# Working around Terraform data source limitations on AWS

*Ram Kandaswamy, Amazon Web Services (AWS)*

May 2025 ([document history](#))

This guide provides automated solutions for handling one-time DevOps setup tasks that can't be addressed with standard resources when using HashiCorp Terraform on AWS. It covers two use cases: [revision management for AWS Batch job definitions](#) and [Amazon Bedrock agent deployments](#).

The guide discusses how you can use null resources and other key components in Terraform to extend your infrastructure automation beyond traditional resource boundaries. The `terraform_data` type lets you inject custom scripts, run remote commands, and orchestrate complex deployment scenarios. By implementing null resources, you can create adaptive infrastructure that meets your unique operational challenges. This solution helps you transition from manual interventions to a programmable infrastructure that simplifies your DevOps process.

## About Terraform

Terraform is a popular infrastructure as code (IaC) tool by HashiCorp that enables users to define and manage their cloud and on-premises infrastructure by using a human-readable configuration file. As an IaC tool, Terraform solves the problem of manual provisioning and managing of infrastructure, which can be time-consuming, error-prone, and difficult to replicate. You can write infrastructure configurations in a declarative language, such as YAML or HashiCorp Configuration Language (HCL), and then use Terraform to create and manage the corresponding infrastructure resources.

AWS provides a native IaC feature with the [CloudFormation service](#). Some organizations use Terraform to manage their infrastructure, especially when they have hybrid cloud and on-premises resource management needs.

## Targeted business outcomes

Using the solutions described in this guide to define and manage your infrastructure provides the following benefits:

- **Protecting enterprise investments:** The `terraform_data` type in Terraform extends traditional enterprise systems with cloud infrastructure when standard resources are insufficient. It runs custom scripts, commands, and processes to maintain business continuity during cloud migrations. You can integrate your existing tools and workflows into your DevOps processes while meeting compliance requirements that differ from standard cloud configurations. This helps you enforce specific policies and perform specialized actions beyond what traditional Terraform resources can provide.
- **Business agility:** Terraform's modular architecture supports complex deployments and system integrations through the use of custom provisioners. Your teams can build solutions for unique technical challenges without waiting for official provider support. This capability helps you:
  - Manage mixed environments of legacy and cloud systems.
  - Implement rapid prototypes of new infrastructure patterns.
  - Adapt quickly to changing business requirements.
  - Support ongoing digital transformation initiatives.
- **Business continuity:** You can use custom provisioners and null resources to automate infrastructure operations by:
  - Eliminating manual interventions in deployment workflows.
  - Reducing human error in processes.
  - Orchestrating system updates with minimal downtime.
  - Maintaining uninterrupted business operations during infrastructure changes.

# Use case examples

This guide covers two sample use cases for working around Terraform limitations on AWS:

- Using Terraform to manage revisions in [AWS Batch job definitions](#)
- Using Terraform to address challenges when you [deploy Amazon Bedrock agents](#)

## Managing revisions in AWS Batch job definitions

This example assumes that you're deploying batch jobs by using the AWS Batch service and using Terraform as an IaC tool.

### Challenge

AWS Batch creates a new revision of a job definition with each update, which leads to an accumulation of revisions over time. This can complicate resource management and create confusion about which revisions are current, especially in enterprise environments where job definitions are frequently updated and downstream resources require accurate references to the latest versions.

### Solution

The following Terraform code uses several key components to address AWS Batch revision management.

```
resource "terraform_data" "batch_job_definition_cleanup" {
  triggers_replace = {
    always_run = timestamp()
  }

  provisioner "local-exec" {
    command = "..." # AWS CLI commands to list and de-register older revisions
  }
}
```

In this code:

- `terraform_data` is combined with a `local-exec` provisioner to run AWS Command Line Interface (AWS CLI) commands during Terraform operations.

- Timestamp triggers ensure that every `terraform apply` command runs the cleanup script.
- AWS CLI integration queries AWS Batch for all active job definition revisions and deregisters older revisions.
- You can add a custom retention configuration to the `command` section to specify how many recent revisions to preserve.

## Benefits

- **Simplified management:** Prevents accumulation of outdated revisions to job definitions.
- **Clear references:** Maintains accurate pointers to current versions of job definitions.
- **Resource optimization:** Reduces clutter in the AWS Batch environment.
- **Automation:** Integrates cleanly with existing Terraform workflows.

This approach demonstrates how Terraform's extensibility features can overcome provider limitations while maintaining IaC best practices. You can use this solution as a template for similar scenarios where dynamic resource discovery and management are needed.

## Deploying Amazon Bedrock agents

This example assumes that you're deploying an Amazon Bedrock agent to automate your DevOps tasks and using Terraform as an IaC tool.

## Challenge

Deploying Amazon Bedrock agents requires a robust, automated workflow that introduces the following technical challenges:

- Complete agent preparation
- Verified readiness state
- Zero manual intervention
- Consistent infrastructure deployment

## Solution

The following Terraform code uses several key components to address Amazon Bedrock agent preparation.

```
resource "terraform_data" "prepare_agent" {
  triggers_replace = {
    agent_state = sha256(jsonencode(aws_bedrockagent_agent.example))
  }

  provisioner "local-exec" {
    command = "aws bedrock-agent prepare-agent --agent-id
${aws_bedrockagent_agent.example.agent_id}"
  }
}

resource "time_sleep" "prepare_agent_sleep" {
  create_duration = "5s"

  lifecycle {
    replace_triggered_by = [terraform_data.prepare_agent]
  }
}
```

In this code:

- `terraform_data` is combined with a `local-exec` provisioner to run AWS CLI commands during Terraform operations. The `terraform_data` named `prepare_agent` uses an AWS CLI command in the provisioner `local-exec` to prepare the agent. This ensures that no manual interventions will be required in the console or AWS CLI command.
- Agent triggers ensure that resource creation starts only after the completion of the `aws_bedrockagent_agent` resource.
- `time_sleep` implements a delay to ensure seamless operations.

This simplistic deployment strategy for Amazon Bedrock agents establishes an initialization process that sleeps for 5 seconds while the agent is getting to the prepared state.

You can enhance this solution by introducing a `wait` (for example, 10 seconds) until the condition is met after agent creation. You can extend this solution further by implementing comprehensive status verification mechanisms that aim for complete agent readiness. For example, you can

implement status checking to prevent premature alias generation and mitigate potential API failures. An adaptive retry mechanism with clearly defined maximum wait times and detailed error tracking will help you troubleshoot failures. Critical considerations include maintaining a consistent deployment process, supporting automated infrastructure setup, and providing transparent progress monitoring.

# Best practices

Follow these guidelines when you use Terraform to automate your DevOps tasks on AWS.

Do's:

- Use `terraform_data` for custom scripts and provisioners.
- Use triggers to control resource recreation.
- Implement a `local-exec` provisioner for complex setup tasks.
- Use `depends_on` for explicit dependency management.
- Store state for idempotent operations.
- Implement proper error handling in scripts.
- Validate and sanitize inputs for security.
- Log output for troubleshooting.
- Use connection blocks for remote execution.
- When you implement features with `terraform_data`, consider it a temporary solution. Regularly check if the provider has added native support for that functionality. When the provider introduces native capability for your `terraform_data` implementation, switch to the provider's official solution.

Don'ts:

- Don't overuse `terraform_data` as a primary resource management tool.
- Avoid storing sensitive information directly in scripts.
- Don't ignore error handling in provisioners.
- Avoid complex, long-running scripts. Don't create null resources with multiple responsibilities and excessively complex workflows.
- Don't create unnecessary dependencies. Follow state management principles and add only necessary triggers and `depends_on` conditions in your code.
- Don't use `terraform_data` for core infrastructure management. Don't replace your standard resource management with custom resources.
- Don't hardcode credentials or sensitive data.
- Don't ignore security best practices.

- **Don't skip input validation.**

### 7 Rs

Seven common migration strategies for moving applications to the cloud. These strategies build upon the 5 Rs that Gartner identified in 2011 and consist of the following:

- Refactor/re-architect – Move an application and modify its architecture by taking full advantage of cloud-native features to improve agility, performance, and scalability. This typically involves porting the operating system and database. Example: Migrate your on-premises Oracle database to the Amazon Aurora PostgreSQL-Compatible Edition.
- Replatform (lift and reshape) – Move an application to the cloud, and introduce some level of optimization to take advantage of cloud capabilities. Example: Migrate your on-premises Oracle database to Amazon Relational Database Service (Amazon RDS) for Oracle in the AWS Cloud.
- Repurchase (drop and shop) – Switch to a different product, typically by moving from a traditional license to a SaaS model. Example: Migrate your customer relationship management (CRM) system to Salesforce.com.
- Rehost (lift and shift) – Move an application to the cloud without making any changes to take advantage of cloud capabilities. Example: Migrate your on-premises Oracle database to Oracle on an EC2 instance in the AWS Cloud.
- Relocate (hypervisor-level lift and shift) – Move infrastructure to the cloud without purchasing new hardware, rewriting applications, or modifying your existing operations. You migrate servers from an on-premises platform to a cloud service for the same platform. Example: Migrate a Microsoft Hyper-V application to AWS.
- Retain (revisit) – Keep applications in your source environment. These might include applications that require major refactoring, and you want to postpone that work until a later time, and legacy applications that you want to retain, because there's no business justification for migrating them.

- Retire – Decommission or remove applications that are no longer needed in your source environment.

A single CI/CD pipeline can use multiple repositories.

## cold cache

A buffer cache that is empty, not well populated, or contains stale or irrelevant data. This affects performance because the database instance must read from the main memory or disk, which is slower than reading from the buffer cache.

## service-level agreement (SLA)

An agreement that clarifies what an IT team promises to deliver to their customers, such as service uptime and performance.

## service-level indicator (SLI)

A measurement of a performance aspect of a service, such as its error rate, availability, or throughput.

## service-level objective (SLO)

A target metric that represents the health of a service, as measured by a [service-level indicator](#).

## shared responsibility model

A model describing the responsibility you share with AWS for cloud security and compliance. AWS is responsible for security *of* the cloud, whereas you are responsible for security *in* the cloud. For more information, see [Shared responsibility model](#).

## SIEM

See [security information and event management system](#).

## single point of failure (SPOF)

A failure in a single, critical component of an application that can disrupt the system.

## SLA

See [service-level agreement](#).

## SLI

See [service-level indicator](#).

## SLO

See [service-level objective](#).

## split-and-seed model

A pattern for scaling and accelerating modernization projects. As new features and product releases are defined, the core team splits up to create new product teams. This helps scale your

organization's capabilities and services, improves developer productivity, and supports rapid innovation. For more information, see [Phased approach to modernizing applications in the AWS Cloud](#).

## SPOF

See [single point of failure](#).

## star schema

A database organizational structure that uses one large fact table to store transactional or measured data and uses one or more smaller dimensional tables to store data attributes. This structure is designed for use in a [data warehouse](#) or for business intelligence purposes.

## strangler fig pattern

An approach to modernizing monolithic systems by incrementally rewriting and replacing system functionality until the legacy system can be decommissioned. This pattern uses the analogy of a fig vine that grows into an established tree and eventually overcomes and replaces its host. The pattern was [introduced by Martin Fowler](#) as a way to manage risk when rewriting monolithic systems. For an example of how to apply this pattern, see [Modernizing legacy Microsoft ASP.NET \(ASMX\) web services incrementally by using containers and Amazon API Gateway](#).

## subnet

A range of IP addresses in your VPC. A subnet must reside in a single Availability Zone.

## supervisory control and data acquisition (SCADA)

In manufacturing, a system that uses hardware and software to monitor physical assets and production operations.

## symmetric encryption

An encryption algorithm that uses the same key to encrypt and decrypt the data.

## synthetic testing

Testing a system in a way that simulates user interactions to detect potential issues or to monitor performance. You can use [Amazon CloudWatch Synthetics](#) to create these tests.

## system prompt

A technique for providing context, instructions, or guidelines to an [LLM](#) to direct its behavior. System prompts help set context and establish rules for interactions with users.

## T

### tags

Key-value pairs that act as metadata for organizing your AWS resources. Tags can help you manage, identify, organize, search for, and filter resources. For more information, see [Tagging your AWS resources](#).

### target variable

The value that you are trying to predict in supervised ML. This is also referred to as an *outcome variable*. For example, in a manufacturing setting the target variable could be a product defect.

### task list

A tool that is used to track progress through a runbook. A task list contains an overview of the runbook and a list of general tasks to be completed. For each general task, it includes the estimated amount of time required, the owner, and the progress.

### test environment

See [environment](#).

### training

To provide data for your ML model to learn from. The training data must contain the correct answer. The learning algorithm finds patterns in the training data that map the input data attributes to the target (the answer that you want to predict). It outputs an ML model that captures these patterns. You can then use the ML model to make predictions on new data for which you don't know the target.

### transit gateway

A network transit hub that you can use to interconnect your VPCs and on-premises networks. For more information, see [What is a transit gateway](#) in the AWS Transit Gateway documentation.

### trunk-based workflow

An approach in which developers build and test features locally in a feature branch and then merge those changes into the main branch. The main branch is then built to the development, preproduction, and production environments, sequentially.

## trusted access

Granting permissions to a service that you specify to perform tasks in your organization in AWS Organizations and in its accounts on your behalf. The trusted service creates a service-linked role in each account, when that role is needed, to perform management tasks for you. For more information, see [Using AWS Organizations with other AWS services](#) in the AWS Organizations documentation.

## tuning

To change aspects of your training process to improve the ML model's accuracy. For example, you can train the ML model by generating a labeling set, adding labels, and then repeating these steps several times under different settings to optimize the model.

## two-pizza team

A small DevOps team that you can feed with two pizzas. A two-pizza team size ensures the best possible opportunity for collaboration in software development.

# U

## uncertainty

A concept that refers to imprecise, incomplete, or unknown information that can undermine the reliability of predictive ML models. There are two types of uncertainty: *Epistemic uncertainty* is caused by limited, incomplete data, whereas *aleatoric uncertainty* is caused by the noise and randomness inherent in the data. For more information, see the [Quantifying uncertainty in deep learning systems](#) guide.

## undifferentiated tasks

Also known as *heavy lifting*, work that is necessary to create and operate an application but that doesn't provide direct value to the end user or provide competitive advantage. Examples of undifferentiated tasks include procurement, maintenance, and capacity planning.

## upper environments

See [environment](#).

## V

### vacuuming

A database maintenance operation that involves cleaning up after incremental updates to reclaim storage and improve performance.

### version control

Processes and tools that track changes, such as changes to source code in a repository.

### VPC peering

A connection between two VPCs that allows you to route traffic by using private IP addresses. For more information, see [What is VPC peering](#) in the Amazon VPC documentation.

### vulnerability

A software or hardware flaw that compromises the security of the system.

## W

### warm cache

A buffer cache that contains current, relevant data that is frequently accessed. The database instance can read from the buffer cache, which is faster than reading from the main memory or disk.

### warm data

Data that is infrequently accessed. When querying this kind of data, moderately slow queries are typically acceptable.

### window function

A SQL function that performs a calculation on a group of rows that relate in some way to the current record. Window functions are useful for processing tasks, such as calculating a moving average or accessing the value of rows based on the relative position of the current row.

### workload

A collection of resources and code that delivers business value, such as a customer-facing application or backend process.

## workstream

Functional groups in a migration project that are responsible for a specific set of tasks. Each workstream is independent but supports the other workstreams in the project. For example, the portfolio workstream is responsible for prioritizing applications, wave planning, and collecting migration metadata. The portfolio workstream delivers these assets to the migration workstream, which then migrates the servers and applications.

## WORM

See [write once, read many](#).

## WQF

See [AWS Workload Qualification Framework](#).

## write once, read many (WORM)

A storage model that writes data a single time and prevents the data from being deleted or modified. Authorized users can read the data as many times as needed, but they cannot change it. This data storage infrastructure is considered [immutable](#).

## Z

### zero-day exploit

An attack, typically malware, that takes advantage of a [zero-day vulnerability](#).

### zero-day vulnerability

An unmitigated flaw or vulnerability in a production system. Threat actors can use this type of vulnerability to attack the system. Developers frequently become aware of the vulnerability as a result of the attack.

### zero-shot prompting

Providing an [LLM](#) with instructions for performing a task but no examples (*shots*) that can help guide it. The LLM must use its pre-trained knowledge to handle the task. The effectiveness of zero-shot prompting depends on the complexity of the task and the quality of the prompt. See also [few-shot prompting](#).

### zombie application

An application that has an average CPU and memory usage below 5 percent. In a migration project, it is common to retire these applications.
