Robust network design with AWS Control Tower

Amazon Web Services ([contributors](#))

September 2024 ([document history](#))

Security plays a crucial role for any organization. One of the key factors of application security is networking. A loophole in networking can open various options for cybercriminals to compromise applications and take control over systems. This guide defines some of the best practices when using AWS Control Tower to design a network at the AWS Organizations level. The goal of the network design is to provide easier management, improved security, and protection for the applications hosted on the AWS Cloud. To help meet this goal, the network design includes inspecting, filtering, and logging the traffic that comes in and goes out to internet from a single centralized network account in AWS.

The approach covered uses a centralized network account with three virtual private clouds (VPCs). Inbound and outbound traffic from spoke VPCs and the internet is filtered by AWS WAF and AWS Network Firewall. AWS Transit Gateway and VPC endpoints help route the traffic.

Prerequisites

- An active [AWS account](#)
- [AWS Control Tower](#) set up
- Knowledge of [Transit Gateway](#)
- Knowledge of networking and network security

Centralized network account

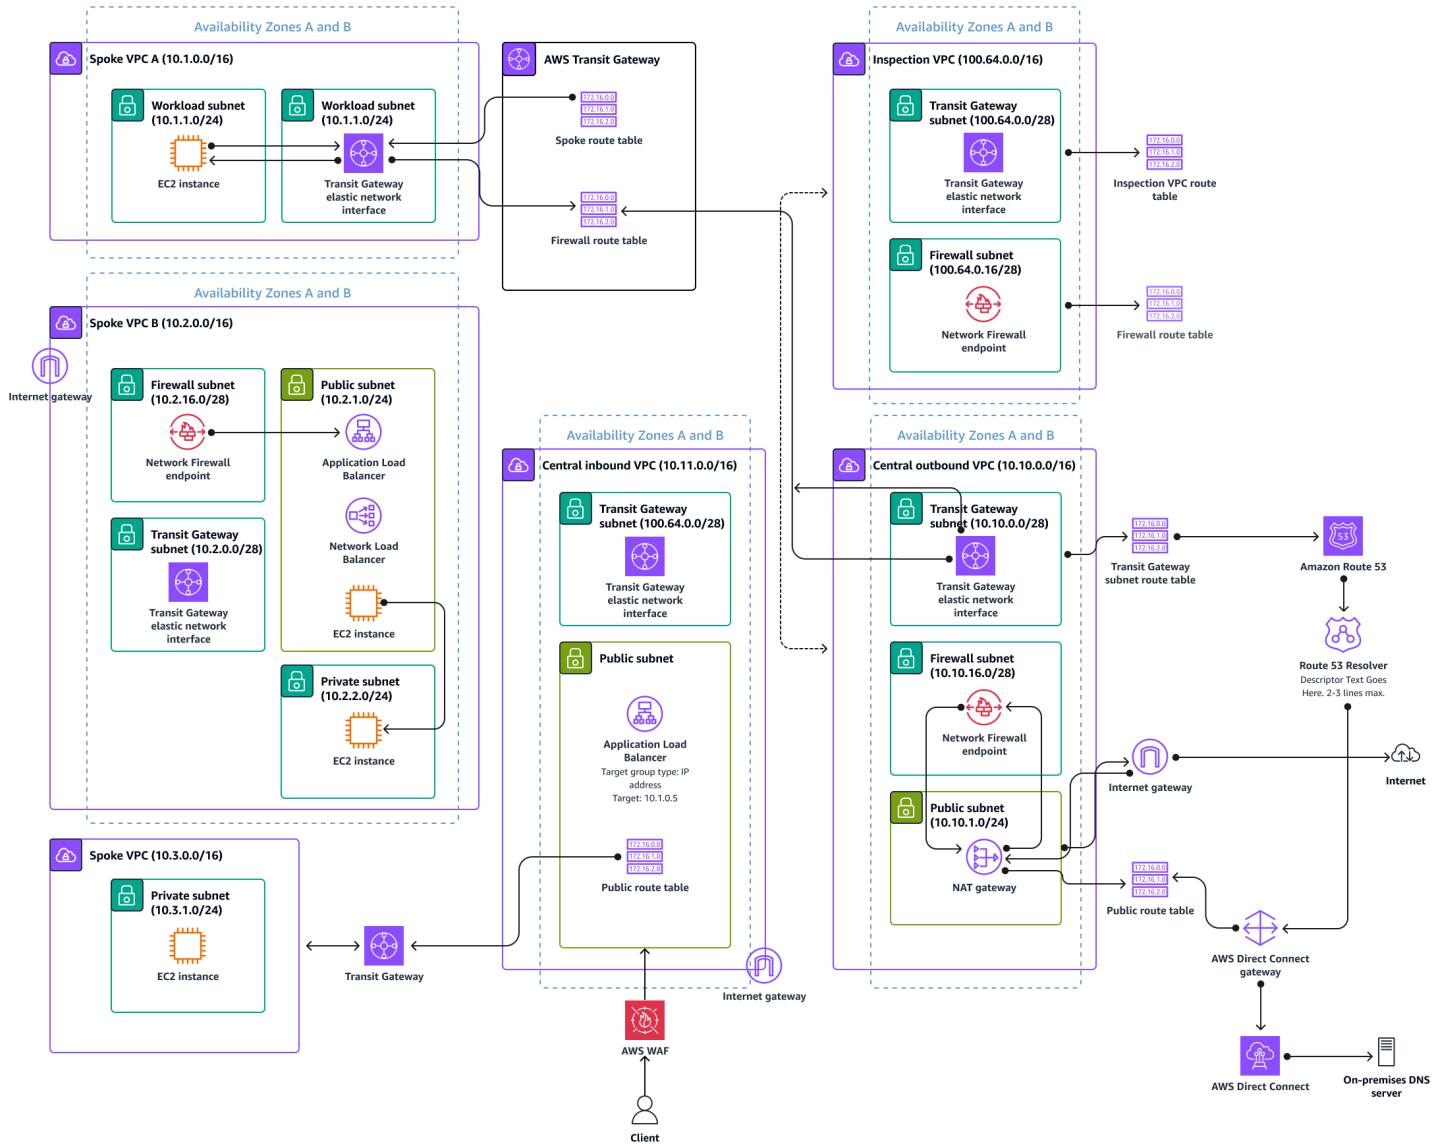

When managing an organization's entire network, we recommend having a separate account that is dedicated for managing networking components or services. First, the networking team requests the creation of an account (network) for managing networking services. After you create the new account, note the account number. Next, change [Amazon Virtual Private Cloud \(Amazon VPC\) IP Address Manager \(IPAM\)](#) control from the AWS Control Tower management account to the network account by providing the account details in IPAM.

The newly created account will be your centralized network account, which will manage the following network services:

- IPAM
- VPC configuration
- Network access control list (ACL)
- Centralized network firewall
- AWS Transit Gateway
- VPC endpoint configuration
- Centralized DNS management
- Centralized inbound traffic
- AWS WAF

Robust network configuration

The following diagram shows how an ideal network should be built to protect the network by filtering malicious traffic that comes into an organization and blocking traffic that is not supposed to reach the internet or specific sites on the internet. The network can also control traffic within the organization based on your organization's security requirements.

All inbound traffic that comes to services hosted by the organization is filtered by AWS WAF and AWS Network Firewall before the traffic reaches the Amazon Elastic Compute Cloud (Amazon EC2) instances. All outbound traffic from the organization is filtered by Network Firewall first before it reaches the destination. Amazon Route 53 manages all the DNS resolutions and provides a

source to query DNS logs. AWS Transit Gateway elastic network interfaces help provide centralized networking.

IPAM

[Amazon VPC IP Address Manager \(IPAM\)](#) is an AWS feature that helps you manage all your organization's public and private IP addresses. IPAM categorizes IP addresses in different business units and specific AWS Regions. IPAM tracks the IP addresses that are already in use and leftover IP addresses. It also helps avoid overlapping IP addresses and provides specific CIDR blocks to the VPC based on the selected netmask.

Delegate IPAM

By default, IPAM configuration for an organization is available in the AWS Control Tower management account. To manage IPAM from the network account, delegate IPAM administration from the AWS Control Tower management account to the network account:

1. In the AWS Control Tower management account, navigate to the Amazon VPC service.
2. Open the Amazon VPC IP Address Manager.
3. In the left pane, choose the organization setting.
4. Choose **Edit**, and then enter the network account number that you noted when you created the account.
5. Save the changes.

After you configure the delegation, you can see those details reflected in the IPAM organization settings of the network account.

Design IPAM hierarchy

Before you start to configure IPAM, analyze the structure that your organization needs based on following criteria:

- The CIDR block that IPAM will use
- The business units for which the network account should be configured through IPAM
- The AWS Regions to be managed through this IPAM

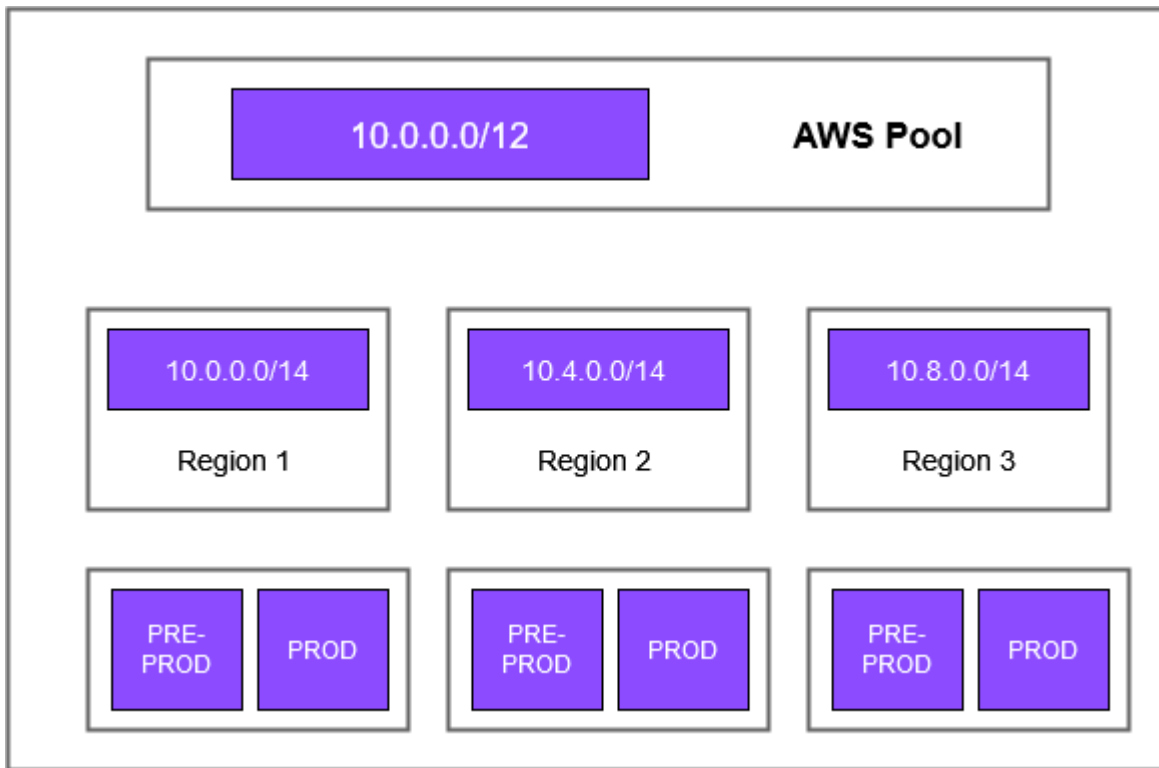

Configure IPAM

To configure IPAM, do the following:

1. Open the AWS Management Console, and navigate to the Amazon VPC IP Address Manager console.
2. Create the IPAM. Enter a name, the operational AWS Regions, and a description.

When the IPAM is created, it will include two scopes:

- Public, used for configuring and using public CIDR blocks
 - Private, used for configuring and using private CIDR blocks
3. Create the top-level IPAM pool. In the following diagram, the top-level pool is AWS Pool.

4. Create the lower-level pools:

- A pool for the Region
- Pools for preproduction and production within the Region

Be sure to specify the appropriate scope for the pools. In general, we recommend using the private scope for most of the network unless you want to host services with a public IP address from your own public CIDR block.

5. Share the IPAM with other AWS Organizations organizational unit (OU) accounts by using AWS Resource Access Manager (AWS RAM). Share the IPAM with each account in which you want to create resources. The accounts should be in organization network range and part of the top-level IPAM pool.

We recommend using IPAM based VPC creation when you create all your VPCs. This helps in making sure that the CIDR blocks of new VPCs are not colliding with the existing VPC. New VPCs are created using the pool configurations that you set up earlier.

Configuring the VPCs

A VPC is a logically isolated network in AWS that resembles a traditional data center network. A robust network usually includes three different VPCs in the network account:

- Firewall VPC
- Inbound VPC
- Outbound VPC

Each of these VPCs is designated for specific purpose. Applications and other services should not be deployed in these VPCs except for those that are described in this guide.

When you create these VPCs, choose the **VPC only** option. Then, choose the **IPAM-allocated IPv4 CIDR block** option, select the relevant IPAM pool, and enter the appropriate netmask.

Firewall VPC

The firewall VPC is dedicated for creating and configuring a firewall by using AWS Network Firewall. In the firewall VPC, create six private subnets:

- Three subnets dedicated for transit gateway attachment
- Three subnets dedicated for the firewall

Inbound VPC

When configuring the network account, consider the traffic that comes to your services that are hosted on AWS. In the inbound VPC, you host an Application Load Balancer. You also configure the organization's standard AWS WAF firewall and other security-related services to help prevent malicious activities that could compromise security. In the inbound VPC, create six subnets:

- Three public subnets for hosting the Application Load Balancer
- Three transit gateway attachment subnets in which you will configure routing to the firewall for any other network CIDR blocks apart from the inbound VPC's CIDR block

Outbound VPC

The outbound VPC controls the traffic that goes out from the network account. In the outbound VPC, create the following six subnets:

- Three public subnets in three different Availability Zones, with a NAT gateway in each subnet.
- Three private subnets in the three Availability Zones, each containing a route table configured with 0.0.0.0/0 route to the ID of the NAT gateway ID that is created in the respective public subnet. Attach transit gateways to the private subnets.

Associate any private hosted zones with the outbound VPC.

VPC Flow Logs

To record all requests to network interfaces for future analysis, configure VPC Flow Logs. For more information, see the [Amazon VPC documentation](#) and the [Configure VPC Flow Logs for centralization across AWS accounts](#) pattern.

Network ACL configurations

A network access control list (network ACL) is a stateless service that validates both inbound and outbound traffic in case any traffic reaching the Application Load Balancer attempts a distributed denial of service attack (DDoS) or any other malicious activities.

To prevent access to the IP address or CIDR block, add a deny rule in both the inbound and outbound sections of the network ACL. In the network ACL, the rule number plays a crucial role in the evaluation of traffic. Be sure to place the deny rules with the appropriate rule number. For more information about network ACLs, see the [AWS Documentation](#).

Centralized network firewall

Deploy AWS Network Firewall in the firewall VPC. This VPC plays a crucial role by hosting the firewall that inspects traffic moving from source to destination and traffic coming from the internet.

Firewall rule group

Define custom rules or use existing AWS Managed Rules for monitoring and managing traffic that flows from the firewall VPC to the internet, and from the internet to the VPC. Based on your requirements, create either stateful or stateless rules:

- **Stateful rules** – Traffic flow direction and other traffic approvals related to the packet are considered when inspecting packets.

This rule group adheres to Suricata compatible intrusion prevention system (IPS) requirements. For more information, see the [Network Firewall documentation](#).

Network Firewall also supports domain-traffic filtering. Traffic to the specific domains listed will be monitored using rules that are defined based on standard network attributes to control traffic flow.

- **Stateless rules** – The stateless rules engine of the Network Firewall analyzes each packet separately for stateless rule groups. Firewalls for networks don't account for context such as traffic direction or other relevant packets.
- **AWS Managed Rules rule groups** – When you use Network Firewall, you get access to AWS Managed Rules rule groups. These collections of preset, usable rules maintain up-to-date security. AWS updates the rule groups based on any new vulnerabilities or threats that are discovered.

Firewall policy

Create the firewall policy, which defines the monitoring and protection behavior of firewall based on the rules that you attach to the firewall policy. These rules can be managed rules provided by AWS or custom stateful or stateless rules that you created.

Firewall

In the firewall VPC, create the firewall by using the firewall policy that you defined. Select the three subnets that are dedicated to the firewall (not the transit gateway subnets). After the firewall is created, make a note of the VPC endpoints created by Network Firewall.

Configure the firewall VPC transit gateway subnet destination of `0.0.0.0/0` to route traffic to these endpoints. While configuring endpoints, make sure that each transit gateway subnet is

matched with its corresponding firewall endpoint subnet. Appropriate subnet mapping helps to ensure high availability of traffic routing and inspection.

Firewall logging

To help analyze traffic that is blocked by the network firewall, enable firewall logging. In addition to identifying unauthorized activities, firewall logging can help you analyze other activities that are happening inside and outside the VPC.

Transit gateway configuration

In the AWS Region where the most AWS resources will be provisioned or applications deployed, create a transit gateway in the network account. When you create the transit gateway, clear the default route table propagation and association. Instead, you will attach and propagate routes in specific transit gateway route tables based on the type of VPC.

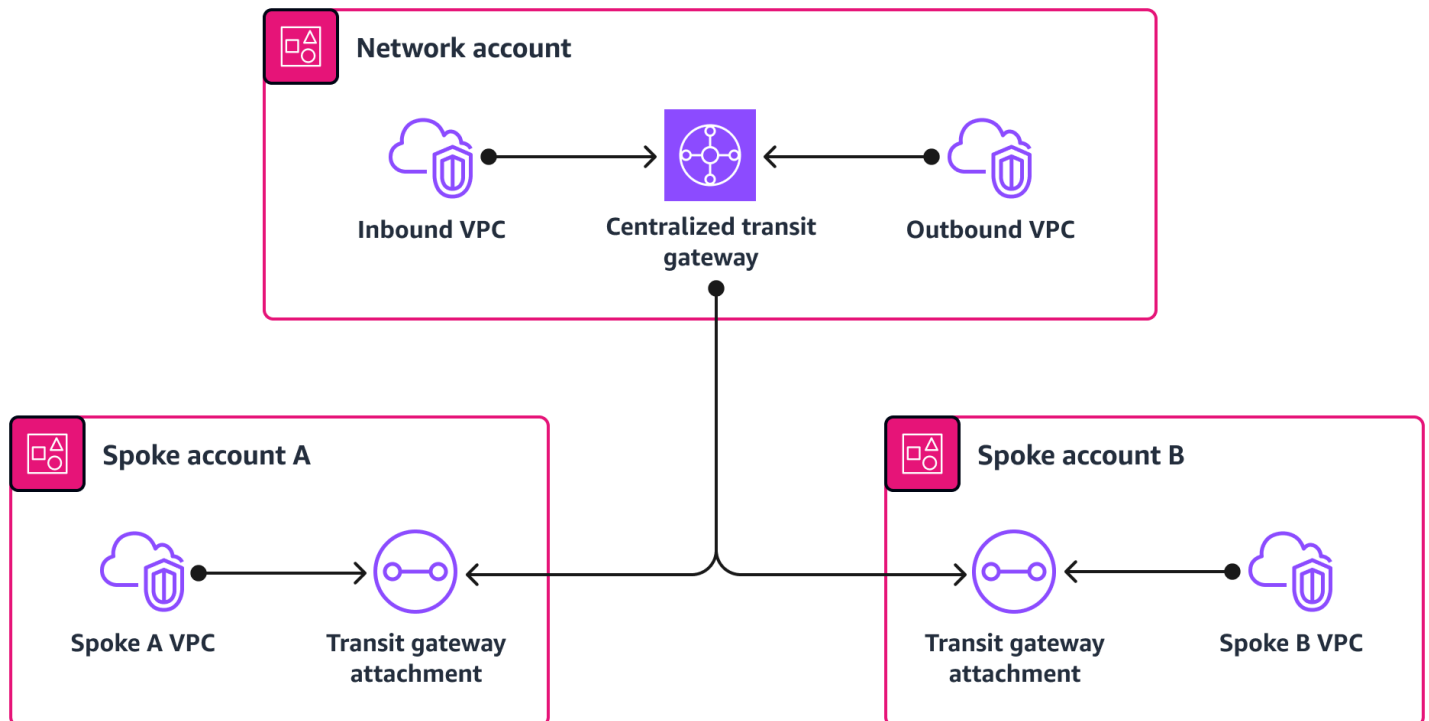

For this transit gateway, create three different transit gateway route tables:

- Inbound VPC transit gateway route table:
 - Association – All VPC attachments whose traffic must be inspected, except for the outbound and firewall VPCs.
 - Propagation – Static route with destination $0.0.0.0/0$ pointing out to the firewall VPC attachment.
- Firewall inspection transit gateway route table:
 - Association – Firewall VPC gateway attachment.
 - Propagation – In the firewall VPC transit gateway route table, configure propagation to route traffic from the firewall VPC to respective VPC attachments. To route traffic to internet after inspection, add a static route with destination $0.0.0.0/0$ pointing to the outbound VPC.
- Outbound transit gateway route table:
 - Association – Associate outbound VPC attachment in this route table.
 - Propagation – Create a static route with destination $0.0.0.0/0$ pointing out to the firewall VPC gateway attachment.

Note

The network account is dedicated to configuring network-related services and components. Don't deploy any additional applications or services in the network account.

The following diagram shows how the traffic from child account VPCs will be routed to and from the centralized network account and the internet or other VPCs.

Configuring the VPC endpoints

VPC endpoints are created in only the outbound VPC, which acts as the source for all VPCs in the organization to reach AWS services securely. This helps with managing the VPC endpoints. It also helps with cost optimization, because there is only a single endpoint source instead of multiple endpoints in individual VPCs.

Gateway endpoint

Gateway VPC endpoints provide reliable connectivity to Amazon Simple Storage Service (Amazon S3) and Amazon DynamoDB without requiring an internet gateway or a NAT gateway for your

VPC. Unlike other types of VPC endpoints, gateway endpoints don't use AWS PrivateLink. Gateway endpoints are offered at no charge. It's good to use them in case you need access for Amazon S3 and DynamoDB from the spoke VPCs through a secure channel.

Interface endpoint

Interface endpoints are helpful for establishing a private communication between services on AWS and endpoints over AWS PrivateLink.

In the outbound VPC, create the required VPC endpoints. For Amazon S3 and DynamoDB, create gateway endpoints in the individual VPCs. Commonly used VPC endpoints include the following:

- Amazon S3 Control
- DynamoDB
- AWS Systems Manager

Architecture

The following diagram shows how applications hosted on EC2 instances or other services in other AWS accounts reach AWS services by using centralized VPC endpoints. In this architecture, the EC2 instance in another account in VPC B can resolve Systems Manager sessions by using VPC endpoints created in VPC A.

This helps in cost savings because VPC endpoints are hosted in the single centralized network account that you can use across organizations. You can create and manage VPC endpoints from a single account.

Decentralized DNS and Route 53 Profiles

In a decentralized DNS architecture, organizations create private hosted zones within their respective AWS accounts and directly associate the necessary VPCs. This approach provides the following benefits:

- Isolation of control
- Reduced scope in the event of an incident

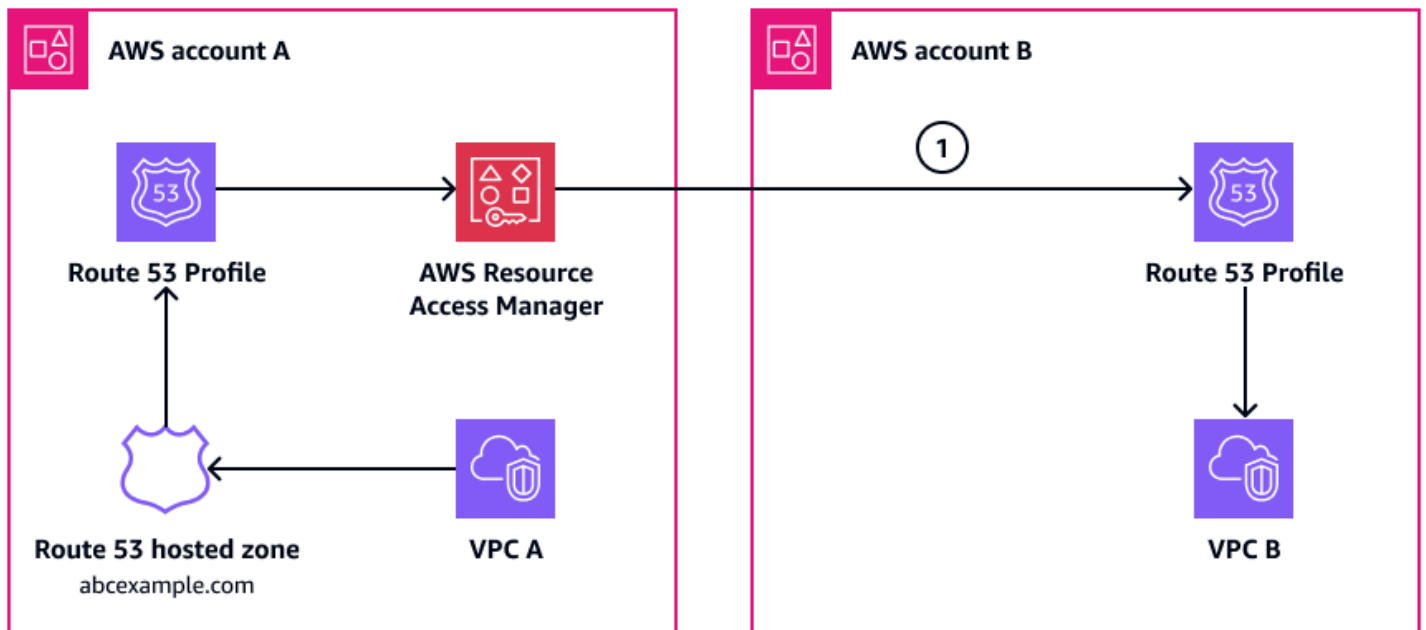

- Enhanced operational flexibility, because teams can independently manage their hosted zones and associated VPCs without relying on a centralized authority

Route 53 Profiles

Amazon Route 53 Profiles streamline the management and sharing of hosted zones, Resolver forwarding rules, and Route 53 DNS firewall rules across different AWS accounts. By managing these resources from a single source, you reduce operational overhead.

You can also associate a hosted zone from other accounts. For example, if you need to configure a private hosted zone that points to your on-premises server, you can create the private hosted zone in a single AWS account and associate it with a Route 53 Profile. If the same hosted zone configuration is required in another account, you can share the Profile with that account and associate the necessary VPCs. This ensures the DNS resolution is handled across multiple accounts without the need to duplicate the hosted zone setup in each account.

The following diagram shows a Route 53 Profile sharing AWS Resource Access Manager (AWS RAM) configuration. Route 53 Profiles can be shared with a single account, an AWS Organizations organizational unit, or across your entire organization.

The diagram shows the following workflow:

1. The Route 53 Profile is shared from account A to account B.

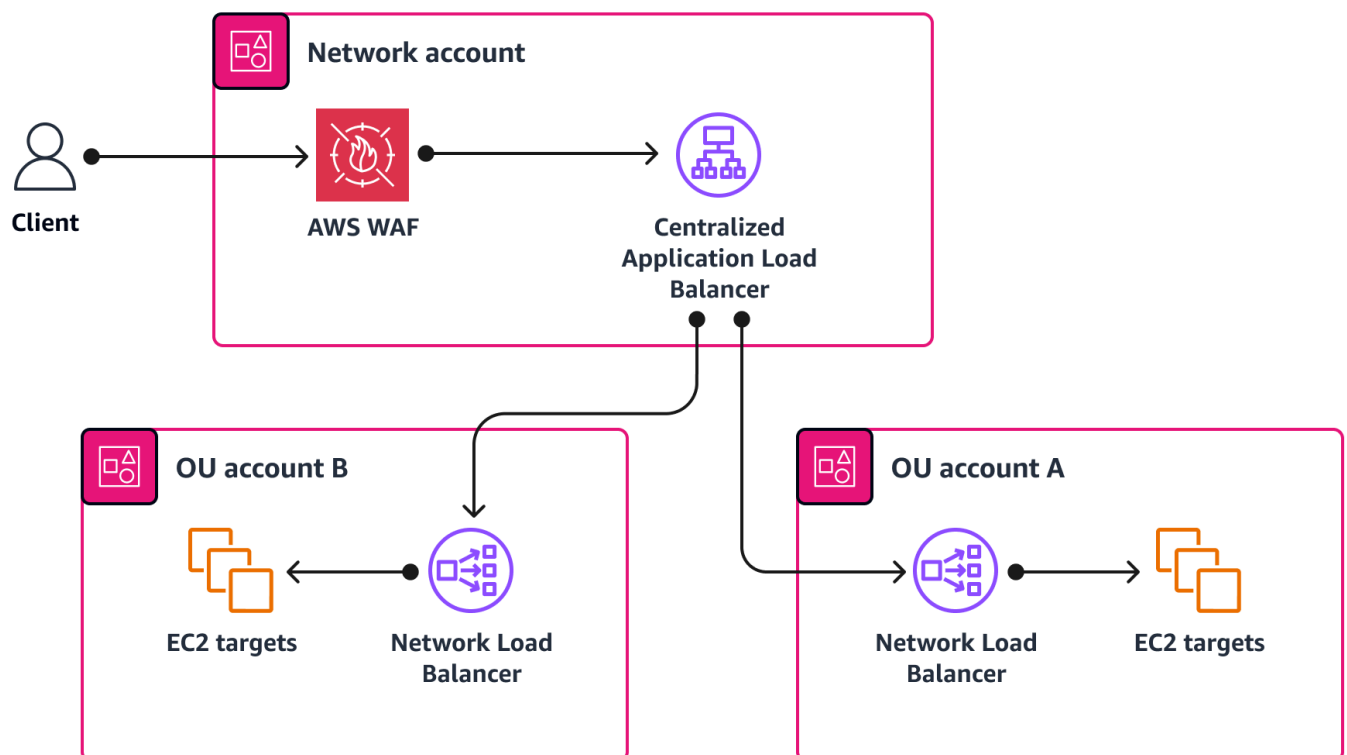

Note

When working with decentralized DNS and Route 53 Profiles, we recommend avoiding duplication of same hosted zone configuration across accounts or VPCs.

AWS WAF

You can use AWS WAF as a source to help protect your application from vulnerability attacks such as cross-site scripting, SQL injections, or DDoS. For the robust network approach, configure AWS WAF in front of the Application Load Balancer and define AWS WAF rules that should be followed across the organization. This will help ensure that any traffic reaching services hosted across the organization meets security best practices and that security is checked before traffic enters the organization's environment.

The following diagram shows inbound traffic coming through AWS WAF to the Application Load Balancer in the network account. From the network account, the traffic is routed to the Network Load Balancers or Application Load Balancer in the OU accounts and sent to the target EC2 instances.

Objectives and benefits

By implementing the configuration set up in this guide, you can achieve the following outcomes:

Numbers

7 Rs

Seven common migration strategies for moving applications to the cloud. These strategies build upon the 5 Rs that Gartner identified in 2011 and consist of the following:

- Refactor/re-architect – Move an application and modify its architecture by taking full advantage of cloud-native features to improve agility, performance, and scalability. This typically involves porting the operating system and database. Example: Migrate your on-premises Oracle database to the Amazon Aurora PostgreSQL-Compatible Edition.
- Replatform (lift and reshape) – Move an application to the cloud, and introduce some level of optimization to take advantage of cloud capabilities. Example: Migrate your on-premises Oracle database to Amazon Relational Database Service (Amazon RDS) for Oracle in the AWS Cloud.
- Repurchase (drop and shop) – Switch to a different product, typically by moving from a traditional license to a SaaS model. Example: Migrate your customer relationship management (CRM) system to Salesforce.com.
- Rehost (lift and shift) – Move an application to the cloud without making any changes to take advantage of cloud capabilities. Example: Migrate your on-premises Oracle database to Oracle on an EC2 instance in the AWS Cloud.
- Relocate (hypervisor-level lift and shift) – Move infrastructure to the cloud without purchasing new hardware, rewriting applications, or modifying your existing operations. You migrate servers from an on-premises platform to a cloud service for the same platform. Example: Migrate a Microsoft Hyper-V application to AWS.
- Retain (revisit) – Keep applications in your source environment. These might include applications that require major refactoring, and you want to postpone that work until a later time, and legacy applications that you want to retain, because there's no business justification for migrating them.

- Retire – Decommission or remove applications that are no longer needed in your source environment.

strangler fig pattern

An approach to modernizing monolithic systems by incrementally rewriting and replacing system functionality until the legacy system can be decommissioned. This pattern uses the analogy of a fig vine that grows into an established tree and eventually overcomes and replaces its host. test environment

See [environment](#).

training

To provide data for your ML model to learn from. The training data must contain the correct answer. The learning algorithm finds patterns in the training data that map the input data attributes to the target (the answer that you want to predict). It outputs an ML model that captures these patterns. You can then use the ML model to make predictions on new data for which you don't know the target.

trusted access

Granting permissions to a service that you specify to perform tasks in your organization in AWS Organizations and in its accounts on your behalf. The trusted service creates a service-linked role in each account, when that role is needed, to perform management tasks for you. For more information, see [Using AWS Organizations with other AWS services](#) in the AWS Organizations documentation.

tuning

To change aspects of your training process to improve the ML model's accuracy. For example, you can train the ML model by generating a labeling set, adding labels, and then repeating these steps several times under different settings to optimize the model.

U

uncertainty

A concept that refers to imprecise, incomplete, or unknown information that can undermine the reliability of predictive ML models. There are two types of uncertainty: *Epistemic uncertainty* is caused by limited, incomplete data, whereas *aleatoric uncertainty* is caused by the noise and randomness inherent in the data. For more information, see the [Quantifying uncertainty in deep learning systems](#) guide.
