Choosing a stickiness strategy for your load balancer

Ryan Griffin, Amazon Web Services (AWS)

July 2024 ([document history](#))

Stickiness is a term that is used to describe the functionality of a load balancer to repeatedly route traffic from a client to a single destination, instead of balancing the traffic across multiple destinations. For example, traffic from client A can be continually routed to a specific server, so that server can maintain session state data. If traffic from client A is routed to two distinct servers, each server might be missing important information that's available to the other server.

Therefore, it's often necessary to maintain a consistent client connection through a load balancer. There are two types of stickiness: sticky sessions and target group stickiness.

- **Sticky sessions** – Maintaining local session data in an Amazon Elastic Compute Cloud (Amazon EC2) instance to simplify application architecture or to improve application performance, because the instance can maintain or cache the session state information locally. AWS currently offers two types of sticky sessions, which this guide discusses in detail: application cookies and load balancer cookies.
- **Target group stickiness** – In blue/green deployments you might have multiple versions of an application deployed, and you might want the client to continue to use the same version of the application during their session. In this case, you can use target group stickiness to route all communications from the client to the same target group instead of the same EC2 instance.

You can use these two stickiness strategies separately or together.

This guide describes different types of load balancer stickiness and applicable use cases, to help you choose a strategy. The guide includes AWS CloudFormation templates that illustrate each strategy.

Sample code

This guide provides an attached .zip file that includes four AWS CloudFormation templates that you can deploy to build a basic architecture and try out each stickiness strategy. We recommend that you deploy these templates in a lab environment to test each approach.

[Download sample code](#)

The download includes these templates:

- `basic.yml` – Sets up an Application Load Balancer without stickiness.
- `targetgroupstickiness.yml` – Demonstrates stickiness based on target groups.
- `stickysessionslb.yml` – Demonstrates sticky sessions with load balancer generated cookies.
- `stickysessionsapp.yml` – Demonstrates sticky sessions with application-based cookies.

To deploy these templates, you will need an active :AWS account and access to the [AWS CloudFormation console](#). For step-by-steps instructions for deploying a CloudFormation template, see [Creating a stack](#) in the AWS CloudFormation documentation.

Load balancer subnets and routing

Let's start with an illustration of how traffic flows when you configure an [Application Load Balancer](#) that faces the internet, to Amazon Elastic Compute Cloud (Amazon EC2) instances in a private subnet. This architecture reflects best practices when deploying an Application Load Balancer that's open to the internet.

Inbound traffic path

The following diagram illustrates the virtual private cloud (VPC) subnets and routing associated with the incoming traffic flow, with the return traffic removed from the diagram for clarity.

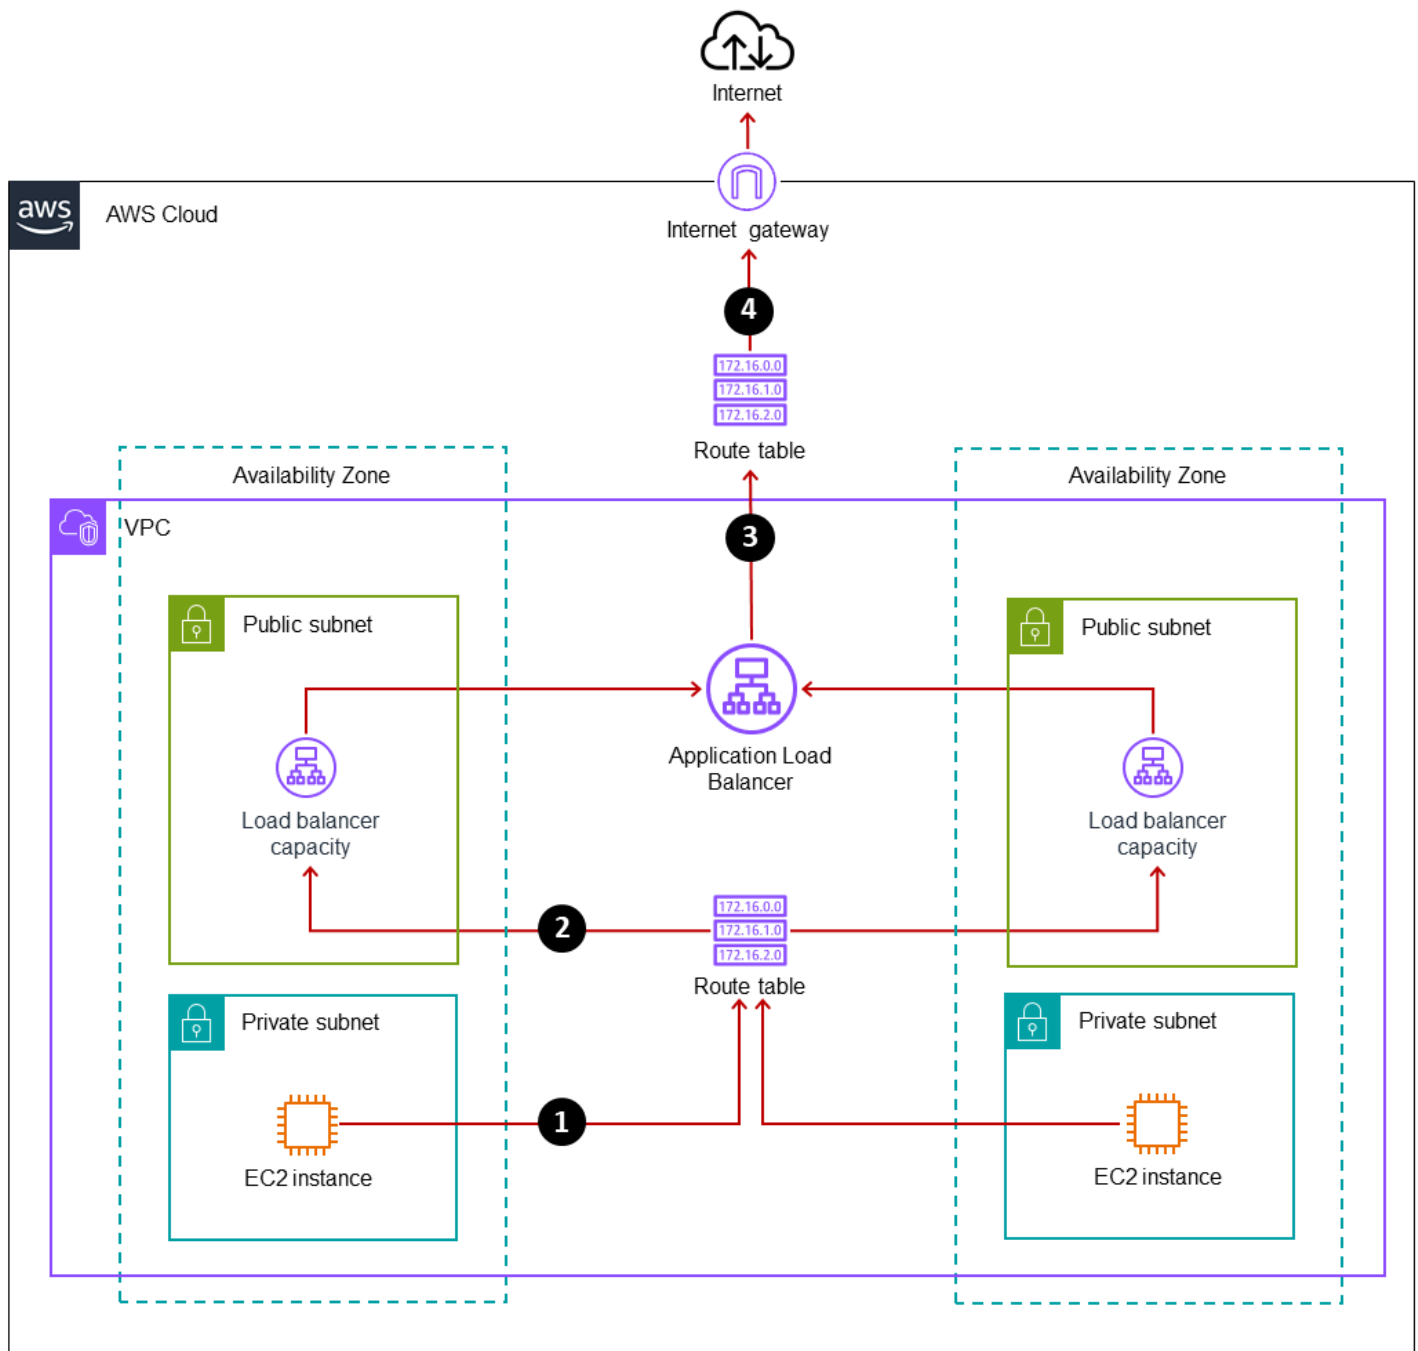

1. Traffic from the internet flows in to the Application Load Balancer DNS name.
2. The Application Load Balancer is associated with two public subnets in the scenario that's illustrated. The Elastic Load Balancing service creates load balancer capacity in each enabled Availability Zone, and sends traffic through the Availability Zone to determine the appropriate routing logic. The Application Load Balancer uses its internal logic to determine which target group and instance to route the traffic to.
3. The Application Load Balancer routes the request to the EC2 instance through a node that's associated with the public subnet in the same Availability Zone. (These nodes are configured, managed, and scaled by the Elastic Load Balancing service and aren't visible to users.)

4. The route table routes the traffic locally within the VPC, between the public subnet and the private subnet, and to the EC2 instance.

Return traffic path

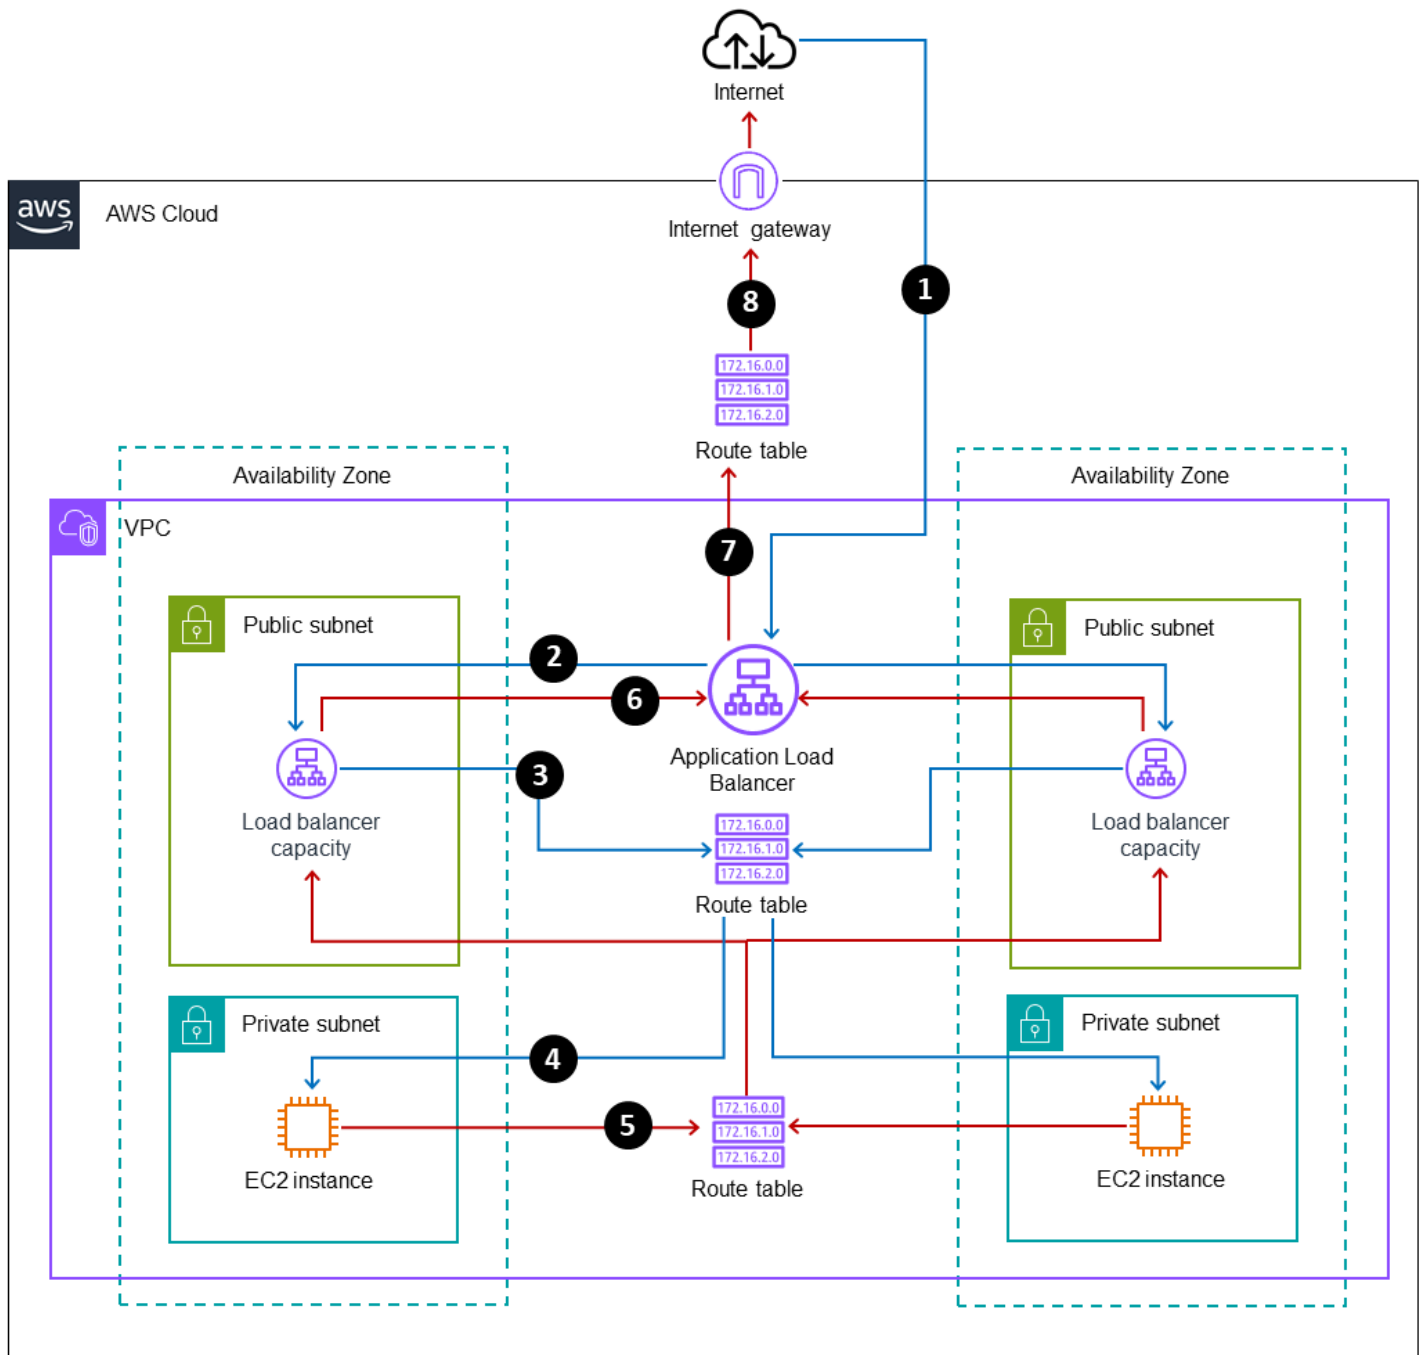

The following diagram illustrates the VPC subnets and routing associated with the traffic path back out to the internet, with the incoming traffic removed from the diagram for clarity.

1. The EC2 instance in the private subnet routes the outbound traffic through the route table.
2. The route table has a local route to the public subnet. It reaches the Application Load Balancer capacity that the traffic entered on, in the corresponding public subnet, by following the path back the way the traffic entered.
3. The Application Load Balancer routes traffic out through its public interface.
4. The public subnet's route table has a default route pointing to an internet gateway, which routes the traffic back out to the internet.

Complete traffic flow diagram

The following diagram combines the inbound and return traffic flows to provide a complete illustration of load balancer routing.

1. Traffic from the internet flows in to the Application Load Balancer DNS name.
2. The Application Load Balancer is associated with two public subnets in the scenario that's illustrated. The Elastic Load Balancing service creates load balancer capacity in each enabled Availability Zone, and sends traffic through the Availability Zone to determine the appropriate routing logic. The Application Load Balancer uses its internal logic to determine which target group and instance to route the traffic to.

3. The Application Load Balancer routes the request to the EC2 instance through a node that's associated with the public subnet in the same Availability Zone. (These nodes are configured, managed, and scaled by the Elastic Load Balancing service and aren't visible to users.)
4. The route table routes the traffic locally within the VPC, between the public subnet and the private subnet, and to the EC2 instance.
5. The EC2 instance in the private subnet routes the outbound traffic through the route table.
6. The route table has a local route to the public subnet. It reaches the Application Load Balancer capacity that the traffic entered on, in the corresponding public subnet, by following the path back the way the traffic entered.
7. The Application Load Balancer routes traffic out through its public interface.
8. The public subnet's route table has a default route pointing to an internet gateway, which routes the traffic back out to the internet.

Which stickiness strategy is right for you?

Answering the following questions will help you determine your load balancer stickiness strategy.

Are you using WebSockets?

- Yes: WebSockets are inherently sticky, so there is no need to use any strategy.
- No: Continue to the next question.

Are you planning a blue/green deployment?

- Yes: At the minimum, use target group stickiness, but continue to the next question.
- No: Continue to the next question.

Do you need some or all the traffic from a client to be routed to the same EC2 instance repeatedly?

- Yes: Continue to the next question.
- No: You do not need to use sticky sessions.

Do you want your application code or client to control the state attributes and duration by using cookies?

- Yes: Use application-based cookies to enable application-based sticky sessions.
- No: Use load balancer generated cookies to enable duration-based sticky sessions.

Application Load Balancer without stickiness

When you use an Application Load Balancer without any form of stickiness, by default, the load balancer uses the round robin method to determine the EC2 instance it should route traffic to.

Template: Use the AWS CloudFormation template `basic.yml` (included in the [sample code .zip file](#)) to try out this functionality.

Note

All CloudFormation templates included with this guide deploy a custom VPC, route tables, routes, an internet gateway, an Application Load Balancer, target groups, listeners, and EC2 instances, to illustrate a specific load balancer stickiness strategy.

Common use cases

Use an Application Load Balancer without stickiness in these scenarios:

- You have a list of targets to route traffic to, but the targets do not maintain session state.
- You're using web servers that do not maintain session state.
- You're using application servers that do not maintain session state.

Steps

Notes

- NAT gateways incur a small cost.
- Multiple EC2 instances use up your free tier hours faster than a single EC2 instance.

1. Deploy the CloudFormation template `basic.yml` in a lab environment.
2. Wait until the health status of your target group instances changes from **initial** to **healthy**.
3. Navigate to the Application Load Balancer URL in a web browser, using HTTP (TCP/80).

For example: `http://alb-123456789.us-east-1.elb.amazonaws.com/`

The webpage displays **Instance 1 - TG1** or **Instance 2 - TG1**.

4. Refresh the page multiple times.

Expected results

The instance that loads the web page (**Instance 1** or **Instance 2**) should change every time, as reflected in the page text. The load balancer logic manages the last target across multiple internal nodes, which may introduce a synchronization delay, so there's a possibility that you will be routed to the same target.

How it works

- In this example, two EC2 instances are assigned to a single target group. The EC2 instances have an Apache web server (httpd) installed, and the `index.html` page text on each EC2 instance is hardcoded to identify that instance.
- The Application Load Balancer runs its internal round robin logic to determine which EC2 instance should receive the traffic.
- Each time you reload the web page, the Application Load Balancer runs its routing logic, and the page displays **Instance 1 - TG1** or **Instance 2 - TG1**.

Target group stickiness

When you use an Application Load Balancer with target group stickiness:

- The Application Load Balancer uses the [target group weight](#) to determine how to balance the incoming traffic between the target groups.
- By default, the Application Load Balancer uses the round robin method [to route requests to the EC2 instances](#) in the destination target group.

Template: Use the AWS CloudFormation template `targetgroupstickiness.yml` (included in the [sample code .zip file](#)) to try out target group stickiness.

Common use cases

Use target group stickiness in these scenarios:

- There are multiple target groups assigned to the load balancer, and the traffic from a client should be consistently routed to instances within that target group.
- Blue/green deployments.

Code changes from basic.yml

A single change has been made to the listener: We modified the Application Load Balancer default actions to specify two target groups (TG1 and TG2) of equal weight, with a stickiness configuration.

basic.yml

```
Listener1:
  Type: 'AWS::ElasticLoadBalancingV
2::Listener'
  Properties:
    LoadBalancerArn: !Ref ALB
    Protocol: HTTP
    Port: 80
    DefaultActions:
```

targetgroupstickiness.yml

```
Listener1:
  Type: 'AWS::ElasticLoadBalancingV
2::Listener'
  Properties:
    LoadBalancerArn: !Ref ALB
    Protocol: HTTP
    Port: 80
    DefaultActions:
```

```
- TargetGroupArn: !Ref TG1
  Type: forward
```

```
- ForwardConfig:
  TargetGroups:
    - TargetGroupArn: !Ref TG1
      Weight: 1
    - TargetGroupArn: !Ref TG2
      Weight: 1
  TargetGroupStickinessConfig
:
    DurationSeconds: 10
    Enabled: true
  Type: forward
```

Steps

Notes

- NAT gateways incur a small cost.
- Multiple EC2 instances use up your free tier hours faster than a single EC2 instance.

1. Deploy the CloudFormation template `targetgroupstickiness.yml` in a lab environment.
2. Wait until the health status of your target group instances changes from **initial** to **healthy**.
3. Navigate to the Application Load Balancer URL in a web browser, using HTTP (TCP/80).

For example: `http://alb-123456789.us-east-1.elb.amazonaws.com/`

The webpage displays one of the following: **Instance 1 - TG1**, **Instance 2 - TG1**, **Instance 3 - TG2**, or **Instance 4 - TG2**.

4. Refresh the page multiple times.

Expected results

Note

The CloudFormation template in this example configures the stickiness to last 10 seconds.

The instances that load the web page should stay within the target group (TG1 or TG2) within the 10-second duration, as reflected in the page text.

After approximately 10 seconds, the stickiness is released and the target group instance set might change.

How it works

- In this example, four EC2 instances are split across two target groups, with two instances per target group. The EC2 instances have an Apache web server (`httpd`) installed, and the `index.html` page text on each EC2 instance is hardcoded to be distinct.
- The Application Load Balancer creates a binding for the user's session toward the destination target group, with an expiration time.
- When you reload the page, the Application Load Balancer checks whether the binding exists and has not expired.
 - If the binding has expired or doesn't exist, the Application Load Balancer runs its routing logic and determines the destination target group.
 - If the binding has not expired, the Application Load Balancer routes traffic to the same target group, but not necessarily to the same EC2 instance.

Sticky sessions with load balancer generated cookies

When you use an Application Load Balancer with a load balancer generated cookie:

- The Application Load Balancer uses the [target group weight](#) to determine how to balance the incoming traffic between the target groups.
- By default, the Application Load Balancer uses the round robin method [to route requests to the EC2 instances](#) in the destination target group.

After traffic has been initially routed to an instance, subsequent traffic will stick to that EC2 instance for a specified duration.

Template: Use the AWS CloudFormation template `stickysessionslb.yml` (included in the [sample code .zip file](#)) to try out sticky sessions with load balancer generated cookies.

Common use cases

Use sticky sessions with load balancer generated cookies in these scenarios:

- PHP web servers
- Servers that maintain temporary session data such as logs, shopping carts, or chat conversations

Code changes from `basic.yml`

The relevant code changes are in the target group configuration, to set the stickiness type to `lb_cookie` and the duration to 10 seconds.

`basic.yml`

```
TG1:
  Type: 'AWS::ElasticLoadBalancingV
2::TargetGroup'
  Properties:
    Name: TG1
    Protocol: HTTP

    TargetType: instance
```

```

  Type: 'AWS::ElasticLoadBalancingV

    TargetType: instance
```

TargetGroupAttributes:

Value: true
- Key: stickiness.type
Value: lb_cookie
- Key: stickiness.lb_cookie.duration_seconds
Value: 10

Steps

Notes

- NAT gateways incur a small cost.
- Multiple EC2 instances will use up your free tier hours faster than a single EC2 instance.

1. Deploy the CloudFormation template `stickysessionslb.yml` in a lab environment.
2. Wait until the health status of your target group instances changes from **initial** to **healthy**.
3. Navigate to the Application Load Balancer URL in a web browser, using HTTP (TCP/80).

For example: `http://alb-123456789.us-east-1.elb.amazonaws.com/`

The webpage displays one of the following: **Instance 1 - TG1**, **Instance 2 - TG1**, **Instance 3 - TG2**, or **Instance 4 - TG1**.

4. Refresh the page multiple times.

Expected results

Note

The CloudFormation template in this example configures the stickiness to last 10 seconds.

The instance that loads the web page should stay the same within the 10-second duration, as reflected in the page text. After approximately 10 seconds, the stickiness is released and the destination instance might change.

How it works

- In this example, two EC2 instances are present in one target group. The EC2 instances have an Apache web server (httpd) installed, and the `index.html` page text on each EC2 instance is hardcoded to be distinct.
- The Application Load Balancer creates a binding for the user's session, which binds toward the destination, with an expiration time.
- When you reload the page, the Application Load Balancer checks whether the binding exists and has not expired.
 - If the binding has expired or doesn't exist, the Application Load Balancer runs its routing logic and determines the destination instance.
 - If the binding has not expired, the Application Load Balancer routes traffic to the same destination instance.

Sticky sessions with application-based cookies

When you use an Application Load Balancer with an application-based cookie:

- The Application Load Balancer uses the [target group weight](#) to determine how to balance the incoming traffic between the target groups.
- By default, the Application Load Balancer uses the round robin method [to route requests to the EC2 instances](#) in the destination target group.
- After traffic has been initially routed to an EC2 instance, the EC2 instance application response should contain a custom application cookie, which is sent back to the client along with an automated Application Load Balancer cookie.
- Subsequent traffic will stick to the EC2 instance if the client sends back the application cookie and the Application Load Balancer cookie.
- The application-based cookie expires after non-use for the configured duration.

Template: Use the AWS CloudFormation template `stickysessionsapp.yml` (included in the [sample code .zip file](#)) to try out sticky sessions with application-based cookies.

Common use cases

Use sticky sessions with application-generated cookies when you want additional control in these scenarios:

- PHP web servers
- Servers that maintain temporary session data such as logs, shopping carts, or chat conversations

Code changes from `basic.yml`

The only code change is in the target group configuration. We added a stickiness configuration to the Application Load Balancer and the target group attributes. The application cookie duration is specified, and the target group has application cookie stickiness enabled.

Steps

Notes

- NAT gateways incur a small cost.
- Multiple EC2 instances will use up your free tier hours faster than a single EC2 instance.

1. Deploy the CloudFormation template `stickysessionslb.yml` in a lab environment.
2. Wait until the health status of your target group instances changes from **initial** to **healthy**.
3. Navigate to the Application Load Balancer URL in a web browser, using HTTP (TCP/80).

For example: `http://alb-123456789.us-east-1.elb.amazonaws.com/`

The webpage displays one of the following: **Instance 1 - TG1**, **Instance 2 - TG1**, **Instance 3 - TG2**, or **Instance 4 - TG2**.

4. Refresh the page multiple times.

Expected results

Note

The CloudFormation template in this example has configured the stickiness to last 10 seconds. Valid stickiness duration configuration is between 1 second and 1 week.

The instance that loads the web page should stay the same, as indicated by the page text.

The stickiness duration doesn't refresh, but is based on the expiration configured in the Application Load Balancer for the application cookie that is generated by the EC2 instance.

Example 1: Wait 5 seconds to refresh the page. The same instance will load and the stickiness will be refreshed for another 10 seconds.

Example 2: Wait longer than 10 seconds to reload the page. The application cookie expires, and you are routed to a different EC2 instance. This new instance generates another application cookie with a 10-second duration.

How it works

- In this example the EC2 instances have an Apache web server (`httpd`) installed. The `httpd.conf` file is configured to return a static `Set-Cookie` value back to the client (your web browser). The `Set-Cookie` value is hardcoded to be `TESTCOOKIE=<somevalue>`.
- Open your browser's **Inspect Element** option, choose the **Network** tab, and then choose the **Get** method, which loads the page. You will see a **Cookies** tab.
- The browser is a client application that is automatically configured to return any subsequent updates to the server with the cookies it receives in the server's `Set-Cookie` response.
- When you reload the page, the cookies received in the initial page load are automatically sent back to the Application Load Balancer.
 - If the cookie has expired (that is, 10 seconds have elapsed since you placed the last call), the Application Load Balancer uses new logic to determine which EC2 instance to route traffic to.
 - If the cookie has not expired, the Application Load Balancer routes traffic to the same EC2 instance.

Numbers

7 Rs

Seven common migration strategies for moving applications to the cloud. These strategies build upon the 5 Rs that Gartner identified in 2011 and consist of the following:

- Refactor/re-architect – Move an application and modify its architecture by taking full advantage of cloud-native features to improve agility, performance, and scalability. This typically involves porting the operating system and database. Example: Migrate your on-premises Oracle database to the Amazon Aurora PostgreSQL-Compatible Edition.
- Replatform (lift and reshape) – Move an application to the cloud, and introduce some level of optimization to take advantage of cloud capabilities. Example: Migrate your on-premises Oracle database to Amazon Relational Database Service (Amazon RDS) for Oracle in the AWS Cloud.
- Repurchase (drop and shop) – Switch to a different product, typically by moving from a traditional license to a SaaS model. Example: Migrate your customer relationship management (CRM) system to Salesforce.com.
- Rehost (lift and shift) – Move an application to the cloud without making any changes to take advantage of cloud capabilities. Example: Migrate your on-premises Oracle database to Oracle on an EC2 instance in the AWS Cloud.
- Relocate (hypervisor-level lift and shift) – Move infrastructure to the cloud without purchasing new hardware, rewriting applications, or modifying your existing operations. You migrate servers from an on-premises platform to a cloud service for the same platform. Example: Migrate a Microsoft Hyper-V application to AWS.
- Retain (revisit) – Keep applications in your source environment. These might include applications that require major refactoring, and you want to postpone that work until a later time, and legacy applications that you want to retain, because there's no business justification for migrating them.

- Retire – Decommission or remove applications that are no longer needed in your source environment.

abstracted services

See [managed services](#).

ACID

See [atomicity, consistency, isolation, durability](#).

active-active migration

A database migration method in which the source and target databases are kept in sync (by using a bidirectional replication tool or dual write operations), and both databases handle transactions from connecting applications during migration. This method supports migration in small, controlled batches instead of requiring a one-time cutover. It's more flexible but requires more work than [active-passive migration](#).

active-passive migration

A database migration method in which the source and target databases are kept in sync, but only the source database handles transactions from connecting applications while data is replicated to the target database. The target database doesn't accept any transactions during migration.

aggregate function

A SQL function that operates on a group of rows and calculates a single return value for the group. Examples of aggregate functions include SUM and MAX.

AI

See [artificial intelligence](#).

AIOps

See [artificial intelligence operations](#).

anonymization

The process of permanently deleting personal information in a dataset. Anonymization can help protect personal privacy. Anonymized data is no longer considered to be personal data.

anti-pattern

A frequently used solution for a recurring issue where the solution is counter-productive, ineffective, or less effective than an alternative.

application control

A security approach that allows the use of only approved applications in order to help protect a system from malware.

artificial intelligence (AI)

The field of computer science that is dedicated to using computing technologies to perform cognitive functions that are typically associated with humans, such as learning, solving problems, and recognizing patterns. For more information, see [What is Artificial Intelligence?](#)

The process of using machine learning techniques to solve operational problems, reduce operational incidents and human intervention, and increase service quality. For more information about how AIOps is used in the AWS migration strategy, see the [operations integration guide](#).

asymmetric encryption

An encryption algorithm that uses a pair of keys, a public key for encryption and a private key for decryption. You can share the public key because it isn't used for decryption, but access to the private key should be highly restricted.

atomicity, consistency, isolation, durability (ACID)

A set of software properties that guarantee the data validity and operational reliability of a database, even in the case of errors, power failures, or other problems.

attribute-based access control (ABAC)

The practice of creating fine-grained permissions based on user attributes, such as department, job role, and team name. For more information, see [ABAC for AWS](#) in the AWS Identity and Access Management (IAM) documentation.

authoritative data source

A location where you store the primary version of data, which is considered to be the most reliable source of information. You can copy data from the authoritative data source to other locations for the purposes of processing or modifying the data, such as anonymizing, redacting, or pseudonymizing it.

Availability Zone

A distinct location within an AWS Region that is insulated from failures in other Availability Zones and provides inexpensive, low-latency network connectivity to other Availability Zones in the same Region.

AWS Cloud Adoption Framework (AWS CAF)

A framework of guidelines and best practices from AWS to help organizations develop an efficient and effective plan to move successfully to the cloud. AWS CAF organizes guidance into six focus areas called perspectives: business, people, governance, platform, security, and operations. The business, people, and governance perspectives focus on business skills and processes; the platform, security, and operations perspectives focus on technical skills and processes. For example, the people perspective targets stakeholders who handle human resources (HR), staffing functions, and people management. For this perspective, AWS CAF provides guidance for people development, training, and communications to help ready the organization for successful cloud adoption. For more information, see the [AWS CAF website](#) and the [AWS CAF whitepaper](#).

AWS Workload Qualification Framework (AWS WQF)

A tool that evaluates database migration workloads, recommends migration strategies, and provides work estimates. AWS WQF is included with AWS Schema Conversion Tool (AWS SCT). It analyzes database schemas and code objects, application code, dependencies, and performance characteristics, and provides assessment reports.

You can create a new branch from an existing branch, and you can then develop features or fix bugs in the new branch. A branch you create to build a feature is commonly referred to as a *feature branch*. When the feature is ready for release, you merge the feature branch back into the main branch. For more information, see [About branches](#) (GitHub documentation).

training

To provide data for your ML model to learn from. The training data must contain the correct answer. The learning algorithm finds patterns in the training data that map the input data attributes to the target (the answer that you want to predict). It outputs an ML model that captures these patterns. You can then use the ML model to make predictions on new data for which you don't know the target.
