipped, when uploaded through the Lambda API or SDKs). Upload larger files with Amazon S3.</p> <p>50 MB (when uploaded through the Lambda console)</p> <p>250 MB The maximum size of the contents of a deployment package, including layers and custom runtimes. (unzipped)</p>
Container image settings size	16 KB
Container image code package size	10 GB (maximum uncompressed image size, including all layers)
Test events (console editor)	10

Resource	Quota
/tmp directory storage	Between 512 MB and 10,240 MB, in 1-MB increments
File descriptors	1,024 <div><div><div><div></div><div>Note</div></div><div>Lambda Managed Instances use the default file descriptor limits from Bottlerocket. For more information, see Understanding the Lambda Managed Instances execution environment.</div></div></div>
Execution processes/threads	1,024 <div><div><div><div></div><div>Note</div></div><div>Lambda Managed Instances use the default process and thread limits from Bottlerocket. For more information, see Understanding the Lambda Managed Instances execution environment.</div></div></div>

Lambda API requests

The following quotas are associated with Lambda API requests.

Resource	Quota
Invocation requests per function per Region (synchronous)	Each instance of your execution environment can serve up to 10 requests per second. In other words, the total invocation limit is 10 times your concurrency limit. See Understanding Lambda function scaling .
Invocation requests per function per Region (asynchronous)	Each instance of your execution environment can serve an unlimited number of requests. In other words, the total invocation limit is based only on concurrency available to your function. See Understanding Lambda function scaling .
Invocation requests per function version or alias (requests per second)	10 x allocated provisioned concurrency
	<div>  Note This quota applies only to functions that use provisioned concurrency. </div>
GetFunction API requests	100 requests per second. Cannot be increased.
GetPolicy API requests	15 requests per second. Cannot be increased.
Remainder of the control plane API requests (excludes invocation, GetFunction, and GetPolicy requests)	15 requests per second across all APIs (not 15 requests per second per API). Cannot be increased.

Other services

Quotas for other services, such as AWS Identity and Access Management (IAM), Amazon CloudFront (Lambda@Edge), and Amazon Virtual Private Cloud (Amazon VPC), can impact your Lambda functions. For more information, see [AWS service quotas](#) in the *Amazon Web Services General Reference*, and [Invoking Lambda with events from other AWS services](#).

Many applications involving Lambda use multiple AWS services. Because different services have different quotas for various features, it can be challenging to manage these quotas across your entire application. For example, API Gateway has a default throttle limit of 10,000 requests per second, whereas Lambda has a default concurrency limit of 1,000. Due to this mismatch, it's possible to have more incoming requests from API Gateway that Lambda can handle. You can resolve this by requesting a Lambda concurrency limit increase to match the expected level of traffic.

Load testing your application allows you to monitor the performance of your application end-to-end before deploying to production. During a load test, you can identify any quotas that may act as a limiting factor for the traffic levels you expect and take action accordingly.

Document history

The following table describes the important changes to the *AWS Lambda Developer Guide* since May 2018. For notification about updates to this documentation, subscribe to the [RSS feed](#).

Change	Description	Date
AWS managed policy updates	Lambda has released a new managed policy <code>AWSLambdaBasicDurableExecutionRolePolicy</code> that provides write permissions to CloudWatch Logs and read/write permissions to durable execution APIs used by Lambda durable functions.	December 1, 2025
Service-linked role for Lambda	Lambda now supports a service-linked role (<code>AWSServiceRoleForLambda</code>) that allows Lambda to terminate instances managed as part of Lambda capacity providers.	November 30, 2025
Lambda Managed Instances	Lambda now supports Managed Instances, which provide dedicated compute capacity for your functions with enhanced performance, security, and control. For details, see Lambda Managed Instances .	November 30, 2025
AWS managed policy updates	Lambda added a new AWS managed policy (<code>AWSLambda</code>	November 30, 2025

BasicDurableExecutionRolePolicy).

AWS managed policy updates	Lambda updated the existing AWS managed policy AWSLambda_FullAccess) allow the kms:DescribeKey and iam:CreateServiceLinkedRole actions.	November 30, 2025
AWS managed policy update	Lambda added a new AWS managed policy (AWSLambdaManagedEC2ResourceOperator) to enable automated Amazon EC2 instance management for Lambda capacity providers . For details, see Lambda updates to AWS managed policies .	November 30, 2025
AWS managed policy update	Lambda added a new AWS managed policy (AWSLambdaServiceRolePolicy). For details, see Lambda updates to AWS managed policies .	November 30, 2025
AWS managed policy updates	Lambda updated two existing AWS managed policies (AWSLambda_ReadOnlyAccess and AWSLambda_FullAccess).	February 20, 2025
Node.js 22.x runtime	Lambda now supports Node.js 22 as a managed runtime and container base image (nodejs22.x).	November 22, 2024

SnapStart support for Python and .NET	Lambda SnapStart is now available for Python and .NET managed runtimes, beginning with python3.12 and dotnet8.	November 18, 2024
Python 3.13 runtime	Lambda now supports Python 3.13 as a managed runtime and container base image.	November 13, 2024
Customer managed encryption for .zip deployment packages	Lambda now supports AWS KMS customer managed key encryption for .zip deployment packages.	November 8, 2024
Support for SnapStart in new Regions	Lambda SnapStart is now available in the following Regions: Europe (Spain), Europe (Zurich), Asia Pacific (Melbourne), Asia Pacific (Hyderabad), and Middle East (UAE).	January 12, 2024
AWS managed policy updates	Lambda updated an existing AWS managed policy (AWSLambdaVPCLAccessExecutionRole).	January 5, 2024
Python 3.12 runtime	Lambda now supports Python 3.12 as a managed runtime and container base image. For more information, see Python 3.12 runtime now available in AWS Lambda on the AWS Compute Blog.	December 14, 2023

Java 21 runtime	Lambda now supports Java 21 as a managed runtime and container base image (java21).	November 16, 2023
Node.js 20.x runtime	Lambda now supports Node.js 20 as a managed runtime and container base image (nodejs20.x). For more information, see Node.js 20.x runtime now available in AWS Lambda on the AWS Compute Blog.	November 14, 2023
provided.al2023 runtime	Lambda now supports Amazon Linux 2023 as a managed runtime and container base image. For more information, see Introducing the Amazon Linux 2023 runtime for AWS Lambda on the AWS Compute Blog.	November 9, 2023
IPv6 support for dual-stack subnets	Lambda now supports outbound IPv6 traffic to dual-stack subnets. For more information, see IPv6 support .	October 12, 2023

[Testing serverless functions and applications](#)

Learn about techniques to debug and automate testing serverless functions in the cloud. There is now a testing chapter and resources included in the Python and Typescript language sections. For details, see [Testing serverless functions and applications](#).

June 16, 2023

[Ruby 3.2 runtime](#)

Lambda now supports a new runtime for Ruby 3.2. For more information, see [Building Lambda functions with Ruby](#).

June 7, 2023

[Response streaming](#)

Lambda now supports streaming responses from functions. For more information, see [Configuring a Lambda function to stream responses](#).

April 6, 2023

[Asynchronous invocation metrics](#)

Lambda releases asynchronous invocation metrics. For more information, see [Asynchronous invocation metrics](#).

February 9, 2023

Runtime version controls	Lambda releases new runtime versions that include security updates, bug fixes, and new features. You can now control when your functions get updated to the new runtime versions. For more information, see Lambda runtime updates .	January 23, 2023
Lambda SnapStart	Use Lambda SnapStart to reduce startup time for Java functions without provisioning additional resources or implementing complex performance optimizations. For more information, see Improving startup performance with with Lambda SnapStart .	November 28, 2022
Node.js 18 runtime	Lambda now supports a new runtime for Node.js 18. Node.js 18 uses Amazon Linux 2. For details, see Building Lambda functions with Node.js .	November 18, 2022
lambda:SourceFunctionArn condition key	For an AWS resource, the <code>lambda:SourceFunctionArn</code> condition key filters access to the resource by the ARN of a Lambda function. For details, see Working with Lambda execution environment credentials .	July 1, 2022

Node.js 16 runtime	Lambda now supports a new runtime for Node.js 16. Node.js 16 uses Amazon Linux 2. For details, see Building Lambda functions with Node.js .	May 11, 2022
Lambda function URLs	Lambda now supports function URLs, which are dedicated HTTP(S) endpoints for Lambda functions. For details, see Lambda function URLs .	April 6, 2022
Shared test events in the AWS Lambda console	Lambda now supports sharing test events with other users in the same AWS account. For details, see Testing Lambda functions in the console .	March 16, 2022
PrincipalOrgId in resource-based policies	Lambda now supports granting permissions to an organization in AWS Organizations. For details, see Using resource-based policies for AWS Lambda .	March 11, 2022
.NET 6 runtime	Lambda now supports a new runtime for .NET 6. For details, see Lambda runtimes .	February 23, 2022
Event filtering for Kinesis, DynamoDB, and Amazon SQS event sources	Lambda now supports event filtering for Kinesis, DynamoDB, and Amazon SQS event sources. For details, see Lambda event filtering .	November 24, 2021

mTLS authentication for Amazon MSK and self-managed Apache Kafka event sources	Lambda now supports mTLS authentication for Amazon MSK and self-managed Apache Kafka event sources. For details, see Using Lambda with Amazon MSK .	November 19, 2021
Lambda on Graviton2	Lambda now supports Graviton2 for functions using arm64 architecture. For details, see Lambda instructions on set architectures .	September 29, 2021
Python 3.9 runtime	Lambda now supports a new runtime for Python 3.9. For details, see Lambda runtimes .	August 16, 2021
New runtime versions for Node.js, Python, and Java	New runtime versions are available for Node.js, Python, and Java. For details, see Lambda runtimes .	July 21, 2021
Support for RabbitMQ as an event source on Lambda	Lambda now supports Amazon MQ for RabbitMQ as an event source. Amazon MQ is a managed message broker service for Apache ActiveMQ and RabbitMQ that makes it easy to set up and operate message brokers in the cloud. For details, see Using Lambda with Amazon MQ .	July 7, 2021

[SASL/PLAIN authentication for self-managed Kafka on Lambda](#)

SASL/PLAIN is now a supported authentication mechanism for self-managed Kafka event sources on Lambda. Customers already using SASL/PLAIN on their self-managed Kafka cluster can now easily use Lambda to build consumer applications without having to modify the way they authenticate. For details, see [Using Lambda with self-managed Apache Kafka](#).

June 29, 2021

[Lambda Extensions API](#)

General availability for Lambda extensions. Use extensions to augment your Lambda functions. You can use extensions provided by Lambda Partners, or you can create your own Lambda extensions. For details, see [Lambda Extensions API](#).

May 24, 2021

[New Lambda console experience](#)

The Lambda console has been redesigned to improve performance and consistency.

March 2, 2021

[Node.js 14 runtime](#)

Lambda now supports a new runtime for Node.js 14. Node.js 14 uses Amazon Linux 2. For details, see [Building Lambda functions with Node.js](#).

January 27, 2021

[Lambda container images](#)

Lambda now supports functions defined as container images. You can combine the flexibility of container tooling with the agility and operational simplicity of Lambda to build applications. For details, see [Using container images with Lambda](#).

December 1, 2020

[Code signing for Lambda functions](#)

Lambda now supports code signing. Administrators can configure Lambda functions to accept only signed code on deployment. Lambda checks the signatures to ensure that the code is not altered or tampered. Additionally, Lambda ensures that the code is signed by trusted developers before accepting the deployment. For details, see [Configuring code signing for Lambda](#).

November 23, 2020

[Preview: Lambda Runtime Logs API](#)

Lambda now supports the Runtime Logs API. Lambda extensions can use the Logs API to subscribe to log streams in the execution environment. For details, see [Lambda Runtime Logs API](#).

November 12, 2020

[New event source to for Amazon MQ](#)

Lambda now supports Amazon MQ as an event source. Use a Lambda function to process records from your Amazon MQ message broker. For details, see [Using Lambda with Amazon MQ](#).

November 5, 2020

[Preview: Lambda Extensions API](#)

Use Lambda extensions to augment your Lambda functions. You can use extensions provided by Lambda Partners, or you can create your own Lambda extensions. For details, see [Lambda Extensions API](#).

October 8, 2020

[Support for Java 8 and custom runtimes on AL2](#)

Lambda now supports Java 8 and custom runtimes on Amazon Linux 2. For details, see [Lambda runtimes](#).

August 12, 2020

[New event source for Amazon Managed Streaming for Apache Kafka](#)

Lambda now supports Amazon MSK as an event source. Use a Lambda function with Amazon MSK to process records in a Kafka topic. For details, see [Using Lambda with Amazon MSK](#).

August 11, 2020

[IAM condition keys for Amazon VPC settings](#)

You can now use Lambda-specific condition keys for VPC settings. For example, you can require that all functions in your organization are connected to a VPC. You can also specify the subnets and security groups that the function's users can and can't use. For details, see [Configuring VPC for IAM functions](#).

August 10, 2020

[Concurrency settings for Kinesis HTTP/2 stream consumers](#)

You can now use the following concurrency settings for Kinesis consumers with enhanced fan-out (HTTP/2 streams): `ParallelizationFactor`, `MaximumRetryAttempts`, `MaximumRecordAgeInSeconds`, `DestinationConfig`, and `BisectBatchOnFunctionError`. For details, see [Using AWS Lambda with Amazon Kinesis](#).

July 7, 2020

[Batch window for Kinesis HTTP/2 stream consumers](#)

You can now configure a batch window (`MaximumBatchingWindowInSeconds`) for HTTP/2 streams. Lambda reads records from the stream until it has gathered a full batch, or until the batch window expires. For details, see [Using AWS Lambda with Amazon Kinesis](#).

June 18, 2020

[Support for Amazon EFS file systems](#)

You can now connect an Amazon EFS file system to your Lambda functions for shared network file access. For details, see [Configuring file system access for Lambda functions](#).

June 16, 2020

[AWS CDK sample applications in the Lambda console](#)

The Lambda console now includes sample applications that use the AWS Cloud Development Kit (AWS CDK) for TypeScript. The AWS CDK is a framework that enables you to define your application resources in TypeScript, Python, Java, or .NET.

June 1, 2020

[Support for .NET Core 3.1.0 runtime in AWS Lambda](#)

AWS Lambda now supports the .NET Core 3.1.0 runtime. For details, see [.NET Core CLI](#).

March 31, 2020

[Support for API Gateway HTTP APIs](#)

Updated and expanded documentation for using Lambda with API Gateway, including support for HTTP APIs. Added a sample application that creates an API and function with CloudFormation. For details, see [Using Lambda with Amazon API Gateway](#).

March 23, 2020

[Ruby 2.7](#)

A new runtime is available for Ruby 2.7, ruby2.7, which is the first Ruby runtime to use Amazon Linux 2. For details, see [Building Lambda functions with Ruby](#).

February 19, 2020

[Concurrency metrics](#)

Lambda now reports the `ConcurrentExecutions` metric for all functions, aliases, and versions. You can view a graph for this metric on the monitoring page for your function. Previously, `ConcurrentExecutions` was only reported at the account level and for functions that use reserved concurrency. For details, see [AWS Lambda function metrics](#).

February 18, 2020

[Update to function states](#)

January 24, 2020

Function states are now enforced for all functions by default. When you connect a function to a VPC, Lambda creates shared elastic network interfaces. This enables your function to scale up without creating additional network interfaces. During this time, you can't perform additional operations on the function, including updating its configuration and publishing versions. In some cases, invocation is also impacted. Details about a function's current state are available from the Lambda API.

This update is being released in phases. For details, see [Updated Lambda states lifecycle for VPC networking](#) on the AWS Compute Blog. For more information about states, see [AWS Lambda function states](#).

Updates to function configuration API output	Added reason codes to StateReasonCode (InvalidSubnet, InvalidSecurityGroup) and LastUpdateStatusReasonCode (SubnetOutOfIPAddresses, InvalidSubnet, InvalidSecurityGroup) for functions that connect to a VPC. For more information about states, see AWS Lambda function states .	January 20, 2020
Provisioned concurrency	You can now allocate provisioned concurrency for a function version or alias. Provisioned concurrency enables a function to scale without fluctuations in latency. For details, see Managing concurrency for a Lambda function .	December 3, 2019
Create a database proxy	You can now use the Lambda console to create a database proxy for a Lambda function. A database proxy enables a function to reach high concurrency levels without exhausting database connections. For details, see Configuring database access for a Lambda function .	December 3, 2019
Percentiles support for the duration metric	You can now filter the duration metric based on percentiles. For details, see AWS Lambda metrics .	November 26, 2019

[Increased concurrency for stream event sources](#)

A new option for [DynamoDB stream](#) and [Kinesis stream](#) event source mappings enables you to process more than one batch at a time from each shard. When you increase the number of concurrent batches per shard, your function's concurrency can be up to 10 times the number of shards in your stream. For details, see [Lambda event source mapping](#).

November 25, 2019

[Function states](#)

When you create or update a function, it enters a pending state while Lambda provisions resources to support it. If you connect your function to a VPC, Lambda can create a shared elastic network interface right away, instead of creating network interfaces when your function is invoked. This results in better performance for VPC-connected functions, but might require an update to your automation. For details, see [AWS Lambda function states](#).

November 25, 2019

[Error handling options for asynchronous invocation](#)

New configuration options are available for asynchronous invocation. You can configure Lambda to limit retries and set a maximum event age. For details, see [Configuring error handling for asynchronous invocation](#).

November 25, 2019

[Error handling for stream event sources](#)

New configuration options are available for event source mappings that read from streams. You can configure [DynamoDB stream](#) and [Kinesis stream](#) event source mappings to limit retries and set a maximum record age. When errors occur, you can configure the event source mapping to split batches before retrying, and to send invocation records for failed batches to a queue or topic. For details, see [Lambda event source mapping](#).

November 25, 2019

[Destinations for asynchronous invocation](#)

You can now configure Lambda to send records of asynchronous invocations to another service. Invocation records contain details about the event, context, and function response. You can send invocation records to an SQS queue, SNS topic, Lambda function, or EventBridge event bus. For details, see [Configuring destinations for asynchronous invocation](#).

November 25, 2019

[New runtimes for Node.js, Python, and Java](#)

New runtimes are available for Node.js 12, Python 3.8, and Java 11. For details, see [Lambda runtimes](#).

November 18, 2019

[FIFO queue support for Amazon SQS event sources](#)

You can now create an event source mapping that reads from a first-in, first-out (FIFO) queue. Previously, only standard queues were supported. For details, see [Using Lambda with Amazon SQS](#).

November 18, 2019

[Create applications in the Lambda console](#)

Application creation in the Lambda console is now generally available. For instructions, see [Managing applications in the Lambda console](#).

October 31, 2019

[Create applications in the Lambda console \(beta\)](#)

You can now create a Lambda application with an integrated continuous delivery pipeline in the Lambda console. The console provides sample applications that you can use as a starting point for your own project. Choose between AWS CodeCommit and GitHub for source control. Each time you push changes to your repository, the included pipeline builds and deploys them automatically. For instructions, see [Managing applications in the Lambda console](#).

October 3, 2019

[Performance improvements for VPC-connected functions](#)

Lambda now uses a new type of elastic network interface that is shared by all functions in a virtual private cloud (VPC) subnet. When you connect a function to a VPC, Lambda creates a network interface for each combination of security group and subnet that you choose. When the shared network interfaces are available, the function no longer needs to create additional network interfaces as it scales up. This dramatically improves startup times. For details, see [Configuring a Lambda function to access resources in a VPC](#).

September 3, 2019

[Stream batch settings](#)

You can now configure a batch window for [Amazon DynamoDB](#) and [Amazon Kinesis](#) event source mappings. Configure a batch window of up to five minutes to buffer incoming records until a full batch is available. This reduces the number of times that your function is invoked when the stream is less active.

August 29, 2019

[CloudWatch Logs Insights integration](#)

The monitoring page in the Lambda console now includes reports from Amazon CloudWatch Logs Insights.

June 18, 2019

[Amazon Linux 2018.03](#)

The Lambda execution environment is being updated to use Amazon Linux 2018.03. For details, see [Execution environment](#).

May 21, 2019

[Node.js 10](#)

A new runtime is available for Node.js 10, nodejs10.x. This runtime uses Node.js 10.15 and will be updated with the latest point release of Node.js 10 periodically. Node.js 10 is also the first runtime to use Amazon Linux 2. For details, see [Building Lambda functions with Node.js](#).

May 13, 2019

[GetLayerVersionByArn API](#)

Use the [GetLayerVersionByArn](#) API to download layer version information with the version ARN as input. Compared to `GetLayerVersion`, `GetLayerVersionByArn` lets you use the ARN directly instead of parsing it to get the layer name and version number.

April 25, 2019

[Ruby](#)

AWS Lambda now supports Ruby 2.5 with a new runtime. For details, see [Building Lambda functions with Ruby](#).

November 29, 2018

[Layers](#)

With Lambda layers, you can package and deploy libraries, custom runtimes, and other dependencies separately from your function code. Share your layers with your other accounts or the whole world. For details, see [Lambda layers](#).

November 29, 2018

[Custom runtimes](#)

Build a custom runtime to run Lambda functions in your favorite programming language. For details, see [Custom Lambda runtimes](#).

November 29, 2018

[Application Load Balancer triggers](#)

Elastic Load Balancing now supports Lambda functions as a target for Application Load Balancers. For details, see [Using Lambda with application load balancers](#).

November 29, 2018

[Use Kinesis HTTP/2 stream consumers as a trigger](#)

You can use Kinesis HTTP/2 data stream consumers to send events to AWS Lambda. Stream consumers have dedicated read throughput from each shard in your data stream and use HTTP/2 to minimize latency. For details, see [Using Lambda with Kinesis](#).

November 19, 2018

Python 3.7	AWS Lambda now supports Python 3.7 with a new runtime. For more information, see Building Lambda functions with Python .	November 19, 2018
Payload limit increase for asynchronous function invocation	The maximum payload size for asynchronous invocations increased from 128 KB to 256 KB, which matches the maximum message size from an Amazon SNS trigger. For details, see Lambda quotas .	November 16, 2018
AWS GovCloud (US-East) Region	AWS Lambda is now available in the AWS GovCloud (US-East) Region.	November 12, 2018
Moved AWS SAM topics to a separate Developer Guide	A number of topics were focused on building serverless applications using the AWS Serverless Application Model (AWS SAM). These topics have been moved to AWS Serverless Application Model developer guide .	October 25, 2018

[View Lambda applications in the console](#)

You can view the status of your Lambda applications on the [Applications](#) page in the Lambda console. This page shows the status of the CloudFormation stack. It includes links to pages where you can view more information about the resources in the stack. You can also view aggregate metrics for the application and create custom monitoring dashboards.

October 11, 2018

[Function execution timeout limit](#)

To allow for long-running functions, the maximum configurable execution timeout increased from 5 minutes to 15 minutes. For details, see [Lambda limits](#).

October 10, 2018

[Support for PowerShell Core language in AWS Lambda](#)

AWS Lambda now supports the PowerShell Core language. For more information, see [Programming model for authoring Lambda functions in PowerShell](#).

September 11, 2018

[Support for .NET Core 2.1.0 runtime in AWS Lambda](#)

AWS Lambda now supports the .NET Core 2.1.0 runtime. For more information, see [.NET Core CLI](#).

July 9, 2018

[Updates now available over RSS](#)

You can now subscribe to an RSS feed to follow releases for this guide.

July 5, 2018

[Support for Amazon SQS as event source](#)

AWS Lambda now supports Amazon Simple Queue Service (Amazon SQS) as an event source. For more information, see [Invoking Lambda functions](#).

June 28, 2018

[China \(Ningxia\) Region](#)

AWS Lambda is now available in the China (Ningxia) Region. For more information about Lambda Regions and endpoints, see [Regions and endpoints](#) in the *AWS General Reference*.

June 28, 2018

Earlier updates

The following table describes the important changes in each release of the *AWS Lambda Developer Guide* before June 2018.

Change	Description	Date
Runtime support for Node.js runtime 8.10	AWS Lambda now supports Node.js runtime version 8.10. For more information, see Building Lambda functions with Node.js .	April 2, 2018
Function and alias revision IDs	AWS Lambda now supports revision IDs on your function versions and aliases. You can use these IDs to track and apply conditional updates when you are updating your function version or alias resources.	January 25, 2018
Runtime support for Go and .NET 2.0	AWS Lambda has added runtime support for Go and .NET 2.0. For more information, see Building Lambda functions with Go and Building Lambda functions with C# .	January 15, 2018
Console Redesign	AWS Lambda has introduced a new Lambda console to simplify your experience and added a Cloud9 Code Editor	November 30, 2017

Change	Description	Date
	to enhance your ability debug and revise your function code.	
Setting Concurrency Limits on Individual Functions	AWS Lambda now supports setting concurrency limits on individual functions. For more information, see Configuring reserved concurrency for a function .	November 30, 2017
Shifting Traffic with Aliases	AWS Lambda now supports shifting traffic with aliases. For more information, see Create a rolling deployment with weighted aliases .	November 28, 2017
Gradual Code Deployment	AWS Lambda now supports safely deploying new versions of your Lambda function by leveraging Code Deploy. For more information, see Gradual code deployment .	November 28, 2017
China (Beijing) Region	AWS Lambda is now available in the China (Beijing) Region. For more information about Lambda regions and endpoints, see Regions and endpoints in the <i>AWS General Reference</i> .	November 9, 2017
Introducing SAM Local	AWS Lambda introduces SAM Local (now known as SAM CLI), a AWS CLI tool that provides an environment for you to develop, test, and analyze your serverless applications locally before uploading them to the Lambda runtime. For more information, see Testing and debugging serverless applications .	August 11, 2017
Canada (Central) Region	AWS Lambda is now available in the Canada (Central) Region. For more information about Lambda regions and endpoints, see Regions and endpoints in the <i>AWS General Reference</i> .	June 22, 2017
South America (São Paulo) Region	AWS Lambda is now available in the South America (São Paulo) Region. For more information about Lambda regions and endpoints, see Regions and endpoints in the <i>AWS General Reference</i> .	June 6, 2017

Change	Description	Date
AWS Lambda support for AWS X-Ray.	Lambda introduces support for X-Ray, which allows you to detect, analyze, and optimize performance issues with your Lambda applications. For more information, see Visualize Lambda function invocations using AWS X-Ray .	April 19, 2017
Asia Pacific (Mumbai) Region	AWS Lambda is now available in the Asia Pacific (Mumbai) Region. For more information about Lambda regions and endpoints, see Regions and endpoints in the <i>AWS General Reference</i> .	March 28, 2017
AWS Lambda now supports Node.js runtime v6.10	AWS Lambda added support for Node.js runtime v6.10. For more information, see Building Lambda functions with Node.js .	March 22, 2017
Europe (London) Region	AWS Lambda is now available in the Europe (London) Region. For more information about Lambda regions and endpoints, see Regions and endpoints in the <i>AWS General Reference</i> .	February 1, 2017
AWS Lambda support for the .NET runtime, Lambda@Edge (Preview), Dead Letter Queues and automated deployment of serverless applications.	<p>AWS Lambda added support for C#. For more information, see Building Lambda functions with C#.</p> <p>Lambda@Edge allows you to run Lambda functions at the AWS Edge locations in response to CloudFront events. For more information, see Customize at the edge with Lambda@Edge.</p>	December 3, 2016
AWS Lambda adds Amazon Lex as a supported event source.	Using Lambda and Amazon Lex, you can quickly build chat bots for various services like Slack and Facebook.	November 30, 2016

Change	Description	Date
US West (N. California) Region	AWS Lambda is now available in the US West (N. California) Region. For more information about Lambda regions and endpoints, see Regions and endpoints in the <i>AWS General Reference</i> .	November 21, 2016
Introduced the AWS SAM for creating and deploying Lambda-based applications and using environment variables for Lambda function configuration settings.	<p>AWS SAM: You can now use the AWS SAM to define the syntax for expressing resources within a serverless application. In order to deploy your application, simply specify the resources you need as part of your application, along with their associated permissions policies in a AWS CloudFormation template file (written in either JSON or YAML), package your deployment artifacts, and deploy the template.</p> <p>Environment variables: You can use environment variables to specify configuration settings for your Lambda function outside of your function code. For more information, see Working with Lambda environment variables.</p>	November 18, 2016
Asia Pacific (Seoul) Region	AWS Lambda is now available in the Asia Pacific (Seoul) Region. For more information about Lambda regions and endpoints, see Regions and endpoints in the <i>AWS General Reference</i> .	August 29, 2016
Asia Pacific (Sydney) Region	Lambda is now available in the Asia Pacific (Sydney) Region. For more information about Lambda regions and endpoints, see Regions and endpoints in the <i>AWS General Reference</i> .	June 23, 2016
Updates to the Lambda console	The Lambda console has been updated to simplify the role-creation process.	June 23, 2016
AWS Lambda now supports Node.js runtime v4.3	AWS Lambda added support for Node.js runtime v4.3. For more information, see Building Lambda functions with Node.js .	April 07, 2016

Change	Description	Date
Europe (Frankfurt) region	Lambda is now available in the Europe (Frankfurt) region. For more information about Lambda regions and endpoints, see Regions and endpoints in the <i>AWS General Reference</i> .	March 14, 2016
VPC support	You can now configure a Lambda function to access resources in your VPC. For more information, see Giving Lambda functions access to resources in an Amazon VPC .	February 11, 2016
Lambda runtime has been updated.	The execution environment has been updated.	November 4, 2015
Versioning support, Python for developing code for Lambda functions, scheduled events, and increase in execution time	<p>You can now develop your Lambda function code using Python. For more information, see Building Lambda functions with Python.</p> <p>Versioning: You can maintain one or more versions of your Lambda function. Versioning allows you to control which Lambda function version is executed in different environments (for example, development, testing, or production). For more information, see Manage Lambda function versions.</p> <p>Scheduled events: You can also set up Lambda to invoke your code on a regular, scheduled basis using the Lambda console. You can specify a fixed rate (number of hours, days, or weeks) or you can specify a cron expression. For more information, see Invoke a Lambda function on a schedule.</p> <p>Increase in execution time: You can now set up your Lambda functions to run for up to five minutes allowing longer running functions such as large volume data ingestion and processing jobs.</p>	October 08, 2015

Change	Description	Date
Support for DynamoDB Streams	DynamoDB Streams is now generally available and you can use it in all the regions where DynamoDB is available . You can enable DynamoDB Streams for your table and use a Lambda function as a trigger for the table. Triggers are custom actions you take in response to updates made to the DynamoDB table. For an example walkthrough, see Tutorial: Using AWS Lambda with Amazon DynamoDB streams .	July 14, 2015
Lambda now supports invoking Lambda functions with REST-compatible clients.	<p>Until now, to invoke your Lambda function from your web, mobile, or IoT application you needed the AWS SDKs (for example, AWS SDK for Java, AWS SDK for Android, or AWS SDK for iOS). Now, Lambda supports invoking a Lambda function with REST-compatible clients through a customized API that you can create using Amazon API Gateway. You can send requests to your Lambda function endpoint URL. You can configure security on the endpoint to allow open access, leverage AWS Identity and Access Management (IAM) to authorize access, or use API keys to meter access to your Lambda functions by others.</p> <p>For an example Getting Started exercise, see Invoking a Lambda function using an Amazon API Gateway endpoint.</p>	July 09, 2015
The Lambda console now provides blueprints to easily create Lambda functions and test them.	Lambda console provides a set of <i>blueprints</i> . Each blueprint provides a sample event source configuration and sample code for your Lambda function that you can use to easily create Lambda-based applications. All of the Lambda Getting Started exercises now use the blueprints.	July 09, 2015
Lambda now supports Java to author your Lambda functions.	You can now author Lambda code in Java. For more information, see Building Lambda functions with Java .	June 15, 2015

Change	Description	Date
Lambda now supports specifying an Amazon S3 object as the function .zip when creating or updating a Lambda function.	You can upload a Lambda function deployment package (.zip file) to an Amazon S3 bucket in the same region where you want to create a Lambda function. Then, you can specify the bucket name and object key name when you create or update a Lambda function.	May 28, 2015
Lambda now generally available with added support for mobile backends	Lambda is now generally available for production use. The release also introduces new features that make it easier to build mobile, tablet, and Internet of Things (IoT) backends using Lambda that scale automatically without provisioning or managing infrastructure. Lambda now supports both real-time (synchronous) and asynchronous events. Additional features include easier event source configuration and management. The permission model and the programming model have been simplified by the introduction of resource policies for your Lambda functions.	April 9, 2015
Preview release	Preview release of the <i>AWS Lambda Developer Guide</i> .	November 13, 2014
